 - Read the value of the target location.
 - Add the “add” value to it using two's complement arithmetic ignoring any carry or overflow.
 - Write the sum back to the target location.
 - Return the original value of the target location.
- Swap (Unconditional Swap): Request contains a single operand, the “swap” value

- Read the value of the target location.
- Write the “swap” value back to the target location.
- Return the original value of the target location.
- CAS (Compare and Swap): Request contains two operands, a “compare” value and a “swap” value
 - Read the value of the target location.
 - Compare that value to the “compare” value.
 - If equal, write the “swap” value back to the target location.
 - Return the original value of the target location.

A given AtomicOp transaction has an associated operand size, and the same size is used for the target location accesses and the returned value. FetchAdd and Swap support operand sizes of 32 and 64 bits. CAS supports operand sizes of 32, 64, and 128 bits.

AtomicOp capabilities are optional normative. Endpoints and Root Ports are permitted to implement AtomicOp Requester capabilities. PCI Express Functions with Memory Space BARs as well as all Root Ports are permitted to implement AtomicOp Completer capabilities. Routing elements (Switches, as well as Root Complexes supporting peer-to-peer access between Root Ports) require AtomicOp routing capability in order to route AtomicOp Requests. AtomicOps are architected for device-to-host, device-to-device, and host-to-device transactions. In each case, the Requester, Completer, and all intermediate routing elements must support the associated AtomicOp capabilities.

AtomicOp capabilities are not supported on PCI Express to PCI/PCI-X Bridges. If need be, Locked Transactions can be used for devices below such Bridges. AtomicOps and Locked Transactions can operate concurrently on the same hierarchy.

Software discovers specific AtomicOp Completer capabilities via three new bits in the Device Capabilities 2 register (see § Section 7.5.3.15). For increased interoperability, Root Ports are required to implement certain AtomicOp Completer capabilities in sets if at all (see § Section 6.15.3.1). Software discovers AtomicOp routing capability via the AtomicOp Routing Supported bit in the Device Capabilities 2 register. Software discovery of AtomicOp Requester capabilities is outside the scope of this specification, but software must set the AtomicOp Requester Enable bit in a Function’s Device Control 2 register before the Function can initiate AtomicOp Requests (see § Section 7.5.3.16).

With routing elements, software can set an AtomicOp Egress Blocking bit (see § Section 7.5.3.16) on a Port-by-Port basis to avoid AtomicOp Requests being forwarded to components that shouldn’t receive them, and might, if operating in NFM, handle each as a Malformed TLP, which by default is a Fatal Error. Each blocked Request is handled as an AtomicOp Egress Blocked error, which by default is an Advisory Non-Fatal Error.

AtomicOps are Memory Transactions, so existing standard mechanisms for managing Memory Space access (e.g., Bus Master Enable, Memory Space Enable, and Base Address registers) apply.

6.15.1 AtomicOp Use Models and Benefits §

AtomicOps enable advanced synchronization mechanisms that are particularly useful when there are multiple producers and/or multiple consumers that need to be synchronized in a non-blocking fashion. For example, multiple producers can safely enqueue to a common queue without any explicit locking.

AtomicOps also enable lock-free statistics counters, for example where a device can atomically increment a counter, and host software can atomically read and clear the counter.

Direct support for the three chosen AtomicOps over PCI Express enables easier migration of existing high-performance SMP applications to systems that use PCI Express as the interconnect to tightly-coupled accelerators, co-processors, or GP-GPUs. For example, a ported application that uses PCI Express-attached accelerators may be able to use the same synchronization algorithms and data structures as the earlier SMP application.

An AtomicOp to a given target generally incurs latency comparable to a Memory Read to the same target. Within a single hierarchy, multiple AtomicOps can be “in flight” concurrently. AtomicOps generally create negligible disruption to other PCI Express traffic.

Compared to Locked Transactions, AtomicOps provide lower latency, higher scalability, advanced synchronization algorithms, and dramatically less impact to other PCI Express traffic.

6.15.2 AtomicOp Transaction Protocol Summary §

Detailed protocol rules and requirements for AtomicOps are distributed throughout the rest of this specification, but here is a brief summary plus some unique requirements.

- AtomicOps are Non-Posted Memory Transactions, supporting 32- and 64-bit address formats.
- FetchAdd, Swap, and CAS each use a distinct type code.
- The Completer infers the operand size from the Length field value and type code in the AtomicOp Request.
- The endian format used by AtomicOp Completers to read and write data at the target location is implementation specific, and permitted to be whatever the Completer determines to be appropriate for the target memory (e.g., little-endian, big-endian, etc.). See § Section 2.2.2 .
- If an AtomicOp Requester supports Address Translation Services (ATS), the Requester is permitted to use a Translated address in an AtomicOp Request only if the Translated address has appropriate access permissions. Specifically, the Read (R) and Write (W) fields must both be Set, and the Untranslated access only (U) field must be Clear. See § Section 2.2.4.1 .
- If a component supporting Access Control Services (ACS) supports AtomicOp routing or AtomicOp Requester capability, it handles AtomicOp Requests and Completions the same as with other Memory Requests and Completions with respect to ACS functionality.
- The No Snoop attribute is applicable and permitted to be Set with AtomicOp Requests, but atomicity must be guaranteed regardless of the No Snoop attribute value.
- The Relaxed Ordering attribute is applicable and permitted to be Set with AtomicOp Requests, where it affects the ordering of both the Requests and their associated Completions.
- Ordering requirements for AtomicOp Requests are similar to those for Non-Posted Write Requests. Thus, if a Requester wants to ensure that an AtomicOp Request is observed by the Completer before a subsequent Posted or Non-Posted Request, the Requester must wait for the AtomicOp Completion before issuing the subsequent Request.
- Ordering requirements for AtomicOp Completions are similar to those for Read Completions.
- Unless there's a higher precedence error, an AtomicOp-aware Completer must handle a Poisoned AtomicOp Request as a Poisoned TLP Received error, and must also return a Completion with a Completion Status of Unsupported Request (UR). See § Section 2.7.2.1 . The value of the target location must remain unchanged.
- If the Completer of an AtomicOp Request encounters an uncorrectable error accessing the target location or carrying out the Atomic operation, the Completer must handle it as a Completer Abort (CA). The subsequent state of the target location is implementation specific.
- AtomicOp-aware Completers are required to handle any properly formed AtomicOp Requests with types or operand sizes they don't support as an Unsupported Request (UR). If the Length field in an AtomicOp Request contains an unarchitected value, the Request must be handled by an AtomicOp-aware Completer as a Malformed TLP. See § Section 2.2.7 .
- If any Function in a Multi-Function Device supports AtomicOp Completer or AtomicOp routing capability, all Functions with Memory Space BARs in that device must decode properly formed AtomicOp Requests and handle any they don't support as an Unsupported Request (UR). Note that in such devices, Functions lacking

AtomicOp Completer capability are forbidden to handle properly formed AtomicOp Requests as Malformed TLPs.

- If an RC has any Root Ports that support AtomicOp routing capability, all RCiEPs in the RC reachable by forwarded AtomicOp Requests must decode properly formed AtomicOp Requests and handle any they don't support as an Unsupported Request (UR).
- With an AtomicOp Request having a supported type and operand size, the AtomicOp-aware Completer is required either to carry out the Request or handle it as Completer Abort (CA) for any location in its target Memory Space. Completers are permitted to support AtomicOp Requests on a subset of their target Memory Space as needed by their programming model (see § Section 2.3.1). Memory Space structures defined or inherited by PCI Express (e.g., the MSI-X Table structure) are not required to be supported as AtomicOp targets unless explicitly stated in the description of the structure.
- For a Switch or an RC, when AtomicOp Egress Blocking is enabled in an Egress Port, and an AtomicOp Request targets going out that Egress Port, the Egress Port must handle the Request as an AtomicOp Egress Blocked error¹⁴¹ (see § Figure 6-2) and must also return a Completion with a Completion Status of UR. If the severity of the AtomicOp Egress Blocked error is non-fatal, this case must be handled as an Advisory Non-Fatal Error as described in § Section 6.2.3.2.4.1.

6.15.3 Root Complex Support for AtomicOps §

RCs have unique requirements and considerations with respect to AtomicOp capabilities.

6.15.3.1 Root Ports with AtomicOp Completer Capabilities §

AtomicOp Completer capability for a Root Port indicates that the Root Port supports receiving at its Ingress Port AtomicOp Requests that target host memory or Memory Space allocated by a Root Port BAR. This is independent of any RCiEPs that have AtomicOp Completer capabilities.

If a Root Port implements any AtomicOp Completer capability for host memory access, it must implement all 32-bit and 64-bit AtomicOp Completer capabilities. Implementing 128-bit CAS Completer capability is optional.

If an RC has one or more Root Ports that implement AtomicOp Completer capability, the RC must ensure that host memory accesses to a target location on behalf of a given AtomicOp Request are performed atomically with respect to each host processor or device access to that target location range.

If a host processor supports atomic operations via its instruction set architecture, the RC must also ensure that host memory accesses on behalf of a given AtomicOp Request preserve the atomicity of any host processor atomic operations.

6.15.3.2 Root Ports with AtomicOp Routing Capability §

As with other PCI Express Transactions, the support for peer-to-peer routing of AtomicOp Requests and Completions between Root Ports is optional and implementation dependent. If an RC supports AtomicOp routing capability between two or more Root Ports, it must indicate that capability in each associated Root Port via the AtomicOp Routing Supported bit in the Device Capabilities 2 register.

141. Though an AtomicOp Egress Blocked error is handled by returning a Completion with UR Status, the error is not otherwise handled as an Unsupported Request. For example, it does not set the Unsupported Request Detected bit in the Device Status register.

An RC is not required to support AtomicOp routing between all pairs of Root Ports that have the AtomicOp Routing Supported bit Set. An AtomicOp Request that would require routing between unsupported pairs of Root Ports must be handled as an Unsupported Request (UR), and reported by the “sending” Port.

The AtomicOp Routing Supported bit must be Set for any Root Port that supports forwarding of AtomicOp Requests initiated by host software or RCiEPs. The AtomicOp Routing Supported bit must be Set for any Root Ports that support forwarding of AtomicOp Requests received on their Ingress Port to RCiEPs.

6.15.3.3 RCs with AtomicOp Requester Capabilities §

An RC is permitted to implement the capability for either host software or RCiEPs to initiate AtomicOp Requests.

Software discovery of AtomicOp Requester capabilities is outside the scope of this specification.

If an RC supports software-initiated AtomicOp Requester capabilities, the specific mechanisms for how software running on a host processor causes the RC to generate AtomicOp Requests is outside the scope of this specification.

IMPLEMENTATION NOTE: GENERATING ATOMICOP REQUESTS VIA HOST PROCESSOR SOFTWARE §

If a host processor instruction set architecture (ISA) supports atomic operation instructions that directly correspond to one or more PCI Express AtomicOps, an RC might process the associated internal atomic transaction that targets PCI Express Memory Space much like it processes the internal read transaction resulting from a processor load instruction. However, instead of “exporting” the internal read transaction as a PCI Express Memory Read Request, the RC would export the internal atomic transaction as a PCI Express AtomicOp Request. Even if an RC uses the “export” approach for some AtomicOp types and operand sizes, it would not need to use this approach for all.

For AtomicOp types and operand sizes where the RC does not use the “export” approach, the RC might use an RC register-based mechanism similar to one where some PCI host bridges use CONFIG_ADDRESS and CONFIG_DATA registers to generate Configuration Requests. Refer to the [PCI] for details.

The “export” approach may permit a large number of concurrent AtomicOp Requests without becoming RC register limited. It may also be easier to support AtomicOp Request generation from user space software using this approach.

The RC register-based mechanism offers the advantage of working for all AtomicOp types and operand sizes even if the host processor ISA doesn’t support the corresponding atomic instructions. It might also support a polling mode for waiting on AtomicOp Completions as opposed to stalling the processor while waiting for a Completion.

6.15.4 Switch Support for AtomicOps §

If a Switch supports AtomicOp routing capability for any of its Ports, it must do so for all of them.

6.16 Dynamic Power Allocation (DPA) Capability §

A common approach to managing power consumption is through a negotiation between the device driver, operating system, and executing applications. Adding Dynamic Power Allocation for such devices is anticipated to be done as an extension of that negotiation, through software mechanisms that are outside of the scope of this specification. Some devices do not have a device specific driver to manage power efficiently. The DPA Capability provides a mechanism to allocate power dynamically for these types of devices. DPA is optional normative functionality applicable to Endpoint Functions that can benefit from the dynamic allocation of power and do not have an alternative mechanism. If supported, the Emergency Power Reduction State, over-rides the mechanisms listed here (see § Section 6.24).

The DPA Capability enables software to actively manage and optimize Function power usage when in the D0 state. DPA is not applicable to power states D1-D3 therefore the DPA Capability is independently managed from the PCI-PM Capability.

DPA defines a set of power substates, each of which with an associated power allocation. Up to 32 substates [0..31] can be defined per Function. Substate 0, the default substate, indicates the maximum power the Function is ever capable of consuming.

Substates must be contiguously numbered from 0 to Substate_Max, as defined in § Section 7.9.12.2 . Each successive substate has a power allocation lower than or equal to that of the prior substate. For example, a Function with four substates could be defined as follows:

1. Substate 0 (the default) defines a power allocation of 25 Watts.
2. Substate 1 defines a power allocation of 20 Watts.
3. Substate 2 defines a power allocation of 20 Watts.
4. Substate 3 defines a power allocation of 10 Watts.

When the Function is initialized, it will operate within the power allocation associated with substate 0. Software is not required to progress through intermediate substates. Over time, software may dynamically configure the Function to operate at any of the substates in any sequence it chooses. Software is permitted to configure the Function to operate at any of the substates before the Function completes a previously initiated substate transition.

On the completion of the substate transition(s) the Function must compare its substate with the configured substate. If the Function substate does not match the configured substate, then the Function must begin transition to the configured substate. It is permitted for the Function to dynamically alter substate transitions on Configuration Requests instructing the Function to operate in a new substate.

In the prior example, software can configure the Function to transition to substate 4, followed by substate 1, followed by substate 3, and so forth. As a result, the Function must be able to transition between any substates when software configures the associated control field.

The Substate Control Enabled bit provides a mechanism that allows the DPA Capability to be used in conjunction with the software negotiation mechanism mentioned above. When Set, power allocation is controlled by the DPA Capability. When Clear, the DPA Capability is disabled, and the Function is not permitted to directly initiate substate transitions based on configuration of the Substate Control register field. At an appropriate point in time, software participating in the software negotiation mechanism mentioned above clears the bit, effectively taking over control of power allocation for the Function.

It is required that the Function respond to Configuration Space accesses while in any substate.

At any instant, the Function must never draw more power than it indicates through its Substate Status. When the Function is configured to transition from a higher power substate to a lower power substate, the Function's Substate Status must indicate the higher power substate during the transition, and must indicate the lower power substate after

completing the transition. When the Function is configured to transition from a lower power substate to a higher power substate, the Function's Substate Status must indicate the higher power substate during the transition, as well as after completing the transition.

Due to the variety of applications and the wide range of maximum power required for a given Function, the transition time required between any substates is implementation specific. To enable software to construct power management policies (outside the scope of this specification), the Function defines two Transition Latency Values. Each of the Function substates associates its maximum Transition Latency with one of the Transition Latency Values, where the maximum Transition Latency is the time it takes for the Function to enter the configured substate from any other substate. A Function is permitted to complete the substate transition faster than the maximum Transition Latency for the substate.

6.16.1 DPA Capability with Multi-Function Devices §

Except as stated below, it is permitted for some or all Functions of a Multi-Function Device to implement a DPA Capability. The power allocation for the Multi-Function Device is the sum of power allocations set by the DPA Capability for each Function. It is permitted for the DPA Capability of a Function to include the power allocation for the Function itself as well as account for power allocation for other Functions that do not implement a DPA Capability. The association between multiple Functions for DPA is implementation specific and beyond the scope of this specification.

Power allocation for VFs is managed using their associated PF's DPA Capability, if implemented. VFs must not implement the Dynamic Power Allocation Capability.

6.17 TLP Processing Hints (TPH) §

TLP Processing Hints is an optional feature that provides hints in Request TLP headers to facilitate optimized processing of Requests that target Memory Space. These Processing Hints enable the system hardware (e.g., the Root Complex and/or Endpoints) to optimize platform resources such as system and memory interconnect on a per TLP basis. The TPH mechanism defines Processing Hints that provide information about the communication models between Endpoints and the Root-complex. Steering Tags are system-specific values used to identify a processing resource that a Requester explicitly targets. System software discovers and identifies TPH capabilities to determine the Steering Tag allocation for each Function that supports TPH.

6.17.1 Processing Hints §

The Requester provides hints to the Root Complex or other targets about the intended use of data and data structures by the host and/or device. The hints are provided by the Requester, which has knowledge of upcoming Request patterns, and which the Completer would not be able to deduce autonomously (with good accuracy). Cases of interest to distinguish with such hints include:

DWHR: Device writes then host reads soon

HWDR: Device reads data that the Host is believed to have recently written

D*D*: Device writes/reads, then device reads/writes soon

Includes DWDW, DWDR, DRDW, DRDR

Bi-Directional: Data structure that is shared and has equal read/write access by host and device.

The usage models are mapped to the Processing Hint encodings as described in § [Table 6-13](#).

Table 6-13 Processing Hint Mapping §

PH[1:0] (b)	Processing Hint	Usage Model
00	Bi-directional data structure	Bi-Directional shared data structure
01	Requester	D*D*
10	Target	DWHR HWDR
11	Target with Priority	Same as target but with temporal re-use priority

6.17.2 Steering Tags §

Functions that intend to target a TLP towards a specific processing resource such as a host processor or system cache hierarchy require topological information of the target cache (e.g., which host cache). Steering Tags are system-specific values that provide information about the host or cache structure in the system cache hierarchy. These values are used to associate processing elements within the platform with the processing of Requests.

Software programmable Steering Tag values to be used are stored in an ST Table that is permitted to be located either in the TPH Requester Extended Capability structure (see § Section 7.9.13) or combined with the MSI-X Table (see § Section 7.7), but not in both locations for a given Function. When the ST Table is combined with the MSI-X Table, the 2 most significant bytes of the Vector Control register of each MSI-X Table entry are used to contain the Steering Tag value.

The choice of ST Table location is implementation specific and is discoverable by software. A Function that implements MSI-X is permitted to locate the ST Table in either location (see § Section 7.9.13.2). A Function that implements both MSI and MSI-X is permitted to combine the ST Table with the MSI-X Table and use it, even when MSI-X is disabled (i.e., when MSI is enabled). Each ST Table entry is 2 bytes. The size of the ST Table is indicated in the TPH Requester Extended Capability structure.

For some usage models the Steering Tags are not required or not provided, and in such cases a Function is permitted to use a value of all zeros in the ST field to indicate no ST preference. The association of each Request with an ST Table entry is device specific and outside the scope of this specification.

6.17.3 ST Modes of Operation §

The ST Table Location field in the TPH Requester Extended Capability structure indicates where (if at all) the ST Table is implemented by the Function. If an ST Table is implemented, software can program it with the system-specific Steering Tag values.

Table 6-14 ST Modes of Operation §

ST Mode Select [2:0] (b)	ST Mode Name	Description
000	No ST Mode	The Function must use a value of all zeros for all Steering Tags.
001	Interrupt Vector Mode	Each Steering Tag is selected by an MSI/MSI-X interrupt vector number. The Function is required to use the Steering Tag value from an ST Table entry that can be indexed by a valid MSI/MSI-X interrupt vector number.

ST Mode Select [2:0] (b)	ST Mode Name	Description
010	Device Specific Mode	It is recommended for the Function to use a Steering Tag value from an ST Table entry, but it is not required.
All other encodings	Reserved	Reserved for future use.

In the No ST Mode of operation, the Function must use a value of all zeros for each Steering Tag, enabling the use of Processing Hints without software-provided Steering Tags.

In the Interrupt Vector Mode of operation, Steering Tags are selected from the ST Table using MSI/MSI-X interrupt vector numbers. For Functions that have MSI enabled, the Function is required to select tags within the range specified by the Multiple Message Enable field in the MSI Capability structure. For Functions that have MSI-X enabled, the Function is required to select tags within the range of the MSI-X Table size. If the ST Table Size is smaller than the enabled range of interrupt vector numbers, the Function is permitted to either not use TPH for certain transactions, to use TPH with a Steering Tag of 0 or to use TPH with an implementation defined mechanism used to select a Steering Tag value from the ST Table. If the ST Table Size is larger than the enabled range of interrupt vector numbers, ST Table Entries corresponding to out of range interrupt vector numbers are ignored by the Function.

In the Device Specific Mode of operation, the assignment of the Steering Tags to Requests is device specific. The number of Steering Tags used by the Function is permitted to be different than the number of interrupt vectors allocated for the Function, irrespective of the ST Table location, and Steering Tag values used in Requests are not required to come from the architected ST Table.

A Function that is capable of generating TPH Requests is required to support the No ST Mode of operation. Support for other ST Modes of operation is optional. Only one ST Mode of operation can be selected at a time by programming ST Mode Select.

IMPLEMENTATION NOTE: ST TABLE PROGRAMMING §

To ensure that deterministic Steering Tag values are used in Requests, it is recommended that software either quiesce the Function or disable the TPH Requester capability during the process of performing ST Table updates. Failure to do so may result in non-deterministic values of ST values being used during ST Table updates.

6.17.4 TPH Capability §

TPH capabilities are optional normative. Each Function capable of generating Request TLPs with TPH is required to implement a TPH Requester Extended Capability structure. Functions that support processing of TLPs with TPH as Completers are required to indicate TPH Completer capability via the Device Capabilities 2 register. TPH is architected to be applied for transactions that target Memory Space, and is applicable for transaction flows between device-to-host, device-to-device and host-to-device. In each case for TPH to be supported, the Requester, Completer, and all intermediate routing elements must support the associated TPH capabilities.

Software discovers the Requester capabilities via the TPH Requester Extended Capability structure and Completer capabilities via the Device Capabilities 2 Register (see § Section 7.5.3.15). Software must program the TPH Requester Enable field in the TPH Requester Extended Capability structure to enable the Function to initiate Requests with TPH.

TPH only provides additional information to enable optimized processing of Requests that target Memory Space, so existing mechanisms and rules for managing Memory Space access (e.g., Bus Master Enable, Memory Space Enable, and Base Address registers) are not altered.

6.18 Latency Tolerance Reporting (LTR) Mechanism §

The Latency Tolerance Reporting (LTR) mechanism enables Endpoints to report their service latency requirements for Memory Reads and Writes to the Root Complex, so that power management policies for central platform resources (such as main memory, RC internal interconnects, and snoop resources) can be implemented to consider Endpoint service requirements. The LTR Mechanism does not directly affect Link power management or Switch internal power management, although it is possible that indirect effects will occur.

The implications of “latency tolerance” will vary significantly between different device types and implementations. When implementing this mechanism, it will generally be desirable to consider if service latencies impact functionality or only performance, if performance impacts are linear, and how much it is possible for the device to use buffering and/or other techniques to compensate for latency sensitivities.

The Root Complex is not required to honor the requested service latencies, but is strongly encouraged to provide a worst case service latency that does not exceed the latencies indicated by the LTR mechanism.

LTR support is discovered and enabled through reporting and control registers described in § Chapter 7. . Software must not enable LTR in an Endpoint unless the Root Complex and all intermediate Switches indicate support for LTR. Note that it is not required that all Endpoints support LTR to permit enabling LTR in those Endpoints that do support it. When enabling the LTR mechanism in a hierarchy, devices closest to the Root Port must be enabled first.

If an LTR Message is received at a Downstream Port that does not support LTR or if LTR is not enabled, the Message must be treated as an Unsupported Request.

Figure 6-15 Latency Fields Format for LTR Messages §

No-Snoop Latency and Snoop Latency: As shown in § Figure 6-15, these fields include a Requirement bit that indicates if the device has a latency requirement for the given type of Request. If the Requirement bit is Set, the LatencyValue and LatencyScale fields describe the latency requirement. If the Requirement bit is Clear, there is no latency requirement and the LatencyValue and LatencyScale fields are ignored. With any LTR Message transmission, it is permitted for a device to indicate that a requirement is being reported for only no-snoop Requests, for only snoop Requests, or for both types of Requests. It is also permitted for a device to indicate that it has no requirement for either type of traffic, which it does by clearing the Requirement bit in both fields.

Each field also includes value and scale fields that encode the reported latency. Values are multiplied by the indicated scale to yield an absolute time value, expressible in a range from 1 ns to $2^{25} \times (2^{10} - 1) = 34,326,183,936$ ns.

Setting the value and scale fields to all 0's indicates that the device will be impacted by any delay and that the best possible service is requested.

If a device doesn't implement or has no service requirements for a particular type of traffic, then it must have the Requirement bit clear for the associated latency field.

When directed to a non-D0 state by a Write to the PMCSR register, if a device's most recently transmitted LTR message (since the last DL_Down to DL_Up transition) reported one or both latency fields with any Requirement bit set, then it must send a new LTR Message with both of the Requirement bits clear prior to transitioning to the non-D0 state. If subsequently directed back to D0 by a Write to the PMCSR register, it is recommended that the device send a new LTR Message to re-establish its latency requirements after the transition back to D0.

When the LTR Mechanism Enable bit is cleared, if a device's most recently sent LTR Message (since the last DL_Down to DL_Up transition) reported latency tolerance values with any Requirement bit set, then one of the following applies:

- If the bit was cleared due to a Configuration Write to the Device Control 2 Register, the device must send a new LTR Message with all the Requirement bits clear.
- If the bit was cleared due to an FLR, the device *MUST@FLIT* send a new LTR Message with all the Requirement bits clear.

When a Downstream Port goes to DL_Down status, any previous latencies recorded for that Port must be treated as invalid.

An LTR Message from a device reflects the tolerable latency from the perspective of the device, for which the platform must consider the service latency itself, plus the delay added by the use of Clock Power Management (CLKREQ#), if applicable. The service latency itself is defined as follows:

- When a device issues a Non-Posted Request, service latency of that Request is the delay from transmission of the last symbol of the Request TLP to the receipt of the first symbol of the first Completion TLP for that Request¹⁴².
- When a device issues one or more Posted Requests such that it cannot issue another Posted Request due to Flow Control backpressure, service latency of the blocked Request is the delay from the transmission of the last symbol of the previous Posted Request to the receipt of the first symbol of the DLLP returning the credit(s) that allows transmission of the blocked Request¹¹⁸.

If Clock Power Management is used, then the platform implementation-dependent period between when a device asserts CLKREQ# and the device receives a valid clock signal constitutes an additional component of the platform service latency that must be comprehended by the platform when setting platform power management policy.

It is recommended that Endpoints transmit an LTR Message Upstream shortly after LTR is enabled, and subsequently when the Endpoint's service requirements change.

It is strongly recommended that Endpoints send no more than two LTR Messages within any 500 μ s time period, except where required to by the specification. Downstream Ports must not generate an error if more than two LTR Messages are received within a 500 μ s time period, and must properly handle all LTR messages regardless of the time interval between them.

Multi-Function Devices (MFDs) associated with an Upstream Port must transmit a "conglomerated" LTR Message Upstream according to the following rules:

- The acceptable latency values for the Message sent Upstream by the MFD must reflect the lowest values associated with any Function.
 - It is permitted that the snoop and no-snoop latencies reported in the conglomerated Message are associated with different Functions.

142. For this definition, all of the symbols of a DLLP or TLP are included. For 8b/10b, the first and last symbols are framing symbols (SDP, STP or END, see § Section 4.2.1). For 128b/130b, the first symbol of a packet is the first symbol of a framing token (SDP or STP) and the last symbol of a packet is the last symbol of a CRC or LCRC (see § Section 4.2.2).

- If none of the Functions report a requirement for a certain type of traffic (snoop/no-snoop), the Message sent by the MFD must not set the Requirement bit corresponding to that type of traffic.
- The MFD must transmit a new LTR Message Upstream when any Function of the MFD changes the values it has reported internally in such a way as to change the conglomerated value earlier reported by the MFD.

Switches must collect the Messages from Downstream Ports that have the LTR mechanism enabled and transmit a “conglomerated” Message Upstream according to the following rules:

- If a Switch supports the LTR feature, it must support the feature on its Upstream Port and all Downstream Ports.
- A Switch Upstream Port is permitted to transmit LTR Messages only when its LTR Mechanism Enable bit is Set or shortly after software clears its LTR Mechanism Enable bit as described earlier in this section.
- The acceptable latency values for the Message sent Upstream by the Switch must be calculated as follows:
 - If none of the Downstream Ports receive an LTR Message containing a requirement for a certain type of traffic (snoop/no-snoop), then any LTR Message sent by the Switch must not set the Requirement bit corresponding to that type of traffic.
 - Define LTRdnport[N] as the value reported in the LTR Message received at Downstream Port N, with these adjustments if applicable:
 - LTRdnport[N] is effectively infinite if the Requirement bit is clear or if a Not Permitted LatencyScale value is used
 - LTRdnport[N] must be 0 if the Requirement bit is 1 and the LatencyValue field is all 0's regardless of the LatencyScale value
 - Define LTRdnportMin as the minimum value of LTRdnport[N] across all Downstream Ports
 - Define Lswitch as all latency induced by the Switch
 - If Lswitch dynamically changes based on the Switch's operational mode, the Switch must not allow Lswitch to exceed 20% of LTRdnportMin, unless Lswitch for the Switch's lowest latency mode is greater, in which case the lowest latency state must be used
 - Calculate the value to transmit upstream, LTRconglomerated, as $\text{LTRdnportMin} - \text{Lswitch}$, unless this value is less than 0 in which case LTRconglomerated is 0
 - If LTRconglomerated is 0, both the LatencyValue and LatencyScale fields must be all 0's in the conglomerated LTR message
- A new LTR message must be transmitted Upstream if the conglomerated latencies are changed as a result of DL_Down invalidating the previous latencies recorded for that Port.
- If a Switch Downstream Port has the LTR Mechanism Enable bit cleared, the Latency Tolerance values recorded for that Port must be treated as invalid, and the latencies to be transmitted Upstream updated and a new conglomerated Message transmitted Upstream if the conglomerated latencies are changed as a result.
- A Switch must transmit an LTR Message Upstream when any Downstream Port/Function changes the latencies it has reported in such a way as to change the conglomerated latency reported by the Switch.
- A Switch must not transmit LTR Messages Upstream unless triggered to do so by one of the events described above.

The RC is permitted to delay processing of device Request TLPs provided it satisfies the device's service requirements.

When the latency requirement is updated during a series of Requests, it is required that the updated latency figure be comprehended by the RC prior to servicing a subsequent Request. In all cases the updated latency value must take effect within a time period equal to or less than the previously reported latency requirement. It is permitted for the RC to comprehend the updated latency figure earlier than this limit.

IMPLEMENTATION NOTE: OPTIMAL USE OF LTR §

It is recommended that Endpoints transmit an updated LTR Message each time the Endpoint's service requirements change. If the latency tolerance is being reduced, it is recommended to transmit the updated LTR Message ahead of the first anticipated Request with the new requirement, allowing the amount of time indicated in the previously issued LTR Message. If the tolerance is being increased, then the update should immediately follow the final Request with the preceding latency tolerance value.

Typically, the Link will be in ASPM L1, and, if Clock Power Management (Clock PM) is supported, CLKREQ# will be deasserted, at the time an Endpoint reaches an internal trigger that causes the Endpoint to initiate Requests to the RC. The following text shows an example of how LTR is applied in such a case. Key time points are illustrated in § Figure 6-16.

Figure 6-16 CLKREQ# and Clock Power Management §

Time A is a platform implementation-dependent period between when a device asserts CLKREQ# and the device receives a valid clock signal. This value will not exceed the latency in effect.

Time B is the device implementation-dependent period between when a device has a valid clock and it can initiate the retraining sequence to transition from L1 ASPM to L0.

Time C is the period during which the transition from L1 ASPM to L0 takes place

Time D for a Read transaction is the time between the transmission of the END symbol in the Request TLP to the receipt of the STP symbol in the Completion TLP for that Request. Time D for a Write transaction is the time between the transmission of the END symbol of the TLP that exhausts the FC credits to the receipt of the SDP symbol in the DLLP returning more credits for that Request type. This value will not exceed the latency in effect.

Time E is the period where the data path from the Endpoint to system memory is open, and data transactions are not subject to the leadoff latency.

The LTR latency semantic reflects the tolerable latency seen by the device as measured by one or both of the following:

Case 1: the device may or may not support Clock PM, but has not deasserted its CLKREQ# signal - The latency observed by the device is represented in § Figure 6-16 as the sum of times C and D.

Case 2: the device supports Clock PM and has deasserted CLKREQ#- The latency observed by the device is represented as the sum of times A, C, and D.

To effectively use the LTR mechanism in conjunction with Clock PM, the device will know or be able to measure times B and C, so that it knows when to assert CLKREQ#. The actual values of Time A, Time C, and Time D may vary dynamically, and it is the responsibility of the platform to ensure the sum will not exceed the latency.

Figure 6-17 Use of LTR and Clock Power Management §

In a very simple model, an Endpoint may choose to implement LTR as shown in § Figure 6-17. When an Endpoint determines that it is idle, it sends an LTR Message with the software configured maximum latency or the maximum latency the Endpoint can support.

When the Endpoint determines that it has a need to maintain sustained data transfers with the Root Complex, the Endpoint sends a new LTR Message with a shorter latency (at Time E). This LTR Message is sent prior to the next data flush by a time equal to the maximum latency sent before (the time between Time E and Time D'). In between Time E and Time A', the Endpoint can return to a low power state, while the platform transitions to a state where it can provide the shorter latency when the device next needs to transmit data.

Note that the RC may delay processing of device Request TLPs, provided it satisfies the device's service requirements. If, for example, an Endpoint connected to Root Port 1 reports a latency tolerance of 100 μ s, and an Endpoint on Root Port 2 report a value of 30 μ s, the RC might implement a policy of stalling an initial Request following an idle period from Root Port 1 for 70 μ s before servicing the Request with a 30 μ s latency, thus providing a perceived service latency to the first Endpoint of 100 μ s. This RC behavior provides the RC the ability to batch together Requests for more efficient servicing.

It is possible that, after it is determined that the RC can service snoop and no-snoop Requests from all Endpoints within the maximum snoop and maximum no-snoop time intervals, this information may be communicated to Endpoints by updating the Max Snoop LatencyValue, Max Snoop LatencyScale and Max No-Snoop LatencyValue, Max No-Snoop LatencyScale fields. The intention of this communication would be to prevent Endpoints from sending needless LTR updates.

When an Endpoint's LTR value for snoop Requests changes to become larger (looser) than the value indicated in the Max Snoop LatencyValue/Scale fields, it is recommended that the Endpoint send an LTR message with the snoop LTR value indicated in the Max Snoop LatencyValue/Scale fields. Likewise, when an Endpoint's LTR value for no-snoop Requests changes to become larger (looser) than the value indicated in the Max No-Snoop LatencyValue/Scale fields, it is recommended that the Endpoint send an LTR message with the no-snoop LTR value indicated in the Max No-Snoop LatencyValue/Scale fields.

It is recommended that Endpoints buffer Requests as much as possible, and then use the full Link bandwidth in bursts that are as long as the Endpoint can practically support, as this will generally lead to the best overall platform power efficiency.

Note that LTR may be enabled in environments where not all Endpoints support LTR, and in such environments, Endpoints that do not support LTR may experience suboptimal service.

6.19 Optimized Buffer Flush/Fill (OBFF) Mechanism §

The Optimized Buffer Flush/Fill (OBFF) Mechanism enables a Root Complex to report to Endpoints (throughout a hierarchy) time windows when the incremental platform power cost for Endpoint bus mastering and/or interrupt activity is relatively low. Typically this will correspond to time that the host CPU(s), memory, and other central resources

associated with the Root Complex are active to service some other activity, for example the operating system timer tick. The nature and determination of such windows is platform/implementation specific.

An OBFF indication is a hint - Functions are still permitted to initiate bus mastering and/or interrupt traffic whenever enabled to do so, although this will not be optimal for platform power and should be avoided as much as possible.

OBFF is indicated using either the WAKE# signal or a message (see § Section 2.2.8.9). The message is to be used exclusively on interconnects where the WAKE# signal is not available. WAKE# signaling of OBFF or CPU Active must only be initiated by a Root Port when the system is in an operational state, which in an ACPI compliant system corresponds to the S0 state. Functions that are in a non-D0 state must not respond to OBFF or CPU Active signaling.

OBFF messages use Message Routing 100b, "Local - Terminate at Receiver" (see § Table 2-20), and are only permitted to be transmitted in the Downstream direction. There are multiple OBFF events distinguished. When using the OBFF Message, the OBFF Code field (see § Figure 2-65 and § Figure 2-66) is used to distinguish between different OBFF cases:

1111b “CPU Active”

System fully active for all Device actions including bus mastering and interrupts

0001b “OBFF”

System memory path available for Device memory read/write bus master activities

0000b “Idle”

System in an idle, low power state

Others

All other codes are Reserved.

These codes correspond to various assertion patterns of WAKE# when using WAKE# signaling, as shown in § Figure 6-18. There is one negative-going transition when signaling OBFF and two negative going transitions each time CPU Active is signaled. The electrical parameters required when using WAKE# are defined in the WAKE# Signaling section of [CEM-2.0] (or later).

Figure 6-18 Codes and Equivalent WAKE# Patterns §

When an OBFF Message is received that indicates a Reserved code, the Receiver, if OBFF is enabled, must treat the indication as a “CPU Active” indication.

An OBFF Message received at a Port that does not implement OBFF or when OBFF is not enabled must be handled as an Unsupported Request (UR). This is a reported error associated with the receiving Port (see § Section 6.2). If a Port has OBFF enabled using WAKE# signaling, and that Port receives an OBFF Message, the behavior is undefined.

OBFF indications reflect central resource power management state transitions, and are signaled using WAKE# when this is supported by the platform topology, or using a Message when WAKE# is not available. OBFF support is discovered and enabled through reporting and control registers described in § Chapter 7. . Software must not enable OBFF in an Endpoint unless the platform supports delivering OBFF indications to that Endpoint.

When the platform indicates the start of a CPU Active or OBFF window, it is recommended that the platform not return to the Idle state in less than 10 μ s. It is permitted to indicate a return to Idle in advance of actually entering platform idle, but it is strongly recommended that this only be done to prevent late Endpoint activity from causing an immediate exit from the idle state, and that the advance time be as short as possible.

It is recommended that Endpoints not assume CPU Active or OBFF windows will remain open for any particular length of time.

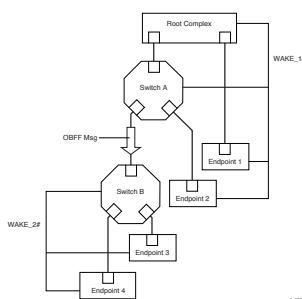

Figure 6-19 Example Platform Topology Showing a Link Where OBFF is Carried by Messages §

§ Figure 6-19 shows an example system where it is necessary for a Switch (A) to translate OBFF indications received using WAKE# into OBFF Messages, which in this case are received by another Switch (B) and translated back to using WAKE# signaling. A HwInit configuration mechanism (set by hardware or firmware) is used to identify cases such as shown in this example (where the link between Switch A and Switch B requires the use of OBFF Messages), and system firmware/software must configure OBFF accordingly.

When a Switch is configured to use OBFF Message signaling at its Upstream Port and WAKE# at one or more Downstream Ports, or vice-versa, when enabled for OBFF, the Switch is required to convert all OBFF indications received at the Upstream Port into the appropriate form at the Downstream Port(s).

When using WAKE#, the enable for any specific Root Port enables the global use of WAKE# unless there are multiple WAKE# signals, in which case only the associated WAKE# signals are affected. When using Message signaling for OBFF, the enable for a particular Root Port enables transmission of OBFF messages from that Root Port only. To ensure OBFF is fully enabled in a platform, all Root Ports indicating OBFF support must be enabled for OBFF. It is permitted for system firmware/software to selectively enable OBFF, but such enabling is beyond the scope of this specification.

To minimize power consumption, system firmware/software is strongly recommended to enable Message signaling of OBFF only when WAKE# signaling is not available for a given link.

OBFF signaling using WAKE# must only be reported as supported by all components connected to a Switch if it is a shared WAKE# signal. In these topologies it is permitted for software to enable OBFF for components connected to the Switch even if the Switch itself does not support OBFF.

It is permitted, although not encouraged, to indicate the same OBFF event more than once in succession.

When a Switch is propagating OBFF indications Downstream, it is strongly encouraged to propagate all OBFF indications. However, especially when using Messages, it may be necessary for the Switch to discard or collapse OBFF indications. It is permitted to discard and replace an earlier indication of a given type when an indication of the same or a different type is received.

Downstream Ports can be configured to transmit OBFF Messages in two ways, which are referred to as Variation A and Variation B. For Variation A, the Port must transmit the OBFF Message if the Link is in the L0 state, but discard the Message when the Link is in the Tx_L0s or L1 state. This variation is preferred when the Downstream Port leads to Devices that are expected to have communication requirements that are not time-critical, and where Devices are expected to signal a non-urgent need for attention by returning the Link state to L0. For Variation B, the Port must

transmit the OBFF Message if the Link is in the L0 state, or, if the Link is in the Tx_L0s or L1 state, it must direct the Link to the L0 state and then transmit the OBFF Message. This variation is preferred when the Downstream Port leads to devices that can benefit from timely notification of the platform state.

When initially configured for OBFF operation, the initial assumed indication must be the CPU Active state, regardless of the logical value of the WAKE# signal, until the first transition is observed.

When enabling Ports for OBFF, it is recommended that all Upstream Ports be enabled before Downstream Ports, and Root Ports must be enabled after all other Ports have been enabled. For hot pluggable Ports this sequence will not generally be possible, and it is permissible to enable OBFF using WAKE# to an unconnected hot pluggable Downstream Port. It is recommended that unconnected hot pluggable Downstream Ports not be enabled for OBFF message transmission.

IMPLEMENTATION NOTE: OBFF CONSIDERATIONS FOR ENDPOINTS §

It is possible that during normal circumstances, events could legally occur that could cause an Endpoint to misinterpret transitions from an Idle window to a CPU Active window or OBFF window. For example, a non-OBFF Endpoint could assert WAKE# as a wakeup mechanism, masking the system's transitions of the signal. This could cause the Endpoint to behave in a manner that would be less than optimal for power or performance reasons, but should not be unrecoverable for the Endpoint or the host system.

In order to allow an Endpoint to maintain the most accurate possible view of the host state, it is recommended that the Endpoint place its internal state tracking logic in the CPU Active state when it receives a request that it determines to be host-initiated, and at any point where the Endpoint has a pending interrupt serviced by host software.

6.20 PASID §

In Non-Flit Mode, the PASID TLP Prefix is an End-End TLP Prefix as defined in [§ Section 2.2.1](#). Layout of the PASID TLP Prefix is shown in [§ Figure 6-20](#) and [§ Table 6-15](#).

In Flit Mode, the PASID, when present, is included in [OHC-A1](#) or [OHC-A4](#).

When a PASID is present, the PASID value, in conjunction with the requester ID, identifies the Process Address Space ID associated with the Request. Each Function has a distinct set of PASID values. PASID values used by one Function are unrelated to PASID values used by any other Function.

PASID is permitted only for specific types of TLPs:

- Requests that include an Address with [Address Type \(AT\)](#) of Untranslated or Translated (see [§ Section 2.2.4.1](#)).
- Address Translation Requests (i.e., MRd with AT=01b), ATS Invalidation Request Messages, Page Request Messages, Address routed messages in Flit Mode, and PRG Response Messages (see [§ Section 10.1.3](#)).

PASID is not permitted on any other type of TLP.

6.20.1 Managing PASID Usage §

Usage of PASID is permitted only when specifically enabled.

For Endpoint Functions (including Root Complex Integrated Devices), the following rules apply:

- A Function is not permitted to send and receive TLPs with a PASID unless PASID Enable is Set (see § Section 7.8.9.3):
- A Function is not permitted to generate Requests using Translated Addresses and a PASID unless both PASID Enable and Translated Requests with PASID Enable are Set.
- A Function must have a mechanism for associating use of a PASID with a particular Function context. This mechanism is outside the scope of this specification.
- A Function must have a mechanism to request that it gracefully stop using a specific PASID. This mechanism is device specific but must satisfy the following rules:
 - A Function may support a limited number of simultaneous PASID stop requests. Software should defer issuing new stop requests until older stop requests have completed.
 - A stop request in one Function must not affect operation of any other Function.
 - A stop request must not affect operation of any other PASID within the Function.
 - A stop request must not affect operation of transactions that are not associated with a PASID.
 - When the stop request mechanism indicates completion, the Function has:
 - Stopped queuing new Requests for this PASID.
 - Completed all Non-Posted Requests associated with this PASID.
 - Flushed to the host all Posted Requests addressing host memory in all TCs that were used by the PASID. The mechanism used for this is device specific (for example: a non-relaxed Posted Write to host memory or a processor read of the Function can flush TC0; a zero length read to host memory can flush non-zero TCs).
 - Optionally flushed all Peer-to-Peer Posted Requests to their destination(s). The mechanism used for this is device specific.
 - Complied with additional rules described in Address Translation Services (§ Chapter 10.) if Address Translations or Page Requests were issued on the behalf of this PASID.

For Root Complexes, the following rules apply:

- A Root Complex must have an implementation specific mechanism for indicating support for PASID.
- A Root Complex that supports PASID must have an implementation specific mechanism for enabling them. By default usage of PASID is disabled.
- A Root Complex that supports PASID may optionally have an implementation specific mechanism for enabling them at a finer granularity than the entire Root Complex (e.g., distinct enables for a specific Root Port, Requester ID, Bus Number, Requester ID, or Requester ID/PASID combination).

6.20.2 PASID Information Layout §

In Flit Mode, the PASID information is contained in OHC-A1 or OHC-A4. In Non-Flit Mode, the PASID information is contained in a PASID TLP Prefix.

6.20.2.1 PASID TLP Prefix - Non-Flit Mode §

A TLP may contain at most one PASID TLP Prefix.

Figure 6-20 PASID TLP Prefix §

Table 6-15 PASID TLP Prefix §

Bits	Description
Byte 0 bits 7:5	100b - indicating TLP Prefix
Byte 0 bit 4	1b - indicating End-End TLP Prefix
Byte 0 bits 3:0	0001b - indicating PASID TLP Prefix
Byte 1 bit 7	Privileged Mode Requested - If Set indicates a Privileged Mode entity in the Endpoint is issuing the Request, If Clear, indicates a Non-Privileged Mode entity in the Endpoint is issuing the Request. Usage of this bit is specified in § Section 6.20.2.4 .
Byte 1 bit 6	Execute Requested - If Set indicates the Endpoint is requesting Execute Permission. If Clear, indicates the Endpoint is not requesting Execute Permission. Usage of this bit is specified in § Section 6.20.2.3 .
Byte 1 bit 3: Byte 3 bit 0	Process Address Space ID (PASID) - This field contains the PASID value associated with the TLP. Usage of this field is defined in § Section 6.20.2.2 .

6.20.2.2 PASID field (Flit Mode and Non-Flit Mode) §

The PASID field identifies the user process associated with a Request.

The PASID field is 20 bits wide. Endpoints and Root Complexes need not support the entire range of the field. For Endpoints, the Max PASID Width field indicates the supported range of PASID values (§ Section 7.8.9.2). For Root Complexes, an implementation specific mechanism is used to provide this information.

Endpoints are not permitted to send TLPs with a PASID unless the PASID Enable bit (§ Section 7.8.9.3) is Set. Endpoints that support PASID must signal Unsupported Request (UR) when they receive a TLP with a PASID and the PASID Enable bit is Clear.

Root Complexes may optionally support TLPs with a PASID. The mechanism used to detect whether a Root Complex supports PASID is implementation specific.

For Endpoints, the following rules apply:

- The Endpoint is not permitted to send TLPs with a PASID value greater than or equal to $2^{\text{Max PASID Width}}$.
- The Endpoint is optionally permitted to signal an error when it receives a Request with a PASID value greater than or equal to $2^{\text{Max PASID Width}}$. This is an Unsupported Request error associated with the Receiving Port (see § Section 6.2).

For Root Complexes, the following rules apply:

- A Root Complex is not permitted to send a TLP with a PASID value greater than it supports.
- A Root Complex is optionally permitted to signal an error when it receives a Request with a PASID value greater than it supports. This is an Unsupported Request error associated with the Receiving Port (see § Section 6.2).

For Completers, the following rules apply:

- For Untranslated Memory Requests, the PASID value and the Untranslated Address are both used in determining the Translated Address used in satisfying the Request. For address translation related TLPs, usage of this field is defined in Address Translation Services (§ Chapter 10.).

IMPLEMENTATION NOTE: PASID WIDTH HOMOGENEITY §

The PASID value is unique per Function and thus the original intent was that the width of the PASID value supported by that Function could be based on the needs of that Function. However, current system software typically does not follow that model and instead uses the same PASID value in all Functions that access a specific address space. To enable this, system software will typically ensure a common system PASID width for Root Complex and persistent translation agents. Such system software will typically disable ATS on any hot plugged Endpoint Functions or translation agents reporting PASID width support which is less than that of the common system PASID width.

The Root Complex, Endpoints, and translation agents, are often implemented independently of system software, therefore it is strongly recommended that hardware implement the maximum width of 20 bits to ensure interoperability with system software.

Endpoints may, in an implementation specific way, be able to map the 20 bit system PASID to an internal representation carrying a smaller width. If this is done, it is critical that the Endpoint do so without impacting system software, which has no mechanism to differentiate such implementation from those that implement the full 20 bit width natively.

6.20.2.3 Execute Requested §

If the Execute Requested bit is Set, the Endpoint is requesting permission for the Endpoint to Execute instructions in the memory range associated with this request. The meaning of Execute permission is outside the scope of this specification.

Endpoints are not permitted to send TLPs with the Execute Requested bit Set unless the Execute Permission Supported bit (§ Section 7.8.9.2) and the Execute Permission Enable bit (§ Section 7.8.9.3) are both Set.

For Root Complexes, the following rules apply:

- Support for Execute Requested by the Root Complex is optional. The mechanism used to determine whether a Root Complex supports Execute Requested is implementation specific.
 - It is strongly recommended that Root Complexes not support Execute Requested.
- A Root Complex that supports the Execute Requested bit must have an implementation specific mechanism to enable it to use the bit. This mechanism must default to disabled.
- A Root Complex that supports the Execute Requested bit is permitted to have an implementation specific mechanism to enable use of the bit at a finer granularity (e.g., for a specific Root Port, for a specific Bus Number, for a specific Requester ID, or for a specific Requester ID/PASID combination), and its default value is implementation specific.

For Completers, the following rules apply:

- Completers have a concept of an effective value of the bit. For a given Request, if the Execute Requested bit is supported and its usage is enabled for the Request, the effective value of the bit is the value in the Request; otherwise the effective value of the bit is 0b.
- For Untranslated Memory Read Requests, Completers use the effective value of the bit as part of the protection check. If this protection check fails, Completers treat the Request as if the memory was not mapped.
- For Memory Requests, other than an Untranslated Memory Read Request, the bit is Reserved. For address translation related TLPs, usage of this bit is defined in Address Translation Services (§ Chapter 10.).

6.20.2.4 Privileged Mode Requested §

If Privileged Mode Requested is Set, the Endpoint is issuing a Request that targets memory associated with Privileged Mode. If Privileged Mode Requested is Clear, the Endpoint is issuing a Request that targets memory associated with Non-Privileged Mode.

The meaning of Privileged Mode and Non-Privileged Mode and what it means for an Endpoint to be operating in Privileged or Non-Privileged Mode depends on the protection model of the system and is outside the scope of this specification.

Endpoints are not permitted to send a TLP with the Privileged Mode Requested bit Set unless both the Privileged Mode Supported bit (§ Section 7.8.9.2) and the Privileged Mode Enable bit (§ Section 7.8.9.3) are Set.

For Root Complexes, the following rules apply:

- Support for the Privileged Mode Requested bit by the Root Complex is optional. The mechanism used to determine whether a Root Complex supports the Privileged Mode Requested bit is implementation specific.
- A Root Complex that supports the Privileged Mode Requested bit should have an implementation specific mechanism to enable it to use the bit.
- A Root Complex that supports the Privileged Mode Requested bit may have an implementation specific mechanism to enable use of the bit at a finer granularity (e.g., for a specific Root Port, for a specific Bus Number, for a specific Requester ID, or for a specific Requester ID/PASID combination).

For Completers, the following rules apply:

- Completers have the concept of an effective value of the bit. For a given Request, if the Privileged Mode Requested bit is supported and its usage is enabled for the Request, the effective value of the bit is the value in the Request; otherwise the effective value of the bit is the 0b.
- For Untranslated Memory Requests, Completers use the effective value of the bit as part of its protection check. If this protection check fails, Completers treat the Request as if the memory was not mapped.

- For address translation related TLPs, usage of this bit is defined in Address Translation Services (§ Chapter 10).

6.2.1 Precision Time Measurement (PTM) Mechanism §

6.2.1.1 Introduction §

Precision Time Measurement (PTM) enables precise coordination of events across multiple components with independent local time clocks. Ordinarily, such precise coordination would be difficult given that individual time clocks have differing notions of the value and rate of change of time. To work around this limitation, PTM enables components to calculate the relationship between their local times and a shared PTM Master Time: an independent time domain associated with a PTM Root.

Enhanced Precision Time Measurement (ePTM) places additional requirements on PTM Devices. Support for ePTM is indicated by the ePTM Capable bit.

PTM defines the following:

- PTM Requester - A Function capable of using PTM as a consumer associated with an Endpoint or an Upstream Port.
- PTM Responder - A Function capable of using PTM to supply PTM Master Time associated with a Port or an RCRB.
- Time Source - A local clock associated with a PTM Responder.
- PTM Root - The source of PTM Master Time for a PTM Hierarchy. A PTM Root must also be a Time Source and is typically also a PTM Responder.

Each PTM Root supplies a single PTM Master Time to all of the PTM Hierarchy: a set of PTM Requesters associated with a single PTM Root.

§ Figure 6-21 illustrates some example system topologies using PTM. These are only illustrative examples, and are not intended to imply any limits or requirements.

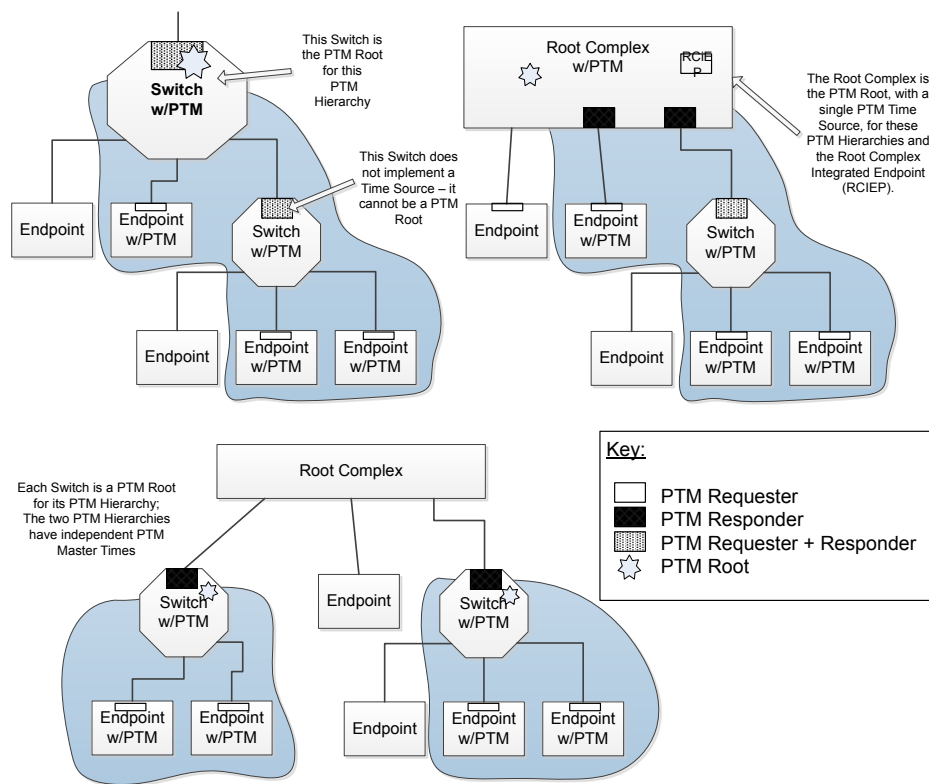

Figure 6-21 Example System Topologies using PTM §

IMPLEMENTATION NOTE:

PTM AND RETIMERS §

PCIe Retimers can impact PTM accuracy by introducing asymmetric link delays. Retimers designed to maintain symmetric link delays will enable the best PTM accuracy. The larger and more variable the asymmetry, the greater the impact to PTM. Consult the manufacturer's documentation to determine the suitability of a Retimer implementation for use with PTM.

6.21.2 PTM Link Protocol §

When using PTM between two components on a Link, the Upstream Port, which acts on behalf of the PTM Requester, sends PTM Requests to the Downstream Port on the same Link, which acts on behalf of the PTM Responder.

Figure 6-22 Precision Time Measurement Link Protocol §

§ Figure 6-22 illustrates the PTM link protocol. The points t1, t2, t3, and t4 in the above diagram represent timestamps captured locally by each Port as they transmit and receive PTM Messages. The component associated with each Port stores these timestamps from the 1st PTM dialog in internal registers for use in the 2nd PTM dialog, and so on for subsequent PTM dialogs.

The Upstream Port, on behalf of the PTM Requester, initiates the PTM dialog by transmitting a PTM Request message.

The Downstream Port, on behalf of the PTM Responder, has knowledge of or access (directly or indirectly) to the PTM Master Time.

During each dialog, the Downstream Port populates the PTM ResponseD message based on timestamps stored during previous PTM dialogs, as defined in § Section 6.21.3.2 .

Once each component has historical timestamps from the preceding dialog, the component associated with the Upstream Port can combine its timestamps with those passed in the PTM ResponseD message to calculate the PTM Master Time using the following formula:

$$\text{PTM Master Time at } t1' = t2' - \frac{\left((t4 - t1) - (t3 - t2) \right)}{2}$$

Equation 6-2 PTM Master Time §

The values t1, t2, t3, t4, and t2' indicate the timestamps captured during the PTM dialog as illustrated in § Figure 6-22.

PTM capable components would typically record the results of these timestamp calculations, and may make them available to software via implementation specific means. Herein, this document refers to this resultant timing information as the component's "PTM context".

For a Switch implementing PTM, the time synchronization mechanism(s) within the Switch itself are implementation specific.

IMPLEMENTATION NOTE: PTM THEORY AND OPERATION §

The timestamps captured during the PTM dialogs enable the calculation of the timing relationship between the PTM Requester and PTM Responder. The value $(t_3 - t_2)$ measures the time consumed by the PTM Responder for a given PTM dialog. The time $(t_4 - t_1)$ is the time from request to response. Therefore $((t_4 - t_1) - (t_3 - t_2))$ effectively gives the round trip message transit time between the two components, and that quantity divided by 2 approximates the Link delay - the time difference between t_1 and t_2 . It is assumed that the Link transit times from PTM Requester to PTM Responder and back again are symmetric, which is typically a good assumption (see also the Implementation Note on PTM Timestamp Capture Mechanisms).

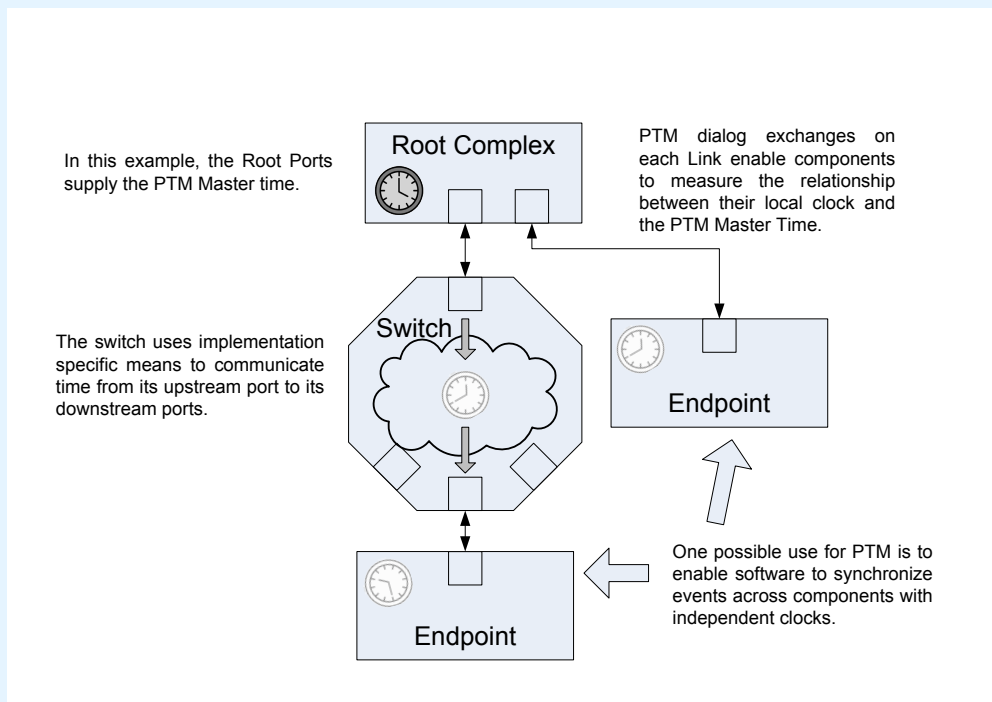

Figure 6-23 Precision Time Measurement Example §

§ Figure 6-23 illustrates a simple device hierarchy employing PTM. Each Upstream Port initiates PTM dialogs to establish the relationship between its local time and the PTM Master Time provided by the Root Port.

In this example, the Switch initiates PTM dialogs on its Upstream Port to obtain the PTM Master Time for use in fulfilling PTM Request Message received at its Downstream Ports. This Switch employs implementation specific means to communicate the PTM Master Time from its Upstream Port to its Downstream Ports.

PTM capable components can make their PTM context available for inspection by software, enabling software to translate timing information between local times and PTM Master Time. In turn, this capability enables software to coordinate events across multiple components with very fine precision.

Similarly, it is strongly recommended that platforms implementing PTM also make the PTM Master Time available to software.

6.21.3 Configuration and Operational Requirements §

Software must not have the PTM Enable bit Set in the PTM Control register on a Function associated with an Upstream Port unless the associated Downstream Port on the Link already has the PTM Enable bit Set in its associated PTM Control register.

PTM support by a Function is indicated by the presence of a PTM Extended Capability structure. It is not required that all Endpoints in a hierarchy support PTM, and it is not required for software to enable PTM in all Endpoints that do support it.

If a PTM Message is received by a Port that does not support PTM, or by a Downstream Port when the PTM Enable bit is clear, the Message must be treated as an Unsupported Request. This is a reported error associated with the Receiving Port (see § Section 6.2). A properly formed PTM Response received by an Upstream Port that supports PTM, but for which the PTM Enable bit is clear, must be silently discarded.

As observed through PTM, the PTM Master Time must satisfy the following behavioral requirements:

- Time values must be monotonic, and strictly increasing.
- The perceived granularity must be no greater than the value reported in the Local Clock Granularity field of the PTM Capability Register.
- The perceived time must start no later than when the PTM Root processes its first PTM Request Message.

Referring to § Figure 6-22, the following rules define timestamp capture:

- A PTM Requester must update its stored t1 timestamp when transmitting a PTM Request Message, even if that transmission is a replay.
- A PTM Responder must update its stored t2 timestamp when receiving a PTM Request Message, even if received TLP is a duplicate.
- A PTM Responder must update its stored t3 timestamp when transmitting a PTM Response or ResponseD Message, even if that transmission is a replay.
- A PTM Requester must update its stored t4 timestamp when receiving a PTM Response Message, even if received TLP is a duplicate.

In NFM, Timestamps must be based on the STP Symbol or Token that frames the TLP, as if observing the first bit of that Symbol or Token at the Port's pins.

In FM, a single Flit is permitted to include zero or one PTM Messages, and Timestamps must be based on the Flit_Marker (see § Section 4.2.3.4.2) that has the PTM Message contained in this Flit bit Set, as if observing the Flit_Marker Indicator bit at the Port's pins. Typically this will require an implementation specific adjustment to compensate for the inability to directly measure the time at the actual pins, as the time will commonly be measured at some internal point in the Rx or Tx path. The accuracy and consistency of this measurement are not bounded by this specification, but it is strongly recommended that the highest practical level of accuracy and consistency be achieved.

As illustrated in § Figure 2-68, the bytes within the Propagation Delay[31:0] field are such that:

- Data Byte 0 contains Propagation Delay [31:24] (most significant byte)
- Data Byte 1 contains Propagation Delay [23:16]
- Data Byte 2 contains Propagation Delay [15:8]
- Data Byte 3 contains Propagation Delay [7:0] (least significant byte)

All implementations compliant to this document are required to follow the above interpretation (Propagation Delay interpretation A). Due to ambiguity in earlier versions of this document, some implementations made this interpretation (Propagation Delay interpretation B):

- Data Byte 0 contains Propagation Delay [7:0] (least significant byte)
- Data Byte 1 contains Propagation Delay [15:8]
- Data Byte 2 contains Propagation Delay [23:16]
- Data Byte 3 contains Propagation Delay [31:24] (most significant byte)

To allow implementations using interpretation A to interoperate with implementations using interpretation B the PTM Propagation Delay Adaptation Capability can be used. For an Upstream Port, this capability applies to the interpretation of received PTM ResponseD Messages, for a Downstream Port, this capability applies to the interpretation of transmitted PTM ResponseD Messages. Support for the PTM Propagation Delay Adaptation Capability is indicated by Setting the PTM Propagation Delay Adaptation Capable bit in the PTM Capability Register. When supported, the Port must use interpretation A, unless the PTM Propagation Delay Adaptation Interpretation B bit in the Link Control Register is Set, in which case the Port changes to interpretation B. For a Switch, if the PTM Propagation Delay Adaptation Capable bit is Set, then all Ports of the Switch must support the PTM Propagation Delay Adaptation Capability, and each Switch Port must be controlled independently by the value of the PTM Propagation Delay Adaptation Interpretation B bit in the Link Control Register for the Port.

It is strongly recommended that software not enable PTM on a link until it has first assured, either by means of the PTM Propagation Delay Adaptation Capability or in an implementation specific manner, that both Ports on the Link are able to compatibly interpret the Propagation Delay value.

6.21.3.1 PTM Requester Role §

- Support for the PTM Requester role is indicated by setting the PTM Requester Capable bit in the PTM Capability Register.
- PTM Requesters are permitted to request PTM Master Time only when PTM is enabled. The mechanism for directing a PTM Requester to issue such a request is implementation specific.
 - Upstream Ports obtain PTM Master Time via PTM dialogs as described in § Section 2.2.8.10 .
 - The mechanism by which RCiEPs request PTM Master Time is implementation specific.
- Once having issued a PTM Request Message, the Upstream Port must not issue another PTM Request Message prior to the receipt of a PTM Response Message, PTM ResponseD Message, Reset, or the passage of 100 μ s without a corresponding PTM Message from the Downstream Port.
- Upon receiving a PTM Response, the Upstream Port must wait at least 1 μ s before issuing another PTM Request Message.
- For Multi-Function Devices (MFDs) containing multiple PTM Requesters, the Upstream Port associated with that MFD must issue a single PTM dialog during each PTM context refresh. PTM Requesters within the MFD maintain their individual PTM contexts using this one, Device-wide PTM dialog. The mechanism for refreshing multiple PTM contexts from one PTM dialog is implementation specific.
- An Upstream Port *MUST@FLIT* invalidate its internal PTM context when any of the following occur. If ePTM is supported, then an Upstream Port must invalidate its internal PTM context when any of the following occur:
 - A PTM Request is replayed.
 - A duplicate PTM ResponseD TLP is received.

- The relationship between PTM Master Time and the Upstream Port's local time changes, as determined by implementation specific criteria. For example, this may occur as a result of a transition to a non-D0 state or due to accumulated PPM drift.

These events are grouped under the label “Local Time Invalidation Event” in § Figure 6-24.

- If ePTM is supported, an Upstream Port, upon replaying a PTM TLP, must invalidate its PTM context until two successive PTM dialogs have been completed successfully and without replays.

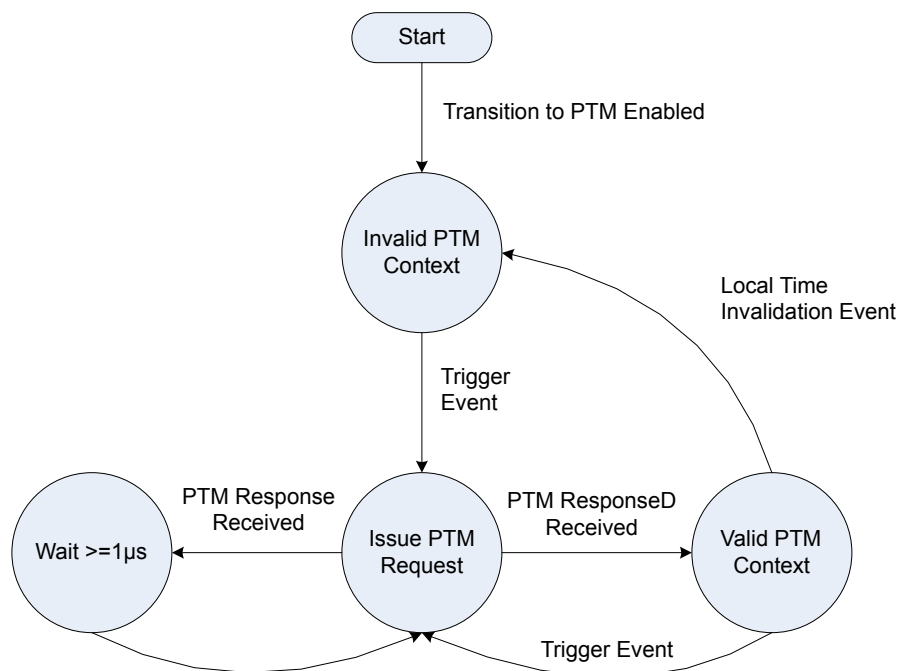

Figure 6-24 PTM Requester Operation §

IMPLEMENTATION NOTE:

PTM INVALIDATION ON THE RECEPTION OF DUPLICATE TLPs §

Duplicate TLPs are detected and discarded in the Data Link Layer, whereas PTM messages are identified in the Transaction Layer. In some implementations it may be difficult or excessively complicated to distinguish a duplicate PTM TLP from other duplicate TLPs.

Because Upstream Ports are permitted to invalidate their internal PTM context for implementation specific criteria, a PTM Requester is allowed to invalidate its internal PTM context upon the reception of any duplicate TLP in addition to any duplicate PTM TLP. Similarly, if ePTM is supported, then a PTM Responder is allowed to invalidate its historical timestamps (t2 - t3) upon the reception of any duplicate TLP.

6.21.3.2 PTM Responder Role §

- Support for the PTM Responder role is indicated by setting the PTM Responder Capable bit in the PTM Capability register.
- Switches and Root Complexes are permitted to implement the PTM Responder Role.
 - A PTM capable Switch, when enabled for PTM by setting the PTM Enable bit in the PTM Control register associated with the Switch Upstream Port, must respond to all PTM Request Messages received at any of its Downstream Ports.
 - The mechanism by which Root Complexes communicate PTM Master Time to RCiEPs is implementation specific.
- PTM Responders must populate PTM ResponseD Messages as follows (refer to § Figure 6-22 and the accompanying implementation note):
 - The PTM Master Time field is a 64-bit value containing the value of PTM Master Time at the receipt of the PTM Request Message for the current PTM Dialog. In § Figure 6-22, for the 2nd PTM dialog, this is the PTM Master Time at time t2'.
 - The Propagation Delay field is a 32-bit value containing the interval between the receipt of the PTM Request Message and the transmission of the PTM Response Message for the previous PTM dialog. In § Figure 6-22, for the 2nd PTM dialog, this is the time interval between t2 and t3 captured during the 1st PTM dialog.
 - The unit of measurement for both fields is one ns.
 - A PTM Responder with multiple Downstream Ports must populate all PTM ResponseD Messages with values from a single PTM Root across all its PTM Ports Downstream ports.
- Switch Downstream Ports and Root Ports acting as PTM Responders must respond to each PTM Request Message received at their Downstream Ports with either PTM Response or PTM ResponseD according to the following rules:
 - A PTM Responder must not send a PTM Response or PTM ResponseD Message without first receiving a PTM Request Message.
 - Upon receipt of a PTM Request Message, a PTM Responder must attempt to issue a PTM Response or PTM ResponseD Message within 10 μ s.
 - A PTM Responder must issue PTM Response when the Downstream Port does not have valid historical timestamps (t3 - t2) with which to fulfill a PTM Request Message.
 - If ePTM is supported, a PTM Responder must invalidate its historical timestamps (t3 - t2) immediately upon replaying any PTM Response or PTM ResponseD.
 - If ePTM is supported a PTM Responder must, and if ePTM is not supported a PTM Responder is recommended to, invalidate its historical timestamps (t3 - t2) after receiving any duplicate PTM Request.
- A PTM Responder must issue PTM ResponseD when it has stored copies of the values required to populate the PTM ResponseD Message: historical timestamps (t3 - t2) and the PTM Master Time at the receipt of the most recent PTM Request Message (time t2').
- A PTM Responder is permitted to issue PTM Response when it has stored copies of the historical timestamps (t3 - t2) but must request the PTM Master Time from elsewhere. In this case, it is permitted to issue PTM Response messages in response to PTM Request Messages while it retrieves the PTM Master Time if that retrieval is expected to take more than 10 μ s.

- The perceived granularity of the historical timestamps and PTM Master Time values transmitted by a PTM Responder must not exceed that reported in the Local Clock Granularity field of the PTM Capability Register.

6.21.3.3 PTM Time Source Role - Rules Specific to Switches §

In addition to the requirements listed above for the PTM Requester and PTM Responder Roles, Switches must follow these requirements:

- When the Upstream Port is associated with a Multi-Function Device, only a single Function associated with that Upstream Port is permitted to implement the PTM Extended Capability structure. For Switches, all PTM functionality associated with the Switch must be controlled through that structure. It is not required that the Function implementing the PTM Extended Capability structure be the Switch Upstream Port Function.
- The PTM Extended Capability structure for a Switch must indicate support for both the PTM Requester and PTM Responder roles.
- The PTM Extended Capability in the Upstream Port controls all Switches in that Upstream Port.
- A Switch is permitted to act as a PTM Root, or to issue PTM Requests on its Upstream Port to obtain the PTM Master Time for use in fulfilling PTM Requests received at its Downstream Ports. In the latter case the Switch must account for any internal delays within the Switch.
- A Switch is permitted to maintain a local PTM context for use in fulfilling PTM Requests received on its Downstream Ports.
- A Switch which is not acting as a PTM Root must invalidate its local context no more than 10 ms from the last PTM dialog on its Upstream Port. The Switch must then refresh its local PTM context prior to issuing further PTM ResponseD Messages on its Downstream Ports. This requirement for periodic refreshes is optional if it is guaranteed by implementation specific means that the Switch's local clock is phase locked with PTM Master Time.
- Any Switch implementing a local clock for the purpose of maintaining a local PTM context must report the granularity of this clock as defined in the PTM Capabilities structure (§ Section 7.9.15).

IMPLEMENTATION NOTE: PTM TIMESTAMP CAPTURE MECHANISMS §

PTM uses services from both the Data Link and Transaction Layers. Accuracy requires that time measurements be taken as close to the Physical Layer as possible. Conversely, the messaging protocol itself properly belongs to the Transaction Layer. The PTM message protocol applies to a single Link, where the Upstream Port is the requester and the Downstream Port is the responder.

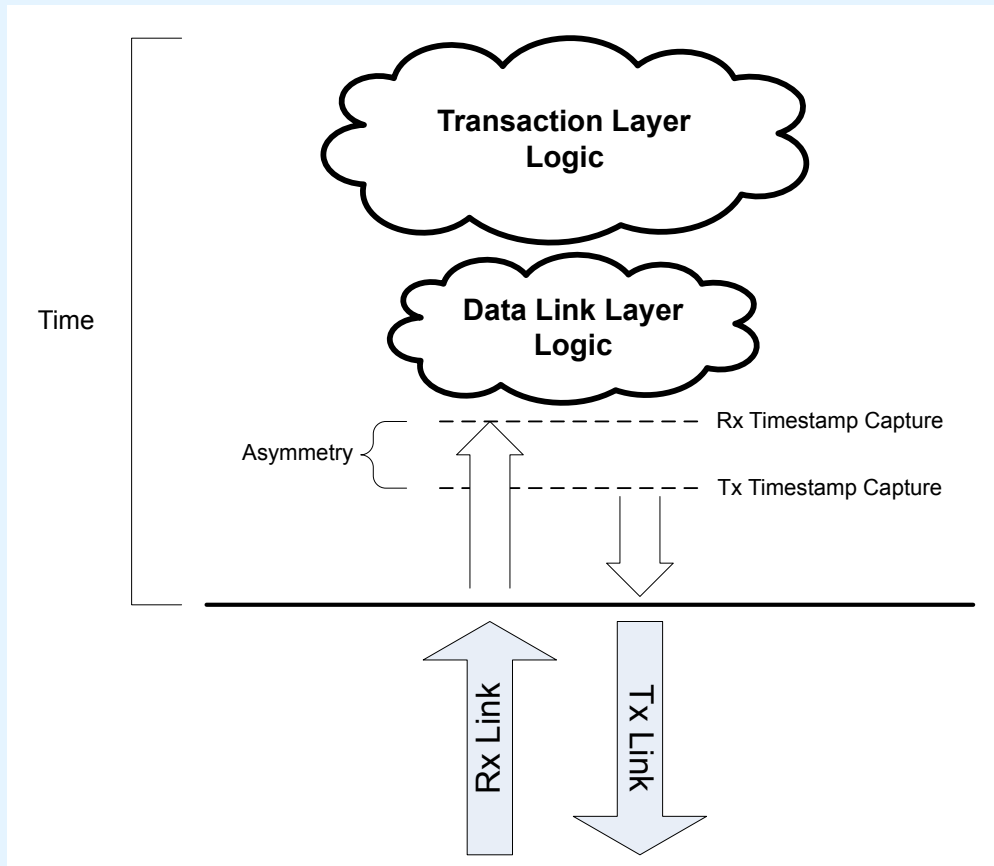

Figure 6-25 PTM Timestamp Capture Example §

§ Figure 6-25 illustrates how to select suitable timestamp capture points. For some implementations, the logic within the Transaction Layer and Data Link Layers is non-deterministic. Implementation details and current conditions have considerable impact on exactly when a particular packet may encounter any particular processing step. This makes it effectively impossible to capture any timestamp that accurately records the time of a particular physical event if timestamps are captured in the higher layers.

6.22 Readiness Notifications (RN) §

Readiness Notifications (RN) is intended to reduce the time software needs to wait before issuing Configuration Requests to a Device or Function following DRS Events or FRS Events. RN includes both the Device Readiness Status (DRS) and

Function Readiness Status (FRS) mechanisms. These mechanisms provide a direct indication of Configuration-Readiness (see Terms and Acronyms entry for Configuration-Ready). When used, DRS and FRS allow an improved behaviour over the Configuration RRS mechanism, and eliminate its associated periodic polling time of up to 1 second following a reset. With appropriate system support, the DRS mechanism can be used to support Devices that require more than 1 second to become Configuration-Ready (see HARDWARE/SOFTWARE RECOMMENDATIONS FOR OPTIMIZING CONFIGURATION READINESS below).

It is permitted that system software/firmware provide mechanisms that supersede the FRS and/or DRS mechanisms, however such software/firmware mechanisms are outside the scope of this specification.

IMPLEMENTATION NOTE: HARDWARE/SOFTWARE RECOMMENDATIONS FOR OPTIMIZING CONFIGURATION READINESS §

It is strongly recommended that implementers of System Software avoid unnecessary delays wherever possible. It is strongly recommended that hardware be designed to eliminate or minimize required delays, and utilize mechanisms provided in this and related specifications to communicate any required delays. Hardware implementers should document hardware behavior sufficiently to enable System Software to implement optimal behaviors.

Even before a Link is in L0, it is possible for System Software to determine if the DRS mechanism can be used to determine when a device becomes Configuration Ready. System Software may do this as follows:

1. If the DRS Supported bit in the Downstream Port above the device is Clear, stop this procedure and follow the procedure in § Section 2.3.1.
2. Check the Downstream Component Presence field in the Downstream Port.
 - If Downstream Component Presence equals Link Up – Component Present and DRS Received, the device is already Configuration Ready.
 - If System Software is informed, through implementation specific mechanisms, that the device supports DRS, continue with Step 3. System Software is strongly recommended to take advantage of such knowledge when available.
 - If Downstream Component Presence equals Link Down – Flit Mode Negotiation Completed or Link Up Component Present:
 - If Flit Mode Status is Set, assume the device also supports DRS since DRS is mandatory if a component supports Flit Mode. Continue with Step 3.
 - Otherwise, continue with Step 7.
 - If Otherwise, if the Link is Up, continue with Step 7.

When System Software determines that DRS is supported by both the Downstream Port and the device below it, the following DRS-Only procedure is strongly recommended:

3. The timeout based procedure defined in § Section 2.3.1 is not used. That procedure supports devices that can take a maximum of 1 second to become Configuration Ready. This DRS-Only procedure supports devices that take longer than 1 second to become Configuration Ready.
4. Either DRS Message Received or Downstream Component Presence are used to determine when the device is or becomes Configuration Ready.
5. The Downstream Component Presence field is used to avoid polling when a component is not present.
6. A non-blocking polling capability is implemented so that unrelated operations are not stalled. Software may configure DRS Signaling Control to generate an interrupt or FRS Message to indicate when polling should occur. It may be desirable to implement a timeout mechanism to terminate polling and indicate an error condition if the timeout expires. The timeout should be determined by system use case requirements. If none applies and a component is known to be present, a value of 10 seconds is recommended.

When System Software cannot determine that DRS is supported by both the Downstream Port and the device below it, then this hybrid approach for determining Configuration Ready is recommended:

7. The timeout based procedure defined in § [Section 2.3.1](#) is run in parallel with the DRS-Only procedure in [Step 4](#) through [Step 6](#).
8. The receipt of a DRS Message indicates the Device is Configuration Ready, and System Software proceeds without further delay to configure the device.
9. If no DRS Message is received within an appropriate period determined by system use case requirements, then System Software may issue a Configuration Request to the Device per the procedure described in § [Section 2.3.1](#).

6.22.1 Device Readiness Status (DRS) §

DRS *MUST@FLIT* be implemented, and the DRS Supported bit in the Link Capabilities 2 register *MUST@FLIT* be Set in all Downstream Ports and in Function 0 of all Upstream Ports. DRS is optional for Ports that do not support Flit Mode.

DRS must be used to indicate when a Device is Configuration-Ready following any of the following Device-level occurrences, which are subsequently referred to as “DRS Events”:

- Exit from [Cold Reset](#)
- Exit from [Warm Reset](#), [Hot Reset](#), [Loopback](#), or [Disabled](#)
- Exit from [L2/L3 Ready](#)
- Any other scenario where the Port transitions from [DL_Down](#) to [DL_Up](#) status.

The DRS Message protocol requirements include the following:

- There is no enable or disable mechanism for DRS.
- It is expressly permitted for Upstream Ports to send DRS Messages even when the [DRS Supported](#) bit is Clear.
- A DRS Message must be transmitted by a DRS-capable Upstream Port following every [DL_Down](#) to [DL_Up](#) transition when all non-VF Functions on the Logical Bus associated with that Upstream Port become ready.
 - A [Type 0 Function](#) is ready when it is [Configuration-Ready](#).
 - A [Type 1 Function](#) that is a Switch Upstream Port is ready when it is [Configuration-Ready](#) and all Functions on its secondary bus are [Configuration-Ready](#).
 - A [Type 1 Function](#) that is not a Switch Upstream Port is ready when the Function itself is [Configuration-Ready](#).
- After a Device transmits a DRS Message, non-VF Functions indicated as [Configuration-Ready](#) by that DRS Message must not return Completions with RRS in response to Configuration Requests unless a subsequent DRS Event occurs.

Additional requirements relating to Switches implementing DRS include:

- Must support DRS functionality in all Ports
- Implementation at each Downstream Port of the [DRS Signaling Control](#) field.
- For any physically-integrated Device that appears beneath a Switch Downstream Port, the DRS sent by the Switch does not indicate Configuration Readiness for that Device
 - For such a Device, implementation and use of DRS is independent of the Switch

Additional requirements for Root Ports and Switch Downstream Ports include:

Implementation of the DRS Message Received bit, which indicates receipt of a DRS Message

IMPLEMENTATION NOTE: DRS MESSAGES AND ACS SOURCE VALIDATION §

Functions are permitted to transmit DRS Messages before they have been assigned a Bus Number. Such messages will have a Requester ID with a Bus Number of 00h. If the Downstream Port has ACS Source Validation enabled, these Messages (see § Section 6.12.1.1) will likely be detected as an ACS Violation error.

6.22.2 Function Readiness Status (FRS) §

When implemented, FRS must be used to indicate a specific Function as being Configuration-Ready following any of the following Function-level occurrences, which are subsequently referred to as “FRS Events”:

- Function Level Reset (FLR)
- Completion of D3_{Hot} to D0 transition
- Setting or Clearing of VF Enable in a PF (SR-IOV)

The FRS Message protocol requirements include the following:

- The Requester ID of the FRS Message must indicate the Function that has changed readiness status (see § Section 2.2.8.6.3)
- The FRS Reason field in the FRS Message must indicate why that Function changed readiness status
- After a Function transmits an FRS Message, the indicated Function(s) must not return Completions with RRS in response to a Configuration Request unless a subsequent DRS Event or FRS Event occurs

Additional requirements for Switches implementing FRS include:

- Must support FRS functionality in the Upstream Port and all Downstream Ports
- The ability to transmit FRS Messages Upstream when required by the FRS protocol

Additional requirements for Physical Functions (PFs) include:

- The ability to transmit FRS Message Upstream when the VF Enable or VF Disable process completes

Additional requirements for Root Ports and Root Complex Event Collectors implementing FRS include:

- Must implement the FRS Queuing Extended Capability (see § Section 7.8.10)

6.22.3 FRS Queuing §

Root Ports and Root Complex Event Collectors that support FRS must implement the FRS Queuing Extended Capability (see § Section 7.8.10).

For a Root Port, the FRS Message Queue contains FRS Messages received by the Root Port or generated by the Root Port.

For a Root Complex Event Collector, the FRS Message Queue contains FRS Messages generated by RCiEPs associated with the Root Complex Event Collector (see § Section 7.9.10) or generated by the Root Complex Event Collector.

The FRS Message Queue must satisfy the following requirements:

- The FRS Message Queue must be empty following Reset.
- For a Root Port, the FRS Message Queue must be emptied when the Link goes to DL_Down.
- FRS Messages must be queued in the order received.
- If the FRS Message Queue is not full at the time an FRS Message is received or is internally generated, that FRS Message must be entered in the queue and the FRS Message Received bit must set to 1b.
- If the FRS Message Queue is full at the time an FRS Message is received or is internally generated, that FRS Message must be discarded and the FRS Message Overflow bit must be set to 1b. The pre-existing FRS Message Queue must be preserved.
- The oldest FRS Message must be visible in the FRS Message Queue register (see § Section 7.8.10.4).
- Writing the FRS Message Queue register must remove the oldest element from the queue.
- When either FRS Message Received or FRS Message Overflow transitions from 0b to 1b, an interrupt must be generated if enabled.

6.23 Enhanced Allocation §

The Enhanced Allocation (EA) Capability is an optional Capability that allows the allocation of I/O, Memory and Bus Number resources in ways not possible with the BAR and Base/Limit mechanisms in the Type 0 and Type 1 Configuration Headers.

It is only permitted to apply EA to certain functions, based on the hierarchical structure of the functions as seen in PCI configuration space, and based on certain aspects of how functions exist within a platform environment (see § Figure 6-26).

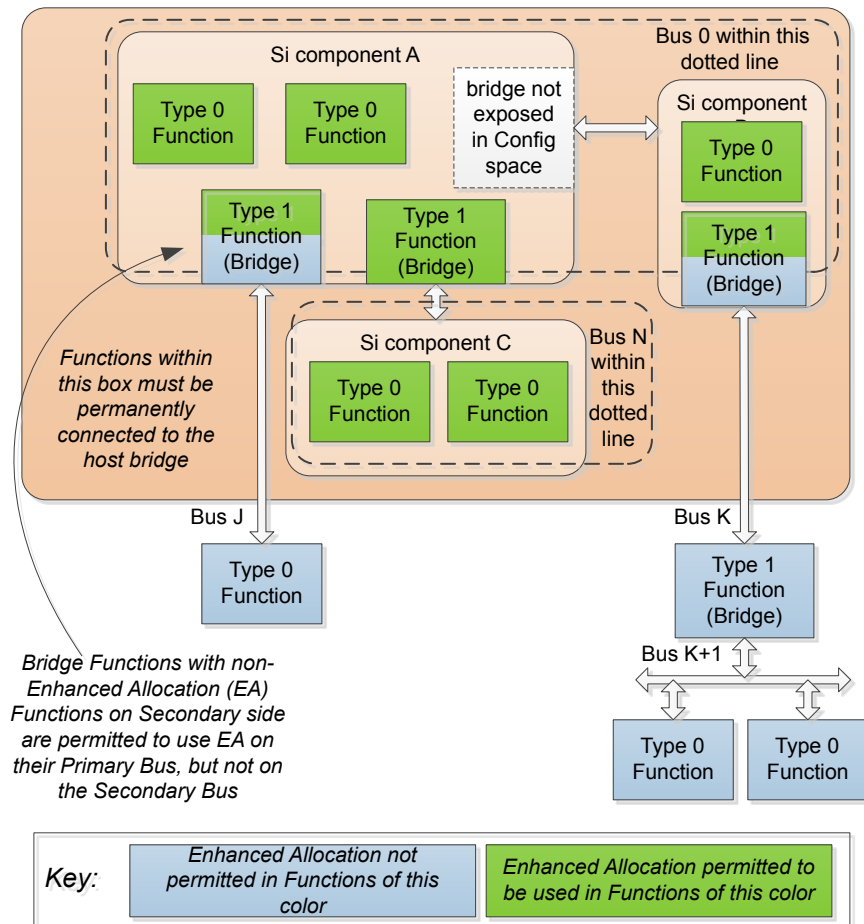

Figure 6-26 Example Illustrating Application of Enhanced Allocation §

Only functions that are permanently connected to the host bridge are permitted to use EA. A bridge function (i.e., any function with a Type 1 Configuration Header), is permitted to use EA for both its Primary Side and Secondary Side if and only if the function(s) behind the bridge are also permanently connected (below one or more bridges) to the host bridge, as shown for “Si component C” in § Figure 6-26.

A bridge function is permitted to use EA only for its Primary Side if the function(s) behind the bridge are not permanently connected to the bridge, as with the bridges above Bus J and Bus K in § Figure 6-26, and in this case the non-EA resource allocation mechanisms in the Type 1 Header for Bus numbers, MMIO ranges and I/O ranges are used for the Secondary side of the bridge. System software must ensure that the allocated Bus numbers are within the range indicated in the Fixed Secondary Bus Number and Fixed Subordinate Bus Number registers of the EA capability. System software must ensure that the allocated MMIO and I/O ranges are within ranges indicated with the corresponding Properties in the EA capability for resources to be allocated behind the bridge. For Bus numbers, MMIO and I/O ranges behind the bridge, hardware is permitted to indicate overlapping ranges in multiple bridge functions, however, in such cases, system software must ensure that the ranges actually assigned are non-overlapping.

Functions that rely exclusively on EA for I/O and Memory address allocation must hardwire all bits of all BARs in the PCI Header to 0. Such Functions must be clearly documented as relying on EA for correct operation, and platform integrators must ensure that only EA-aware firmware/software are used with such Functions.

When a Function allocates resources using EA and indicates that a resource range is associated with an equivalent BAR number, the Function must not request resources through the equivalent BAR, which must be indicated by hardwiring all bits of the equivalent BAR to 0.

For a bridge function that is permitted to implement EA based on the rules above, it is permitted, but not required, for the bridge function to use EA mechanisms to indicate resource ranges that are located behind the bridge Function. In the example shown in in § Figure 6-26, the bridge above Bus N is permitted to use EA mechanisms to indicate the resources used by the two functions in “Si component C”, or that bridge is permitted to not indicate the resources used by the two functions in “Si component C”. System firmware/software must comprehend that such bridge functions are not required to indicate inclusively all resources behind the bridge, and as a result system firmware/software must make a complete search of all functions behind the bridge to comprehend the resources used by those functions.

A Function with an Expansion ROM is permitted to use the existing mechanism or the EA mechanism, but is not permitted to support both. If a Function uses the EA mechanism (EA entry with BEI of 8), the Expansion ROM Base Address and Expansion ROM Enable fields must be hardwired to 0 (see § Section 7.5.1.2.4). The Enable bit of the EA entry is equivalent to the Expansion ROM Enable bit. If a Function uses Expansion ROM Base Address Register mechanism, no EA entry with a BEI of 8 is permitted. In both cases, Expansion ROM Validation, if supported, uses the Expansion ROM Validation Status and Expansion ROM Validation Details fields (see § Section 7.5.1.2.4).

The requirements for enabling and/or disabling the decode of I/O and/or Memory ranges are unchanged by EA, including but not limited to the Memory Space and I/O Space enable bits in the Command register.

Any resource allocated using EA must not overlap with any other resource allocated using EA, except as permitted above for identifying permitted address ranges for resources behind a bridge.

6.24 Emergency Power Reduction State §

Emergency Power Reduction State is an optional mechanism to request that Functions quickly reduce their power consumption. Emergency Power Reduction is a fail-safe mechanism intended to be used to prevent system damage and is not intended to provide normal dynamic power management.

If a Function implements Emergency Power Reduction State, it must also implement the Power Budgeting extended capability and must report Power Budgeting values for this state (see § Section 7.8.1). Devices that are integrated on the system board are not required to implement the Power Budgeting extended capability, but if they do so, they must meet the preceding requirement.

Functions enter and exit this state either autonomously or based on external requests. External requests may be either following a signaling protocol defined in an applicable form factor specification, or by a vendor-specific method. § Table 6-16 defines how the Emergency Power Reduction Supported and Emergency Power Reduction Initialization Required fields determine the mechanisms that are allowed to trigger entry and exit from this state (see § Section 7.5.3.15).

Table 6-16 Emergency Power Reduction Supported Values §

Emergency Power Reduction Supported	Emergency Power Reduction Initialization Required	Entry/Exit Permitted by		
		Form Factor Mechanism	Vendor Specific Mechanism(s)	Autonomous Mechanisms
00b	0	No	Yes	Yes
	1	No	No	No
01b	Any	No	Yes	Yes
10b	Any	Yes	Yes	Yes
11b	Reserved			

Functions may indicate that they require re-initialization on exit from this state:

- If the Emergency Power Reduction Initialization Required bit is Clear (see § Section 7.5.3.15):
 - On entry to this state, the Function either operates normally (perhaps with reduced performance), or enters a device specific “power reduction dormant state”. The Upstream Port of the Device remains operating. Outstanding requests initiated by or directed to the Function must complete normally.
 - On exit from this state, the Function operates normally (perhaps resuming normal performance). Functions that entered a “power reduction dormant state” exit that state. In either case, no software intervention is required.
- If the Emergency Power Reduction Initialization Required bit is Set (see § Section 7.5.3.15):
 - On entry to this state, the Function ceases normal operation. The Upstream Port of the associated Device is permitted to enter DL_Down.
 - If the Upstream Port remains in DL_Up, outstanding requests directed to or initiated by the Function must complete normally.
 - If the Upstream Port enters DL_Down, outstanding request behavior is defined in § Section 2.9.1 . This transition may result in a Surprise Down error.
 - Sticky bits must be preserved in this state.
 - On exit from this state, software intervention is required to resume normal operation. The mechanism used to indicate to software when this is required is outside the scope of this specification (e.g., a device specific interrupt). If the Upstream Port entered DL_Down, all Functions of the Device are reset and a full reconfiguration is required (see § Section 2.9.2).

The following rules apply to the Emergency Power Reduction State:

- A Device supports Emergency Power Reduction State if at least one Function in the Upstream Port indicates support (i.e., Emergency Power Reduction Supported is non-zero).
- Emergency Power Reduction State is associated with a Device. All Functions in a Device that support it enter and exit this state at the same time.
- For SR-IOV devices, if the Emergency Power Reduction Supported field in a VF is non-zero, that VF enters and exits the Emergency Power Reduction State at the same time as its associated PF. For such VFs, the Emergency Power Reduction Detected bit must be hardwired to Zero, but software can use the associated PF's bit to emulate the bit in its VFs.
- Functions where the Emergency Power Reduction Supported field is 00b are not affected by the Emergency Power Reduction State of the Device as long as the Upstream Port remains in DL_Up. The Emergency Power Reduction Detected bit is RsvdZ.
- Functions where the Emergency Power Reduction Supported field is 01b or 10b:
 - Set the Emergency Power Reduction Detected bit when the Device enters Emergency Power Reduction State.
 - Clear the Emergency Power Reduction Detected bit when requested if the Device has exited the Emergency Power Reduction State.
- For Switches, Downstream Switch Ports enter and exit Emergency Power Reduction State at the same time as the associated Upstream Switch Port. The corresponding fields in Configuration Space are reserved for Downstream Switch Ports.
- For SR-IOV Devices, VFs enter and exit Emergency Power Reduction State at the same time as their PF. The corresponding fields in Configuration Space are reserved for VFs.
- Encoding 10b shall not be used unless the associated form factor specification defines a mechanism for requesting Emergency Power Reduction.

- It is strongly recommended that the Emergency Power Reduction Supported field be initialized by hardware or firmware within the Function prior to initial device enumeration. This initialization is permitted to be deferred to device driver load when this is not practical (e.g., when there is no firmware ROM).

IMPLEMENTATION NOTE: DIAGNOSTIC CHECKING OF EMERGENCY POWER REDUCTION DETECTED §

The Emergency Power Reduction Detected bit permits system software to detect that Emergency Power Reduction State was entered, even momentarily. The Emergency Power Reduction Request bit can be used by software to request entry. Normally, software would use a system specific method to enter the Emergency Power Reduction State using external mechanisms.

IMPLEMENTATION NOTE: EMERGENCY POWER REDUCTION STATE: EXAMPLE ADD-IN CARD §

§ Figure 6-27 shows an example multi-Device add-in card supporting Emergency Power Reduction. Note that Device C does not support the Emergency Power Reduction State. Device C might be a Switch that fans out to Devices A and B.

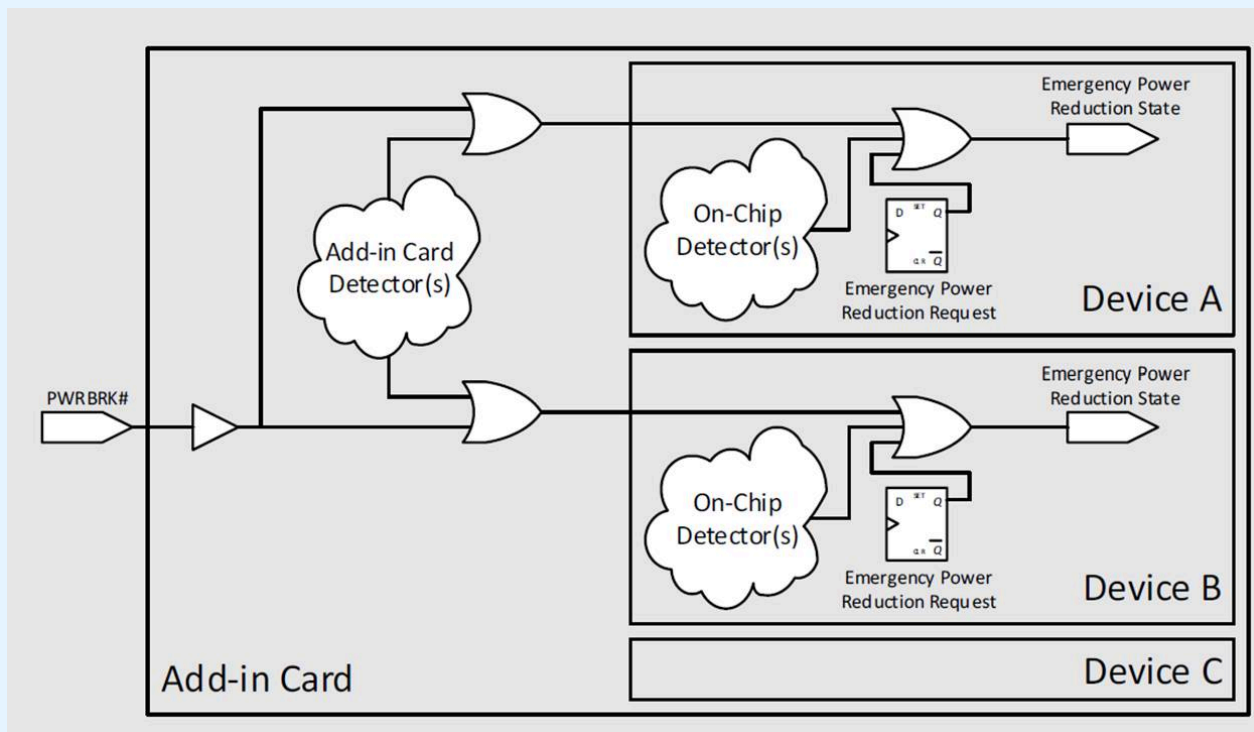

Figure 6-27 Emergency Power Reduction State: Example Add-in Card §

6.25 Hierarchy ID Message §

When software initializes a PCI Hierarchy, it assigns unique Bus and Device numbers to each component so that every Function in the Hierarchy has a unique Routing ID within that Hierarchy. To ensure that Routing IDs are unique in large systems that contain more than one Hierarchy and in clustered systems that contain multiple Hierarchies, additional information is required to augment the Routing ID to produce a unique number. Functions can be uniquely identified by the combination of:

- Unique Identifier for the System (or Root Complex)
- Unique Identifier for the Hierarchy within that Root Complex
- Routing ID within that Hierarchy

The Hierarchy ID Message (see § Section 2.2.8.6.4) is used to provide the additional information needed for a Function to uniquely identify itself in a multi-hierarchy platform.

Hierarchy ID Messages are generated by a Downstream Port upon software request. Received messages at an Upstream Port are reported in the Hierarchy ID Extended Capability (see § Section 7.9.17).

Hierarchy ID Messages are a PCI-SIG-Defined Type 1 VDM. Hierarchy ID Messages can safely be sent at any time and components that do not comprehend them will silently ignore them.

Hierarchy ID Messages typically are sent from a Downstream Port at the top of the Hierarchy (e.g., a Root Port). In systems where the Root Port does not support Hierarchy ID Messages, Hierarchy ID Messages can be sent from Switch Downstream Ports.

The Hierarchy ID Message is intended for use by software, firmware, and/or hardware. When using the Hierarchy ID Message, all bits of the Hierarchy ID, System GUID, System GUID Authority ID fields must be compared, without regard to any internal structure. How this information is used is outside the scope of this specification.

Layout of the Hierarchy ID Message is shown in § Figure 2-61. Fields in the Hierarchy ID Message are as follows:

Hierarchy ID contains the Segment Group Number associated with this Hierarchy (as defined by the *PCI Firmware Specification*). This field can be used in conjunction with the Routing ID to uniquely identify a Function within a System. The value 0000h indicates the default (or only) Hierarchy of the Root Complex. Non-zero values indicate additional Hierarchies.

System GUID[143:0], in conjunction with System GUID Authority ID, provides a globally unique identification for a System.

System GUID[143:136] is byte 14 in the Hierarchy ID Message.

System GUID[135:128] is byte 15 in the Hierarchy ID Message.

System GUID[127:120] is byte 16 in the Hierarchy ID Message.

System GUID[119:112] is byte 17 in the Hierarchy ID Message.

System GUID[111:104] is byte 18 in the Hierarchy ID Message.

System GUID[103:96] is byte 19 in the Hierarchy ID Message.

System GUID[95:88] is byte 20 in the Hierarchy ID Message.

System GUID[87:80] is byte 21 in the Hierarchy ID Message.

System GUID[79:72] is byte 22 in the Hierarchy ID Message.

System GUID[71:64] is byte 23 in the Hierarchy ID Message.

System GUID[63:56] is byte 24 in the Hierarchy ID Message.

System GUID[55:48] is byte 25 in the Hierarchy ID Message.

System GUID[47:40] is byte 26 in the Hierarchy ID Message.

System GUID[39:32] is byte 27 in the Hierarchy ID Message.

System GUID[31:24] is byte 28 in the Hierarchy ID Message.

System GUID[23:16] is byte 29 in the Hierarchy ID Message.

System GUID[15:8] is byte 30 in the Hierarchy ID Message.

System GUID[7:0] is byte 31 in the Hierarchy ID Message.

System GUID Authority ID identifies the mechanism used to ensure that the System GUID is globally unique. The mechanism for choosing which Authority ID to use for a given system is implementation specific. The defined values are shown in § Table 6-17.

Table 6-17 System GUID Authority ID Encoding §

Authority ID	Description
00h	None - System GUID[143:0] is not meaningful.

Authority ID	Description
	System GUID[143:0] must be 0.
01h	<p>Timestamp - System GUID[63:0] contains a timestamp associated with the particular system. Encoding is a Unix 64 bit time (number of seconds since midnight UTC January 1, 1970).</p> <p>The mechanism of choosing the timestamp to represent a system is implementation specific.</p> <p>System GUID[143:64] must be 0.</p>
02h	<p>IEEE EUI-48 - System GUID[47:0] contains a 48 bit Extended Unique Identifier (EUI-48) associated with the particular system. Encoding is defined by the IEEE. See [EUI-48] for details. EUI-48 values are frequently used as network interface MAC addresses.</p> <p>The mechanism of choosing the EUI-48 value to represent a system is implementation specific.</p> <p>System GUID[143:48] must be 0.</p>
03h	<p>IEEE EUI-64 - System GUID[63:0] contains a 64 bit Extended Unique Identifier (EUI-64) associated with the particular system. Encoding is defined by the IEEE. See [EUI-64] for details.</p> <p>The mechanism of choosing the EUI-64 value to represent a system is implementation specific.</p> <p>System GUID[143:64] must be 0.</p>
04h	<p>RFC-4122 UUID - System GUID[127:0] contain a UUID as defined by the IETF in [RFC-4122]. This definition is technically equivalent to [ITU-T-Rec-X-667] or [ISO-IEC-9834-8].</p> <p>The mechanism of choosing the UUID value to represent a system is implementation specific.</p> <p>System GUID[143:128] must be 0</p>
05h	<p>IPv6 Address - System GUID[127:0] contains the unique IPv6 address of one of the network interfaces of the system.</p> <p>The mechanism of choosing the IPv6 value to represent a system is implementation specific.</p> <p>System GUID[143:128] must be 0.</p>
06h to 7Fh	<p>Reserved - System GUID[143:0] contains a unique value. The mechanism used to ensure uniqueness is outside the scope of this specification.</p>
80h to FFh	<p>PCI-SIG Vendor Specific - System GUID Authority ID values 80h to FFh are reserved for PCI-SIG vendor-specific usage.</p> <p>System GUID[143:128] contains a PCI-SIG assigned Vendor ID.</p> <p>System GUID[127:0] contain a unique number assigned by that vendor. The mechanism used for assigning numbers is implementation specific. One possible mechanism would be to use the serial number assigned to the system.</p> <p>The mechanism used to choose between these System GUID Authority IDs is implementation specific. One usage would be to allow a vendor to define up to 128 distinct 128-bit System GUID schemes.</p>

IMPLEMENTATION NOTE: SYSTEM GUID CONSISTENCY AND STABILITY §

To support the purpose of System GUID, software should ensure that a single system uses identical System GUID and System GUID Authority ID values everywhere.

Implementers should carefully consider their stability requirements for the System GUID value. For example, some use cases may require that the value not change when the system is rebooted. In those cases, a mechanism that picks the EUI-48 value associated with the first Ethernet MAC address discovered might be problematic if the result changes due to hardware failure, system reconfiguration, or variations/parallelism in the discovery algorithm.

IMPLEMENTATION NOTE: HIERARCHY ID VS. DEVICE SERIAL NUMBER §

The Device Serial Number mechanism can also be used to uniquely identify a component (see § Section 7.9.3). Device Serial Number may be a more expensive solution to this problem if it involves a ROM associated with each component.

IMPLEMENTATION NOTE:

VIRTUAL FUNCTIONS AND HIERARCHY ID §

The Hierarchy ID capability can be emulated by the Virtualization Intermediary (VI). Doing so provides VF software access to this Hierarchy ID information.

When VF hardware needs access to this information, the VF should implement the Hierarchy ID capability. This provides access to both VF software and hardware.

In some situations, the VF should get the same information as the PF. In other situations, particularly those involving migration of Virtual Machines, it may be appropriate to present the VF with Hierarchy ID information that differs from the associated PF and from other VFs associated with that PF.

The following mechanisms are supported:

	VF Hierarchy ID Capability	Hierarchy ID VF Configurable	Hierarchy ID Writeable	VF Software has access	VF Hardware has access	VF Hierarchy Data / GUID
1	Not Present	n/a	n/a	No	No	Not Emulated
2				Yes	No	Emulated
3	Present	0b	0b	Yes	Yes	Same as PF
4		1b	0b	Yes	Yes	Same as PF
5		1b	1b	Yes	Yes	Configured by VI

In mechanism 1, the Virtualization Intermediary does not emulate the capability. VF software and hardware have no access.

In mechanism 2, the Virtualization Intermediary emulates the capability and returns whatever Hierarchy ID information is desired. VF software has access. VF hardware does not have access.

In mechanisms 3 and 4, VF information is the same as the PF and is automatically filled in from received Hierarchy ID messages. Both VF hardware and software have access.

In mechanism 5, VF information is configured by software (probably the VI). Both VF hardware and software have access.

6.26 Flattening Portal Bridge (FPB) §

6.26.1 Introduction §

The Flattening Portal Bridge (FPB) is an optional mechanism which can be used to improve the scalability and runtime reallocation of Routing IDs and Memory Space resources.

For non-ARI Functions associated with an Upstream Port, the Routing ID consists of a 3-bit Function Number portion, which is determined by the construction of the Upstream Port hardware, and a 13-bit Bus Number and Device number portion, determined by the Downstream Port above the Upstream port.

For ARI Functions associated with an Upstream Port, the Routing ID consists of an 8-bit Function Number portion, and only the 8-bit Bus Number portion is determined by the Downstream Port above the Upstream port.

A bridge that implements the FPB Capability can itself also be referred to as an FPB. The FPB Capability can be applied to any logical bridge, as illustrated in § Figure 6-28.

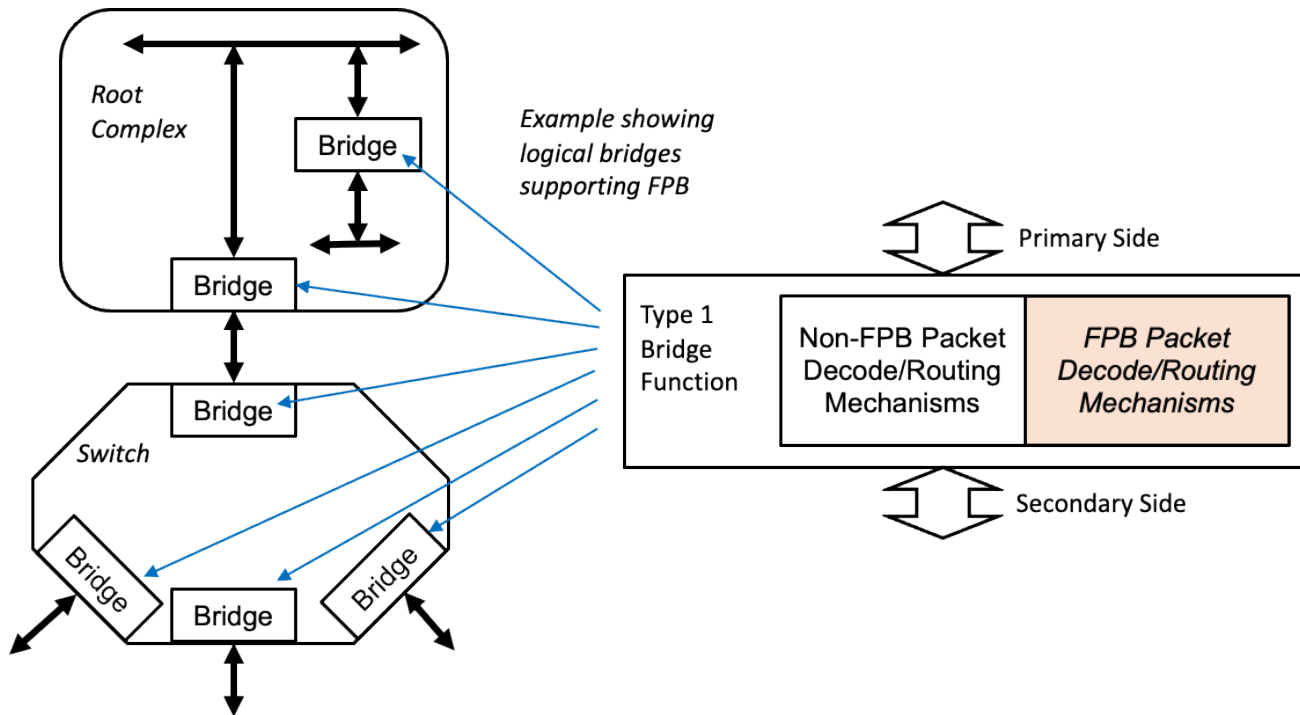

Figure 6-28 FPB High Level Diagram and Example Topology §

FPB changes the way Bus Numbers are consumed by Switches to reduce waste, by “flattening” the way Bus Numbers are used inside of Switches and by Downstream Ports (see § Figure 6-29).

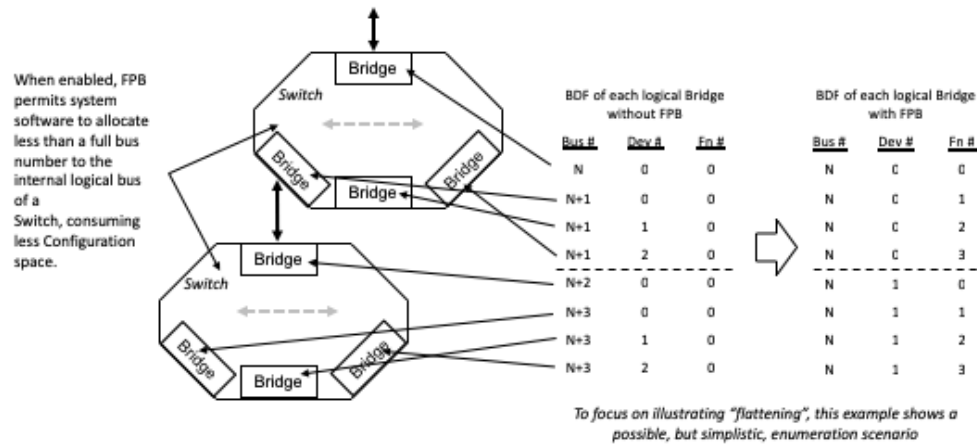

Figure 6-29 Example Illustrating “Flattening” of a Switch §

FPB defines mechanisms for system software to allocate Routing IDs and Memory Space resources in non-contiguous ranges, enabling system software to assign pools of these resources from which it can allocate “bins” to Functions below the FPB. This is done using a bit vector where each bit when Set assigns a corresponding range of resources to the Secondary Side of the bridge (see § Figure 6-30).

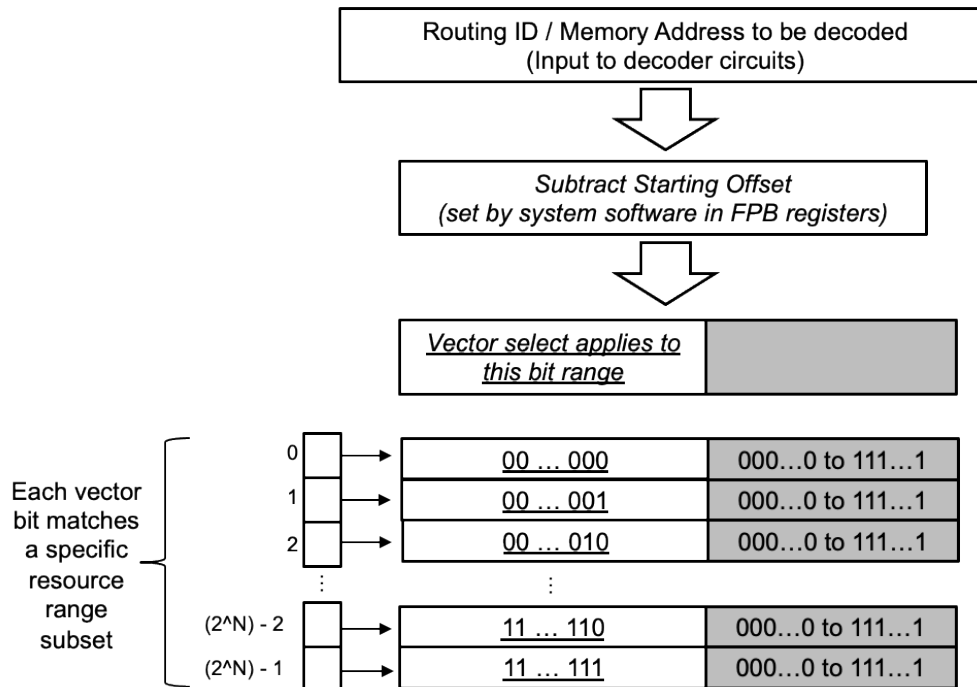

Figure 6-30 Vector Mechanism for Address Range Decoding §

This allows system software to assign Routing IDs and/or Memory Space resources required by a device hot-add without having to rebalance other, already assigned resource ranges, and to return to the pool resources freed, for example by a hot remove event.

FPB is defined to allow both the non-FPB and FPB mechanisms to operate simultaneously, such that, for example, it is possible for system firmware/software to implement a policy where the non-FPB mechanisms continue to be used in parts of the system where the FPB mechanisms are not required (see § Figure 6-31). In this figure, the decode logic is assumed to provide a '1' output when a given TLP is decoded as being associated with the bridge's Secondary Side. The non-FPB decode mechanisms apply as without FPB, so for example only the Bus Number portion (bits 15:8) of a Routing ID is tested by the non-FPB decode logic when evaluating an ID routed TLP.

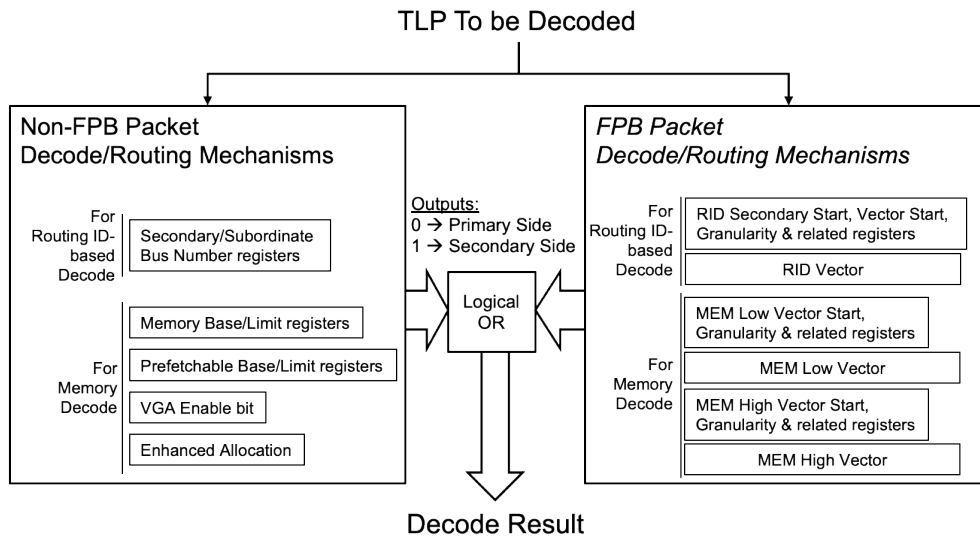

Figure 6-31 Relationship between FPB and non-FPB Decode Mechanisms §

It is important to recognize that, although FPB adds additional ways for a specific bridge to decode a given TLP, FPB does not change anything about the fundamental ways that bridges operate within the Switch and Root Complex architectural structures. FPB uses the same architectural concepts to provide management mechanisms for three different resource types:

1. Routing IDs
2. Memory below 4 GB (“MEM Low”)
3. Memory above 4 GB (“MEM High”)

A hardware implementation of FPB is permitted to support any combination of these three mechanisms. For each mechanism, FPB uses a bit-vector to indicate, for a specific subset range of the selected resource type, if resources within that range are associated with the Primary or Secondary side of the FPB. Hardware implementations are permitted to implement a small range of sizes for these vectors, and system firmware/software is enabled to make the most effective use of the available vector by selecting an initial offset at which the vector is applied, and a granularity for the individual bits within the vector to indicate the size of the resource range to which the bits in a given vector apply.

6.26.2 Hardware and Software Requirements §

The following rules apply when any of the FPB mechanisms are used:

- If system software violates any of the rules concerning FPB, the hardware behavior is undefined.
- It is permitted to implement FPB in any PCI bridge (Type 1) Function, and every Function that implements FPB must implement the FPB Capability (see § Section 7.8.11).
- If a Switch implements FPB then the Upstream Port and all Downstream Ports of the Switch must implement FPB.
- Software is permitted to enable FPB at some Switch Ports and not others.
- A Root Complex is permitted to implement FPB on some Root Ports but not on others.

- A Type 1 Function is permitted to implement the FPB mechanisms applying to any one, two or three of these elemental mechanisms:
 - Routing IDs (RID)
 - Memory below 4 GB (“MEM Low”)
 - Memory above 4 GB (“MEM High”)
- System software is permitted to enable any combination (including all or none) of the elemental mechanisms supported by a specific FPB.
- The error handling and reporting mechanisms, except where explicitly modified in this section, are unaffected by FPB.
- Following any reset of the FPB Function, the FPB hardware must Clear all bits in all implemented vectors.
- Once enabled (through the FPB RID Decode Mechanism Enable, FPB MEM Low Decode Mechanism Enable, and/or FPB MEM High Decode Mechanism Enable bits), if system software subsequently disables an FPB mechanism, the values of the entries in the associated vector are undefined, and if system software subsequently re-enables that FPB mechanism the FPB hardware must Clear all bits in the associated vector.
- If an FPB is implemented with the No_Soft_Reset bit Clear, when that FPB is cycled through $D0 \rightarrow D3_{Hot} \rightarrow D0$, then all FPB mechanisms must be disabled, and the FPB must Clear all bits in all implemented vectors.
- If an FPB is implemented with the No_Soft_Reset bit Set, when that FPB is cycled through $D0 \rightarrow D3_{Hot} \rightarrow D0$, then all FPB configuration state must not change, and the entries in the FPB vectors must be retained by hardware.
- Hardware is not required to perform any type of bounds checking on FPB calculations, and system software must ensure that the FPB parameters are correctly programmed
 - It is explicitly permitted for system software to program Vector Start values that cause the higher order bits of the corresponding vector to surpass the resource range associated with a given FPB, but in these cases system software must ensure that those higher order bits of the vector are Clear.
 - Examples of errors that system software must avoid include duplication of resource allocation, combinations of start offsets with set vector bits that could create “wrap-around” or bounds errors

The following rules apply to the FPB Routing ID (RID) mechanism:

- FPB hardware must consider a specific range of RIDs to be associated with the Secondary side of the FPB if the Bus Number portion falls within the Bus Number range indicated by the values programmed in the Secondary and Subordinate Bus Number registers logically OR'd with the value programmed into the corresponding entry in the FPB RID Vector.
- System software must configure the Configuration Request Type 1 to Type 0 conversion mechanisms in a Bridge Function before attempting to pass Configuration Requests through that Bridge.
- System software must either program the legacy and FPB mechanisms for Configuration Request Type 1 to Type 0 conversion in a Bridge Function such that they give identical results, or such that one of the two mechanisms is disabled.
 - If it is intended to use only the FPB RID mechanism for BDF decoding, then system software must ensure that both the Secondary and Subordinate Bus Number registers are 0.
 - If it is intended to enable the FPB RID Decode Mechanism, but to use only the legacy mechanism for Configuration Request Type 1 to Type 0 conversion, then system software must write bits 7:3 of the RID Secondary Start field to 0 0000b.
- System software must ensure that the FPB routing mechanisms are configured such that Configuration Requests targeting Functions Secondary side of the FPB will be routed by the FPB from the Primary to Secondary side of the FPB.

When ARI is not enabled, the FPB RID mechanism can be applied with different granularities, programmable by system software through the FPB RID Vector Granularity field in the FPB RID Vector Control 1 Register. § Figure 6-32 illustrates the relationships between the layout of RIDs and the supported granularities. The reader may find it helpful to refer to this figure when considering the requirements defined below and in the definition of the Flattening Portal Bridge (FPB) Capability (see § Section 7.8.6).

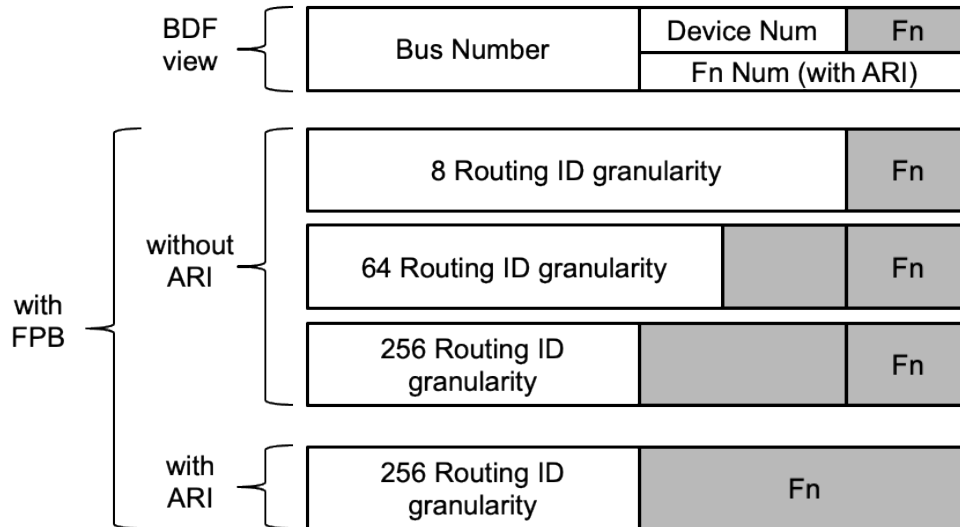

Figure 6-32 Routing IDs (RIDs) and Supported Granularities §

- System software must program the FPB RID Vector Granularity and FPB RID Vector Start fields in the FPB RID Vector Control 1 Register per the constraints described in the descriptions of those fields.
- For all FPBs other than those associated with Upstream Ports of Switches:
 - When ARI Forwarding is not supported, or when the ARI Forwarding Enable bit in the Device Control 2 Register is Clear, FPB hardware must convert a Type 1 Configuration Request received on the Primary side of the FPB to a Type 0 Configuration Request on the Secondary side of the FPB when bits 15:3 of the Routing ID of the Type 1 Configuration Request matches the value in the RID Secondary Start field in the FPB RID Vector Control 2 Register, and system software must configure the FPB accordingly.
 - When the ARI Forwarding Enable bit in the Device Control 2 Register is Set, FPB hardware must convert a Type 1 Configuration Request received on the Primary side of the FPB to a Type 0 Configuration Request on the Secondary side of the FPB when the Bus Number portion of the Routing ID of the Type 1 Configuration Request matches the value in the Bus Number address (bits 15:8 only) of the RID Secondary Start field in the FPB RID Vector Control 2 Register, and system software must configure the FPB accordingly.
- For FPBs associated with Upstream Ports of Switches only, when the FPB RID Decode Mechanism Enable bit is Set, FPB hardware must use the FPB Num Sec Dev field of the FPB Capabilities register to indicate the quantity of Device Numbers associated with the Secondary Side of the Upstream Port bridge, which must be used by the FPB in addition to the RID Secondary Start field in the FPB RID Vector Control 2 Register to determine when a Configuration Request received on the Primary side of the FPB targets one of the Downstream Ports of the Switch, determining in effect when such a Request must be converted from a Type 1 Configuration Request to a Type 0 Configuration Request, and system software must configure the FPB appropriately.
 - System software configuring FPB must comprehend that the logical internal structure of a Switch will change depending on the value of the FPB RID Decode Mechanism Enable bit in the Upstream Port of a Switch.

- Downstream Ports must use their corresponding RID values, and their Requester IDs and Completer IDs, as determined by the Upstream Port's FPB Num Sec Dev and RID Secondary Start values
 - All implemented Functions in the range determined by the Switch Upstream Port Function's RID Secondary Start and FPB Num Sec Dev must be Switch Downstream Ports associated with that Switch Upstream Port; System Software is required to scan all Functions in this range to determine which are implemented.
 - It is strongly recommended that System Software assign the RID Secondary Start such that the Bus and Device Numbers are not the same as for the Switch Upstream Port; otherwise, the resulting hardware behavior is undefined.
- For FPBs associated with Upstream Ports of Switches only, hardware must comprehend that Configuration Requests targeting the Upstream Port itself and any Downstream Ports of the Switch flattened into the range of Function Numbers with the same Bus and Device Numbers as the Upstream Port itself will be converted from Type 1 to Type 0 by the Downstream Port above the Switch, but any other Downstream Ports of the Switch flattened into successive Device Numbers will not be converted from Type1 to Type0 by the Downstream Port above the Switch and so must effectively be converted from Type 1 to Type 0 by the Switch Upstream Port itself.
This is a special case, but the concept is not unique to FPB, and is a reflection of the definition of the relationship between Bus/Device Numbers and Function Numbers – Function Numbers are always determined by the hardware of the Upstream Port, whereas the Bus and Device Numbers for an Upstream Port are always determined by the Downstream Port immediately above the Upstream Port.
- FPBs must implement bridge mapping for INTx virtual wires (see § Section 2.2.8.1)
 - Hardware and software must apply this algorithm (or the logical equivalent) to determine which entry in the FPB RID Vector applies to a given Routing ID (RID) address:
 - IF the RID is below the value of FPB RID Vector Start, then the RID is out of range (below the start) and so cannot be associated with the Secondary side of the bridge, ELSE
 - calculate the offset within the vector by first subtracting the value of FPB RID Vector Start, then dividing this according to the value of FPB RID Vector Granularity to determine the bit index within the vector.
 - IF the bit index value is greater than the length indicated by FPB RID Vector Size Supported, then the RID is out of range (beyond the top of the range covered by the vector) and so cannot be associated with the Secondary side of the bridge, ELSE
 - if the bit value within the vector at the calculated bit index location is 1b, THEN the RID address is associated with the Secondary side of the bridge, ELSE the RID address is associated with the Primary side of the bridge.

The following rules apply to the FPB MEM Low mechanism:

The FPB MEM Low mechanism can be applied with different granularities, programmable by system software through the FPB MEM Low Vector Granularity field in the FPB MEM Low Vector Control Register. § Figure 6-33 illustrates the relationships between the layout of addresses in the memory address space below 4 GB to which the FPB MEM Low mechanism applies. The reader may find it helpful to refer to this figure when considering the requirements defined below and in the definition of the Flattening Portal Bridge (FPB) Capability (see § Section 7.8.11).

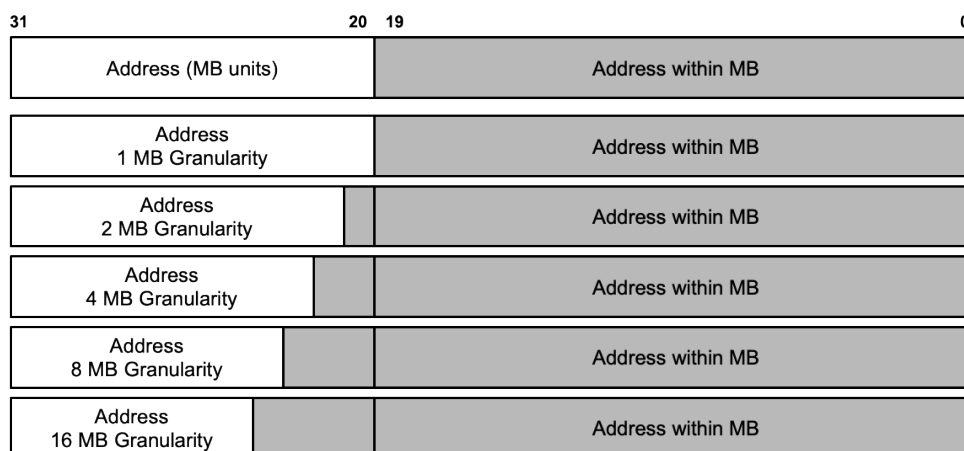

Figure 6-33 Addresses in Memory Below 4 GB and Effect of Granularity §

- System software must program the FPB MEM Low Vector Granularity and FPB MEM Low Vector Start fields in the FPB MEM Low Vector Control Register per the constraints described in the descriptions of those fields.
- FPB hardware must consider a specific Memory address to be associated with the Secondary side of the FPB if that Memory address falls within any of the ranges indicated by the values programmed in other bridge Memory decode registers (enumerated below) logically OR'd with the value programmed into the corresponding entry in the FPB MEM Low Vector. Other bridge Memory decode registers include:
 - Memory Base/Limit registers
 - Prefetchable Base/Limit registers
 - VGA Enable bit in the Bridge Control Register
 - Enhanced Allocation (EA) Capability (if supported)
 - FPB MEM High mechanism (if supported and enabled)
- Hardware and software must apply this algorithm (or the logical equivalent) to determine which entry in the FPB MEM Low Vector applies to a given Memory address:
 - If the Memory address is below the value of FPB MEM Low Vector Start, then the Memory address is out of range (below) and so is not associated with the Secondary side of the bridge by means of this mechanism, else
 - calculate the offset within the vector by first subtracting the value of FPB MEM Low Vector Start, then dividing this according to the value of FPB MEM Low Vector Granularity to determine the bit index within the vector.
 - If the bit index value is greater than the length indicated by FPB MEM Low Vector Size Supported, then the Memory address is out of range (above) and so is not associated with the Secondary side of the bridge by means of this mechanism, else
 - if the bit value within the vector at the calculated bit index location is 1b, then the Memory address is associated with the Secondary side of the bridge, else the Memory address is associated with the Primary side of the bridge.

The following rules apply to the FPB MEM High mechanism:

- System software must program the FPB MEM High Vector Granularity and FPB MEM High Vector Start Lower fields in the FPB MEM High Vector Control 1 Register per the constraints described in the descriptions of those fields.

- FPB hardware must consider a specific Memory address to be associated with the Secondary side of the FPB if that Memory address falls within any of the ranges indicated by the values programmed in other bridge Memory decode registers (enumerated below) logically OR'd with the value programmed into the corresponding entry in the FPB MEM High Vector. Other bridge Memory decode registers include:
 - Memory Base/Limit registers
 - Prefetchable Base/Limit registers
 - VGA Enable bit in the Bridge Control Register
 - Enhanced Allocation (EA) Capability (if supported)
 - FPB MEM Low mechanism (if supported and enabled)
- Hardware and software must apply this algorithm to determine which entry in the FPB MEM High Vector applies to a given Memory address:
 - If the Memory address is below the value of FPB MEM High Vector Start Upper/FPB MEM High Vector Start Lower, then the Memory address is out of range (below) and so is not associated with the Secondary side of the bridge by means of this mechanism, else
 - calculate the offset within the vector by first subtracting the value of FPB MEM High Vector Start Upper/FPB MEM High Vector Start Lower, then dividing this according to the value of FPB MEM High Vector Granularity to determine the bit index within the vector.
 - If the bit index value is greater than the length indicated by FPB MEM High Vector Size Supported, then the Memory address is out of range (above) and so is not associated with the Secondary side of the bridge by means of this mechanism, else
 - if the bit value within the vector at the calculated bit index location is 1b, then the Memory address is associated with the Secondary side of the bridge, else the Memory address is associated with the Primary side of the bridge.

IMPLEMENTATION NOTE: FPB ADDRESS DECODING §

FPB uses a bit vector mechanism to decode ranges of Routing IDs, and Memory Addresses above and below 4 GB. A bridge supporting FPB contains the following for each resource type/range where it supports the use of FPB:

- A Bit vector
- A Start Address
- A Granularity

These are used by the bridge to determine if a given address is part of the range decoded by FPB as associated with the secondary side of the bridge. An address that is determined not to be associated with the secondary side of the bridge using either or both of the non-FPB decode mechanisms and the FPB decode mechanisms is (by default) associated with the primary side of the bridge. Here, when we use the term “associated” we mean, for example, that the bridge will apply the following handling to TLPs:

- Associated with Primary, Received at Primary → Unsupported Request (UR)
- Associated with Primary, Received at Secondary → Forward upstream
- Associated with Secondary, Received at Primary → Forward downstream
- Associated with Secondary, Received at Secondary → Unsupported Request (UR)

In FPB, every bit in the vector represents a range of resources, where the size of that range is determined by the selected granularity. If a bit in the vector is Set, it indicates that TLPs addressed to an address within the corresponding range are to be associated with the secondary side of the bridge. The specific range of resources each bit represents is dependent on the index of that bit, and the values in the Start Address & Granularity. The Start Address indicates the lowest address described by the bit vector. The Granularity indicates the size of the region that is represented by each bit. Each successive bit in the vector applies to the subsequent range, increasing with each bit according to the Granularity.

For example, consider a bridge using FPB to describe a MEM Low range. FPB MEM Low Vector Start has been set to FC0h, indicating that the range described by the bit vector starts at address FC00 0000. FPB MEM Low Vector Granularity has been set to 0000b, indicating that each bit represents a 1 MB range.

From these values we can determine that bit 0 of the vector represents a 1MB range starting at FC000 0000 (FC00 0000-FC0F FFFF), bit 1 represents FC10 0000-FC1F FFFF, etc.

Bits in the vector that are set to 0 indicate that the range is not included in the range described by FPB. In the above example, If bit 0 is Clear, packets addressed to anywhere between FC00 0000 and FC0F FFFF should not be routed to the secondary bus of the bridge due to FPB.

IMPLEMENTATION NOTE:

HARDWARE AND SOFTWARE CONSIDERATIONS FOR FPB §

FPB is intended to address a class of issues with PCI/PCIe architecture that relate to resource allocation inefficiency. These issues can be categorized as “static” or “dynamic” use case scenarios, where static use cases refer to scenarios where resources are allocated at system boot and then typically not changed again, and dynamic use cases refer to scenarios where run-time resource rebalancing (e.g., allocation of new resources, freeing of resources no longer needed) is required, due to hot add/remove, or by other needs.

In the Static cases there are limits on the size of hierarchies and number of Endpoints due to the use of additional Bus Numbers and the lack of use of Device Numbers caused by the PCI/PCIe architectural definition for Switches and Downstream Ports. FPB addresses this class of problems by “flattening” the use of Routing IDs (RIDs) so that Switches and Downstream Ports are able to make more efficient use of the available RIDs.

For the Dynamic cases, without FPB, the “best known method” to avoid rebalancing has been to reserve large ranges of Bus Numbers and Memory Space in the bridge above the relevant Port or Endpoint such that hopefully any future needs can be satisfied within the pre-allocated ranges. This leads to potentially unused allocations, which makes the Routing ID issues worse, and in a resource constrained platform this approach is difficult to implement, even for relatively simple cases, where, for example, one might have an add-in card implementing a single Endpoint replaced by another add-in card that has a Switch and two Endpoints, so that although an initial allocation of just one Bus would have been sufficient, the initial allocation breaks immediately with the new add-in card.

For Memory Space the pre-allocation approach is problematic when hot-plugged Endpoints may require the allocation of Memory Space below 4 GB, which by its nature is a limited resource, which is quickly used up by pre-allocation of even relatively small amounts, and for which pre-allocation is unattractive because of the multiple system elements placing demands on system address space allocation below 4 GB.

FPB includes mechanisms to enable discontinuous resource range allocation/reallocation for both Requester IDs and Memory Space. The intent is to allow system software the ability to maintain resource “pools” which can be allocated (and freed back to) at run-time, without disrupting other operations in progress as is required with rebalancing.

To support the run time use of FPB by system software, FPB hardware implementations should avoid introducing stalls or other types of disruptions to transactions in flight, including during the times that system software is modifying the state of the FPB hardware. It is not, however, expected that hardware will attempt to identify cases where system software erroneously modifies the FPB configuration in a way that does affect transactions in flight. Just as with the non-FPB mechanisms, it is the responsibility of system software to ensure that system operation is not corrupted due to a reconfiguration operation.

It is not explicitly required that system firmware/software perform the enabling and/or disabling of FPB mechanisms in a particular sequence, however care should be taken to implement resource allocation operations in a hierarchy such that the hardware and software elements of the system are not corrupted or caused to fail.

6.27 Vital Product Data (VPD) §

Vital Product Data (VPD) is the information that uniquely defines items such as the hardware, software, and microcode elements of a system. The VPD provides the system with information on various FRUs (Field Replaceable Unit) including Part Number, Serial Number, and other detailed information. VPD also provides a mechanism for storing information such as performance and failure data on the device being monitored. The objective, from a system point of view, is to collect this information by reading it from the hardware, software, and microcode components.

Support of VPD within add-in cards is optional depending on the manufacturer. Though support of VPD is optional, add-in card manufacturers are encouraged to provide VPD due to its inherent benefits for the add-in card, system manufacturers, and for Plug and Play.

The mechanism for accessing VPD is documented in § Section 7.9.18.

VPD for PCI Express is unchanged from the definition in the [PCI-3.0]. That definition, in turn, was based on earlier versions of the [PCI] as well as the [PLUG-PLAY-ISA-1.0a].

Vital Product Data is made up of Small and Large Resource Data Types.

Table 6-19 Small Resource Data Type Tag Bit Definitions §

Offset	Field Name		
Byte 0	Value = 0xxx xyyyb		
	Bit 7	Small Resource Type	0b
	Bits 6:3	Small Item Name	xxxx
	Bits 2:0	Length in bytes	yy
Bytes 1 to n	Actual information		

Table 6-20 Large Resource Data Type Tag Bit Definitions §

Offset	Field Name		
Byte 0	Value = 1xxx xxxxb		
	Bit 7	Large Resource Type	1b
	Bits 6:0	Large Item Name	xxxxxxx
Byte 1	Length in bytes of data items bits[7:0] (lsb)		
Byte 2	Length in bytes of data items bits[15:8] (msb)		
Bytes 3 to n	Actual data items		

The first VPD tag is the Identifier String (02h) and provides the product name of the device.

One VPD-R (10h) tag is used as a header for the read-only keywords. The VPD-R list (including tag and length) must checksum to zero. Attempts to write the read-only data will be executed as a no-op.

One VPD-W (11h) tag is used as a header for the read-write keywords. The storage component containing the read/write data is a non-volatile device that will retain the data when powered off.

The last tag must be the End Tag (0Fh).

A small example of the resource data type tags used in a typical VPD is shown in § Table 6-21.

Table 6-21 Resource Data Type Flags for a Typical VPD §

TAG 02h	Identifier String	Large Resource Data Type
TAG 10h	VPD-R list containing one or more VPD keywords	Large Resource Data Type
TAG 11h	VPD-W list containing one or more VPD keywords	Large Resource Data Type
TAG 0Fh	End Tag	Small Resource Data Type

6.27.1 VPD Format §

Information fields within a VPD resource type consist of a three-byte header followed by some amount of data (see § Figure 6-34). The three-byte header contains a two-byte keyword and a one-byte length. A keyword is a two-character (ASCII) mnemonic that uniquely identifies the information in the field. The last byte of the header is binary and represents the length value (in bytes) of the data that follows.

Figure 6-34 VPD Format §

VPD keywords are listed in two categories: read-only fields and read/write fields. Unless otherwise noted, keyword data fields are provided as ASCII characters. Use of ASCII allows keyword data to be moved across different enterprise computer systems without translation difficulty.

An example of the “add-in card serial number” VPD item is as follows:

Table 6-22 Example of Add-in Serial Card Number §

Byte 0	53h “S”	Keyword: SN
Byte 1	4Eh “N”	
Byte 3	08h	Length: 8
Byte 4	30h “0”	Data: “00000194”
Byte 5	30h “0”	
Byte 6	30h “0”	
Byte 7	30h “0”

Byte 11	34h “4”	

6.27.2 VPD Definitions §

This section describes the current VPD large and small resource data tags plus the VPD keywords. This list may be enhanced at any time. Companies wishing to define a new keyword should contact the PCISIG. All unspecified values are reserved for SIG assignment.

6.27.2.1 VPD Large and Small Resource Data Tags §

VPD is contained in four types of Large and Small Resource Data Tags. The following tags and VPD keyword fields may be provided in PCI devices.

Table 6-23 VPD Large and Small Resource Data Tags §

Tag	Description
Large resource type Identifier String Tag (02h)	This tag is the first item in the VPD storage component. It contains the name of the add-in card in alphanumeric characters.
Large resource type VPD-R Tag (10h)	This tag contains the read only VPD keywords for an add-in card.
Large resource type VPD-W Tag (11h)	This tag contains the read/write VPD keywords for an add-in card.
Small resource type End Tag (0Fh)	This tag identifies the end of VPD in the storage component.

6.27.2.2 Read-Only Fields §

Table 6-24 VPD Read-Only Fields §

Keyword	Name	Description
PN	Add-in Card Part Number	This keyword is provided as an extension to the Device ID (or Subsystem ID) in the Configuration Space header in § Figure 6-34.
EC	Engineering Change Level of the Add-in Card	The characters are alphanumeric and represent the engineering change level for this add-in card.
FG	Fabric Geography	Reserved for legacy use by [PICMG] specifications.
LC	Location	Reserved for legacy use by [PICMG] specifications.
MN	Manufacture ID	This keyword is provided as an extension to the Vendor ID (or Subsystem Vendor ID) in the Configuration Space header in § Figure 6-34. This allows vendors the flexibility to identify an additional level of detail pertaining to the sourcing of this device.
PG	PCI Geography	Reserved for legacy use by [PICMG] specifications.
SN	Serial Number	The characters are alphanumeric and represent the unique add-in card Serial Number.

Keyword	Name	Description
TR	Thermal Reporting	<p>This keyword provides a standard interface for reporting four fields: AFI Level, MaxTherm, DTherm, and MaxAmbient. The data area for this field is four bytes long. This data is encoded as a 4-byte binary value in little endian order (byte 0 contains bits 7:0). This value contains the four fields as follows: AFI Level bits [3:0], MaxTherm bits [7:4], DTherm bits [11:8], and MaxAmbient bits [19:12] are placed in bits 19:0. Bits 31:20 are Reserved and must be set to 000h. Field description is provided within the [CEM]. This keyword is intended to be used only in designs based on that form factor specification.</p> <p>Note that due to the character nature of the VPD encoding mechanism, this binary value is permitted to start on any byte boundary within the VPD.</p>
Vx	Vendor Specific	This is a vendor specific item and the characters are alphanumeric. The second character (x) of the keyword can be 0 through 9 or A through Z.
CP	Extended Capability	This field allows a new capability to be identified in the VPD area. Since dynamic control/status cannot be placed in VPD, the data for this field identifies where, in the device's memory or I/O address space, the control/status registers for the capability can be found. Location of the control/status registers is identified by providing the index (a value between 0 and 5) of the Base Address register that defines the address range that contains the registers, and the offset within that Base Address register range where the control/status registers reside. The data area for this field is four bytes long. The first byte contains the ID of the extended capability. The second byte contains the index (zero based) of the Base Address register used. The next two bytes contain the offset (in little-endian order) within that address range where the control/status registers defined for that capability reside.
RV	Checksum and Reserved	The first byte of this item is a checksum byte. The checksum is correct if the sum of all bytes in VPD (from VPD address 0 up to and including this byte) is zero. The remainder of this item is reserved space (as needed) to identify the last byte of read-only space. The read-write area does not have a checksum. This field is required.
FF	Form Factor	<p>This keyword indicates a string that identifies the form factor and version associated with this add-in-card. Values are a lower case string. The string consists of a list of one or more elements separated by colons (":").</p> <p>The first element is a sequence of lowercase strings separated by periods that identifies the specification(s) associated with the form factor. The first element string is the reserved domain name associated with the authority defining that form factor (i.e., like those used in [DNS] records), followed by one or more strings that identify a particular form factor, followed by a Version Number for that form factor specification. Any characters in the form factor name other than "a" to "z", "0" to "9", "*", "?", and "-" are dropped (e.g., M.2 becomes m2). The character "*" represents a wild card (arbitrary characters, including "."). The value "-" is used to indicate no form factor. The value "?" or the absence of the FF keyword is used to indicate that the form factor is unknown.</p> <p>Subsequent elements are optional and contain attributes describing variations of that form factor (e.g., size, connector, keying, ...). These elements are defined by the indicated form-factor specification and consist of either an "option" string or a "key=value" string. Valid characters in the "option" or "key" portion are "a" to "z", "0" to "9", "*", "?", and "-". The "value" portion may contain any character other than the colon ":". The order of attributes is not significant. Attributes are not permitted when the first element is "-" or "?" (no form factor or unknown form factor).</p> <p>Examples are:</p> <ul style="list-style-type: none"> • com.pcisig.cem.4.0 • com.pcisig.cem.* • com.pcisig.m2.1.0:2280 • com.pcisig.m2.1.0:size=2280:key=M • com.pcisig.m2.1.0:bga

Keyword	Name	Description
		<ul style="list-style-type: none"> • <code>org.snia.sff-ta-1001.1.0.2</code> <p>A given add-in card is permitted to claim conformance to multiple form factor specifications. This is indicated by using the wild card character “*” or by using multiple FF fields (which in turn could use the wild card character).</p> <p>When the form factor of a slot does not match some FF keyword of the add-in card in that slot, this indicates the presence of one or more “Carrier Cards” to convert power and sideband signals of the slot to those of the add-in card. The mechanism(s) used to identify a particular Carrier Card and to describe how it operates are outside the scope of this specification.</p>

6.27.2.3 Read/Write Fields §

Table 6-25 VPD Read/Write Fields §

Keyword	Name	Description
Vx	Vendor Specific	This is a vendor specific item and the characters are alphanumeric. The second character (x) of the keyword can be 0 through 9 or A through Z.
Yx	System Specific	This is a system specific item and the characters are alphanumeric. The second character (x) of the keyword can be 0 through 9 or B through Z.
YA	Asset Tag Identifier	This is a system specific item and the characters are alphanumeric. This keyword contains the system asset identifier provided by the system owner.
RW	Remaining Read/Write Area	This descriptor is used to identify the unused portion of the read/write space. The product vendor initializes this parameter based on the size of the read/write space or the space remaining following the Vx VPD items. One or more of the Vx, Yx, and RW items are required.

6.27.2.4 VPD Example §

The following is an example of a typical VPD.

Table 6-26 VPD Example §

Offset	Item Value
0	Large Resource Type ID String Tag (02h) 82h “Product Name”
1	Length 0021h
3	Data “ABCD Super-Fast Widget Controller”
36	Large Resource Type VPD-R Tag (10h) 90h
37	Length 0059h
39	VPD Keyword “PN”
41	Length 08h
42	Data “6181682A”

Offset	Item Value
50	VPD Keyword “EC”
52	Length 0Ah
53	Data “4950262536”
63	VPD Keyword “SN”
65	Length 08h
66	Data “00000194”
74	VPD Keyword “MN”
76	Length 04h
77	Data “1037”
81	VPD Keyword “RV”
83	Length 2Ch
84	Data Checksum
85	Data Reserved (00h)
128	Large Resource Type VPD-W Tag (11h) 91h
129	Length 007Ch
131	VPD Keyword “V1”
133	Length 05h
134	Data “65A01”
139	VPD Keyword “Y1”
141	Length 0Dh
142	Data “Error Code 26”
155	VPD Keyword “RW”
157	Length 61h
158	Data Reserved (00h)
255	Small Resource Type End Tag (0Fh) 78h

6.28 Native PCIe Enclosure Management §

NPEM is an optional PCIe Extended Capability that provides mechanisms for enclosure management. This mechanism is designed to provide management for enclosures containing PCIe SSDs that is consistent with the established capabilities in the storage ecosystem.

This section defines the architectural aspects of the mechanism. The NPEM extended capability is defined in § Section 7.9.19.

An enclosure is any platform, box, rack, or set of boxes that contain one or more PCIe SSDs. The NPEM capability provides storage related enclosure control (e.g., status LED control) for a PCIe SSD. The NPEM capability may reside in a Downstream port, or an Endpoint (i.e., the PCIe SSD). § Figure 6-35 shows an example configuration with a single Downstream Port containing the NPEM capability and vendor specific logic to control the associated LEDs.

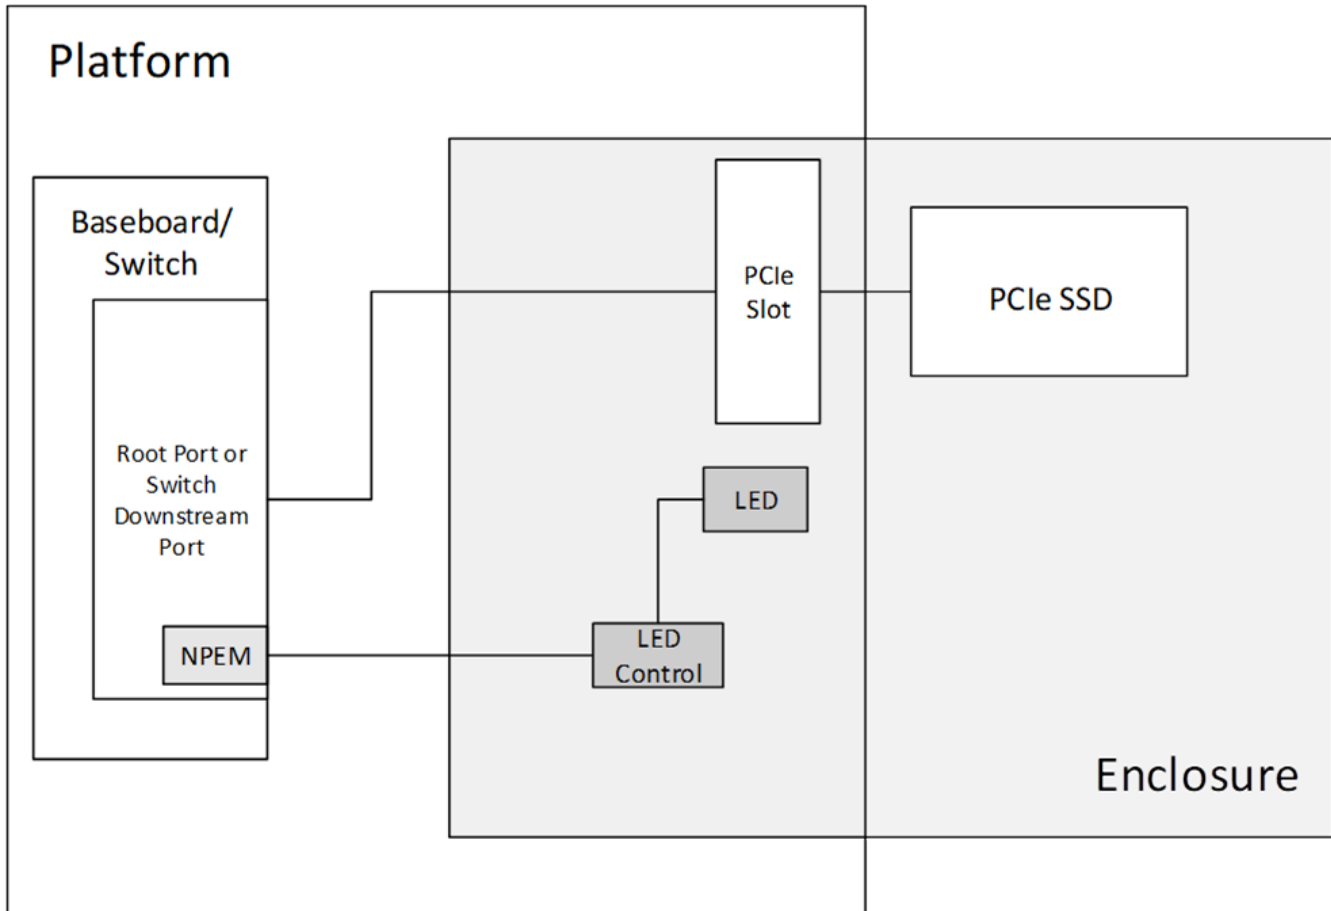

Figure 6-35 Example NPEM Configuration using a Downstream Port §

§ Figure 6-36 shows an example configuration with the NPEM capability located in the Upstream Port (in this case, the SSD function).

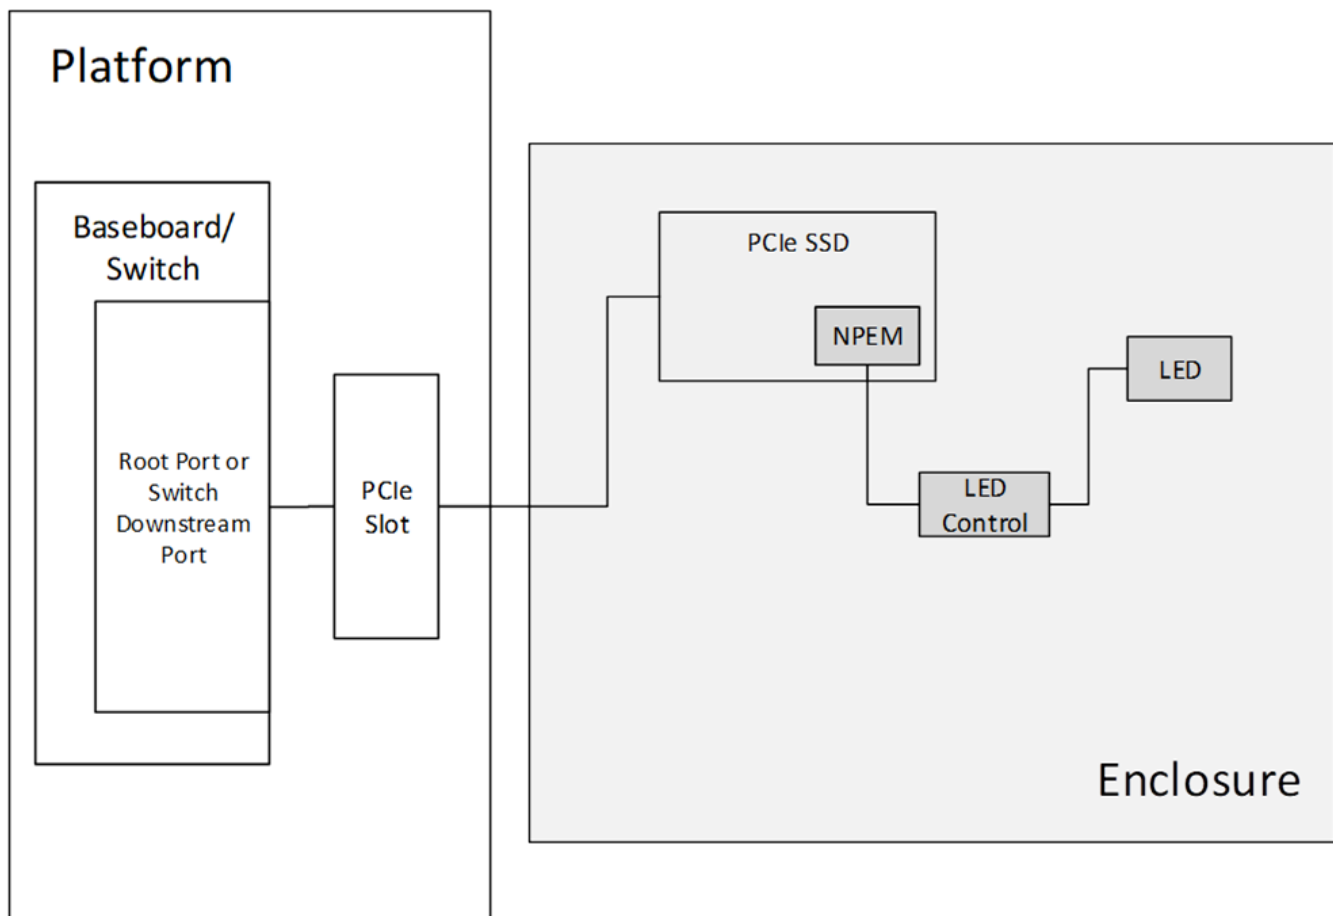

Figure 6-36 Example NPEM Configuration using an Upstream Port §

Software issues an NPEM command by writing to the NPEM Control register to change the indications associated with an SSD. NPEM Command is a single write to the NPEM Control register that changes the state of zero or more bits. NPEM indicates a successful completion to software using the command completed mechanism. § Figure 6-37 shows the overall flow.

This specification defines the software interface provided by the NPEM capability. The Port to enclosure interface, enclosure, enclosure to LED interface, number of LEDs per SSD, and associated LED blink patterns are all outside the scope of this specification.

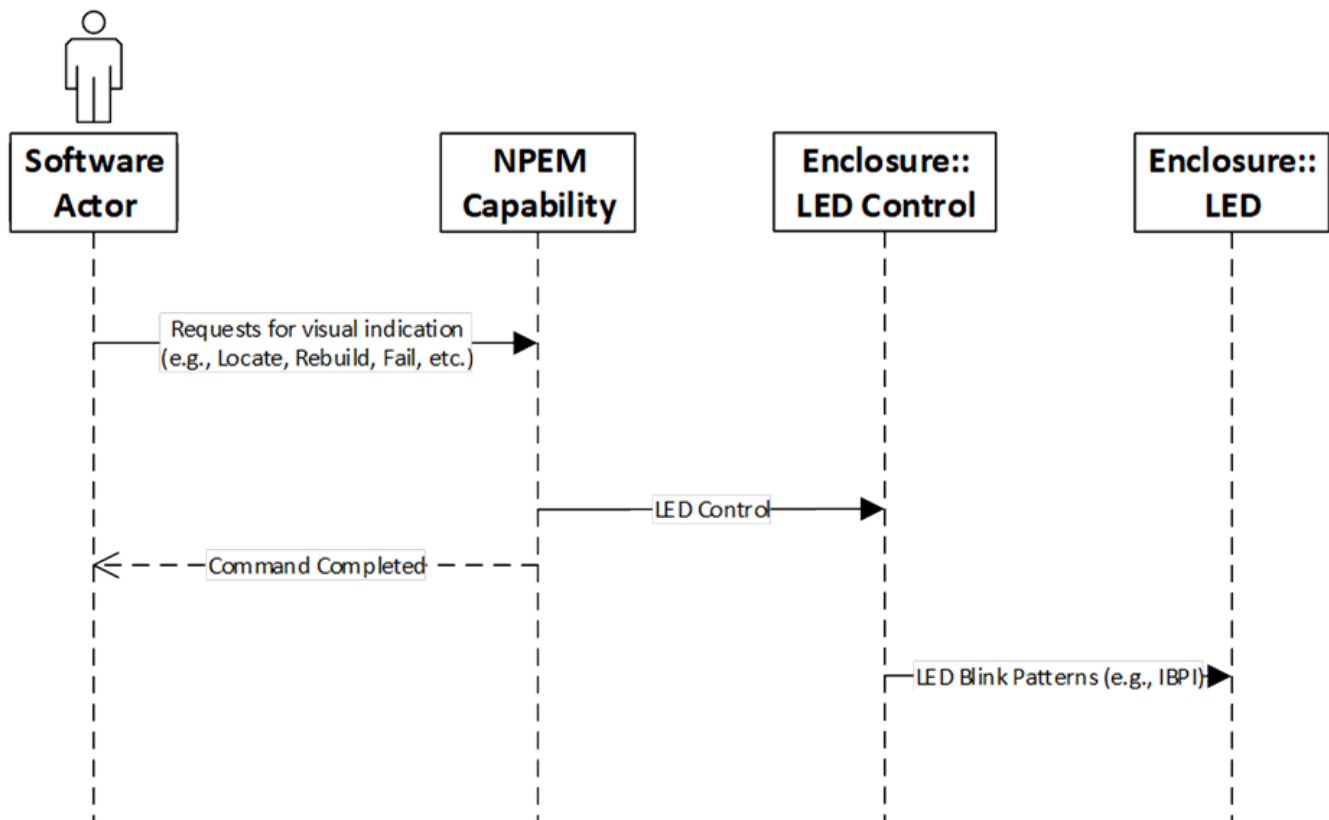

Figure 6-37 NPEM Command Flow ⁵

NPEM provides a mechanism for system software to issue a reset to the LED control element within the enclosure by means of the NPEM Reset mechanism, which is independent of the PCIe Link itself. The NPEM command completed mechanism also applies to NPEM Reset.

Storage system admin or software controls the indications for various device states through the NPEM capability.

IMPLEMENTATION NOTE:

NPEM STATES §

§ Table 6-27 shows an example of NPEM states and a possible meaning that some enclosures may assign to the architected NPEM states.

Table 6-27 NPEM States §

NPEM State	Actor	Definition
OK	System Admin or Storage Software	OK state may mean the drive is functioning normally. This state may implicitly mean that an SSD is present, powered on, and working normally as seen by the software. A more granular indication of drive not physically present or present but not powered up are both outside the scope of this specification.
Locate	System Admin	Locate state may mean the specific drive is being identified by an admin.
Fail	Storage Software	Fail state may mean the drive is not functioning properly
Rebuild	Storage Software	Rebuild state may mean this drive is part of a multi-drive storage volume/array that is rebuilding or reconstructing data from redundancy on to this specific drive.
PFA	Storage Software	PFA stands for Predicted Failure Analysis. This state may mean the drive is still functioning normally but predicted to fail soon.
Hot Spare	Storage Software	Hot Spare state may mean this drive is marked to be automatically used as a replacement for a failed drive and contents of the failed drive may be rebuilt on this drive.
In A Critical Array	Storage Software	In A Critical Array state may mean the drive is part of a multi-drive storage array and that array is degraded.
In A Failed Array	Storage Software	NPEM In A Failed Array state may mean the drive is part of a multi-drive storage array and that array is failed.
Invalid Device Type	Storage Software	Invalid Device Type state may mean the drive is not the right type for the connector (e.g., An enclosure supports SAS and NVMe drives and this drive state indicates that a SAS drive is plugged into an NVMe slot).
Disabled	Storage Software	Disabled state may mean the drive in this slot is disabled. A removal of this drive from the slot may be safe. The power from this slot may be removed.

IMPLEMENTATION NOTE:

SOFTWARE POLLING OF NPEM COMMAND COMPLETED §

Different NPEM implementations may vary widely in how long they take to complete NPEM commands, from instantaneous to tens of ms. To avoid or minimize software polling overheads, it is recommended that software implement one or both of the following optimizations.

Instead of software writing a command and then immediately polling for completion, it is recommended that software reverse this order. When ready to write a new command, software first polls for completion of the previous command, and then writes the new command. This enables overlapped operation, often completely hiding the time it takes hardware to execute an NPEM command. To enable this polling model, software must initialize the hardware following a reset by writing a no-op command in order to have hardware generate the first NPEM command completion.

For the case where an NPEM command has not completed when software polls the bit, it is recommended that software not continuously “spin” on polling the bit, but rather poll under interrupt at a reduced rate; for example at 10 ms intervals.

6.29 Conventional PCI Advanced Features Operation §

For Conventional PCI devices integrated into a Root Complex, the Conventional PCI Advanced Features Capability (AF) provides mechanisms for using advanced features originally developed for PCI Express.

- The Function Level Reset (INITIATE_FLR) mechanism enables software to quiesce and reset hardware with Function-level granularity.

FLR applies on a per Function basis. Only the targeted Function is affected by the FLR operation.

- The Transactions Pending (TP) mechanism is used to indicate that the Function has issued one or more non-posted transactions (including Delayed Transactions) which have not been completed.

The FLR and TP mechanisms defined here are strictly for Conventional PCI devices integrated into a Root Complex where the implementation permits non-posted transactions for a given Conventional PCI Function to complete even if the value of the Bus Master Enable bit in its Command Register is 0b. Implementations that do not meet this requirement must not implement the FLR and TP mechanisms.

FLR modifies the Function state as follows:

Function registers and Function-specific state machines must be set to their initialization values as specified in this document, except for the following bits, which must not be modified: Fast Back-to-Back Transactions Enable, Cache Line Size, Latency Timer, Interrupt Line, PME_En, PME_Status.

Note that the controls that enable the Function to initiate bus transactions are cleared, including the Bus Master Enable bit in the Command Register, the MSI Enable bit in the MSI Capability Structure, and the like, effectively causing the Function to become quiescent.

After an FLR has been initiated, the Function must complete the FLR within 100 ms. If software initiates an FLR when the Transactions Pending bit is 1b, then software must not initialize the Function until allowing adequate time to achieve reasonable certainty that any outstanding transactions will have completed. The Transactions Pending bit must be clear upon completion of the FLR.

FLR modifies Function state not described by this specification (in addition to state that is described by this specification), and so the following criteria must be applied using Function-specific knowledge to evaluate the Function's behavior in response to an FLR:

- The Function must not give the appearance of an initialized adapter with an active host on any external interfaces controlled by that Function. The steps needed to terminate activity on external interfaces are outside of the scope of this specification.
 - For example, a network adapter must not respond to queries that would require adapter initialization by the host system or interaction with an active host system, but is permitted to perform actions that it is designed to perform without requiring host initialization or interaction. If the network adapter includes multiple Functions that operate on the same external network interface, this rule affects only those aspects associated with the particular Function reset by FLR.
- The Function must not retain within itself software readable state that potentially includes secret information associated with any preceding use of the Function. Main host memory assigned to the Function must not be modified by the Function.
 - For example, a Function with internal memory readable directly or indirectly by host software must clear or randomize that memory.
- The Function must return to a state such that normal configuration of the Function's PCI interface will cause it to be useable by drivers normally associated with the Function

When an FLR is initiated, the targeted Function must behave as follows:

- The Function must complete normally the configuration write that initiated the FLR operation and then initiate the FLR.
- While an FLR is in progress:
 - The Function must not respond to any request on the bus (i.e., requests targeting the Function will Master Abort).

The Transactions Pending (TP) bit indicates that the Function has issued one or more non-posted transactions which have not been completed. This field may be used by software to determine when a Function has become quiescent.

IMPLEMENTATION NOTE:

AVOIDING ISSUES WITH PENDING TRANSACTIONS §

An FLR causes a Function to lose track of any pending (outstanding non-posted) transactions. Depending upon the specific implementation of the RC-integrated PCI Function, if software issues an FLR while there are pending transactions, there is a possibility for data corruption as described in the “[Avoiding Data Corruption From Stale Completions](#)” Implementation Note.

To avoid potential issues with Root Complex implementations where Stale Completions are possible or a Discard Timer is present, it is recommended that software use an algorithm similar to the following:

1. Software that's performing the FLR synchronizes with other software that might potentially access the Function directly, and ensures that such accesses will not occur during this algorithm.
2. Software clears the entire [Command register](#), disabling the Function from mastering any new transactions.
3. Software polls the [Transactions Pending](#) bit in the [AF Status Register](#) either until it's clear or until it's been long enough to achieve reasonable certainty that any remaining outstanding Transactions will never complete. On many systems, the [Transactions Pending](#) bit will usually clear within a few milliseconds, so software might choose to poll during this initial period using a tight software loop. On rare cases when the [Transactions Pending](#) bit doesn't clear by this time, software will need to poll for a longer system-specific period (potentially seconds), so software might choose to conduct this polling using a timer-based interrupt polling mechanism.
4. Software initiates the [FLR](#).
5. Software waits 100 ms.
6. Software reconfigures the Function and enables it for normal operation.

6.30 Data Object Exchange (DOE) §

Data Object Exchange (DOE) is an optional mechanism for system firmware/software to perform data object exchanges with a Function or RCRB. Software discovers DOE support via the Data Object Exchange (DOE) Extended Capability structure. Because DOE depends on Configuration Requests it is not usable for peer-to-peer operations directly between Functions, although system software can provide a mechanism to relay data objects between Functions if such capabilities are desired. When DOE is implemented in an RCRB, it is permitted to block peer-to-peer operation via implementation specific means.

DOE is a prerequisite Extended Capability for a Function to support in-band access by system firmware/software using Configuration Requests to Component Measurement and Authentication (CMA). CMA in turn builds on [\[SPDM\]](#).

It is permitted to implement DOE in any type of Function, and in an RCRB. It is permitted to implement DOE more than once in a single Function or RCRB.

DOE uses the terms “type” and “feature” with specific meanings. A data object type indicates a group of one or more data objects, and can be used to determine how to further construct or parse a specific data object. Every data object includes an indication of its type. Data object types are defined by particular vendors and distinguished by Vendor ID. It is permitted for features/types defined by one vendor to require the use of features/types defined by another vendor.

A feature is a capability of some sort that uses data objects. A feature can be associated with one or more data object types. Each specific feature defines the mechanism(s) used by software to discover support for the feature, for example

by means of a capabilities bit in Configuration Space, or implied by the presence of an associated Extended Capability structure. A feature using data objects must specify the scope of the specific features in relation to the Function(s) implementing that feature via DOE, for example if only the Function itself is associated with the feature, or if Function 0 of a Multi-Function Device represents the Device as a whole, etc.

It is permitted, but not recommended, for a feature using data object exchanges to require that a Function implement a unique instance of DOE for that specific feature, and/or to allow sharing of a DOE instance to only a specific set of features using data object exchange, and/or to allow a Function to implement multiple instances of DOE supporting the specific feature.

It is permitted to use DOE when a Function is in non-D0 states, although it is permitted for a specific data object feature to restrict operation in non-D0 states.

IMPLEMENTATION NOTE: SUPPORTING MULTIPLE HARDWARE/SOFTWARE BINDINGS §

When multiple features are supported by a device, or when a given feature can be used by more than one software entity at a time, it is typically necessary to coordinate the use of the hardware/software interface between entities implementing the multiple features. SPDM Version 1.2.0 introduced the SPDM connection model, addressing some important needs, but not itself addressing the hardware/software interface problems arising when multiple software entities need to maintain different contexts and/or configurations. DOE provides two basic mechanisms for addressing this type of issue.

One option is that specific data object features may require the use of dedicated instances of DOE, particularly to allow system software to assign ownership of a specific DOE instance with the software entity using the specific data object feature(s) associated with that particular instance. For example, data object features A and B may perform different tasks, and so by instantiating dedicated instances of DOE for each, system software avoids the need to implement ownership control and arbitration mechanisms between A and B.

When this is done, if the underlying hardware uses shared resources to implement A and B, then the hardware may require the ability to maintain separate contexts for each data object feature, because system software will allow the two features to be operated at the same time.

Alternatively, for CMA/SPDM and related use cases, the optional Connection ID mechanism can eliminate the need for multiple DOE instances. Typically, the Connection ID mechanism provides much better scaling, and it is recommended that the Connection ID mechanism be used where applicable, instead of requiring the use of dedicated DOE instances. § Figure 6-38 illustrates a “stack diagram” where six applications are all using CMA/SPDM over DOE in three groups.

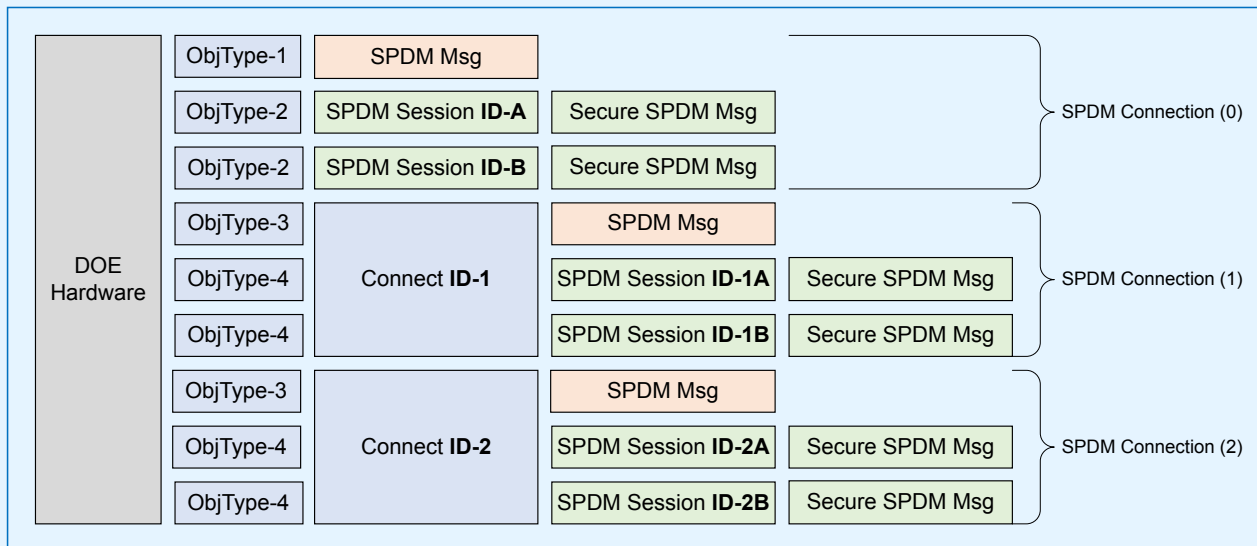

Figure 6-38 Stack Diagram Illustration of Multiple Sessions and Connections §

In each case, two distinct SPDM uses are shown, A and B, and within each group, the SPDM configuration must be the same, but each group may have distinct requirements from the others, e.g., different hashing algorithms. The SPDM Driver and PCI Driver software components must coordinate the establishment of each connection, including the assignment of a Connection ID, and, at run time, must manage the transfer of data objects across

the DOE interface itself to ensure that multiple software entities cannot attempt to access the DOE Mailbox registers during the transfer of a single data object. However, context is maintained in the device for each session. § Figure 6-39 illustrates at a high level how these elements relate to each other.

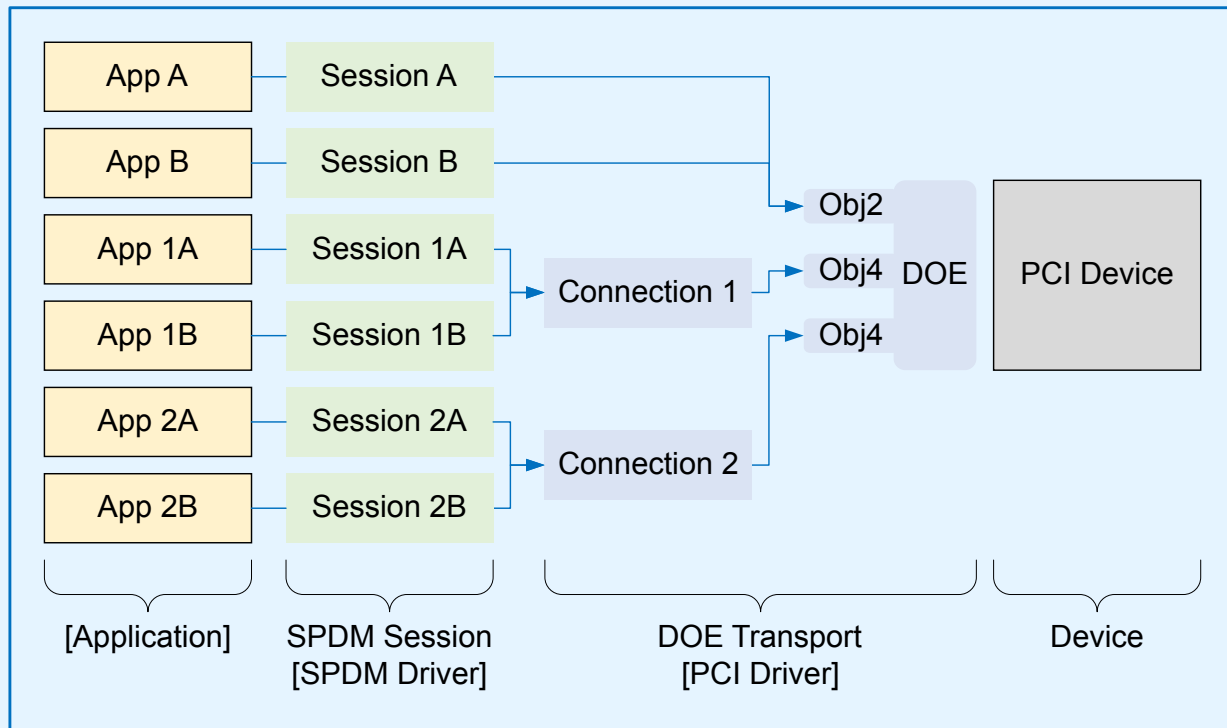

Figure 6-39 Example Showing Relationships of Software and Hardware Elements §

6.30.1 Data Objects and Features §

Data objects must consist of 2 DW to 256K DW, as shown in § Figure 6-40.

Figure 6-40 DOE Data Object Format §

The first DW of a data object must be formatted as defined in § Table 6-28 and illustrated in § Figure 6-41.

Figure 6-41 DOE Data Object Header 1 §

Table 6-28 DOE Data Object Header 1 §

Bit Location	Description
15:0	Vendor ID - PCI-SIG Vendor ID of the entity that defined the type of data object.
23:16	Data Object Type - The type of data object.

The Second DW of a data object must be formatted as defined in § Table 6-29 and illustrated in § Figure 6-42.

Figure 6-42 DOE Data Object Header 2 §

Table 6-29 **DOE Data Object Header 2** §

Bit Location	Description
17:0	Length – Length of the data object being transferred in number of DWs including the 2 DWs of the Data Object Header, encoded such that a value of 0 0002h indicates 2 DWs, and a value of 0 0000h indicates 2 ¹⁸ DWs. A value of 0 0001h is not allowed.
29:18	Connection ID – For data object types using Connection ID, this field contains the Connection ID. For all other data object types, this field is Reserved.

Each data object is uniquely identified by the Vendor ID of the vendor publishing the data object definition and a Data Object Type value assigned by that vendor (see § Table 6-28). See § Table 6-33 for a list of data objects defined by PCI-SIG. Data objects of a specific type are permitted to vary in size and composition.

Unless a data object type definition specifies a different requirement, the following rules apply:

- If the number of DW transferred does not match the Length indicated in DOE Data Object Header 2 for a data object, then the entire data object must be silently discarded.
- If the Length indicated in DOE Data Object Header 2 is shorter than expected for a specific data object, then the data object must be silently discarded.
- If the Length indicated in DOE Data Object Header 2 is greater than expected for a specific data object, then the portion of the data object up to the expected length must be processed normally and the remainder of the data object must be silently discarded.
- If the data object type is not supported, then that data object must be silently discarded.

6.30.1.1 DOE Discovery Feature §

The DOE Discovery feature must be implemented, and provides a means for software to discover the data object types supported by a DOE instance. The DOE Discovery type consists of the request and response data objects, with the 3rd DW of the data object content as defined in § Table 6-30 and § Table 6-31 respectively. Where indicated in § Table 6-33, response data objects include a 4th DW, as defined in § Table 6-32. The DOE Discovery data object feature must be operable in D0, D1, D2 and D3_{hot}.

Figure 6-43 **DOE Discovery Request Data Object Contents (3rd DW)** §Table 6-30 **DOE Discovery Request Data Object Contents (3rd DW)** §

Bit Location	Description
7:0	Index – Indicates DOE Discovery entry index queried. Indices must start at 00h and increase monotonically by 1.
15:8	DOE Discovery Version – must be 02h if the Capability Version in the <u>Data Object Exchange Extended Capability</u> is 02h or greater.

Bit Location	Description
31:16	Reserved Reserved - Requesters must place 0000h in this field. Responders must ignore the value in this field.

Figure 6-44 DOE Discovery Response Data Object Contents (3rd DW) §

Table 6-31 DOE Discovery Response Data Object Contents (3rd DW) §

Bit Location	Description
15:0	Vendor ID – PCI-SIG Vendor ID of the entity that defined the type of data object. FFFFh if index is invalid or out of range.
23:16	Data Object Type – Indicates the identity of the data object type associated with the Index value supplied with the DOE Discovery Request. The PCI-SIG defined data object type for DOE Discovery must be implemented at index 00h. The index values used for other data object types is implementation specific and has no meaning defined by this specification. Undefined if Vendor ID value is FFFFh.
31:24	Next Index – Indicates the next DOE Discovery Index value. If the responding DOE instance supports entries with indices greater than the index indicated in the received DOE Discovery Request, it must increment the queried index by 1 and return the resulting value in this field. Must be 00h to indicate the final entry. Undefined if Vendor ID value is FFFFh.

Figure 6-45 DOE Discovery Response Data Object Contents (4th DW) §

Table 6-32 DOE Discovery Response Data Object Contents (4th DW) §

Bit Location	Description
17:0	Max DO Length – Maximum length supported for this data object type, expressed as a number of DWs including the 2 DWs of the Data Object Header, encoded such that a value of 0 0002h indicates 2 DWs, and a value of 0 0000h indicates 2^{18} DWs. A value of 0 0001h is not permitted. Undefined if Vendor ID value is FFFFh.

Bit Location	Description
31:18	Additional Info – The contents of this field are Data Object Type specific. Values are defined for each Data Object Type in § Table 6-33. Undefined if Vendor ID value is FFFFh.

PCI-SIG defined data object types are defined in § Table 6-33.

Table 6-33 PCI-SIG Defined Data Object Types (Vendor ID = 0001h) §

Vendor ID (h)	Data Object Type (h)	Description
0001	00	DOE Discovery – Every DOE instance must support this data object feature and associated type, both indicated by this entry. A requester uses DOE Discovery to discover all other Data Object types supported by the DOE instance. Must not include the <u>DOE Discovery Response Data Object Contents (4th DW)</u> .
0001	01	CMA-SPDM – Data object type for SPDM messages. See § Section 6.31 . Permitted to include the <u>DOE Discovery Response Data Object Contents (4th DW)</u> . The <u>Additional Info</u> field is Reserved.
0001	02	Secured CMA-SPDM – Data object type for SPDM secure sessions. See Section § Section 6.31.4 If this type is supported, then the CMA/SPDM (01h) type must also be supported. Permitted to include the <u>DOE Discovery Response Data Object Contents (4th DW)</u> . The <u>Additional Info</u> field is Reserved.
0001	03	CMA/SPDM with Connection ID – Data object type for SPDM messages with Connection ID. If this type is supported, then the CMA/SPDM (01h) type must also be supported. Required to include the DOE Discovery Response Data Object Contents 4th DW. Bits 11:0 of the Additional Info field must indicate the largest supported Connection ID value, such that all Connection IDs must be in the range from 0 to the indicated value: 0000 0000 0000b 1 Connection ID ... 1111 1111 1111b 4096 Connection IDs Bits 13:12 of the <u>Additional Info</u> field are Reserved.
0001	04	Secured CMA/SPDM with Connection ID – Data object type for SPDM secure sessions with Connection ID. If this type is supported, then the CMA/SPDM (01h) and CMA/SPDM with Connection ID (03h) types must also be supported. Required to include the DOE Discovery Response Data Object Contents 4th DW. Bits 11:0 of the Additional Info field must indicate the largest supported Connection ID value, such that all Connection IDs must be in the range from 0 to the indicated value: 0000 0000 0000b 1 Connection ID

Vendor ID (h)	Data Object Type (h)	Description
		... 1111 1111 1111b 4096 Connection IDs Bits 13:12 of the <u>Additional Info</u> field are Reserved.
0001	05	Async Message – Data object type for messages generated asynchronously by the device. Required to include the DOE Discovery Response Data Object Contents 4th DW.
0001	06 to FF	Reserved

6.30.1.2 DOE Async Message §

The DOE Async Message data object feature allows a DOE instance to transfer device-initiated messages with system software, enabling the device to act as a requester in cases where otherwise the host would act as requester. The DOE Async Message data object type consists of 1 DW that indicates the contents, defined in § Table 6-34, which, for Async Message REQUEST (01h) or Async Message RESPONSE (02h), must be followed by an encapsulated DOE data object. The encapsulated data object must be a full data object as illustrated in § Figure 6-40.

Table 6-34 DOE Async Message Data Object Contents (1 DW) §

Bit Location	Description
7:0	Variety – Indicates Async Message variety: 00h Async Message GET 01h Async Message REQUEST 02h Async Message RESPONSE 03h Async Message DONE 04-FFh Reserved
31:8	Reserved – Requesters must place 00 0000h in this field. Responders must ignore the value in this field.

Each data object type definition must specify if that type is permitted to use the Async Message mechanism.

The following data object types are permitted in the encapsulated data object:

- CMA/SPDM
- Secure CMA/SPDM
- CMA/SPDM with Connection ID
- Secure CMA/SPDM with Connection ID

An Async Message is not permitted in the encapsulated data object.

A DOE instance advertises support for sending DOE Async Messages by having the DOE Async Message Support bit Set. A DOE instance is only allowed to send DOE Async Messages, when the DOE Async Message Enable bit is Set.

For a DOE instance to send a DOE Async Message to the host, it must Set DOE Async Message Status and wait to receive a DOE Async Message GET from the host.

System software supporting DOE Async Message must check the DOE Async Message Status bit, and, when that bit is Set and the system software is ready to process the message, then, the host must send an Async Message GET. The DOE instance must in response return the Async Message REQUEST. System software then, in turn, must send Async Message RESPONSE. If the DOE instance has more Async Messages to transfer, then the device must return another Async Message REQUEST, to which system software must return a corresponding Async Message RESPONSE. If the DOE instance has no more Async Messages to send, it must return Async Message DONE and Clear DOE Async Message Status.

A DOE instance must only return Async Message REQUEST in response to a received Async Message GET. It is permitted but not required for system software to abort (as defined in § Section 6.30.1) other data object transfers to give priority to Async Message transfers.

6.30.2 Operation §

Other than the DOE Discovery feature, DOE is used to transport data objects as part of a feature defined outside of DOE itself. This section defines requirements of DOE itself, although in some cases these requirements are permitted to be modified per the definition of a specific feature.

For features that define request/response protocols, unless there is a feature-specific requirement, a DOE instance must complete processing a received data object and, if a data object is required in response, must generate the response and Set the Data Object Ready bit in the DOE Status register within 1 second after the DOE Go bit was Set in the DOE Control Register, otherwise the DOE instance must Set the DOE Error bit in the DOE Status register within the same time limit. At any time, the system firmware/software is permitted to set the DOE Abort bit in the DOE Control Register, and the DOE instance must Clear the Data Object Ready bit, if not already Clear, and Clear the DOE Error bit, if already Set, in the DOE Status Register, within 1 second.

Once the transfer of a specific data object has been started, except in case of error or abort, that transfer must be completed before the transfer of another data object is started.

If a single DOE instance supports multiple data object features, system firmware/software is permitted to interleave data objects associated with different data object features, if and only if the data object features allow such interleaving.

Data object buffering requirements are determined by the data object feature(s) supported, and data object features must ensure that maximum data object sizes are well defined. When required, the Max DO Length must be used to indicate the maximum length supported for a specific data object type. All data object types that are defined to require the use of Capability Version 02h or greater in the Data Object Exchange Extended Capability must require the use of Max DO Length.

It is strongly recommended that implementations ensure that the functionality of the DOE Abort bit is resilient, including that DOE Abort functionality is maintained even in cases where device firmware is malfunctioning.

An FLR to a Function must result in the aborting of any DOE transfer in progress. Data object features must specify the handling of FLR and, as appropriate, other conditions that impact the data object feature. While an FLR is in-progress, all writes to the DOE Write Data Mailbox must be dropped, and all reads to the DOE Read Data Mailbox must be terminated with UR, or return all 0's. If these or other erroneous actions are detected while an FLR is in progress, it is permitted that, upon exit from FLR, the DOE Error bit be Set.

If software permits DOE operations to overlap with potential FLRs, software cannot depend on the RRS mechanism, but rather must use time-based mechanisms or FRS to determine the completion of an FLR.

It is not required that FLR result in any type of reset to the internal processing engine for DOE operations, although such behavior is permitted, and may be required or forbidden by specific data object features.

DOE errors cover errors in the operation of DOE itself, and, except as noted below, do not extend to errors associated with a data object feature. Any of the following events must result in the DOE Error bit being Set:

- A Poisoned Configuration Write to any of the DOE registers
- Overflow of the Write Data Mailbox mechanism
- Optionally, if the associated data object feature does not provide an alternate mechanism for reporting such errors, the transfer of a data object that does not correspond to the expected length of that data object

No response must be generated when the DOE Error bit is Set because of a condition associated with the receipt of a data object that would, in a non-error condition, have an associated data object response, no response must be generated.

Hardware behavior is undefined unless software issues writes to the DOE Write Data Mailbox Register and reads from the DOE Read Data Mailbox Register with all Bytes enabled. It is permitted, but not required, for hardware to check for accesses without all Bytes enabled, and if checked, it is strongly recommended that violations result in the DOE Error bit being Set.

The optional DOE Attention Mechanism supports improved power management of DOE implementations, by enabling a DOE instance to temporarily enter an unresponsive state, and providing software a mechanism to direct the instance back to a responsive state. If the DOE Attention Mechanism Support bit is Set, for backwards compatibility, the default is that the DOE instance must remain in a responsive state. System software is recommended to Set the DOE Attention Not Needed bit when it is acceptable for the DOE instance to enter and stay in a state where it is not immediately available for use. When that bit is Clear, the DOE instance must remain in a state where it is ready to respond in a timely way to system software. The DOE At Attention bit, when Set, indicates the DOE interface is presently in a state of readiness. This bit must only be Cleared if the DOE Attention Not Needed bit in the DOE Control Register is Set. It is permitted for this bit to remain Clear for up to 50 ms following the Clearing of DOE Attention Not Needed.

IMPLEMENTATION NOTE:

EXCHANGE OF DATA OBJECTS §

Exchange of Data Objects Data objects are exchanged through the mailboxes provided by the Data Object Exchange (DOE) Extended Capability. The DOE mailbox is defined to flexibly support a variety of data objects, and as a result of the definition of specific data objects and their associated features, it is necessary to provide the information required for requesters and responders to appropriately size their data buffers and robustly implement the associated feature.

At the level of individual DW transfers, the DOE responder can use the Completions for the DOE mailbox Configuration Read and Write operations as a flow control mechanism. It should be understood by hardware designers, however, that delaying Configuration Completions will typically stall the software operating DOE, and in some cases may also cause stalls in other software/hardware operations.

The DOE Busy bit can be used to indicate that the DOE responder is temporarily unable to accept a data object. It is necessary for a DOE requester to ensure that individual data object transfers are completed, and that a request/response contract is completed, for example using a mutex mechanism to block other conflicting traffic for cases where such conflicts are possible. The following example shows how system firmware/software transfers a request from system firmware/software to a DOE instance, and the response back to system firmware/software from the DOE instance:

1. System firmware/software checks that the DOE Busy bit is Clear to ensure that the DOE instance is ready to receive a DOE request.
2. System firmware/software writes the entire data object, starting with the first DWORD, a DWORD at a time via the DOE Write Data Mailbox Register.
3. System firmware/software writes 1b to the DOE Go bit.
4. The DOE instance consumes the DOE request from the DOE mailbox.
5. The DOE instance generates a DOE Response and Sets the Data Object Ready bit and generates a DOE Software notification, if supported and enabled.
6. System firmware/software waits for an interrupt if applicable, checks/polls the Data Object Ready bit and, provided it is Set, reads data from the DOE Read Data Mailbox Register and then writes any value to the DOE Read Data Mailbox Register to indicate a successful read, starting with the first DWORD, a DWORD at a time until the entire DOE Response is read.

The above example does not illustrate error handling or additional software mechanisms necessary to manage cases where more than one software entity could potentially attempt to use DOE.

6.30.3 Interrupt Generation §

A DOE instance is permitted to support the generation of DOE interrupts, as indicated by the DOE Interrupt Support bit in the DOE Capabilities Register. If DOE interrupts are supported, the DOE instance must support MSI and/or MSI-X. INTx interrupt signaling is not permitted with DOE. DOE interrupts are enabled by the DOE Interrupt Enable bit in the DOE Control Register. DOE interrupts are indicated by the DOE Interrupt Status bit in the DOE Status register.

If enabled (see § Section 6.1.4.3), an interrupt message must be triggered when the associated vector is unmasked (see § Section 6.1.4.5 Per-vector Masking and Function Masking), the DOE Interrupt Enable bit is Set, and the value of the DOE Interrupt Status bit transitions from 0b to 1b.

The interrupt message will use the vector indicated by the DOE Interrupt Message Number field in the DOE Capabilities Register. Multiple DOE instances in the same Function or RCRB are permitted to use the same interrupt vector.

6.31 Component Measurement and Authentication (CMA-SPDM) §

Component Measurement and Authentication/SPDM (CMA-SPDM) defines optional security features based on the adaptation of the data objects and underlying protocol defined in [SPDM]. These provide mechanisms to perform security exchanges (where this term is used generically to refer to all defined capabilities of [SPDM]) with a component, or Device/Function. It is intended that CMA-SPDM inherit all new capabilities of [SPDM] as that specification is enhanced, and identifiable by the versioning mechanisms defined for [SPDM]. CMA-SPDM is part of a layered architecture intended to support a consistent and structured approach to security (see § Figure 6-46).

As security requirements evolve, and sometimes older technologies become compromised, for example by new types of attacks that had not been foreseen, so that they are no longer considered secure, CMA-SPDM is intended to balance the need for maintaining sufficient security against the sometimes conflicting goal of maximizing interoperability. Backwards compatibility will be maintained wherever possible, but this may not be possible in all cases.

It must also be understood that many aspects of security, including the establishment of policies, and the evaluation of specific trust decisions, very often cannot be made locally to a specific device or platform, and so are necessarily outside the scope of this specification. CMA-SPDM should be understood as a tool that provides a common framework for some key elements of security.

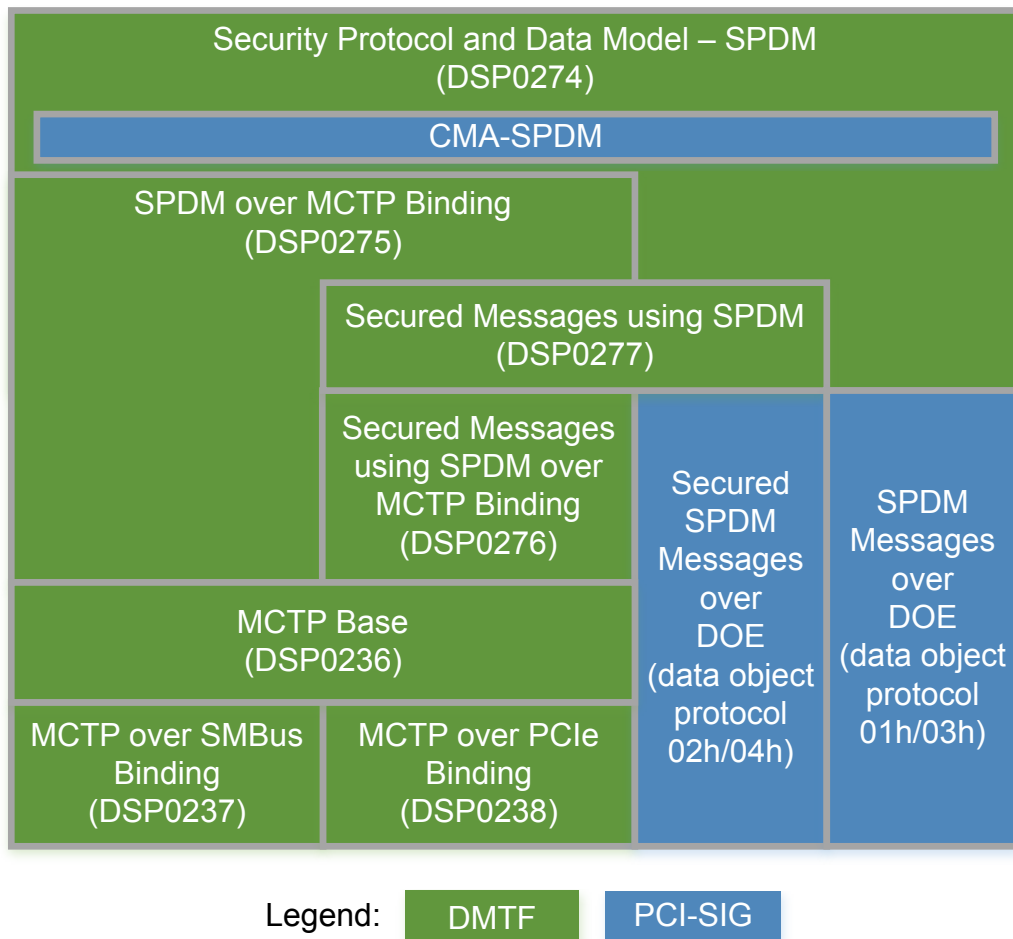

Figure 6-46 CMA-SPDM as Part of a Layered Architecture §

CMA-SPDM can use the Data Object Exchange (DOE) Capability (See § Section 6.30) as a mechanism for security exchanges, and can also be used for out-of-band or other in-band security exchanges, for example using MCTP [SPDM-MCTP] Binding.

It is possible to use CMA-SPDM in many scenarios—for example:

- Remote system administrators can dynamically generate a manifest of cryptographic identities of components of a system, especially at the level of removable units (e.g., add-in-cards/modules), without physical examination of the system, via a BMC or other platform root-of-trust.
- The identity of a Function can be verified by OS drivers before assigning resources to the Function during runtime/hot-plug scenarios without requiring a host reboot.
- Virtual Machine Monitors (VMMs) or TEE Security Managers (TSMs – see Chapter 11) can establish the hardware and firmware identities of a Function before assigning it to a Virtual Machine, and provide a service such to enable these to be confirmed by the Virtual Machine guest directly with the assigned Function.

The high-level overview of the CMA-SPDM security features and their associated PCIe-specific requirements are given in the following sections, whereas the foundational architecture, protocol and message definitions for the security

exchanges used by CMA-SPDM are defined in [SPDM]. The messages exchanged between the requester and a responder for the CMA-SPDM security features are denoted as CMA-SPDM Messages.

IMPLEMENTATION NOTE:

UNDERSTANDING AND IMPLEMENTING CMA-SPDM §

CMA-SPDM is part of a layered architecture to support device and platform security (see § Figure 6-46). Building on the DMTF Security Protocol & Data Model specification [SPDM], CMA-SPDM provides a “mapping” of that foundation, with the intent that future [SPDM] enhancements can, in most cases, be implemented without requiring modifications to CMA-SPDM. In addition to device authentication & firmware measurement, capabilities such as mutual authentication and cryptographic key exchange are also possible. Following [SPDM], CMA-SPDM uses the term “requester” to refer to agents initiating CMA-SPDM protocol requests, and “responder” to refer to an agent that ultimately services those requests and generates responses.

Depending on the use models supported, it may be desirable to implement support for more than one way of transporting CMA-SPDM requests and responses.

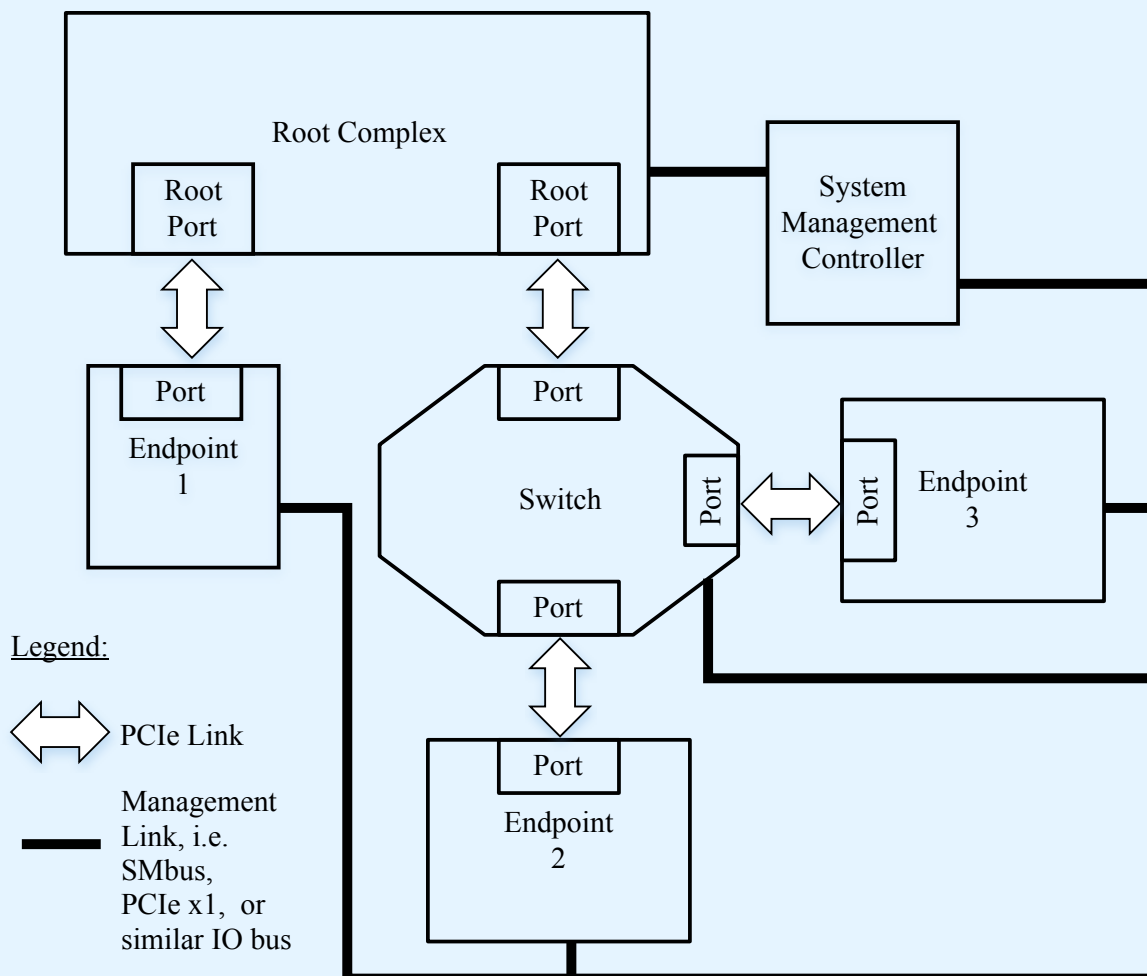

Figure 6-47 Example System Showing Multiple Access Mechanisms §

§ Figure 6-48 shows an example of a device that supports multiple platform use models and multiple access mechanisms. In this example, there is a System Management Controller that has an out-of-band connection to the other elements in the platform, enabling it to use CMA-SPDM even when the PCIe Links are not active and/or Fundamental Reset is active. When the PCIe Links are operating, CMA-SPDM can be used via [SPDM-MCTP]. The Root Complex can use CMA-SPDM over DOE. It is a platform implementation choice of which methods are used.

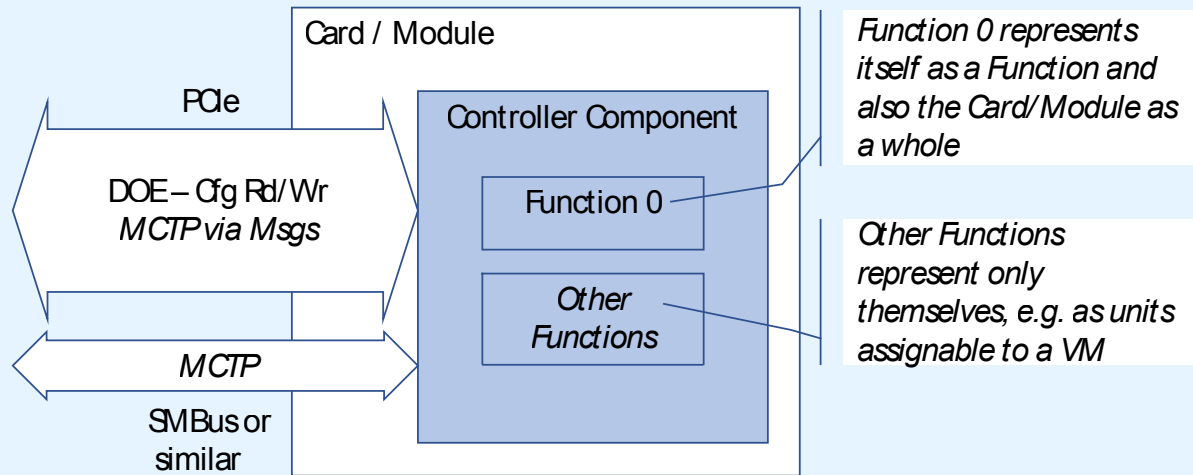

Figure 6-48 Example Add-In-Card Supporting CMA-SPDM §

Correspondingly, a device controller can support CMA-SPDM in multiple ways, depending on the associated form-factor and platform requirements and implementation choices. For maximum flexibility it may be desirable to support all of the following:

- Out-of-band (e.g., over SMBus, I2C, I3C, etc.) using MCTP, according to the specifications for [SPDM] + CMA-SPDM + [SPDM-MCTP]
- In-band using MCTP encapsulated in PCIe Messages, according to the specifications for [SPDM] + CMA-SPDM + [SPDM-MCTP] + [MCTP-VDM]
- In-band using the Configuration mailbox mechanism defined by the DOE Extended Capability, according to the specifications for [SPDM] + CMA-SPDM + DOE

Or, when the requirements for a specific implementation do not require this level of flexibility, it may be preferable to support only one or two of these approaches.

The platform requirements for CMA-SPDM are determined by the use cases supported. Example use cases that apply to an add-in-card as a unit include:

- Before platform boot, a management controller checks the add-in-card out of band.
- During platform boot, system firmware checks the add-in card in-band via DOE.
- During run-time, a management controller or system software/firmware checks the add-in-card via [MCTP-VDM].

To support use cases where the management controller and system firmware/software communicate the results of their checks with each other, it is necessary that the results of those checks be consistent, subject to any changes applied since earlier checks were made. It is for this use case that Function 0 is required to match identically the results received via these other mechanisms.

For use cases where the add-in-card is being evaluated as a unit, the device controller can, through implementation specific means, attest and/or measure other board elements, to ensure that the identity and integrity of the add-in-card as a whole is correct. How this can be done is outside the scope of CMA-SPDM.

For improved interoperability, CMA-SPDM requires support for certain algorithms, while allowing support for any of the algorithms supported by [SPDM]. Flexibility is allowed for Responder algorithm selection with the intent that device vendors can, if desired, align their choices with common standards such as those defined in the Commercial National Security Algorithm (CNSA) Suite and in NIST Special Publication 800-57.

The applications of CMA/SPDM are numerous and varied. For complex environments, the issues of secure identity provisioning, measurement collection/reporting, and verification of attested state may require evaluating additional standards and industry best practices. Examples include:

- TCG Reference Integrity Manifest (RIM) Information Model: <https://trustedcomputinggroup.org/resource/tcg-reference-integrity-manifest-rim-information-model>
- OCP Attestation of System Components v1.0 Requirements and Recommendations: <https://www.opencompute.org/documents/attestation-v1-0-20201104-pdf>

IMPLEMENTATION NOTE: OVERVIEW OF THREAT MODEL §

A detailed threat model analysis typically requires consideration of the context in which a system is operating and the composition of the system along with many other factors, and as such cannot be provided here. A high level overview of the types of threats for which CMA-SPDM may be applicable includes:

- Remote and Local software-based attacks, e.g., to install corrupted device firmware or roll back device firmware to an older version
- Threats from attacker in physical possession of the device including:
 - Software-based (similar to above)
 - Presentation (“impersonation”)
 - Hardware attacks of various sorts
- Attacks during manufacturing, provisioning or maintenance, including:
 - Provisioning of improper configuration and/or firmware
 - Improper “repair” of a module

CMA-SPDM requires the leaf certificate to include the information typically used by system software for device driver binding. This requirement is intended to support scenarios where an attacker device attempts to gain access to system resources by appearing to be a valid device type. Responding devices can include the device serial number value in the leaf certificate to simplify system implementation of policies that require specific unit instances to be identified, for example to support scenarios where a modified unit is substituted for a valid, but otherwise identical, unit.

6.31.1 Removed §

6.31.2 Removed §

6.31.3 CMA-SPDM Rules §

CMA-SPDM defines how the responder role as defined in [SPDM] must be implemented for PCIe devices, regardless of the communication path(s) implemented between the requester(s) and the responder.

It is permitted, but not required, to support CMA-SPDM and the responder role as defined in [SPDM] at the level of individual Functions. When this is done, then the Function(s) must implement both CMA-SPDM and DOE. For a multi-Function device, each Function implementing the responder role must implement CMA-SPDM and DOE. For Switches that support CMA-SPDM, each Switch Port Function implementing the responder role must implement CMA-SPDM and DOE.

It is permitted, but not required, for CMA-SPDM to be implemented using one or more access mechanisms other than DOE, in support of various use models (e.g. see § Figure 6-46). When a use model requires CMA-SPDM to be applied at the level of a replaceable unit it may be necessary to support security exchanges operated by means other than DOE. For example, an add-in-card being evaluated by a Baseboard Management Controller (BMC), or similar element, may use MCTP over a sideband bus. For devices that implement such support, the certificate chain in slot 0 (referring to slots as defined in [SPDM]) must match identically the certificate chain in slot 0 returned by Function 0 via DOE, if DOE is also supported.

CMA-SPDM does not apply to Root Ports, and a Root Port must not implement CMA-SPDM.

The value of all measurements must always reflect the firmware in use at the time of the measurement being read, including for components that support runtime update of firmware without a system reset.

When using CMA-SPDM with DOE:

- The instance of DOE used for CMA-SPDM must support:
 - the DOE Discovery data object protocol,
 - the CMA-SPDM data object protocol,
 - if IDE is supported, the IDE_KM data object protocol using Secured CMA-SPDM (See § Section 6.31.4),
 - and no other data object protocol(s).
- A responder must support operation when the associated Function is in the D0 state, and is permitted but not required to support operation in non-D0 states.
- Behavior is undefined if a Function that does not support operation in non-D0 states is transitioned into a non-D0 state during a CMA-SPDM protocol operation.
 - It is strongly recommended that system software avoid placing a Function into a non-D0 state while a CMA-SPDM protocol operation is taking place.
- An FLR to a Function during the processing of a CMA-SPDM request must result in that Function terminating its processing of the request, and that Function not returning a response to the request.
 - An FLR to a Function during the DOE transfer of a CMA-SPDM request or response data object must follow the rules defined in § Section 6.30 .

When using CMA-SPDM with a transport mechanism other than DOE:

- A Responder must support operation whenever that transport is active, including cases where the device is in Conventional Reset, unless exceptions are allowed through means outside the scope of this specification
- CMA-SPDM context must be maintained by the Responder such that each transport mechanism (including DOE, when implemented) functions independently of all other transport mechanisms.
 - All transport mechanisms must be treated as independent SPDM connections.
- When CMA-SPDM via DOE in Function 0 is also supported, the certificate chain from slot 0 retrieved via DOE must match the certificate chain from slot 0 retrieved via any/all other transport mechanisms.

For the CMA-SPDM data object type or SPDM with connection ID data object type, the SPDM message payloads must start from “Data Object DW 0”. The SPDM message payloads must follow [SPDM] specification Generic SPDM message field definitions, starting with SPDM version, Request Response Code, Param 1 and Param 2. The Byte mapping of SPDM Messages is shown in § Figure 6-49. If required, SPDM Message payloads must be padded with 0’s to maintain DW alignment, when using DOE.

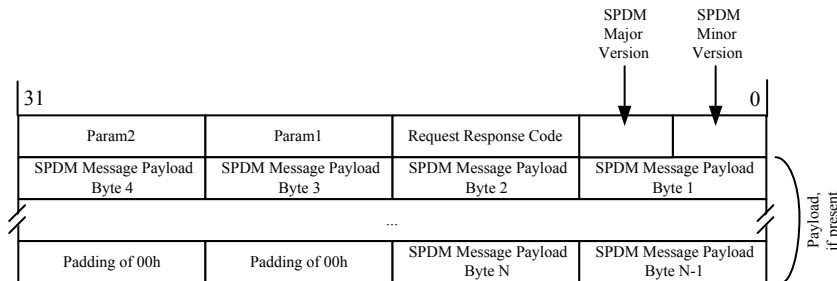

Figure 6-49 Byte Mapping of SPDM Messages Including Example Payload §

Without the connection ID, one DOE instance can only have one SPDM connection. With the connection ID, one DOE instance can have multiple SPDM connections. The maximum valid connection ID can be discovered by using DOE Discovery Data Object Protocol.

Some components provide a debug mode where a debugger is granted access to hardware security properties, allowing the debugger to influence the measurement process itself. It is strongly recommended that components report when a debug mode is active. The reporting mechanism is outside the scope of this specification. It can be SPDM debug and device mode in measurement record or DICE operation flags in DiceTcbInfo.

- For BaseAsymAlgo, Requesters must support all, and Responders must support one or more of the following:
 - TPM_ALG_RSASSA_3072
 - TPM_ALG_ECDSA_ECC_NIST_P256
 - TPM_ALG_ECDSA_ECC_NIST_P384
- For BaseHashAlgo, Requesters must support all, and Responders must support one or both of the following:
 - TPM_ALG_SHA_256
 - TPM_ALG_SHA_384
- For MeasurementSpecification, Requesters and Responders must support the following:
 - DMTF measurement specification format
- Requesters and responders must, for MeasurementHashAlgo, Requesters must support all, and Responders must support one or both of the following:

- TPM_ALG_SHA_256
- TPM_ALG_SHA_384
- It is permitted for Requesters and Responders to support additional algorithms defined for [SPDM] beyond those required.
- Responders must implement a Cryptographic Timeout (CT), as defined in [SPDM], of not more than 2^{23} μ s.
 - Per [SPDM] CT is in turn indicated through the value of CTEExponent.
 - It is strongly recommended that the CT be as short as practical.

6.31.4 Secured CMA-SPDM §

Secured CMA-SPDM provides security for data object protocols based on [SPDM] mechanisms, including the IDE key management (IDE_KM) protocol. Once a secure session has been established per [SPDM] (Revision 1.1 or later), it is permitted, and for some uses required, to use Secured CMA-SPDM to transfer other Data Objects with integrity/encryption, using the algorithm negotiated in the SPDM session establishment, per [Secured SPDM].

It is permitted to continue to perform non-secured CMA-SPDM operations after a session has been established, provided the specific use allows non-secure transport.

Secured CMA-SPDM data objects must be formatted per [Secure-SPDM]. It is permitted for specific data object protocols to constrain the use and content of optional fields, but if no such constraints are applied then the use of such fields is implementation specific.

An FLR to a Function for which there is an established secure session must not change the state of the secure session. However, as with non-secured CMA-SPDM, an FLR to a Function during the processing of a CMA-SPDM request must result in that Function terminating its processing of the request, and that Function not returning a response to the request, and this may impact the usability of the secure session and possibly render the secure session unusable.

For the Secured CMA-SPDM data object type or Secured CMA-SPDM with connection ID data object type, the Secured CMA-SPDM message payloads must start from “Data Object DW 0”. The Secured CMA-SPDM message payloads must follow the Secured CMA-SPDM specification Secure Message fields definition, starting with Session ID. “Sequence Number” field must be absent (S=0). “Random Data” field must be absent (R=0). The “Application Data” field must be the in-session SPDM message. The Byte mapping of Secured CMA-SPDM Messages is shown in § Figure 6-50. If required, Secured CMA-SPDM Message payloads must be padded with 0’s to maintain DW alignment, when using DOE.

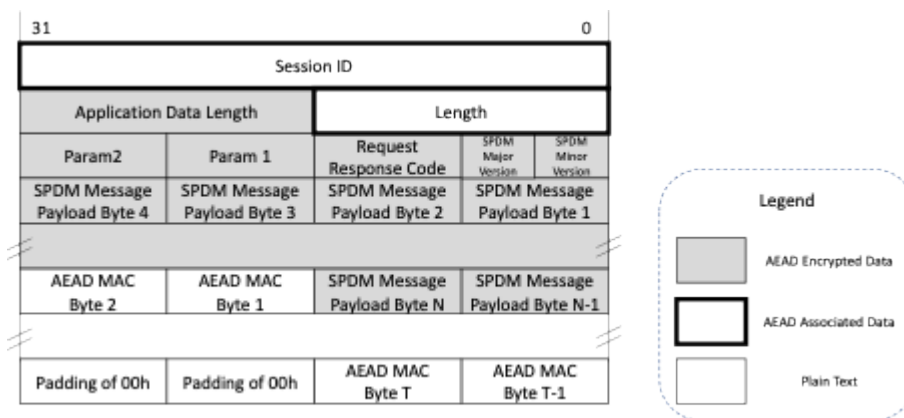

Figure 6-50 Byte Mapping of Secured CMA-SPDM Messages Including Example Payload §

Additional Rules:

- Requesters and Responders must support ENCRYPT_CAP and MAC_CAP.
- For DHE group, Requesters must support all, and Responders must support one or both of the following:
 - secp256r1
 - secp384r1
- For AEAD structure, Requesters and Responders must support the following:
 - AES-256-GCM with 16 Byte MAC
- For KeySchedule structure, Requesters and Responders must support the following:
 - SPDM Key Schedule
- For Secured Message format, Requesters and Responders must support the following:
 - DSP0277 Secured Messages opaque data format as defined in Section 8 of DSP0277, if SPDM 1.1 or below is used.
 - DSP0274 General opaque data format as defined in Section 14 of SPDM 1.2, if SPDM 1.2 or above is used. The OtherParamsSupport field of NEGOTIATE_ALGORITHMS request and ALGORITHMS response must set the bit for OpaqueDataFmt1.
- Requesters and Responders must use DSP0277 specification version as the Secured Message transport binding version (format as defined in Section 6 of DSP0277) required in the OpaqueData fields of KEY_EXCHANGE request / KEY_EXCHANGE_RSP response / PSK_EXCHANGE request / PSK_EXCHANGE_RSP response messages defined in DSP0274, when using DOE.
- Requesters and Responders may support mutual authentication. If mutual authentication is supported, for ReqBaseAsymAlgo, Requesters and Responders must support one or more of the following:
 - TPM_ALG_RSASSA_3072
 - TPM_ALG_ECDSA_ECC_NIST_P256
 - TPM_ALG_ECDSA_ECC_NIST_P384
- Requesters and Responders are permitted to implement additional algorithms defined in [SPDM]

6.32 Deferrable Memory Write §

The Deferrable Memory Write (DMWr) is an Optional Non-Posted Request that enables a scalable high-performance mechanism to implement shared work queues and similar capabilities. With DMWr, devices can have a single shared work queue and accept work items from multiple non-cooperating software agents in a non-blocking way. A DMWr Completer, i.e., a Function whose DMWr Completer Supported bit is Set, is a Function that supports being the target of DMWr Requests.

The mechanisms for generating DMWr Requests are outside the scope of this document. For cases where a DMWr Requester supports generation of DMWr Requests directly via software mechanisms, it is recommended that the software thread that invoked the Request is informed of the corresponding Completion Status in an implementation specific manner.

As with AtomicOps (See § Section 6.15), the use model for DMWr requires that, from the initial trigger to generate a DMWr Request, the subsequent routing to the Completer, the Completer's resulting actions, and the return of the corresponding Completion, that each of these be "atomic" in the sense that a single trigger must result in a single Request, which must not be subdivided, being acted upon by the Completer in such a way that no observer can see a partial result, and a single Completion being returned to the Requester, without subdivision. Therefore, the following rules apply:

- Switches and Root Complexes that support DMWr routing must route DMWr Requests and Completions without modification.
- DMWr Completers must ensure that operations performed on behalf of a given DMWr Request are performed atomically with respect to each host processor or device access to that target location range.
- The internal implementation of DMWr Requesters and Completers to enforce the required “atomic” behavior is outside the scope of this document.

The target of a DMWr Request that is not a DMWr Completer (i.e., a Function whose DMWr Completer Supported bit is Clear) responds as per the Request handling rule for a Request Type that is not supported (see § Section 2.3.1). In Non-Flit Mode, components designed to earlier revisions of this specification that treat the Request Type value corresponding to DMWr Request as Reserved are permitted to treat a received DMWr Request as a Malformed TLP.

The following requirements apply to DMWr Completers:

- Functions indicate their ability to act as DMWr Completers by Setting DMWr Completer Supported and by indicating the largest DMWr TLP that the Function can receive (see DMWr Lengths Supported).
- Properly formed DMWr Requests must be handled as a Successful Completion (SC), Request Retry Status (RRS), Unsupported Request (UR), or Completer Abort (CA).
 - Properly formed DMWr Requests with types or operand sizes not supported by the Completer, or targeting an address not intended by the device’s programming model to be a target of DMWr Requests, or crossing an address boundary between two different resources, must be handled as Completer Abort (CA), and the value of the target location must remain unchanged.
 - Switches that support DMWr Routing but do not support serving as a DMWr Completer must handle properly formed DMWr Requests that target internal resources of the Switch as Completer Abort (CA), and the value of the target location must remain unchanged.
- When a DMWr Request cannot be completed successfully due to a temporary condition, the Completer is permitted to return a Completion with Request Retry Status (RRS)
 - When this is done, the value of the target location must remain unchanged, and the Completer must not assume that the Requester will repeat the request.
 - This is not an error
- Completers are permitted to use implementation specific mechanisms to determine when to use the RRS Completion Status in order to establish policies for fairness or for other reasons, and these mechanisms may be based on Requester ID, Traffic Class, PASID, payload contents, or other criteria as may be appropriate.
- Completers supporting DMWr are allowed to implement a restricted programming model.
 - If a Request that is not a DMWr targets an address intended by the device’s programming model to be a target of DMWr Requests, it is strongly recommended that the value of the target location remain unchanged, and, if the Request is a Non-Posted Request, that the Completion returned does not include any sensitive information.
 - See Implementation Note: Optimizations Based on a Restricted Programming Model in § Section 2.3.1 for additional general guidance.
- Completers supporting DMWr that return Successful Completion (SC) must guarantee that the observed update granularity will not be smaller than 64 bytes, or the size of the Request, whichever is smaller.
 - This requirement applies to DMWr targeting “plain” memory, a shared work queue, or other implementation specific structures, when such operations are supported by the programming model of the Completer.
 - See also § Section 2.4.3 and § Section 2.4.4.

- If any Function in a Multi-Function Device associated with an Upstream Port supports DMWr Completer or DMWr routing capability, all Functions with Memory Space BARs in that device must decode properly formed DMWr Requests and handle any they don't support as an Unsupported Request (UR).
 - In such devices, Functions lacking DMWr Completer capability are forbidden from handling properly formed DMWr Requests as Malformed TLPs.
- Unless there is a higher precedence error, a DMWr-aware Completer must handle a Poisoned DMWr Request as a Poisoned TLP Received error (see § Section 2.7.2.1).
 - The Completer must return a Completion with a Completion Status of either Unsupported Request (UR) or Request Retry Status (RRS).
 - The value of the target location must remain unchanged.
- If the Completer of a DMWr Request encounters an uncorrectable error accessing the target location, the Completer must handle it as a Completer Abort (CA).
 - The subsequent state of the target location is implementation specific.
- Completers are permitted to support DMWr Requests on a subset of their target Memory Space as needed by their programming model (see § Section 2.3.1).
 - Memory Space structures defined or inherited by PCI Express (e.g., the MSI-X Table structure) are not required to be supported as DMWr targets unless explicitly stated in the description of the structure.
- If an RC has any Root Ports that support DMWr routing capability, all RCiEPs in the RC reachable by forwarded DMWr Requests must decode properly formed DMWr Requests and handle any they do not support as an Unsupported Request (UR).

The following requirements apply to Root Complexes and Switches that support DMWr routing:

- Root Ports and Switch Ports indicate their support of DMWr routing by Setting DMWr Request Routing Supported and by indicating the largest DMWr TLP that the associated Function supports (see DMWr Lengths Supported).
- Switches and Root Ports supporting the DMWr routing capability or DMWr Completer capability (or both) that receive a properly formed DMWr Requests must either forward it to another Port or handle it as a Successful Completion (SC), Request Retry Status (RRS), Unsupported Request (UR), Completer Abort (CA), or DMWr Egress Blocked error.
- If a Switch supports DMWr routing for any of its Ports, it must do so for all of them.
- For Switches and Root Ports supporting the DMWr routing capability, if a DMWr Request is received that crosses a decoding boundary between two different destinations, the Ingress Port must not propagate the Request, and must return a Completion with a Completion Status of UR.
- For a Switch or an RC, when DMWr Egress Blocking is enabled in an Egress Port and a DMWr Request targets going out that Egress Port, then the Egress Port must handle the Request as a DMWr Egress Blocked error and must also return a Completion with a Completion Status of UR.
 - If the severity of the DMWr Egress Blocked error is non-fatal, then this case must be handled as an Advisory Non-Fatal Error as described in § Section 6.2.3.2.4.1.
 - This is a reported error associated with the Egress Port (see § Section 6.2).
- For an RC, support for peer-to-peer routing of DMWr Requests and Completions between Root Ports is optional and implementation specific.
 - When supported, the associated Ports must Set the DMWr Request Routing Supported in the Device Capabilities 3 Register.
 - When supported, DMWr TLPs must be routed without modifying the size of the data payload.
 - Even when DMWr Request Routing Supported is Set in two Root Ports, it is implementation specific whether forwarding is supported between those Ports.

- If one Root Port in a Root Complex supports DMWr Completer or DMWr Routing, a DMWr Request received by that Port that is routed to another Root Port that does not support DMWr must be handled as an Unsupported Request (UR).
 - This is a reported error associated with the Ingress Port (See [§ Section 6.2](#)).

The following requirements apply to DMWr Requesters:

- A Function is only permitted to generate DMWr Requests when the DMWr Requester Enable bit in the Device Control 3 register is Set.
- When a DMWr Request is completed with Request Retry Status (RRS), the Requester is permitted, but not required, to re-issue the Request.
 - The Requester is permitted to use any implementation specific criteria to determine if/when to re-issue the Request.
 - Subsequent Requests are permitted to be the same or modified.

IMPLEMENTATION NOTE: CONSIDERATIONS FOR THE USE OF DEFERRABLE MEMORY WRITE (DMWR) §

The intended use model for the Deferrable Memory Write (DMWr) is to implement efficient hardware/software interface control mechanisms, using specialized hardware in the Completer to process the DMWr Request and generate the appropriate Completion Status. For example, a device could implement “enqueue registers” that enable commands to the device to be issued via a single DMWr Request, and based on the Completion Status the device can indicate to the Requester of the command was accepted.

Users of DMWr must understand the functional implications of transaction ordering. A DMWr Request is a Non-Posted Request with Data, which means that Posted Requests are permitted to pass DMWr Requests. Additionally, there is no guaranteed ordering among all types of Non-Posted Requests (see Table 2-4, entries B3, B4, C3 & C4).

As with all types of “control” mechanisms, it is necessary for all participants to comprehend the specific requirements placed by the particular mechanism, and these will vary between different systems and different device types. In many cases it will be necessary to distinguish Requests issued from different software environments (e.g., from multiple Virtual Machine guests where the guests use different drivers) all sharing the same work queue. PASID is one mechanism that can be used for this purpose, although there are many alternatives (e.g., different ranges of addresses could be assigned to each environment that would be mapped to the same resources in the Completer). In some systems, system and application level software is capable of generating DMWr Requests according to a specific template (§ Figure 6-51), where bits 31:0 are defined by the system architecture, the P bit at bit 31 indicates if user (0b) or supervisor (1b) code triggered the Request, and bits 19:0 of the payload include the PASID to indicate the context in which the Request was generated.

Figure 6-51 Example DMWr Data Payload Template §

For performance reasons it is not recommended that DMWr be used for sending bulk data.

Being a Non-Posted Request, DMWr TLPs require a Completion. In addition, PCIe ordering rules dictate that Non-Posted TLPs cannot pass Posted TLPs, making Posted transactions preferable for improved performance.

Because DMWr TLPs and Memory Read Request TLPs can pass each other, and DMWr TLPs can be deferred by the Completer, care must be taken by Device and Device Driver manufacturers when attempting to read a memory location that is also the target of an outstanding DMWr Transaction, if this is even supported by the programming model of the Completer. Because of these properties, use of DMWr TLPs when transferring large amounts of data is not recommended.

When DMWr Transactions are used to enable a shared work queue, care must be taken to ensure that no Requesters are denied access indefinitely to the queue due to competition with other Requesters. Software entities that submit work to such a queue may choose to implement a flow control mechanism or rely on a particular programming model to ensure that all entities are able to make forward progress, for example to

include a feedback mechanism or an indication from the Function to software on the state of the queue, or a timer that delays DMWr Requests after a Completion with Completion Status RRS. The DMWr mechanism does not itself provide protection against software entities issuing Requests (either maliciously or unintentionally) at a rate high enough to cause problems with other software entities accessing the single shared work queue. The details of such mechanisms and programming models are outside of the scope of this specification.

6.33 Integrity & Data Encryption (IDE) §

Integrity & Data Encryption (IDE) provides confidentiality, integrity, and replay protection for TLPs Transmitted and Received between two Ports. It flexibly supports a variety of use models, while providing broad interoperability. The cryptographic mechanisms are aligned to industry best practices and can be extended as security requirements evolve. The security model considers threats from physical attacks on Links, including cases where an adversary uses lab equipment, purpose-built interposers, malicious Extension Devices, etc. to examine data intended to be confidential, modify TLP contents, reorder and/or delete TLPs. TLPs can be secured as they transit Switches, extending the security model to address attacks mounted by reprogramming Switch routing mechanisms, or using “malicious” Switches. IDE can be used to secure traffic within trusted execution environments, also known as trust domains, composed of multiple components – the frameworks for such composition are outside the scope of IDE.

IDE establishes an IDE Stream between two Ports (see § Figure 6-52). There are two types of IDE Streams: a Selective IDE Stream applies to selected TLPs as determined by association rules defined in this section, and a Link IDE Stream applies to all TLPs Transmitted using a particular TC except those that are associated with a Selective IDE Stream. When there are no Switches between the Ports, then it is possible to secure all, or only selected, TLP traffic on the Link, using Link IDE or Selective IDE, respectively. There is no required relationship, or restriction, between Link IDE and Selective IDE. It is possible to use both Link IDE and Selective IDE between two directly connected Ports, as shown in § Figure 6-52 between Ports A and B, in which case TLPs associated with the Selective IDE Stream are secured using that Stream’s key set, and all other TLPs are secured using the key set for the Link IDE Stream. Such a configuration may be desirable if, for example, different security policies are applied to the Selective IDE TLPs than to other Link traffic. It is possible to use Selective IDE in cases where the IDE Terminus is a Switch Port, as shown between Ports C and D. IDE does not establish security beyond the boundary of the two terminal Ports, and mechanisms for securing and/or isolating secure traffic within a Component are outside the scope of this document. Again referring to the example shown in § Figure 6-52, the Selective IDE Streams between Ports C and G, and between Ports G and H, are secured as they pass through the Switch. All other Link IDE and Selective IDE streams illustrated are secured by IDE from Port to Port, but must be secured by implementation specific means within the Component past the terminal Port. By implication, when Link IDE is used with TLPs flowing “hop-by-hop” through one or more Switches, it is necessary to ensure acceptable security is maintained within the Switch(es), but how this is done is outside the scope of this document.

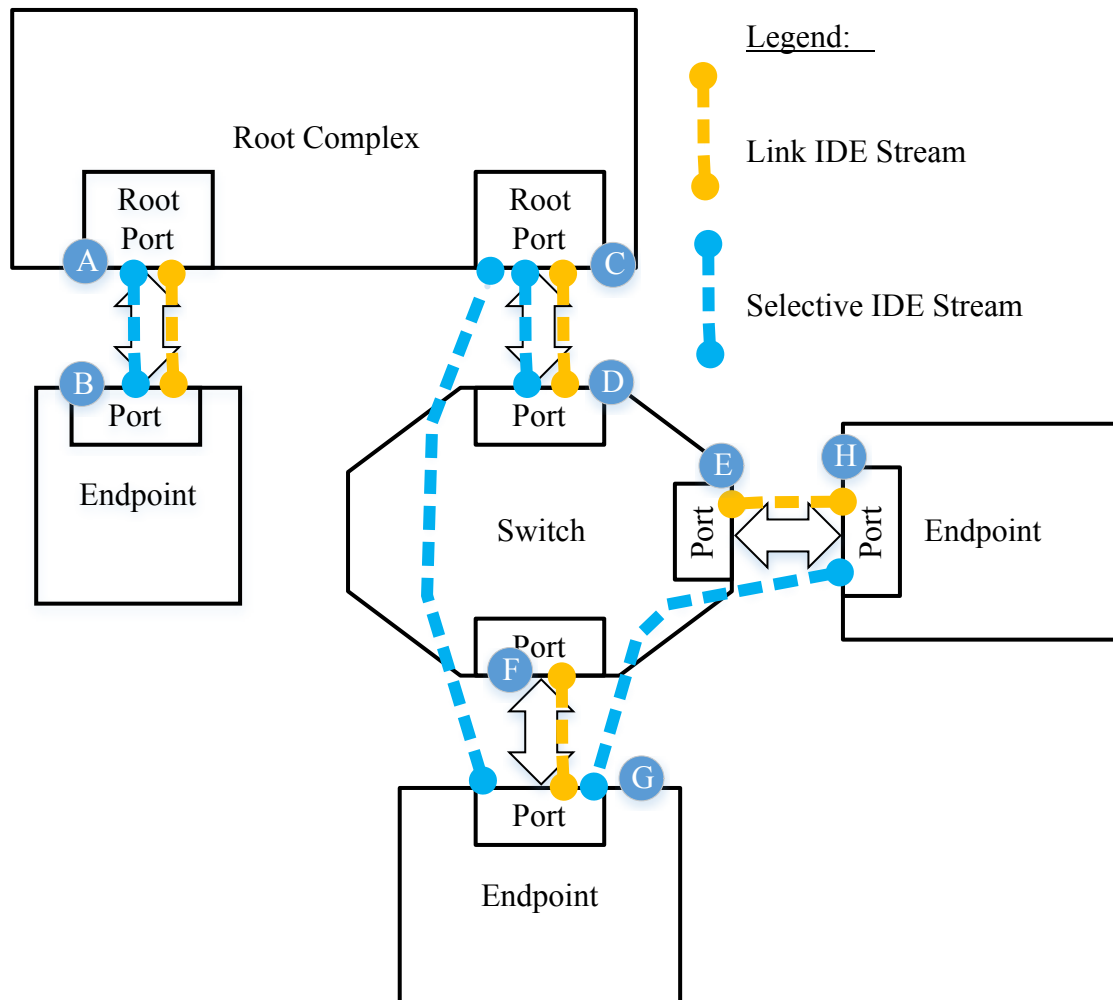

Figure 6-52 IDE Secures TLPs Between Ports §

In addition to the in-line securing of TLPs, as a “data plane” capability, IDE defines interoperable mechanisms for establishing Streams and programming keys, as a “control plane” capability, based on industry specifications. For example, for an Endpoint connected directly to the Root Complex (A to B above), one way to establish IDE is to use IDE Key Management (IDE_KM – see § Section 6.33.3) via DOE to allow host Firmware/Software to configure the Ports, including securely programming the IDE keys into both Ports. In another example, for two Endpoints communicating peer to peer (G to H above), the two Endpoints can implement communication directly via [MCTP-VDM] and [Secured-MCTP], where one will take the Requester role and the other the Responder role, and then applying the IDE_KM flow for secure key establishment. In an alternate example, it is also possible for some kind of management controller to apply IDE_KM over a sideband management connection, to program IDE keys in Ports throughout a system. The mechanisms for a management controller to program keys into a Root Complex are outside the scope of this document.

Policies for establishing trust between elements in a platform are outside the scope of IDE. It is strongly recommended that a platform-appropriate policy be implemented via platform-specific means. It is not necessary that this policy be applied prior to establishing IDE Streams, and in some cases it may be preferable to establish IDE first, and subsequently

apply security policy mechanisms, or to apply some policy mechanisms prior to establishing IDE and some additional mechanisms after.

IMPLEMENTATION NOTE:

THREAT MODEL AND RELATED CONSIDERATIONS FOR IDE §

This implementation note provides a very general treatment of the threat model assumed for IDE. A detailed treatment will necessarily require knowledge of the platform environment and other elements that are outside the scope of this document.

This threat model covers:

Attacks using a logic analyzer or interposer type device, including e.g. “rogue” Retimers, where the attack devices attempt to add or delete TLPs, observe TLP payload data, and/or reorder TLPs. Example attacks include delaying a flag write to bypass a data write causing stale data to be accepted, or delaying a read to bypass a write to same location causing a stale value to be read. Reordering is discussed in more detail in the Implementation Note "Detection of Improper Reordering".

IDE secures host systems against device substitution attacks because, once authenticated key exchange is completed, a subsequent attack by a different unit trying to masquerade as the authenticated unit will fail because the masquerading unit cannot generate IDE TLPs using the correct key.

Provided an implementation includes appropriate self-protection measures, IDE also supports the detection of attacks involving the removal of a unit, for example by moving the unit to a different system and attempting to operate the unit masquerading as the authenticated host.

It is assumed that in an attack, the attacker will thwart error reporting attempts, e.g. by blocking Messages from the Port that detected the error, and such reporting messages are only intended to be used in debugging improperly configured systems. If a specific use model requires timely detection of security failures, some type of “heartbeat” mechanism should be used, rather than assuming that the failure will be reported directly.

This threat model does not cover:

Security exposures caused by inadequate Device implementation. For example, implementations are necessarily required to secure local keys, interconnects, and memory, including, for example, local memory implemented on an add-in-card using discrete memory components. IDE does not protect against on-die traffic redirection, for example between Functions of a Multi-Function Device.

Debug mechanisms should be given careful review as they can easily cause information exposure when improperly implemented. It is strongly recommended that debug state be reported using measurement mechanisms, and that any change in debug configuration that could expose data intended to be secured result in a transition to Insecure (see § Section 6.33.1).

There are many considerations regarding secure key generation, programming, and storage, and it is strongly encouraged that non-experts consult with experts to evaluate all levels of implementation to ensure that good practices are followed. In all cases, it is essential to avoid exposure of plain text keys by any means including debug features such as tracers, configuration registers etc.

If partial header encryption (see § Section 6.33.4) is not used, “side channel” attacks may be possible in some cases based on attacker analysis of the information included in the headers. For example, see <https://www.ieee-security.org/TC/SP2015/papers-archived/6949a640.pdf>.

Considerations:

IDE secures TLP traffic from one Port to another Port. TLP content is not secured on-die by IDE past the terminal Partner Ports, and so it is necessary to provide appropriate implementation specific protective measures based on use model requirements to ensure that TLP traffic is secured prior to transmission, and following reception.

IDE assumes the implementation of appropriate isolation mechanisms to ensure that information remains secured beyond the Port to Port connection secured via IDE. In some cases, entire components can be considered “secure” and there is no need to distinguish traffic on-die, in other cases the establishment of one or more Trusted Execution Environments (TEEs) may be needed to isolate secure traffic from non-secure traffic, and different secure environments from each other. Although it is permitted to establish more than one IDE Stream between the same two Ports, this is not generally needed or useful, because it is assumed that once on-die, all secure traffic is “equally” secure, and using separate IDE Streams provides no additional protection. The details of how such TEEs are implemented and managed are outside the scope of IDE. The T bit is used for TEE management mechanisms (see § Chapter 11.). IDE mechanisms ensure that the T bit (like other TLP content) is secured during transit.

Good practices for implementing TEEs include, but are not limited to:

- Securing secrets through the use of local encryption, access control, and/or other mechanisms
- Ensuring that secure data cannot “leak” due to errors, power management, or other operations
- Detecting inappropriate attempts to reconfigure IDE, e.g. writes to any of the IDE control registers, and/or other internal conditions that could compromise secure data and taking appropriate measures, including potentially forcing the Port into Insecure
- Ensuring that secret keys are never exposed or stored in non-secure buffers
- Ensuring that the establishment & management of TEEs is itself secure

The implementation of TEEs can be very complex, and it is strongly recommended that persons with appropriate security expertise are intimately involved in the development and validation of components and systems.

Although Link IDE applies to all kinds of TLPs, Selective IDE can only be applied to certain types of TLPs (see § Table 6-35). Memory operations are required to be supported for virtually all use models, and are supported by Selective IDE. I/O operations are not commonly used, and are not supported by Selective IDE to simplify design and validation. Selective IDE can be applied to Messages, and, optionally, to Configuration Requests & Completions. Selective IDE can be applied to TLPs with Prefixes, but Local TLP Prefixes are not protected when the TLP is associated with a Selective IDE Stream. In NFM, End-End TLP Prefixes are protected along with the associated TLP, and in FM, OHC content is protected along with other Header content.

6.33.1 IDE Stream and TEE State Machines §

Conceptually, the initialization of a Link or Selective IDE Stream involves multiple steps, although some of these steps can be merged or performed in a different order. The first step is to establish the authenticity and identity of the components containing the two Partner Ports to be the IDE Terminuses of the IDE Stream. This may be done using CMA-SPDM, by implementation specific means, or in some cases implicitly. The second step is to establish the IDE Stream keys – the IDE Key Management (IDE_KM – § Section 6.33.3) provides a way to do this. Third, the Secure Connection must be configured, and, finally, the establishment of the IDE Stream is triggered.

Conceptually, each IDE Stream is associated at each Partner Port with a state machine illustrated in § Figure 6-53.

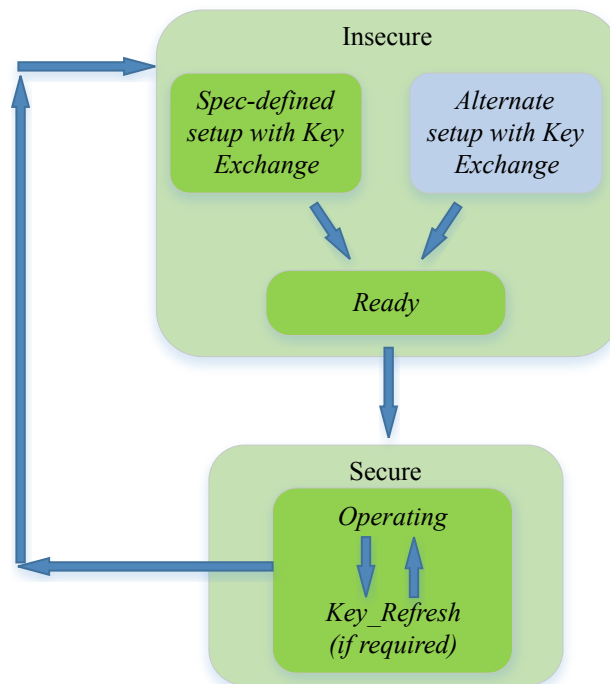

Figure 6-53 IDE Stream State Machine §

- The Insecure state indicates that the necessary steps to operate the IDE Stream have not been completed, or that some event has ended the operation of a previously operating IDE Stream.
 - Typically the Insecure will include various conceptual substates that are not directly observable by the hardware, and only the system firmware/software configuring the IDE Stream will have the ability to comprehend when all necessary steps have been completed.
 - The Ready conceptual sub-state of the Insecure state is entered when all necessary configuration has been performed; this condition must be tracked by system firmware/software.
 - In many cases it will not be possible for hardware to distinguish when all necessary configuration has been performed, and there is no requirement for hardware to track the transition into the Ready sub-state.
- The IDE Stream State Machine for a specific Stream of a Port must transition from Secure to Insecure when the corresponding Link/Selective IDE Stream Enable bit is Cleared.
 - As further discussed below, it is essential that the Port internally block all transmissions that are intended to be secure if the corresponding IDE Stream State Machine is not in the Secure state.
- If at any time a condition compromising the security of the IDE Stream is detected at the Port, the Port must transition to Insecure.
 - It is permitted to transition to Insecure for implementation specific reasons.

A trusted execution environment (TEE) using IDE must prevent the transmission of TLPs intended to be secure using non-IDE TLPs, and must reject non-IDE TLPs received if the TEE requires those TLPs to be secure. A specific architecture for devices that support TEEs is defined by TDISP (see § Chapter 11.). In order to precisely define the normative requirements for IDE in relation to TEEs, we will assume that TEEs have internal states that correspond to those shown in § Figure 6-54.

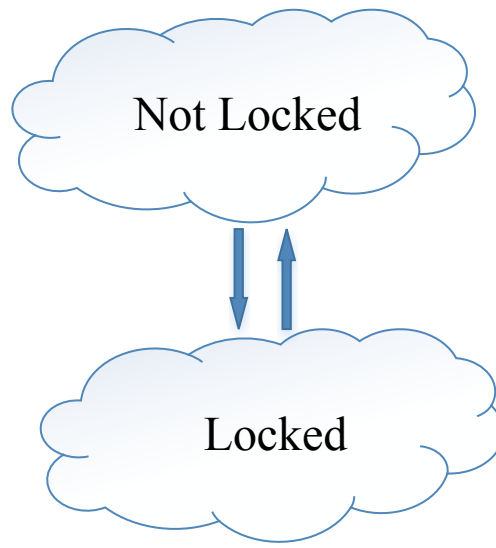

Figure 6-54 IDE Stream State Machine §

TDISP (see § Chapter 11.) defines specific requirements that extend the following rules, that apply broadly to all TEEs using IDE:

- A TEE must distinguish between at least two operating conditions, that may be called by any names but here will be called Not Locked and Locked.
 - A TEE must transition to the Locked state if and only if all IDE Streams required for the secure operation of the TEE are in the Secure state.
 - A TEE must transition to the Not Locked state if any IDE Stream required for the secure operation of the TEE is in the Insecure state.
- A TEE using an IDE Stream must precisely define the essential configuration information that could affect the security of the IDE Stream, and, once that IDE Stream is established, that essential configuration information must be confirmed and maintained by secure means so as to detect “adversary-in-the-middle” (AITM) attacks attempted during or after IDE Stream establishment, and changes to that information blocked and/or detected, as to detect/prevent attacks during operation.
 - The specific configuration information to which this requirement applies is implementation specific and dependent on the hardware elements involved, the security attributes required, and potentially on assumptions of use, all of which are outside the scope of this specification.
 - How the information is confirmed is implementation specific, but would typically include securely transferring a data structure that contains a local snapshot of the information to a secure partner to be compared against the expected values.

6.33.2 IDE Stream Establishment §

To establish IDE Streams interoperably based on this specification, system firmware/software acts as a central authority to create and program keys into the two Partner Ports. The following rules apply:

- For Endpoints, including Functions of a Multi-Function Device, associated with an Upstream Port, only Function 0 must implement the IDE Extended Capability.
- For Switches, including cases where one or more Functions of a Multi-Function Device represent the Upstream Port of a Switch, the IDE Extended Capability must only be implemented in Function 0, and implemented such that Function 0 represents the Multi-Function Device as a whole.
- For a Downstream Port, the Bridge Function associated with the Port must implement the IDE Extended Capability.
- All Ports other than Root Ports must implement support for key management by means of the IDE key management (IDE_KM) protocol defined in § Section 6.33.3 .
 - For Switch and Root Ports it is permitted for one Port to provide the DOE and CMA-SPDM responder function on behalf of other Ports as defined in § Section 6.33.3 .
 - Root Ports are permitted to implement support for the IDE_KM protocol.

It is also permitted for systems to implement the IDE_KM protocol via MCTP (see § Section 6.33.3).

It is also permitted for system firmware/software to enable pass-through communications between the two Partner Ports, where one of the two takes the Requester Role and the other takes the Responder Role, implementing the IDE_KM protocol defined below directly between the two Partner Ports (as an example see the Selective IDE Stream between Ports G and H in § Figure 6-52). How this is discovered and enabled is outside the scope of this specification.

6.33.3 IDE Key Management (IDE_KM) §

IDE Key Management (IDE_KM) builds upon [SPDM] and [Secured-SPDM], and can be used over multiple transports (see § Figure 6-55).

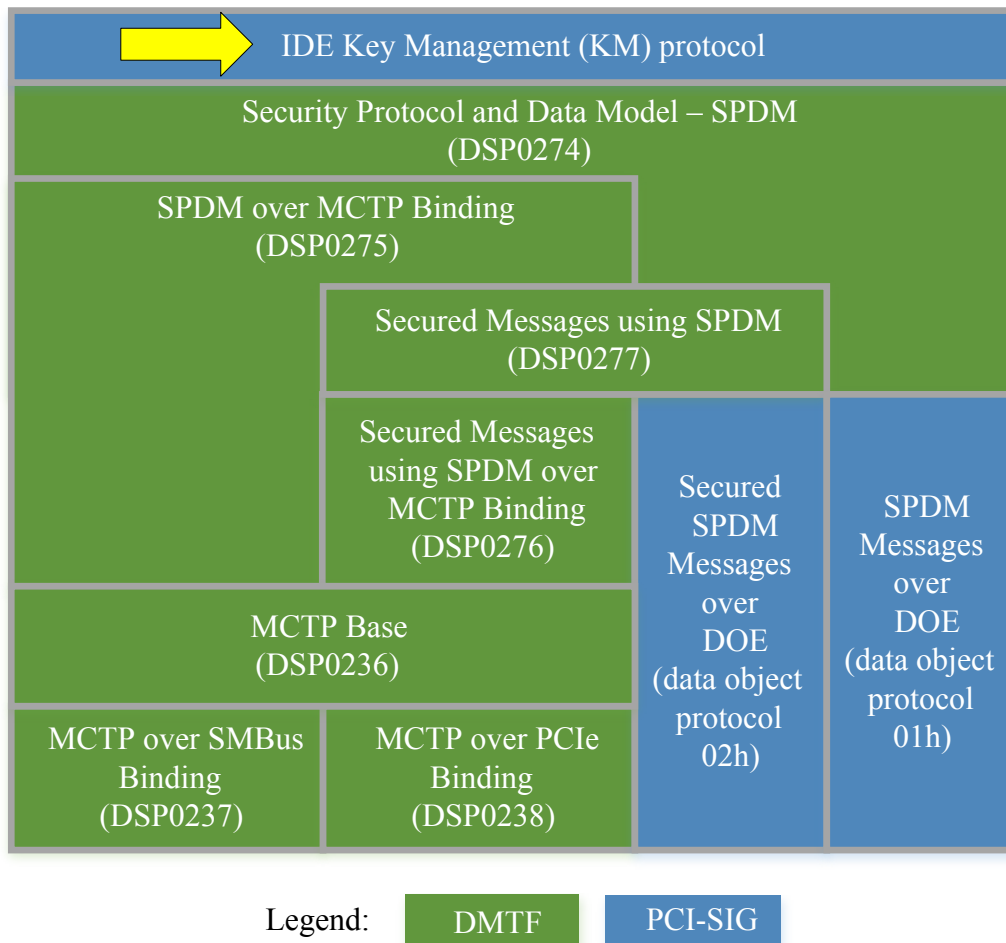

Figure 6-55 IDE Key Management (IDE_KM) and Related Specifications & Capabilities [§]

The following rules define the IDE key management (IDE_KM) protocol, and must be followed for Ports that support the use of IDE_KM:

- The IDE_KM protocol uses the data objects defined below, where:
 - The Requester must use the [SPDM] VENDOR_DEFINED_REQUEST format, the Responder must use the [SPDM] VENDOR_DEFINED_RESPONSE format.
 - The StandardID field of the VENDOR_DEFINED_REQUEST/ VENDOR_DEFINED_RESPONSE must contain the value assigned in [SPDM] to identify PCI-SIG.
 - The VendorID field of the VENDOR_DEFINED_REQUEST/ VENDOR_DEFINED_RESPONSE must contain the value 0001h, which is assigned to the PCI-SIG.
 - The VendorDefinedReqPayload/VendorDefinedRespPayload field of the VENDOR_DEFINED_REQUEST/VENDOR_DEFINED_RESPONSE must be the data object content as defined below.
 - The VENDOR_DEFINED_REQUEST/VENDOR_DEFINED_RESPONSE must in turn form the Application Data field of a Secured Message per [Secured-SPDM].

- It is strongly recommended that the cryptographic strength used in the secure session be at least as strong as selected for IDE itself.
- If any IDE_KM data object is received that has not been transferred securely per [Secured-SPDM], the received data object must not be used for key management, and, if it is a request, must not result in a response.
- The size of the VendorDefinedReqPayload/VendorDefinedRespPayload must match the size of the data object defined below.
 - If the size does not match, the received data object must not be used for key management, and, if it is a request, must not result in a response.
- For Endpoint Functions, including Functions of a Multi-Function Device, associated with an Upstream Port, Function 0 must implement DOE and CMA-SPDM for Authentication and key exchange, including the secure session establishment mechanism (see [SPDM]) and the IDE key management (IDE_KM) protocol as a Responder, as defined below.
 - IDE operates at a per-Port level, and Function 0 of an Upstream Port must be used for the purposes of establishing the authenticity and identity of the associated Component, performing key exchange, and the configuration and management of IDE Stream(s) for that Port.
- Each Upstream Port Function, regardless of Function Number, representing a Switch for which Link IDE Stream Supported and/or Selective IDE Streams Supported are Set, including in Multi-Function Devices, must implement DOE and CMA-SPDM supporting the IDE key management (IDE_KM) protocol as a Responder, as defined below.
- It is permitted for a Root Complex to:
 - support the IDE_KM protocol using a DOE instance for some or all Root Ports per-Port, or using some Root Ports to represent other Root Ports
 - implement a DOE instance in an RCRB supporting IDE_KM for Root Ports,
 - use implementation specific key management.
- For Switches and Root Complexes, it is permitted for one Port to implement the IDE_KM interface as a responder for itself and for other Ports of the Switch/Root Complex.
- Ports are permitted to support the IDE_KM protocol transported via MCTP.
- Within each data object, the Protocol ID field in bits [7:0] of the first DW must be 00h to indicate IDE.
- The Object ID field in bits [15:8] of the first DW indicates the IDE_KM data object type and is encoded as:
 - 00h: Query (QUERY)
 - 01h: Query Response (QUERY_RESP)
 - 02h: Key Programming (KEY_PROG)
 - 03h: Key Programming Acknowledgement (KP_ACK)
 - 04h: Key Set Go (K_SET_GO)
 - 05h: Key Set Stop (K_SET_STOP)
 - 06h: Key Set Go/Stop Acknowledgement (K_GOSTOP_ACK)
 all other encodings Reserved.
- A Requester is permitted to use QUERY to determine the capabilities and configuration of a Port (see § Figure 6-56)
 - The PortIndex field must be used to indicate the Port addressed by the QUERY.
- A Responder must respond to a QUERY indicating a PortIndex value of 00h.

- IDE_KM assigns unique Port numbers (PortIndex) for each Port of an Endpoint, Switch or Root Complex, implementing IDE_KM.
- For a Switch that supports the IDE_KM responder role:
 - The Switch Upstream Port must implement the responder role for itself and the Upstream Port must respond to a PortIndex of 00h.
 - Downstream Ports of the Switch that are represented by the Upstream Port must respond to PortIndex ranging from 01h to FFh, where the order is established by the Device/Function numbers assigned by the Switch construction to the Downstream Ports from lowest to highest.
 - It is permitted for a Switch to implement a responder capability in a Downstream Port, for example by implementing a DOE instance in the Downstream Port, in which case that Downstream Port must respond to a PortIndex of 00h.
 - It is permitted for that Port to represent other Downstream Ports, in which case the represented Downstream Ports must respond to PortIndex ranging from 01h to FFh, where the order is established by the Device/Function numbers assigned by the Switch construction to the Downstream Ports from lowest to highest.
- For a Root Port that supports the IDE_KM Responder role:
 - The Root Port must implement the responder role for itself and must respond to a PortIndex of 00h.
 - It is permitted for that Port to represent other Root Ports, in which case the represented Root Ports must respond to PortIndex ranging from 01h to FFh, where the order is established by the Device/Function numbers assigned by the Root Complex construction to the Root Ports from lowest to highest.
- For an Endpoint Upstream Port that supports the IDE_KM responder role, the Port must respond to a PortIndex of 00h.
- Ports/RCRBs implementing the [SPDM] responder role must respond to a QUERY with QUERY_RESP (see § Figure 6-57).
 - The PortIndex field must contain the PortIndex field value from the corresponding QUERY.
 - The MaxPortIndex field value must indicate the maximum PortIndex value for the Ports represented by this Port/RCRB.
 - If only one Port is represented, including for all Endpoint Upstream Ports, the MaxPortIndex field must be 00h.
 - The Bus Number field must contain the Bus Number of the Function corresponding to the PortIndex field value.
 - The Segment field must:
 - for Ports that are not Root Ports, be zero
 - for Root Ports, contain the Segment Number value for the Root Port, or zero if the Root Complex implements only one Segment.
 - For Non-ARI Functions the Device/Function Number field must contain the Device and Function number of the Function corresponding to the PortIndex field value.
 - For ARI Functions the Function Number field must contain the Function number of the Function corresponding to the PortIndex field value.
 - The remainder of QUERY_RESPONSE must consist of the contents of the IDE Extended Capability Structure, other than the IDE Extended Capability Header itself, for the addressed Port.
 - The Supported Algorithms and Selected Algorithm field values returned in QUERY_RESP must be compared against the values read from the corresponding fields in the Responder Port's IDE Extended Capability structure and if non-matching values are detected then the

IDE_KM protocol for this secure session must be aborted, or other appropriate corrective action taken to avoid a possible “downgrade” attack.

- Requesters must not issue other requests after issuing a QUERY command until receipt of the corresponding QUERY_RESP.
- KEY_PROG, KP_ACK, K_SET_GO, K_SET_STOP and K_GOSTOP_ACK all apply to a single Sub-Stream, direction (Tx or Rx) and Key Set.
 - The Key Sub-Stream field indicates the Key Sub-Stream, using the same encodings as defined for the Sub-Stream identifier (see § Section 6.33.5)
 - The direction is indicated by the RxTxB bit encoded:
 - 0b – Receive
 - 1b - Transmit
 - The Key Set field indicates the Key Set, corresponding to the K bit value in the IDE TLP Prefix (NFM)/OHC-C (FM).
- For Ports implementing the Responder role, key programming and the ability to select the initial value of the IV must be supported using the KEY_PROG command (see § Figure 6-58).
 - The length of the key must correspond to the length indicated in the Selected Algorithm field for the Stream.
 - The Requester must not send another KEY_PROG command to the same Port until it has received a KP_ACK from the Port.
 - If the Requester does not receive a KP_ACK from the Responder within 1 second plus a sufficient time to account for transport delay the Requester is permitted to consider that the Responder is not operating correctly.
 - Fields specific to the KEY_PROG command are:
 - PortIndex, indicating the Port to which the key is to be programmed, corresponding to the order established in the QUERY_RESP
 - Stream ID
 - Key, which must be of the size required for the Selected Algorithm for the Stream
 - IFV, indicating the initial value for the invocation field of the IV, which must be 64 bits in size, and must initially set to the value 0000_0001h upon establishment of the Stream and when performing a key refresh.
- A Port implementing the Responder role must acknowledge receipt of a KEY_PROG command by returning KP_ACK, defined in § Figure 6-59.
 - The Status field must indicate the result of the KEY_PROG command, encoded as:
 - 00h: Successful
 - 01h: Failed to parse command – Incorrect Length
 - 02h: Failed to parse command – Unsupported value in PortIndex
 - 03h: Failed to parse command – Unsupported value in other field(s)
 - 04h: Unspecified Failure
 - 05-FFh: Reserved – Must not be used in generating KP_ACK, but if received must be treated as Unspecified Failure
 - The Responder must return KP_ACK within 1 second of the receipt of the KEY_PROG command.
 - It is strongly recommended to return KP_ACK as quickly as possible.

- Return of KP_ACK, regardless of Status, indicates the Port is able to receive and process another KEY_PROG command .
- Mechanisms for generating keys are outside the scope of this document.
- It is strongly recommended to complete key programming for a Stream before Setting the Enable bit in the IDE Extended Capability entry for that Stream.
 - It is permitted, but strongly not recommended, to Set the Enable bit in the IDE Extended Capability entry for a Stream prior to the completion of key programming for that Stream.
- If the Enable bit is Set in the IDE Extended Capability entry for a Stream, but that IDE Stream is not already in Secure, the receipt of a K_SET_GO for must trigger the Port to Transmit/Receive IDE TLPs for the indicated Stream, Sub-Stream, direction and Key Set.
 - The agent implementing the Requester role for IDE_KM must send K_SET_GO commands to enable the Receivers at both IDE Partner Ports, and then send K_SET_GO commands to enable the Transmitters at both IDE Partner Ports.
 - The Port must use the indicated Key Set for IDE TLP transmissions associated with the IDE Stream, Sub-Stream, and direction starting not more than 10 ms after the receipt of the K_SET_GO command to enable the Transmitter.
 - The Port must be capable of processing received IDE TLPs using the indicated Key Set within 10 ms after the receipt of the K_SET_GO command enabling the Receiver.
 - The Port must respond by returning an K_GOSTOP_ACK once it is capable of receiving another IDE_KM Request.
- If the Enable bit is Set in the IDE Extended Capability entry for a Stream, and that IDE Stream is already in Secure (a key refresh operation), the receipt of a K_SET_GO for must trigger the Port to Transmit/Receive IDE TLPs for the indicated Stream, Sub-Stream, direction and Key Set.
 - The agent implementing the Requester role for IDE_KM must send K_SET_GO commands to enable the Receivers at both IDE Partner Ports, and then send K_SET_GO commands to enable the Transmitters at both IDE Partner Ports.
 - The Port must use the indicated Key Set for IDE TLP transmissions associated with the IDE Stream, Sub-Stream, and direction starting not more than 10 ms after the receipt of the K_SET_GO command to enable the Transmitter.
 - The Port must be capable of processing received IDE TLPs using the indicated Key Set within 10 ms after the receipt of the K_SET_GO command enabling the Receiver.
 - For each Sub-Stream of the Stream, until the Port receives an IDE TLP using the new key set, as indicated by the K bit value toggling, the Port must continue to accept IDE TLPs using the established key set.
 - Once the Port receives an IDE TLP using the new key set on a Sub-Stream it must invalidate and render unreadable the old key set, and discard subsequently received IDE TLPs using the old key set on that Sub-Stream.
 - The Port must respond by returning an K_GOSTOP_ACK once it is capable of receiving another IDE_KM Request.
- If the Enable bit in the IDE Extended Capability for a Stream is Clear, the receipt of K_SET_GO for both receive and transmit must cause the Port to become ready to Transmit/Receive IDE TLPs for the indicated Stream and Sub-Stream within 10 ms following the receipt of the last K_SET_GO, after which system software is permitted to Set the Enable bit for the Stream. When the Enable bit is Set:
 - The Port must be capable of processing received IDE TLPs using the Key Set armed by the received K_SET_GO Request.
 - System software must ensure that the Partner Ports initiate IDE TLPs sequenced appropriately so that a Port will not receive an IDE TLP before the Enable bit has been set.

- The Port must respond by returning an K_GOSTOP_ACK once it is capable of receiving another IDE_KM Request.

It is strongly recommended that all Sub-Streams in both directions be fully programmed before Setting the Enable bit for the Stream.

- Is permitted for the IDE_KM Requester to transmit the K_SET_STOP command, defined in § Figure 6-61, to indicate that a Key Set must stop being used at a Port for the indicated Stream, Sub-Stream, and direction.
 - The Port implementing the responder role must invalidate and render unreadable the indicated Key Set not more than 10 ms after the receipt of the K_SET_STOP command.
 - Upon receipt of the KEY_STOP command, for the indicated Key Set and direction, all keys must be invalidated and rendered unreadable.
 - It should be observed that this action does not directly transition the Stream to Insecure, but any subsequent attempt to use the indicated Key Set will result in the Stream transitioning to Insecure.
 - The Port must respond by returning an K_GOSTOP_ACK once it is capable of receiving another IDE_KM Request.
- When an error is detected in a received K_SET_GO or K_SET_STOP (such as an invalid Stream ID), it is recommended that no K_GOSTOP_ACK be returned.
- When using DOE for IDE_KM, or when IDE is enabled/disabled using the Enable bit for an IDE Stream, the following rules apply:
 - For a Configuration Request that triggers the start IDE, the Port must first return the Configuration Completion as a non-IDE TLP, and then trigger the start of IDE.
 - For a Configuration Request that stops IDE, the Port must first return the Configuration Completion as an IDE TLP, and then stop IDE.

An IDE error condition will occur if system software fails to ensure the correct sequencing of IDE enablement at the two Partner Ports.

- For a given IDE Stream, once a secure [SPDM] session has been used to respond to one QUERY or KEY_PROG request:
 - While the secure [SPDM] session that was used for initial key programming remains open, all QUERY and/or KEY_PROG requests that are received through a different secure [SPDM] session must be discarded by the Responder, and must not result in a response.
 - If the secure [SPDM] session that was used for initial key programming is closed, any subsequent QUERY and/or KEY_PROG requests received through a different secure [SPDM] session must first cause the responder to invalidate and render unreadable all keys must for the IDE Stream, then transition that IDE Stream to the Insecure state, and only then respond to the QUERY/KEY_PROG request, unless it can be ensured through implementation specific means that the new session has been established with the same requester as performed the initial key programming.

Figure 6-61 Key Set Stop (K_SET_STOP) Data Object §

Figure 6-62 Key Set Go/Stop Acknowledgement (K_GOSTOP_ACK) Data Object §

For implementations not requiring interoperable authentication and key exchange, it is permitted to use other mechanisms for key management.

Rules related to keys:

- Key size must be 256 bits.
- Following key exchange, implementation specific means must be used to ensure key security - the specific requirements for maintaining key security are platform and use case specific, and are out of scope for this document.
- Separately generated keys must be used for the Transmitter and the Receiver, and for each Sub-Stream.
 - It is strongly recommended that all keys for all Streams be separately generated.
- To support key updates without requiring an active IDE Stream to be put into a quiescent state, two key sets are defined, and the appropriate key set indicated in the IDE TLP Prefix (NFM)/OHC-C (FM) by the Transmitter via the K bit.
 - The initial value of the K bit is permitted to be 0b or 1b, although it is recommended the initial value be 0b. Software must ensure that the selected key set has been provided with keys in both Partner Ports.
 - Once the Transmitter has indicated a change of key set via the K bit, the Receiver must mark the other key set/bank invalid until it is reprogrammed.
 - The specific requirements for the frequency of key updates are determined by platform security requirements that are outside the scope of this document.
 - It is generally recommended that hardware provide enough key storage and management resources to support changing the keys for at least one active Stream without disruption to IDE operation.
 - It is expected that key update operations for multiple streams may need to be performed by firmware/software in a serialized fashion based on hardware key storage and management resource limitations.

IMPLEMENTATION NOTE: UNDERSTANDING THE IDE KEY MANAGEMENT FLOW §

The following diagram illustrates a detailed example key programming flow using the IDE_KM protocol defined above, although it should be understood that there are many possible variations on this flow.

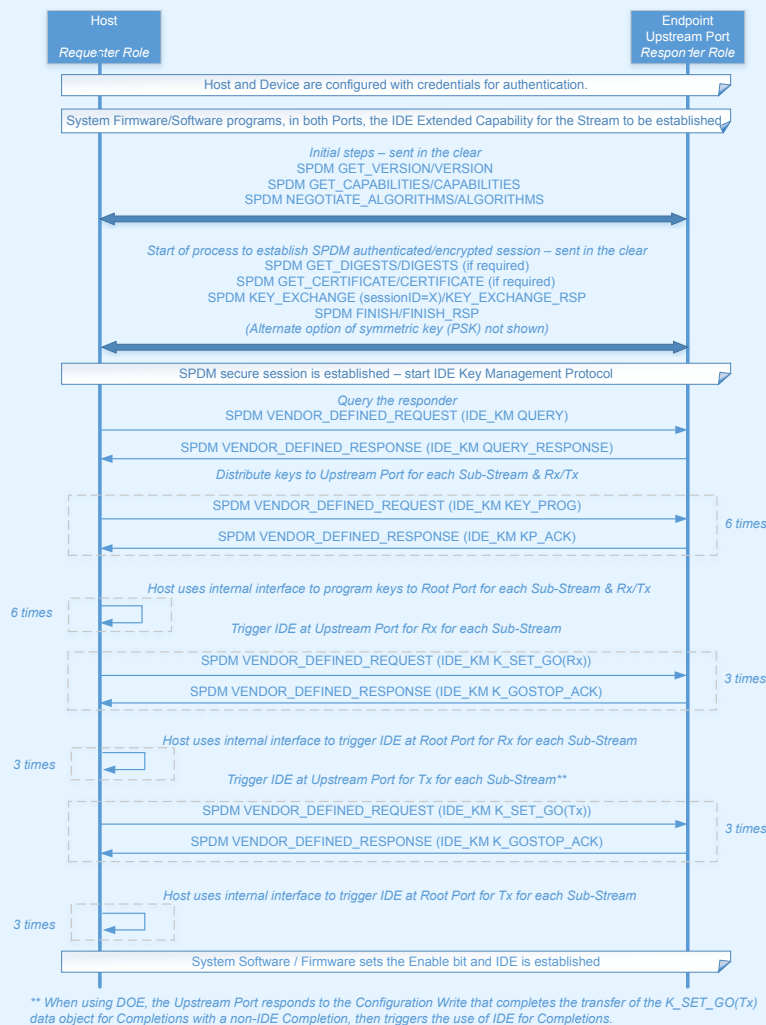

Figure 6-63 IDE_KM Example §

6.33.4 IDE TLPs §

TLPs secured by IDE are called IDE TLPs. In Non-Flit Mode, all IDE TLPs must use the IDE prefix (see § Figure 6-64), and this prefix must precede all other End-End TLP prefixes. In Flit Mode, all IDE TLPs must include OHC-C.

Figure 6-64 IDE TLP Prefix (NFM) §

The IDE Prefix (NFM) includes:

- M bit – When Set, indicates this TLP includes a MAC
 - When aggregation is not used, the M bit must be Set for all IDE TLPs.
 - Rules for the use of aggregation are given below.
- K bit – Indicates the key set used for this TLP
 - After Transmitting a TLP with the K bit toggled for any Sub-Stream, subsequent TLP Transmissions for different Sub-Streams of the same Stream must also use the new value for the K bit.
 - After receiving a TLP with the K bit toggled, the Receiver must transition to the new key and IV set for that TLP and all subsequent TLPs associated with the Sub-Stream, and must mark the old key and IV set invalid until reprogrammed.
 - Such transitions must not affect other Sub-Streams of the IDE Stream at the Receiver.
- T bit – When Set, indicates the TLP originated from within a trusted execution environment (see § Section 6.33.1).
 - If the TEE-IO Supported bit in the Device Capabilities Register is Clear:
 - It is permitted for IDE TLPs to originate from both trusted and non-trusted execution environments, and the value of the T bit does not modify the handling of TLPs within IDE per se; the rules for trusted execution environments are not defined in this document.
 - The T bit must be Clear unless the use of the T bit has been explicitly defined by TEE management mechanisms outside the scope of this document.
 - If the TEE-IO Supported bit in the Device Capabilities Register is Set, this bit must be used for TEE management mechanisms as defined in § Chapter 11. .
- P bit – When Set, indicates the TLP includes PCRC.
 - Must only be Set when the M bit is also Set.
- Sub-Stream[2:0] – Indicates the Sub-Stream identifier value
- Stream_ID[7:0] – Indicates the associated Stream ID value
- PR_Sent_Counter[7:0] – For non-UIO Non-Posted Requests and Completions the value must be determined according to the rules below. This field must be Reserved for Posted Requests and for UIO Requests/ Completions.

In Flit Mode:

- The presence of MAC and/or PCRC are indicated using the TS field.
- The K bit, T bit, Sub-Stream, Stream_ID, and PR_Sent_Counter are included in OHC-C, and have the same meaning as in the IDE Prefix.

IDE uses Galois/Counter Mode (GCM) as defined in [AES-GCM], referred to as AES-GCM. For IDE TLPs, TLP data payload content forms the “Plaintext”, also known as P , as defined in [AES-GCM], and the TLP Header and certain other elements (defined below) form the “Additional Authenticated Data”, also known as A , as defined in [AES-GCM].

The Message Authentication Code (MAC)¹⁴³ size, also known as t , as defined in [AES-GCM], must be 96b (see § Figure 6-65).

Figure 6-65 MAC Layout §

Flow Control credit accounting for IDE TLPs must handle the MAC as covered by the Header Credit.

For IDE TLPs, AES-GCM can be applied to each IDE TLP, or aggregation can be used to apply AES-GCM to multiple IDE TLPs, reducing the per-TLP overhead for the IDE TLP MAC. For a Link IDE Stream, local prefixes must be covered by the MAC (see § Figure 6-66, § Figure 6-67, § Figure 6-70, and § Figure 6-71). For Selective IDE Streams, local prefixes must not be covered by the MAC (see § Figure 6-68, § Figure 6-69, § Figure 6-72, and § Figure 6-73).

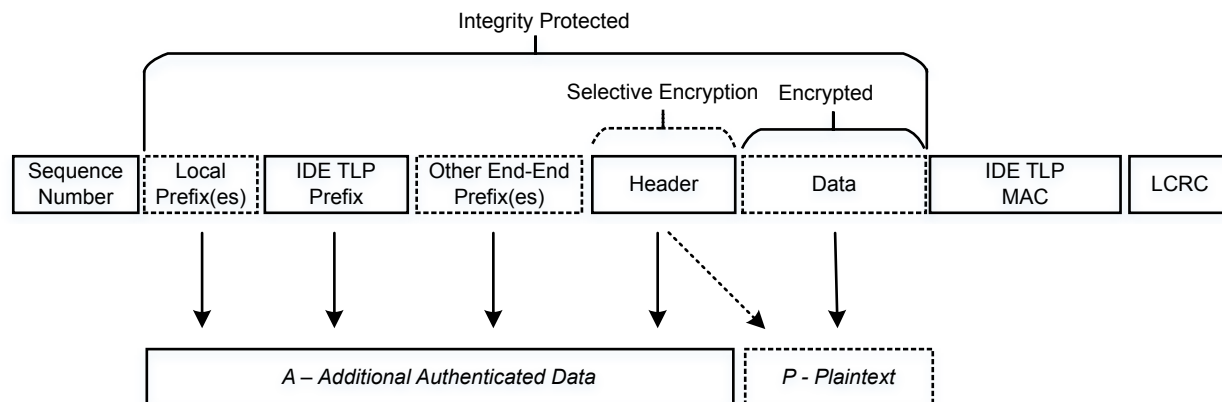

Figure 6-66 Example of IDE TLP for a Link IDE Stream without Aggregation (Non-Flit Mode) §

143. Referred to as “authentication tag” or T in [AES-GCM] but renamed here to avoid confusion with other uses of “tag”

Figure 6-67 IDE TLP – Example Showing Aggregation of Two TLPs for a Link IDE Stream (Non-Flit Mode) §

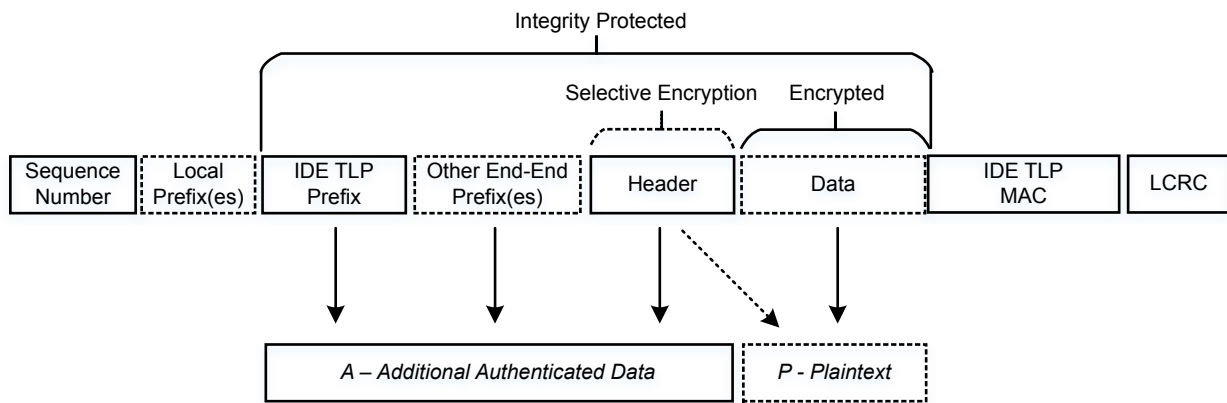

Figure 6-68 IDE TLP – Example of IDE TLP for a Selective IDE Stream without Aggregation (Non-Flit Mode) §

Figure 6-69 IDE TLP – Example Showing Aggregation of Two TLPs for a Selective IDE Stream (Non-Flit Mode) §

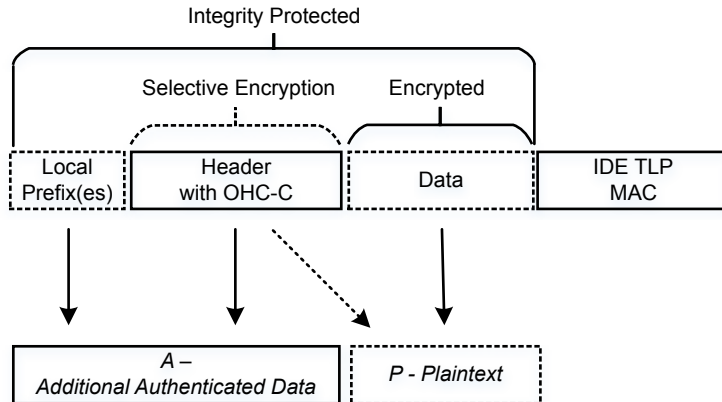

Figure 6-70 Example of IDE TLP for a Link IDE Stream without Aggregation (Flit Mode) §

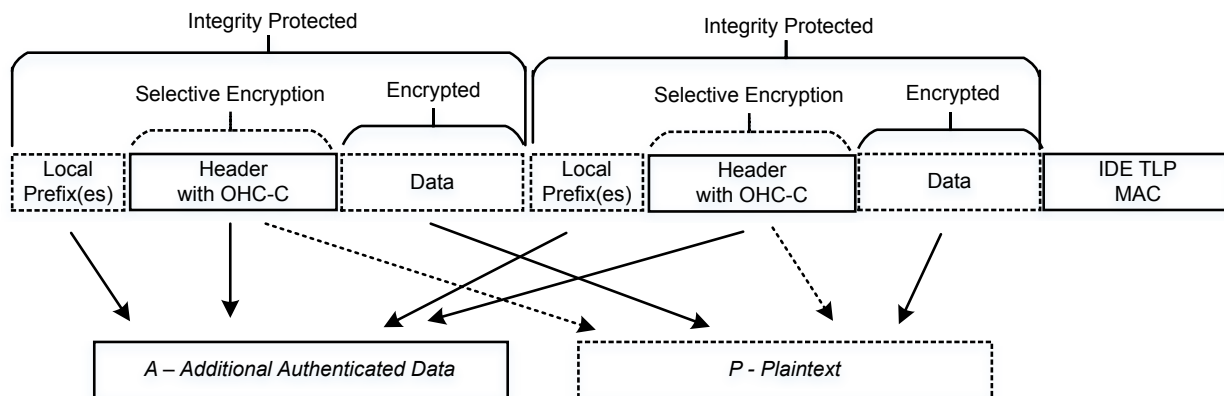

Figure 6-71 IDE TLP - Example Showing Aggregation of Two TLPs for a Link IDE Stream (Flit Mode) §

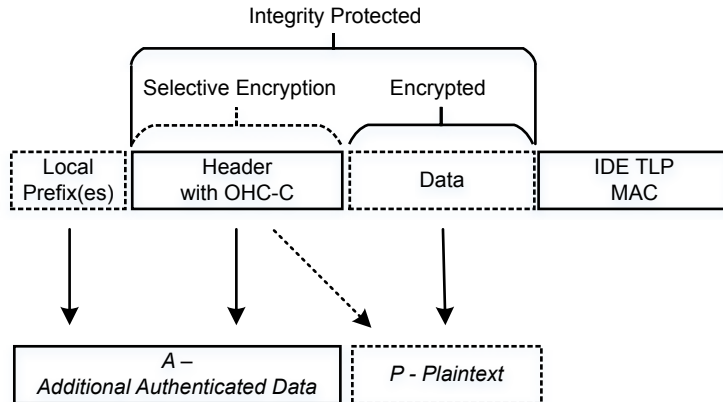

Figure 6-72 IDE TLP – Example of IDE TLP for a Selective IDE Stream without Aggregation (Flit Mode) §

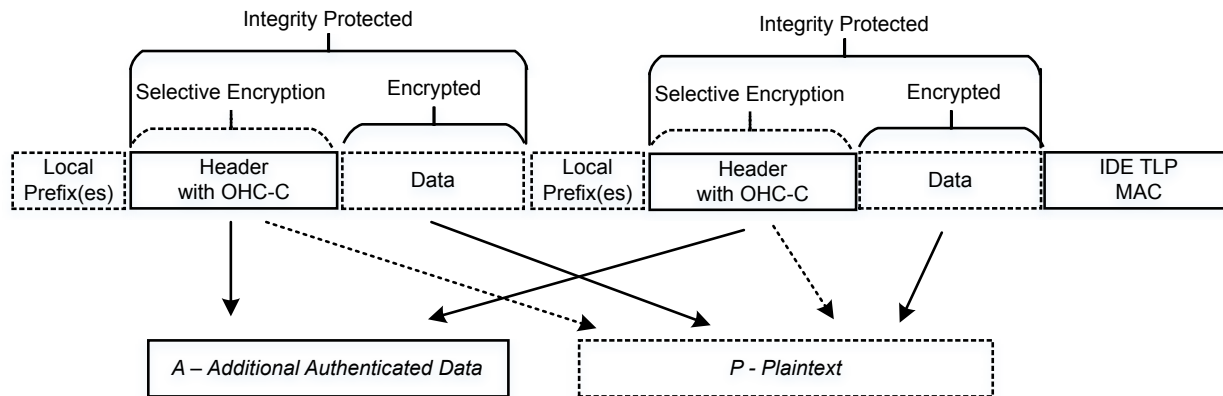

Figure 6-73 IDE TLP – Example Showing Aggregation of Two TLPs for a Selective IDE Stream (Flit Mode) §

The inputs *A* and *P* must be formed by concatenating the included TLP content in Byte order as defined in § Section 2.1.2. Although the *A* and *P* content is conceptually concatenated as illustrated in these figures, the content placement in the IDE TLPs is the same as in non-IDE TLPs. Once the *A* and *P* content is constructed, [AES-GCM] defines how *A* and *P* must be padded – this padding is not illustrated here, and the padding is used in the [AES-GCM] calculations but is not included in the TLPs transmitted/received. When aggregation is used, the *A* and *P* content for aggregated TLPs is conceptually concatenated, for each type of content, prior to padding.

Partial header encryption provides the ability to reduce potential exposure to side-channel attacks by encryption some portions of the Header of an IDE Memory Request while maintaining information that is required for TLP routing and low-level TLP processing in the clear. § Figure 6-74 illustrates, at a high level, the application of partial header encryption.

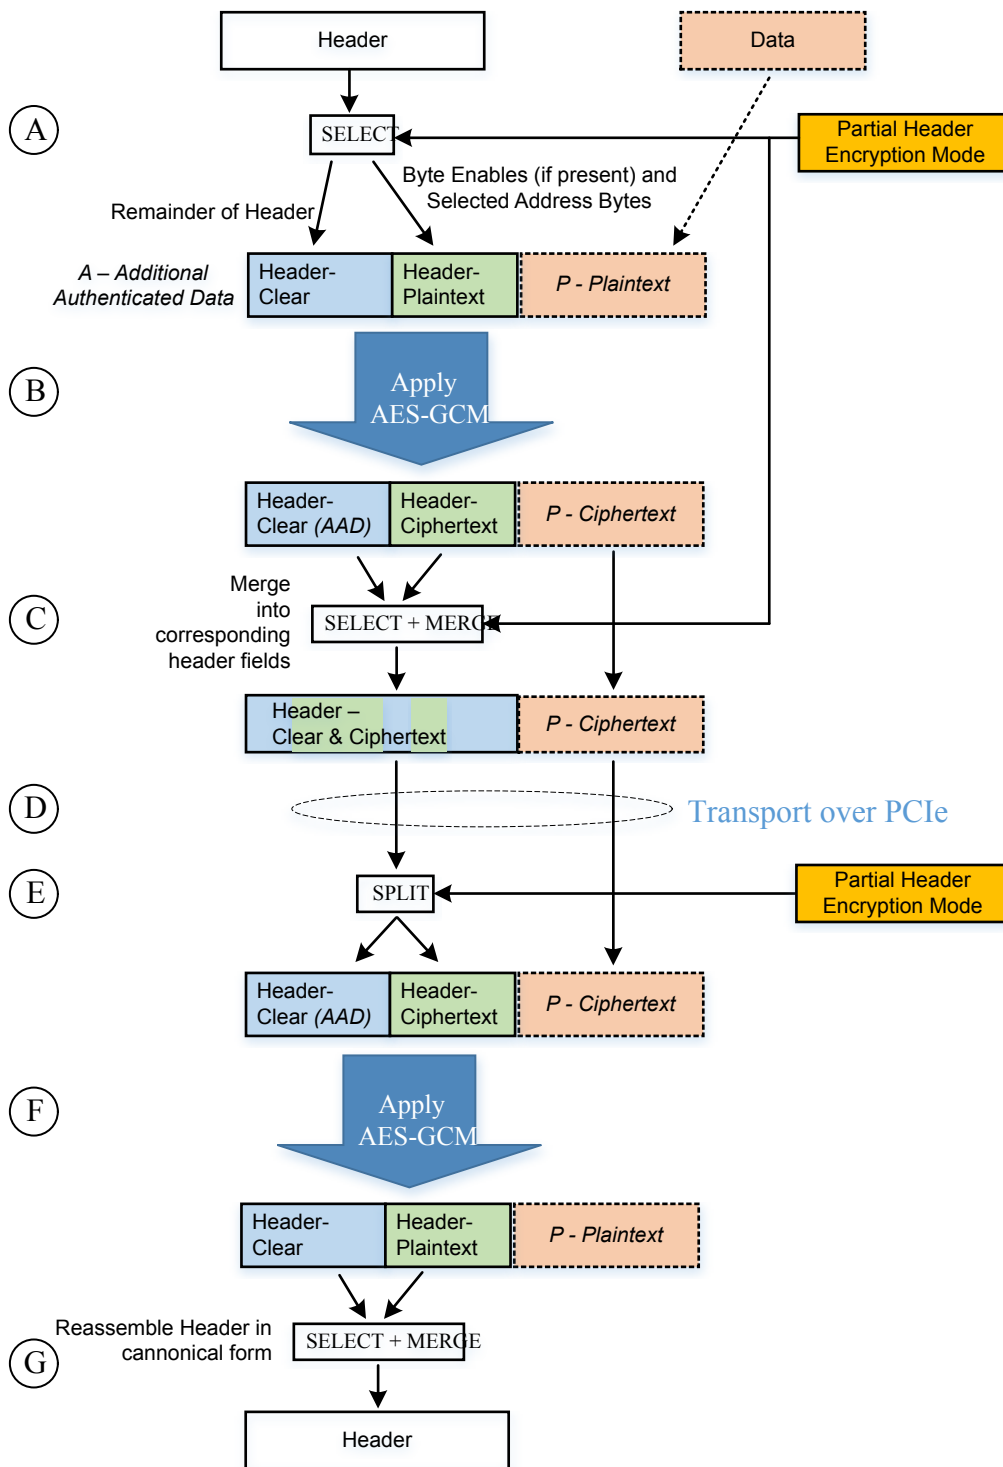

Figure 6-74 High Level Flow For Partial Header Encryption §

In partial header encryption, the encrypted portions of the Header are determined by the setting in the Partial Header Encryption Mode field of the Selective IDE Stream Control Register or Link IDE Control Register.

Rules for partial header encryption:

- When encrypted, the First DW BE and Last DW BE fields must be in the first byte of P
 - In NFM, the First DW BE and Last DW BE fields must be encrypted in all Memory Requests, except for AtomicOp Requests, Translation Requests, and Memory Read/DMWr Requests with the TH bit Set.
 - In FM, for Memory Requests, if OHC-A1 is present, then the First DW BE and Last DW BE fields must be encrypted.
- Address bits selected for encryption must follow the First DW BE and Last DW BE fields, if included, in P , and are formed as:
 - Address[17:2]:
 - Byte +0: Address[17:10]
 - Byte +1: Address[9:2]
 - Address[25:2]:
 - Byte +0: Address[25:18]
 - Byte +1: Address[17:10]
 - Byte +2: Address[9:2]
 - Address[33:2]:
 - Byte +0: Address[33:26]
 - Byte +1: Address[25:18]
 - Byte +2: Address[17:10]
 - Byte +3: Address[9:2]
 - Address[41:2]:
 - Byte +0: Address[41:34]
 - Byte +1: Address[33:26]
 - Byte +2: Address[25:18]
 - Byte +3: Address[17:10]
 - Byte +4: Address[9:2]
- At the Transmitter, the Header content selected for encryption is concatenated at the front of P and removed from A , increasing the size of P and decreasing the size of A accordingly.
- If PCRC is enabled when using partial header encryption:
 - Relative ordering of bits for PCRC input is maintained, with the same Header content used as for P .
 - For the PCRC calculation only, the selected portions of the header must be padded to 64bits with 0's in the most significant bits.
- At the receiver, the operation is reversed in order to apply AES-GCM to the A and C content and then finally the complete header is reconstructed.
- The PCRC is calculated at the receiver using the decrypted P content and the Header portion padded to 64bits with 0's in the most significant bits.
- When an error causes an IDE TLP with partial header encryption to be logged in the Header Log Register, the header fields selected for partial header encryption are permitted to contain all 0's or the encrypted values,

but must not contain the decrypted values unless through implementation-specific means it is assured that doing so will not violate any security requirements.

§ Figure 6-75 through § Figure 6-78 illustrate the application of partial header encryption.

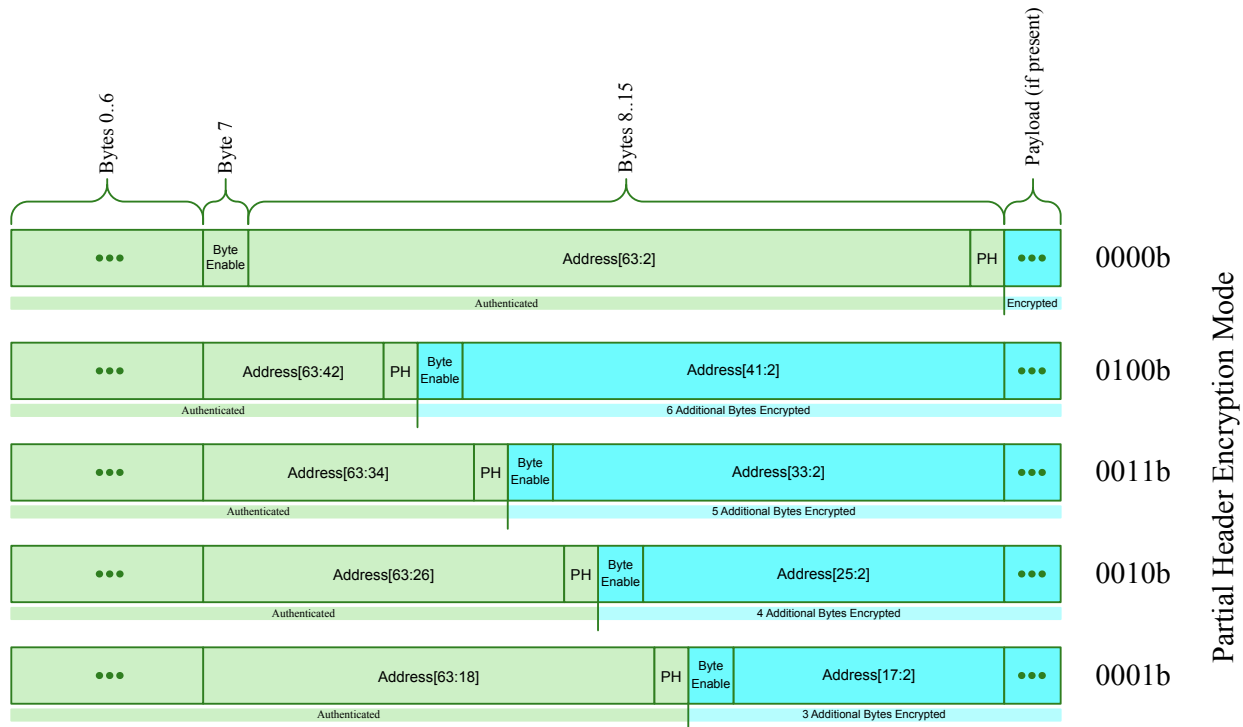

Figure 6-75 Partial Header Encryption in NFM with Byte Enables §

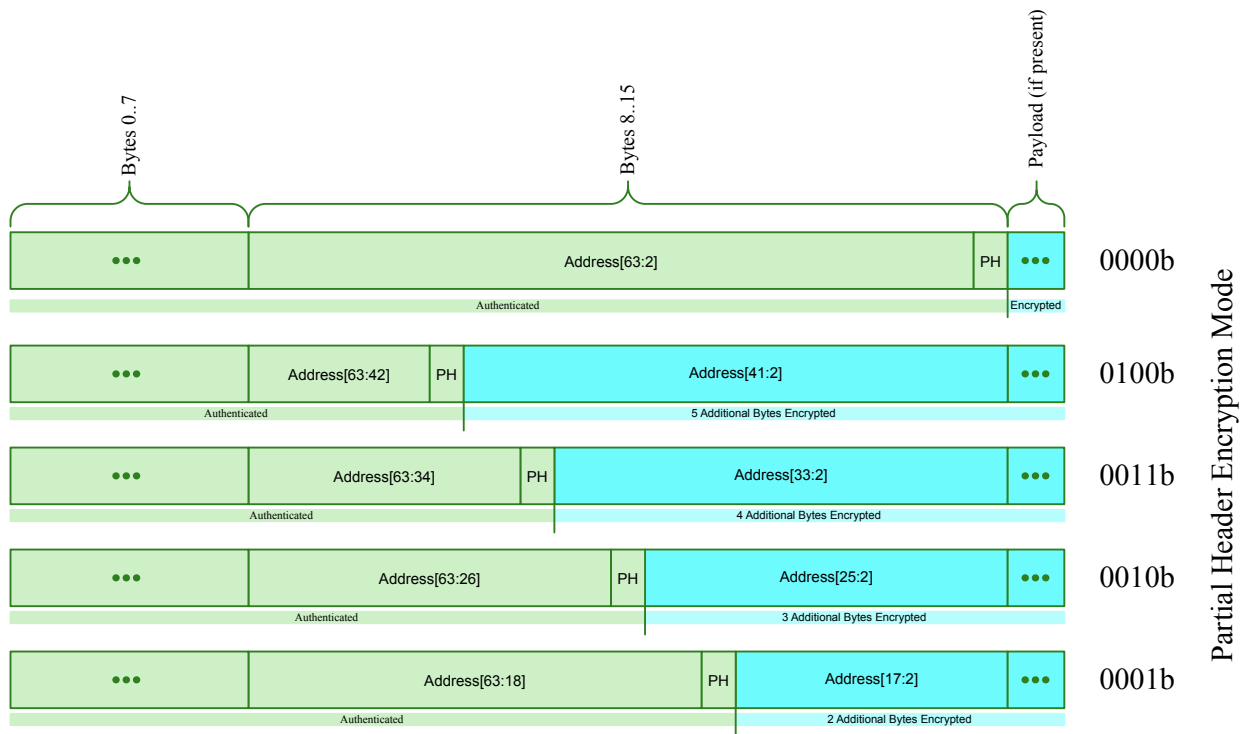

Figure 6-76 Partial Header Encryption in NFM without Byte Enables §

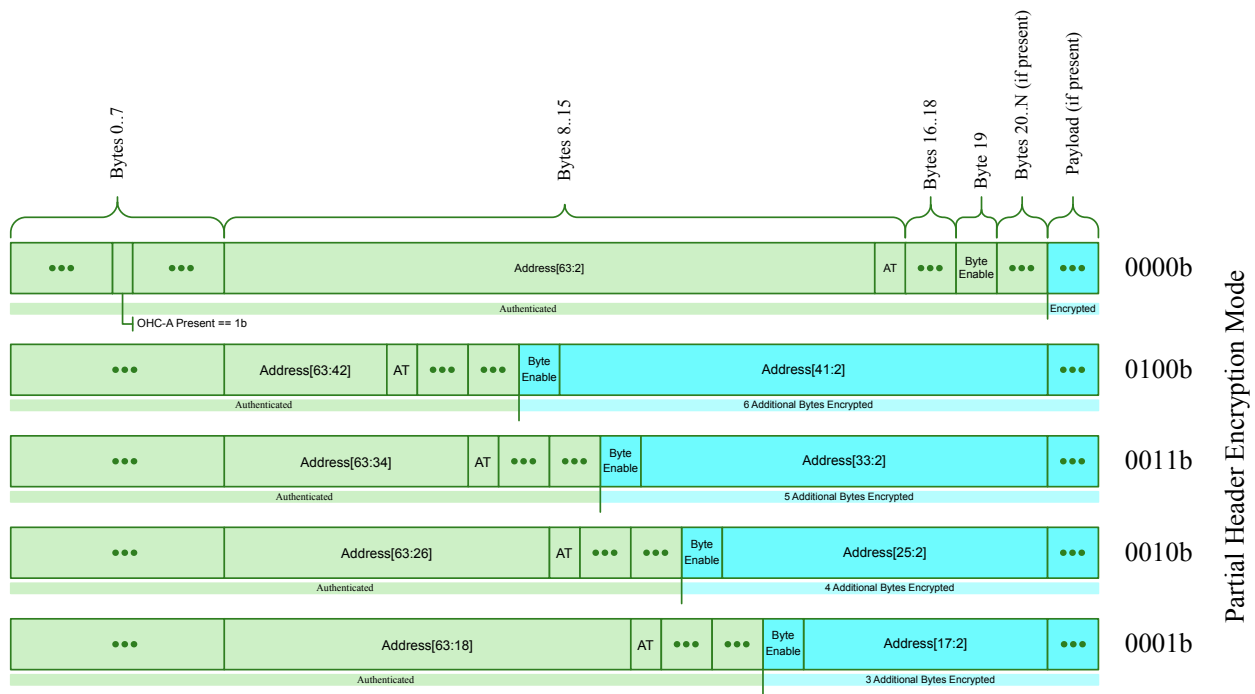

Figure 6-77 Partial Header Encryption in FM with OHC-A1 §

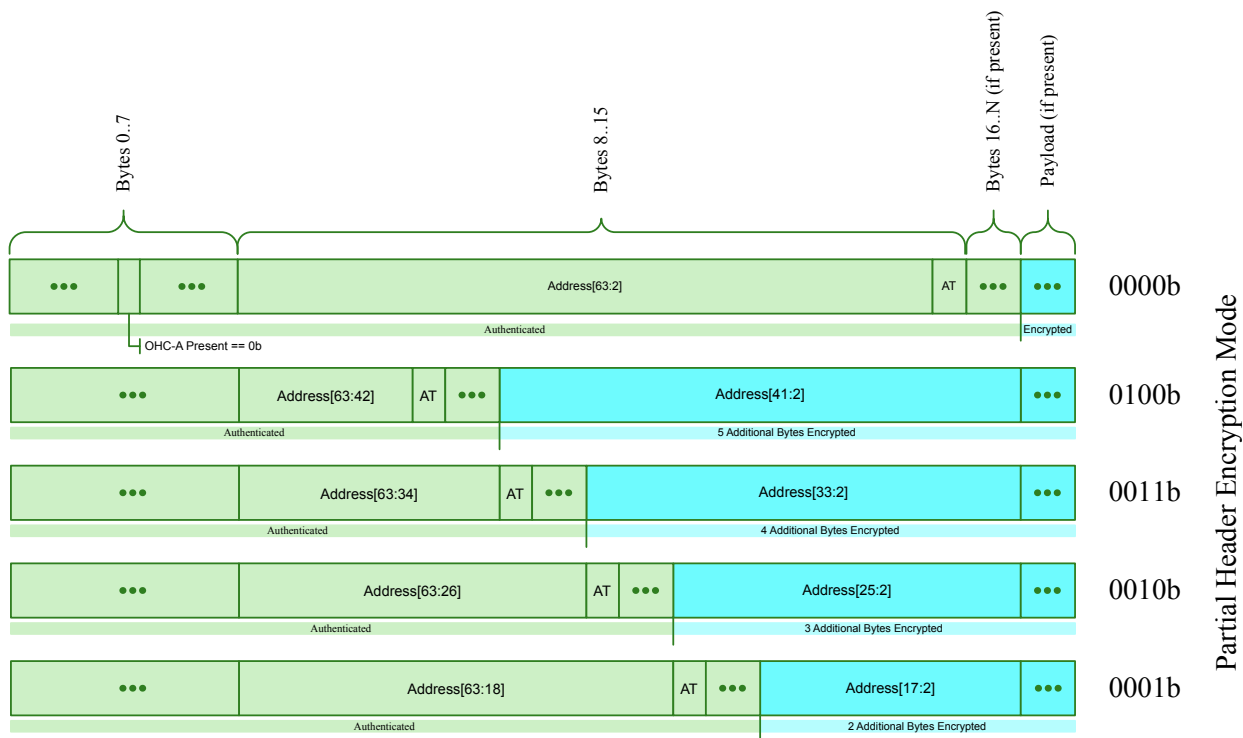

Figure 6-78 Partial Header Encryption in FM without OHC-A1 §

The use of Local TLP Prefixes with IDE TLPs is permitted. Local TLP Prefixes, if present, must precede the IDE Prefix (NFM). For Link IDE Streams, Local TLP Prefixes must be included in *A*. For Selective IDE Streams, Local TLP Prefixes must not be included in *A* or *P*.

The IDE Prefix (NFM) must be included in *A*. All OHC content (FM) must be included in *A*.

In NFM, the use of other End-End TLP Prefixes, besides the IDE Prefix, with IDE TLPs is permitted. End-End TLP Prefixes, if present, must follow the IDE Prefix, and must be included in *A*.

When aggregation is used, all TLPs associated with a single MAC are considered to be part of an “aggregated unit.”

As defined in [AES-GCM], a single invocation is performed for each TLP when aggregation is not used, and for each aggregated unit when aggregation is used.

As with all TLPs, IDE TLPs are covered by Data Link Layer mechanisms, such that physical Link errors are detected and corrected before received TLPs are presented to the receiver’s cryptographic processing mechanisms.

The use of ECRC with IDE TLPs is not permitted. If ECRC is enabled for non-IDE TLPs, then IDE TLPs must be formed as if ECRC were not enabled, and the TD bit in the TLP Header must be Clear.

To enable the detection of faults in the encryption/decryption logic, which occur outside of the path protected by the MAC, IDE implementations are permitted optionally to support the Plaintext CRC (PCRC) mechanism, for which the following rules apply:

- Software must only enable PCRC when both Partner Ports support the PCRC mechanism.
 - It is permitted to enable the PCRC mechanism on a per-IDE Stream basis.

- When PCRC is enabled for an IDE Stream, all Transmitted TLPs associated with that Stream that include a MAC must also include PCRC, if and only if there is *P* content in the TLP or aggregated unit of TLPs.
 - In NFM, presence of a MAC is indicated by the M bit in the IDE Prefix being Set and presence of the PCRC is indicated by the P bit in the IDE Prefix being Set
 - In FM, the TS field is used to indicate presence of MAC / PCRC (see § Section 2.2.1.2 .
 - When aggregation is used, the TLPs of an aggregated unit that do not include a MAC also must not include PCRC (see § Figure 6-79).

Figure 6-79 Example Illustrating PCRC Application to Two Aggregated IDE TLPs for a Link IDE Stream (NFM) §

- In NFM, when PCRC is enabled for an IDE Stream, the ultimate Receiver must check that all received TLPs or aggregated units associated with that Stream that include *P* content and a MAC (as indicated by the M bit in the IDE Prefix) also have the P bit in the IDE Prefix Set.
 - If, for a TLP, the P bit in the IDE Prefix is Clear and the M bit is Set, the Receiver must report this as a PCRC Check Failed error.
- PCRC must be calculated across all *P* content¹⁴⁴ for a given invocation of AES-GCM, and per the following:
 - The polynomial used has coefficients expressed as 04C1 1DB7h
 - The seed value must be FFFF FFFFh
 - All *P* content must be included in the PCRC calculation
 - PCRC calculation starts with bit 0 of byte 0 and proceeds from bit 0 to bit 7 of each byte of *P*
 - The result of the PCRC calculation must be complemented, mapped as shown in § Table 2-55 (following the same mapping as for ECRC), and appended to the *P* content, and encrypted/decrypted along with the other *P* content, with the encrypted PCRC value appended to the other *P* content and preceding the MAC (see § Figure 6-79).
- The PCRC must only be checked by the ultimate Receiver of the IDE TLP including PCRC.
 - A failure of the PCRC check indicates that one or more bits of the data payload have been corrupted — the Receiver's use of the data payload is outside the scope of this specification, but it is strongly recommended that the corrupted data not be used as if it were uncorrupted.
 - PCRC Check Failed is a reported error.
- Flow Control credit accounting for IDE TLPs that include PCRC must handle the PCRC as covered by the Header Credit.

144. As with ECRC, the PCRC is calculated using the TLP as-transmitted, including, for any data payload, all bytes as-transmitted regardless of the byte enable values.

IMPLEMENTATION NOTE: PCRC REUSE OF ECRC LOGIC §

In most respects, PCRC is calculated in the same way as ECRC, and the CRC polynomial is the same.

In some implementations it may be possible to re-use the same logic for PCRC calculation as is used for ECRC, when both PCRC and ECRC are supported.

ECRC is not allowed on IDE TLPs, and so no TLP could have both PCRC and ECRC.

These rules apply to Selective IDE Stream TLPs:

- § Table 6-35 defines which TLP types are permitted for a Selective IDE Stream.
 - TLP types that are not permitted for a Selective IDE Stream are still permitted to be used, and can be secured using Link IDE, if enabled.
- Receipt of an IDE TLP associated with a Selective IDE Stream that is not a permitted TLP Type is an IDE Check Failed error.
 - The Receiver must transition to Insecure for the associated IDE Stream.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 6-35 TLP Types for Selective IDE Streams §

TLP Type	Description	Permitted for Selective IDE Streams
MRd	Memory Read Request	Y
MRdLk	Memory Read Request-Locked	Y
MWr	Memory Write Request	Y
IORd	I/O Read Request	N
IOWr	I/O Write Request	N
CfgRd0	Type 0 Configuration Read Request	N
CfgWr0	Type 0 Configuration Write Request	N
CfgRd1	Type 1 Configuration Read Request	Y
CfgWr1	Type 1 Configuration Write Request	Y
DMWr	Deferrable Memory Write	Y
Msg	Message Request	Y when Routed by ID, Routed by Address, or Routed to Root complex ¹⁴⁵ N for other routing mechanisms
MsgD	Message Request with data	Y when Routed by ID, Routed by Address, or Routed to Root complex ¹⁴⁶ N for other routing mechanisms

145. Routed to Root Complex is permitted only when the Partner Port is a Root Port, as indicated by the Default Stream bit being Set.

146. Routed to Root Complex is permitted only when the Partner Port is a Root Port, as indicated by the Default Stream bit being Set.

TLP Type	Description	Permitted for Selective IDE Streams
Cpl	Completion without Data	Y
CplD	Completion with Data.	Y
CplLk	Completion for Locked Memory Read without Data	Y
CplDLk	Completion for Locked Memory Read – otherwise like CplD.	Y
FetchAdd	Fetch and Add AtomicOp Request	Y
Swap	Unconditional Swap AtomicOp Request	Y
CAS	Compare and Swap AtomicOp Request	Y
LPrfx	Local TLP Prefix	Allowed to be present, but not secured if TLP is associated with a Selective IDE Stream
EPrfx (applicable in NFM only)	End-End TLP Prefix	Y if the TLP is part of a Selective IDE Stream

- All IDE TLPs must be associated with an IDE Stream, identified via an IDE Stream ID.
 - Software must assign IDE Stream IDs such that two Partner Ports use the same value for a given IDE Stream.
 - Software must assign IDE Stream IDs such that every enabled IDE Stream associated with a given terminal Port is assigned a unique Stream ID value at that Port
 - It is permitted for a platform to further restrict the assignment of Stream IDs.
- When only a Link IDE Stream is enabled for a particular TC, all TLPs using that TC must be secured using the corresponding Link IDE Stream.
- For a Transmitter to associate a specific TLP with a specific Selective IDE Stream, the following criteria must be satisfied:
 - The Selective IDE Stream Enable bit in the Selective IDE Stream Control Register must be Set.
 - The TLP type must be permitted for Selective IDE Streams (see § Table 6-35).
 - The TC of the TLP must match the TC value in the Selective IDE Stream Control Register.
 - For a Configuration Request, the Selective IDE for Configuration Requests Enable bit must be Set (applicable to Root Ports only).
 - For a Completion, the Stream ID must match those in the corresponding Non-Posted Request.
 - If an ACS mechanism in the Port redirects the TLP towards the Root Complex, the Default Stream bit must be Set, indicating that the Selective IDE Stream targets the Root Complex. See § Section 6.12.3 .
 - For a Routed-to-Root-Complex Message, the Default Stream bit must be Set, indicating that the Selective IDE Stream targets the Root Complex.
 - For an ID-Routed Message, the destination RID must be greater than or equal to the RID Base and less than or equal to the RID Limit in the Selective IDE RID Association Register block, unless:
 - The ID-Routed Message is associated with a Default Stream, in which case the destination RID must be ignored, or
 - there is an exception made based on implementation-specific criteria.

Additionally, in Flit Mode, the destination Segment value must also match the value of Segment Base in the Selective IDE RID Association Register block.

- Unless there is an exception made via implementation specific means, when ATS is supported and enabled, all Translation Requests and Untranslated Memory Requests are associated with the default Stream, otherwise for a Memory Request not already associated with a Default Stream, the destination address must be greater than or equal to the Memory Base value and less than or equal to Memory Limit value in a Selective IDE Address Association Register block (as applies when targeting a specific Function's BAR or the Base/Limit range of addresses assigned to a Device)¹⁴⁷.
- For a TLP not already associated with any other Stream, the Default Stream bit must be Set.
- The TLP is selected or precluded through implementation specific means. For example, the Transmitter could associate all Memory Requests initiated by one or more internal Functions with a specific Selective IDE Stream, particularly when it is known that the Partner Port is a Root Port, and that all Requests initiated by that internal Function target system memory.
- If the TEE-Limited Stream bit in the Selective IDE Stream Control Register is Set, Requests with the T bit Set are associated with this Selective IDE Stream.
 - Requests that otherwise would be associated with this Selective IDE Stream and have the T bit Clear must be Transmitted as non-IDE TLPs if Link IDE is not enabled, or as Link IDE TLPs if Link IDE is enabled.
- TLPs not determined by the Transmitter to be associated with a specific Selective IDE Stream or that are precluded through implementation-specific means, must not be associated with any Selective IDE Stream.
- If supported, the TEE-Limited Stream bit must be configured in both Partner Ports before enabling a Selective IDE Stream.
 - It is permitted for the Partner Ports to have different values for the TEE-Limited Stream bit.
- Separate TCs must use separate Selective IDE Streams.
- Software must ensure that Selective IDE Streams are assigned to RID and address ranges that are not overlapping.
 - If software violates this rule by programming overlapping ranges, hardware must associate a given TLP with one Selective IDE Stream matching the RID/address range, but it is implementation specific which Selective IDE Stream from the overlapping set is associated.

These rules apply to IDE Fail Messages:

- Receivers must accept IDE Fail Messages received as IDE TLPs and also as non-IDE TLPs.
- When an IDE Fail Message is to be transmitted on an enabled Stream that is in the Insecure state, the Message must be transmitted as a non-IDE TLP. This includes cases where the transition of that Stream to Insecure was the trigger for the IDE Fail Message.
- When an IDE Fail Message is to be transmitted on an enabled Stream that is in the Secure state, the Message must be transmitted as an IDE TLP. This includes cases where the transition to Insecure on a Selective IDE Stream is the trigger for the IDE Fail Message, and the transmission Stream is either a different Selective IDE Stream or a Link IDE Stream.

These rules apply to TLPs other than IDE Fail Messages:

- When ready to schedule a TLP to be Transmitted that is associated with an enabled Stream that is in the Insecure state, the Transmitter must instead discard the TLP.

147. As with the Base/Limit address routing mechanism for Type 1 (Bridge) Functions, the IDE Address Association mechanism does not consider the value of the AT field to determine TLP routing.

- When Link IDE is Enabled for a given TC, and a TLP is received on that TC as a non-IDE TLP, the Receiver must discard the TLP.
- When both Link IDE Stream and one or more Selective IDE Stream Stream(s) are enabled at the same Port, for Transmitted TLPs the Selective IDE Stream(s) take precedence: selected TLPs must be associated with the Selective IDE Stream(s); TLPs not associated with any Selective IDE Stream must use Link IDE.
 - If both Link IDE and Selective IDE are enabled, and a TLP to be Transmitted is associated with an enabled Selective IDE Stream that is in the Insecure state, the Transmitter must not use Link IDE for the TLP and must instead discard the TLP.
- At the ultimate Receiver, IDE TLPs must be associated with the Stream ID indicated in the IDE Prefix (NFM)/OHC-C (FM).
- Once Link IDE has been enabled (see § Section 6.33.3), for each Sub-Stream of the Stream, until the Port receives an IDE TLP on that Sub-Stream, the Port must continue to accept non-IDE TLPs of the FC type corresponding to that Sub-Stream.
 - Once the Port receives an IDE TLP on a Sub-Stream it must discard non-IDE TLPs on that Sub-Stream for as long as the associated Stream is enabled.
- For Root Ports, when Selective IDE for Configuration Requests Enable for a particular Selective IDE Stream is Set, all Configuration Requests that match that Selective IDE Stream must be Transmitted as IDE TLPs associated with that Selective IDE Stream.
 - After enabling Selective IDE for Configuration Requests it is recommended that system software perform a Configuration Request using that Selective IDE Stream, so that the Partner Port will be triggered to reject subsequent Configuration Requests not associated with the Selective IDE Stream.
 - How the Root Complex ensures that only authorized system software generates Configuration Requests is outside the scope of this document.
- Once Selective IDE for Configuration Requests Enable for a particular Selective IDE Stream is Set by system software, it is strongly recommended that system software not Clear the bit for as long as the Selective IDE Stream itself is enabled.
- Specific Selective IDE Streams on Root Ports for which Selective IDE for Configuration Requests Enable is Set must transmit Configuration Requests that are associated with those Selective IDE Streams as Type 1 Configuration Requests.
- Configuration Requests associated with a Selective IDE Stream will be received at an Upstream Port as Type 1 Configuration Requests.
- Configuration Requests received as IDE TLPs that are directed to pass through the Switch must pass without modification through a Switch when Flow-Through IDE Stream Enabled is Set in both the Upstream Port and the Egress Downstream Port.
- Configuration Requests that are not directed to pass through a Switch must be accepted by the Receiver provided the Target RID is an implemented Function either associated with that Upstream Port or a Downstream Port of a Switch in that Upstream Port. If the Target RID is not an implemented Function, the Configuration Request must be handled as an Unsupported Request.
- For Upstream Ports that are the IDE Terminus of a Selective IDE Stream with Selective IDE for Configuration Requests Supported Set, until the Port receives a Configuration Request as an IDE TLP on that Selective IDE Stream, the Port must continue to accept Configuration Requests as non-IDE TLPs. Once a Configuration Request has been received as an IDE TLP on that Selective IDE Stream, then the Port must accept only Configuration Requests associated with that Selective IDE Stream, and must discard all Configuration Requests received on other IDE Streams or as non-IDE TLPs, for as long as that Selective IDE Stream is enabled.
- For Selective IDE, for TLP types other than Configuration Requests, the requirements for rejecting TLPs are determined by the TEE associated with the Selective IDE Stream (see § Section 6.33.1).

- The use of TLP poisoning, as indicated by the EP bit in the TLP header being Set, is permitted for IDE TLPs when applied by the originating Transmitter.
- For IDE TLPs, it is not permitted to modify any part of a TLP, including the EP bit, at any intermediate point between the two Partner Ports.
- Software must configure Selective IDE such that all Links on the entire path between the Partner Ports are operating either in FM, or in NFM.
- If TEE-IO Supported is Set, for an Endpoint Upstream Port:
 - In Flit Mode, if Segment Captured is Set ¹⁴⁸, on a Selective IDE Stream:
 - A Requester must include OHC-C with the Requester Segment Valid (RSV) bit Set.
 - A Completer must include OHC-A5.
 - A Completer receiving a Request on a Selective IDE Stream other than the Default Stream must handle it as an Unsupported Request if the Requester ID field of the Request is less than the RID Base or greater than the RID Limit in the Selective IDE RID Association Register block of the Stream.
 - In Flit Mode, the Requester Segment value (if included in the Request) must also match the value of Segment Base in the Selective IDE RID Association Register block.
 - A Requester receiving a Completion on a Selective IDE Stream other than the Default Stream must handle it as an Unexpected Completion if the Completer ID field of the Completion is less than the RID Base or greater than the RID Limit in the Selective IDE RID Association Register block of the Stream.
 - In Flit Mode, the Completer Segment value (if included in the Completion) must also match the value of Segment Base in the Selective IDE RID Association Register block.
- If TEE-IO Supported is Set, for a Root Port:
 - A Completer receiving a Request on a Selective IDE Stream for which the Root Port is an IDE Terminus must handle it as an Unsupported Request if the Requester ID field of the Request is less than the RID Base or greater than the RID Limit in the Selective IDE RID Association Register block of the Stream.
 - In Flit Mode, if the Requester Segment Valid (RSV) bit is Set, the Requester Segment value must also match the value of Segment Base in the Selective IDE RID Association Register block.
 - A Requester receiving a Completion on a Selective IDE Stream for which the Root Port is an IDE Terminus must handle it as an Unexpected Completion if the Completer ID field of the Completion is less than the RID Base or greater than the RID Limit in the Selective IDE RID Association Register block of the Stream.
 - In Flit Mode, if the Completion includes OHC-A5, the Completer Segment value must also match the value of Segment Base in the Selective IDE RID Association Register block.

The use of Multicast (see § Section 6.14) with Selective IDE Streams is outside the scope of this specification.

6.33.5 IDE TLP Sub-Streams §

With [AES-GCM] it is desirable to maintain TLPs in-order so that the Transmitter and Receiver can independently maintain IV in sync with each other without the overhead required to transmit the IV for each TLP or aggregated unit. However, certain TLP bypassing is required for deadlock avoidance, and this is reflected in the different types of Flow Control Credit Types – Posted Request header/data payload, Non-Posted Request header/data payload, and Completion header/data payload (see § Section 2.6.1). To provide in-order TLP processing where possible, and to simplify implementations that structure their internal buffering according to these Flow Control Credit types, IDE introduces the concept of a Sub-Stream within which TLP traffic is maintained fully in-order between the IDE Partner Ports. It is ensured

148. The value of Segment Captured indicates that Segment values are being applied – the captured Segment value is not used for the tests defined here.

within IDE Sub-Streams that TLPs travel in-order between the IDE Partner Ports both to reduce the per-TLP overhead as noted, and also to ensure that certain attack scenarios, such as the reordering or replaying by an Adversary-in-the-Middle, of Posted Requests, will be detected by the receiver without additional TLP tracking logic.

With [AES-GCM] it is essential to maintain synchronization between the Partner Ports such that all TLPs associated with an IDE Stream are always routed from one Partner Port to the other. If any IDE TLPs are misrouted the result will typically be an unrecoverable error for the associated IDE Stream (see detailed requirements below).

Each IDE Stream includes Sub-Streams distinguished by TLP type and direction, for which the following rules apply:

- For each Sub-Stream there is a Sub-Stream identifier:
 - 000b – Posted Requests
 - 001b – Non-Posted Requests
 - 010b - Completions
 - Values 011b-110b are Reserved
 - 111b - In NFM, Reserved; In FM, indicates a TLP that includes OHC-C but is not an IDE TLP.
 - In earlier versions of this specification, Sub-Stream was 4 bits in Symbol 3, bits 7:4. Bit 7 is now Reserved. If the TEE-IO Supported bit in the Device Capabilities Register is Set, components must implement bit 7 as Reserved. If TEE-IO Supported is Clear, components are permitted to treat bit 7 as part of Sub-Stream
- For each Sub-Stream, per [AES-GCM], there must be a 96b initialization vector IV of deterministic construction, consisting of:
 - a fixed field in bits 95:64 of the IV, where bits 95:64 are all 0's
 - an invocation field in bits 63:0 of the IV, containing the value of a counter, initially set to the value 0000_0001h for each Sub-Stream upon establishment of the Stream and each time the Sub-Stream key is refreshed, and incremented every time an IV is consumed.
- Each Sub-Stream must support the use of its own unique key value and invocation field initial counter value.

Section 6.99.4. defines additional requirements for Switches and Root Complexes that support peer-to-peer routing of Selective IDE Streams.

The ordering rules defined in § Section 2.4 define constraints on TLP/TLP ordering, but do not provide mechanisms to detect improper reordering. With IDE, counters are used to enable the ultimate Receiver to detect improper reordering of non-UIO TLPs while allowing permitted reordering. These counters and associated mechanisms, including error checks, do not apply to UIO TLPs. Separate sets of these counters must be operated for each IDE Stream, and operated according to the following rules:

- For the Transmitter, two 8 bit counters must be maintained: a count of Posted Requests Transmitted since the last Non-Posted Request or IDE Sync Message was Transmitted, called PR_Sent_Counter-NPR, and a count of Posted Requests Transmitted since the last Completion or IDE Sync Message was Transmitted, called PR_Sent_Counter-CPL
 - Upon entry to the Secure state, both counters must be initialized to 0.
 - Both counters must be incremented for each Posted Request IDE TLP Transmitted associated with the IDE Stream.
 - When a Non-Posted Request associated with the IDE Stream is Transmitted, the PR_Sent_Counter-NPR value must be used in the PR_Sent_Counter field of the IDE Prefix (NFM)/OHC-C (FM) for the Non-Posted Request, and then PR_Sent_Counter-NPR must be reset to zero.

- When a Completion associated with the IDE Stream is Transmitted, the PR_Sent_Counter-CPL value must be used in the PR_Sent_Counter field of the IDE Prefix (NFM)/OHC-C (FM) for the Completion, and then PR_Sent_Counter-CPL must be reset to zero.
- When either the PR_Sent_Counter-NPR or the PR_Sent_Counter-CPL reaches 245, an IDE Sync Message (see § Section 2.2.8.11) must be transmitted to the Partner Port as an IDE TLP.
 - It is permitted to Transmit an IDE Sync Message at other times.
- Every time an IDE Sync Message is Transmitted to the Partner Port, both the PR_Sent_Counter-NPR and PR_Sent_Counter-CPL must be incremented prior to forming the IDE Sync Message, and then both the PR_Sent_Counter-NPR and PR_Sent_Counter-CPL must be reset to zero.
- For the Receiver, two 64 bit counters must be maintained: a count of Posted Requests received since the last Non-Posted Request was received, called PR_Received_Counter-NPR and a count of Posted Requests received since the last Completion was received, called PR_Received_Counter-CPL
 - Upon entry to the Secure state, both counters must be initialized to zero.
 - Both counters must be incremented for each Posted Request IDE TLP received associated with the IDE Stream.
 - When a Non-Posted Request associated with the IDE Stream is received then the PR_Sent_Counter value carried in the IDE prefix (NFM)/OHC-C (FM) must be subtracted from the PR_Received_Counter-NPR, and the PR_Received_Counter-NPR updated with the result. If this subtraction underflows, this is an error – see rules related to error handling below.
 - When a Completion associated with the IDE Stream is received then the PR_Sent_Counter value carried in the IDE prefix (NFM)/OHC-C (FM) must be subtracted from the PR_Received_Counter-CPL, and the PR_Received_Counter-CPL updated with the result. If this subtraction underflows, this is an error – see rules related to error handling below.
 - When an IDE Sync Message associated with the IDE Stream is received then:
 - the PR_Sent_Counter-NPR value carried in the IDE Stream Sync Message must be subtracted from the PR_Received_Counter-NPR, and the PR_Received_Counter-NPR updated with the result,
 - the PR_Sent_Counter-CPL value carried in the IDE Stream Sync Message must be subtracted from the PR_Received_Counter-CPL, and the PR_Received_Counter-CPL updated with the result.

If either subtraction underflows, this is an error – see rules related to error handling in § Section 6.33.7 .

IMPLEMENTATION NOTE: DETECTION OF IMPROPER REORDERING §

As with other TLPs, IDE TLPs need to be reordered to satisfy requirements for deadlock avoidance, but some other forms of reordering are forbidden as IDE TLPs pass over PCIe between Ports. These ordering requirements are defined in § Table 6-36, and are stated in terms of Posted Requests (PR), Non-Posted Requests (NPR), and Completions (Cpl). The following examples illustrate selected reordering cases.

An attack based on TLP reordering (or a delay that has the effect of reordering) can be implemented using a variety of mechanisms that all result in the same observed behavior, and will be detected using the mechanisms defined by IDE.

§ Figure 6-80 illustrates the case where a Posted Request is allowed to bypass a Non-Posted Request, as is required for deadlock avoidance. IDE supports having Posted Requests bypass Non-Posted Requests through the use of Sub-Streams within a given Stream. There is a similar requirement for Posted Request to be able to bypass Completions (not illustrated).

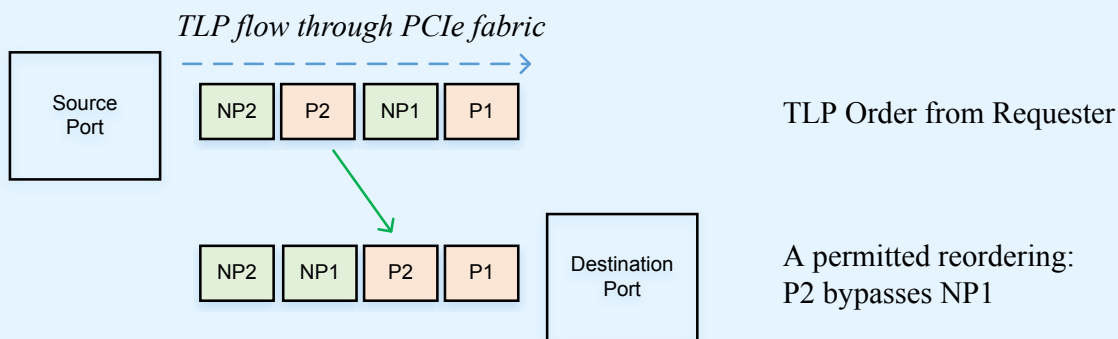

Figure 6-80 Example – Posted Requests Allowed to Bypass Non-Posted Requests §

§ Figure 6-81 illustrates a case where an attacker attempts to bypass a Posted Request with a Non-Posted Request, which could, for example, cause the consumption of stale data. This case will be detected through the use of the PR Sent Counter mechanism, through which the Transmitter at source Port associated with the Stream indicates to the Receiver at the Destination Port how many Posted Requests were transmitted between successive Non-Posted Requests. This indication is carried in the IDE TLP Prefix (NFM)/OHC-C (FM), which is integrity protected and so cannot be modified without detection at the Receiver. In this example, NP1 will carry the indication that a Posted Request (P1) was transmitted, and this will not match the Receiver's count of Posted Requests received, enabling this illegal reordering to be detected.

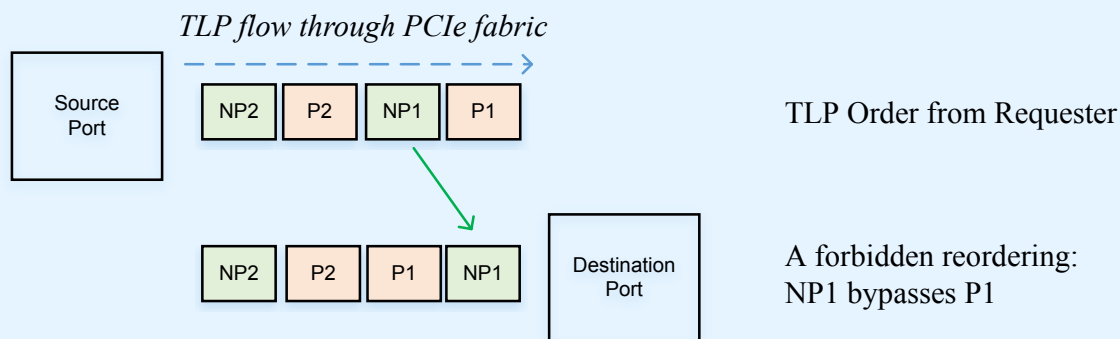

Figure 6-81 Example – Non-Posted Requests Never Allowed to Bypass Posted Requests §

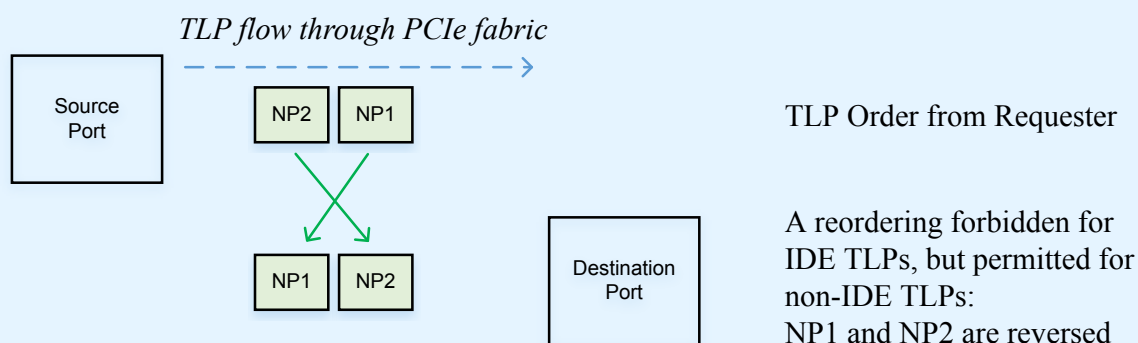

Figure 6-82 Example – Secure Non-Posted Request Reordering Not Allowed Over PCIe Fabric §

Without IDE, Non-Posted Requests are allowed to bypass each other, but within an IDE Stream, reordering of TLPs of the same type is disallowed in order to simplify the operation of the integrity/encryption mechanisms. § Figure 6-82 illustrates that this will cause the reordering of Non-Posted Requests to be detected as an integrity check failure, even though there isn't a security exposure per se.

Note that reordering attacks are possible through Retimers, Switches, and any other device or equipment that can alter the flow of TLPs at any point between the originating Port and the Destination Port.

The counters used to implement the reordering checks are of different sizes in the Transmitter and Receiver. The Transmitter counters only need to be 8 bits wide in order to accommodate the arbitrarily chosen limit of 245 that triggers the required transmission of an IDE Sync Message. Because routing elements can modify the relative order of TLPs in different Sub-Streams, Receivers cannot assume any particular limit on the amount of reordering that can occur, and so the Receiver counters were chosen to be 64 bits wide so as to ensure that under normal operating conditions it is not possible for them to overflow.

6.33.6 IDE TLP Aggregation §

The following rules relate to aggregation (see § Figure 6-67 and § Figure 6-69):

- When aggregation is supported, as indicated at the Port level by the Aggregation Supported bit in the IDE Capability Register, then a Receiver must be capable of supporting:
 - the aggregation within any Sub-Stream of up to the lesser of 8 TLPs, or as many TLPs as can be received based on the outstanding Flow Control credits applicable to that Sub-Stream
 - the receipt of other TLPs that are not part of the Sub-Stream between the TLPs of the aggregated unit.
- When aggregation is supported, as indicated at the Port level by the Aggregation Supported bit in the IDE Capability Register, then for each Sub-Stream where aggregation is to be permitted software must enable aggregation at the Transmitting Port.
- If aggregation is to be used, Software must enable aggregation prior to enabling the IDE Stream.
- When aggregation is enabled, a Transmitter:
 - must apply aggregation only among TLPs within the same Stream and Sub-Stream,
 - must aggregate at most the selected number of TLPs in the corresponding Aggregation Mode field,
 - must limit the number of TLPs aggregated such that the sum of the data payloads of all TLPs of an aggregated unit does not exceed 256 DW,
 - is permitted to Transmit other TLPs that are not part of the Sub-Stream between the TLPs of the aggregated unit,
 - must, when transmitting an IDE Sync Message, treat the IDE Sync Message as the last TLP of an aggregated unit,
 - is permitted to aggregate fewer TLPs than the number permitted.
- When aggregating TLPs, the Transmitter must include a MAC only for the last TLP of the aggregated unit, for which the included MAC must cover the A and P content for all the TLPs of the unit.
 - The Transmitter must treat a TLP as the last TLP of an aggregated unit unless the Transmitter can guarantee that it will transmit another TLP within the aggregated unit within 1 μ s.
- The same key and IV set must be used for all TLPs in an aggregated unit.
- If the K bit is to be toggled, it must only be toggled for the first TLP of an aggregated unit.
 - Receivers must check for violations of this rule – a violation is an IDE Check Failed error.
 - The Receiver must transition to Insecure for the associated IDE Stream.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).
- It is permitted for the TLPs of an aggregated unit to be interleaved with other TLPs, including IDE TLPs associated with other Streams, or non-IDE TLPs.
- All aggregated TLPs of a unit must be processed before it is possible for the Receiver to complete authenticated decryption of the unit.
- If an IDE TLP without a MAC is received at a Receiver where Aggregation is not supported, or if the Receiver detects a violation of any of the rules in this section, this is an IDE Check Failed error.
 - The Receiver must transition to Insecure for the associated IDE Stream.

IMPLEMENTATION NOTE: USE OF AGGREGATION §

To reduce the bandwidth overheads associated with the MAC, the use of aggregation is encouraged. Although aggregation may increase the latency for a Receiver to make use of the received TLPs, typically this increase will not be significant, and in many cases the overall performance should be improved through the use of aggregation.

Although the specific optimizations will depend on traffic types and use model requirements, typically aggregating about 4 TLPs will provide a good balance between the possible bandwidth improvement and the added latency. Typically a Transmitter policy should assume that the Receiver will buffer all the TLPs of an aggregated unit until the Receiver checks are complete before releasing any of the TLPs for further processing. Transmitters can reduce the effective latency impacts of aggregation when there is knowledge of the underlying traffic, for example by ensuring that a doorbell or other “trigger” TLP is either not aggregated, or that an aggregated unit is ended with the transmission of such TLPs.

Receivers should be designed to ensure that aggregated units of TLPs can be buffered with minimal stalling. Typically this implies that the amount of aggregation a Receiver supports should be significantly less than the amount of Receiver Flow Controller buffering advertised.

The IDE TLPs of an aggregated unit may be interleaved with other TLPs, and in some cases this may be required. For example, if we consider a case where a Switch receives a number of aggregated Memory Reads followed by a Memory Write, all of which target the same egress Port. If, at the egress Port, there are insufficient Flow Control credits to transmit all of the Memory Reads, then the Switch may be required to allow the Memory Write to bypass the blocked Memory Reads. Receivers are required to be tolerant to such “interruptions” of an aggregated unit.

6.33.7 Flow-Through Selective IDE Streams §

A Switch or Root Complex is permitted to support Flow-Through Selective IDE Streams without supporting Link IDE Stream or Selective IDE Streams for cases where a Port of the Switch/RC itself is an IDE Terminus. It is also permitted for a Switch/Root Port that is enabled for flow-through IDE to be an IDE Terminus, and in such cases, flow-through IDE TLPs must be routed without modification, and only TLPs for which the Switch/Root Port is the source or ultimate destination must be handled by the Port as an IDE Terminus.

A Switch that supports Flow-Through Selective IDE Streams must implement the IDE Extended Capability at every Port of the Switch.

Switches and RCs that support Flow-Through IDE Streams must, when enabled, implement modified ordering rules defined in § Table 6-36, and § Table 6-37 applied per-Stream, for IDE TLPs that pass through the Switch/RC from a given Ingress Port to a given Egress Port. The entries A2, B3, B4, C3, C4, and D5 are all No to ensure that there is no reordering within any Sub-Stream. In all other cases, the rules defined in § Section 2.4 must be followed; for example: between different Stream IDs, different Ingress Ports, different Egress Ports, or between IDE TLPs and non-IDE TLPs.

Hardware is not required to follow this modified ordering model beyond the TLP flow between the two Partner Ports for an IDE Stream, e.g. within an Endpoint or RC, and so at the system level it must not be assumed that the ordering behavior observed will match the modified IDE Ordering model.

Although Switches/RCs must not reorder IDE TLPs within a Flow-Through IDE Stream based on Relaxed Ordering or IDO, including when ACS mechanisms are being used, it is permitted for those TLPs to have the RO and/or IDO bits Set .

The IDE Sync Message, like all other Messages, is a Posted Request, and the IDE protocol depends on the IDE Sync Message being ordered with all other Posted Requests for a given IDE Stream.

Table 6-36 IDE Revised Ordering Rules for Flow-Through non-UIO IDE Streams - Per Stream §

Row Pass Column?		Posted Request (Col 2)	Non-Posted Request		Completion (Col 5)
			Read Request (Col 3)	NPR with Data (Col 4)	
Posted Request (Row A)		No	<u>Yes</u>	<u>Yes</u>	a) <u>Y/N</u> b) <u>Yes</u>
Non-Posted Request	Read Request (Row B)	No	No	No	<u>Y/N</u>
	NPR with Data (Row C)	No	No	No	<u>Y/N</u>
Completion (Row D)		No	<u>Yes</u>	<u>Yes</u>	No

Table 6-37 IDE Revised Ordering Rules for Flow-Through UIO IDE Streams - Per Stream §

Row Pass Column?	UIO PR-FC TLP (Col U1)	UIO NPR-FC TLP (Col U2)	UIO Completion (Col U3)
UIO PR-FC TLP (Row UA)	No	Yes/No	Yes/No
UIO NPR-FC TLP (Row UB)	Yes/No	No	Yes/No
UIO Completion (Row UC)	Yes	Yes	No

Switches/RCs must not modify Flow-Through IDE TLPs between the ingress and egress Ports.

Switches/RCs must only route IDE TLPs through Ports with the Flow-Through IDE Stream Enabled bit Set. If an IDE TLP is received by an Ingress Port or routed to an Egress Port, and the Port's Flow-Through IDE Stream Enabled bit is Clear, the Port must handle the TLP as a Misrouted IDE TLP error unless there is a higher precedence error. Further:

- For an Ingress Port, the Port must not forward the IDE TLP.
- For an Egress Port, the Port must not Transmit the IDE TLP.
- If the IDE TLP is a Non-Posted Request, the Port must not return a Completion.

The use of ACS in combination with Flow-Through IDE Streams is permitted, but requires care to ensure that the modified ordering defined above will be satisfied. It should also be understood that, because Relaxed Ordering does not apply within the modified ordering rules defined above, certain use cases such as those involving ACS P2P Completion Redirect are likely to have reduced performance.

Because hardware used with IDE will typically be required to satisfy platform-level trust requirements, in many cases ACS is not required to achieve and maintain secure platform behaviors when IDE is in use.

6.33.8 Other IDE Rules §

Rule for Non-Posted IDE Requests:

- If the TEE-IO Supported bit in the Device Capabilities Register is Clear, Requesters of Non-Posted Requests must check that the corresponding received Completion(s) be returned using the same Stream ID and the same T bit value as was associated with the Non-Posted Request – a violation is an IDE Check Failed error.
 - The Requester must transition to Insecure for the associated IDE Stream.
- If the TEE-IO Supported bit in the Device Capabilities Register is Set, Requesters of Non-Posted Requests must check that the corresponding received Completion(s) be returned using the same Stream ID as was associated with the Non-Posted Request – a violation is an IDE Check Failed error.
 - The Requester must transition to Insecure for the associated IDE Stream

The following rules relate to resets:

- Any Conventional Reset to an Upstream Port or to the Bridge Function of a Downstream Port, or any FLR to a Function containing an IDE Extended Capability, must result in all IDE Streams associated with that Function transitioning to the Insecure state, and all keys must be invalidated and rendered unreadable.
 - Additional implementation specific mechanism are required in many cases to ensure security of all associated data is maintained.
- An FLR to a Function that does not contain an IDE Extended Capability must not affect IDE operation
 - In some cases IDE_KM can be affected by an FLR to a Function that does not contain an IDE Extended Capability, but does implement the IDE_KM responder role via DOE – see § Section 6.33.3.

Use of mechanisms that result in the blocking or termination of TLPs, such as exist for AtomicOps, DMWr, and the End-End TLP Prefix Blocking mechanism, must be carefully coordinated with the use of Selective IDE Streams, to avoid the dropping of Selective IDE TLPs in such a way that would result in a IDE Check Failed error.

The following rules relate to the use of Access Control Services (ACS - see § Section 6.12) with IDE.

- When Link IDE is used, ACS mechanisms are permitted to be used as architected without restrictions.
- If Selective IDE is used with ACS to enable Direct I/O as documented in the Implementation Note: ACS Redirect and Guest Physical Addresses (GPAs) (see § Section 6.12.4), ACS mechanisms are permitted to be used as architected without restrictions.
- If Selective IDE is used for P2P communication without any ACS redirect mechanisms enabled, the remaining ACS services are permitted to be used as architected without restrictions.
- Use of Selective IDE for P2P communication with ACS redirect mechanisms enabled has a number of major issues with ordering and portions of Sub-Streams taking different paths. Such use is out of scope of this specification.
- Use of Selective IDE under any use case where ACS services (or any other mechanism) blocks or otherwise terminates IDE TLPs will result in the associated Selective IDE Stream going to Insecure due to the failure of the intended ultimate destination Port to receive the blocked/terminated IDE TLP.

The following rules relate to error handling

- Receipt of a Link IDE TLP or Selective IDE TLP for which there is not an associated IDE Stream is a Misrouted IDE TLP error; this is a reported error associated with the Receiving Port.
- Receipt of a Link IDE TLP by a Switch that targets an Egress Port for which there is not a Link IDE Stream associated with the same TC and in the Secure state is a Misrouted IDE TLP error; this is a reported error associated with the Ingress Port.
- The Transaction Layer must return flow control credit and handle as a Misrouted IDE TLP, but take no other action in response to a received Misrouted IDE TLP.

- The detection of any of the following conditions is IDE Check Failed error, a reported error associated with the Receiving Port (see § Section 6.2).
 - a MAC check failure occurs when the Receiver's check of the MAC of a received TLP, or aggregated unit of TLPs, fails,
 - underflow of the PR-Received-Counter-NPR or PR_Received_Counter-CPL (indicating an improper reordering has been detected),
 - either or both of the PR-Received-Counter-NPR/PR_Received_Counter-CPL 64-bit counters overflow (indicating a failure to receive the Transmitted NPR/CPL TLPs).
 - The Sub-Stream identifier field contains a Reserved/unsupported value.

Upon detection of one or more of these conditions, the IDE Stream State Machine for this IDE Stream must enter Insecure. This is a reported error associated with the Receiving Port (see Section 6.2). The TLP that triggered the error and all subsequent IDE TLPs received associated with the same IDE Stream must be discarded, following update of Flow Control credits, for as long as the associated Stream is enabled. There must be no additional error(s) logged for subsequent TLPs received associated with an IDE Stream already in the Insecure state. These rules also apply to TLPs received while in the Insecure state if that state was reached for reasons other than those listed above.

- Receiving an IDE TLP that is a Completion with UR or UC status is not a security error and must not by itself trigger a transition to Insecure.
- Upon detection of an error associated with an aggregated unit of TLPs, when Advanced Error Reporting is supported, only the last TLP of the unit must be logged in the Header Log Register and TLP Prefix Log Register.
- All IDE Streams associated with a Link must transition to Insecure when DL_Active transitions from asserted to deasserted for that Link.
- Upon transition from Secure to Insecure for any reason, other than that the corresponding Link/Selective IDE Stream Enable bit is Cleared, for a given Stream, the Port must transmit an IDE Fail Message indicating the Stream ID to the Partner Port
- Upon receipt of an IDE Fail Message, for the indicated Stream the Port must transition to Insecure
 - When an IDE Stream enters Insecure due to the receipt of a IDE Fail Message then that transition into Insecure must not result in the Transmission of an IDE fail message.
- Upon entry into Insecure, all active key sets and IVs for the associated IDE Stream must be marked as invalid.
- For an IDE Stream to exit Insecure and return to Secure, the IDE Stream must be re-established using a new key and IV set.
- In the Insecure state, private data associated with the affected IDE Stream(s) must be secured.
 - How this is done is implementation specific.
- To prepare to exit the Insecure state for a Stream and return to the Secure state, software must write a 0b to the corresponding Selective IDE Stream Enable or Link IDE Stream Enable bit, even if it is already 0b.
 - Hardware must not return a Stream to the Secure state until the Enable bit has been written to 0b and subsequently Set.
 - Additional actions not defined here are typically necessary based on specific use model requirements.

To return a Link IDE Stream for TC0/VC0 to the Secure state, it is necessary to reset the Device, e.g. using a Hot Reset, to make it possible for Configuration Requests/Completions to pass across the Link, unless the Device provides an alternate, implementation-specific, mechanism.

- When processing received IDE TLPs, all error checks must be completed, or an equivalent delay must be inserted, prior to signaling an error, such that it is not possible for an external observer to determine at which stage in error checking the error(s) was(were) detected.

The following rules relate to Power Management:

- The No_Soft_Reset bit must be Set
- All state related to keys and counters must be maintained in D0, D1, D2 and D3_{hot}.
 - The IDE Extended Capability is subject to the same rules as other register structures defined by this specification, and because it is itself essential for IDE operation, any condition where the IDE Extended Capability programming is lost also necessarily results in a loss of the ability to maintain IDE operation; Such conditions must result in all IDE Streams transitioning to the Insecure state, and all keys must be invalidated and rendered unreadable.
- It is permitted to support retention of state related to keys and counters in D3_{cold}, however such mechanisms are beyond the scope of this document.

The following rules relate to maintaining a secure local environment:

- Attempts to modify IDE registers, BARs, and other structures that could affect the security of the device or an IDE Stream must be detected
 - The resulting actions are implementation specific
- It is permitted to enter Insecure when a condition is detected that could affect the security of the device or an IDE Stream
 - In some cases, as determined by implementation specific criteria, it may be desirable to implement some other implementation specific action.
- IDE must be enabled in a coordinated way between the two Partner Ports such that both are enabled for IDE prior to either one Transmitting an IDE TLP to the other.
- For Link IDE, software must enable the Upstream Port and then the Downstream Port, while ensuring that no TLPs are transmitted on the Link between these two events.
- For Selective IDE, the Stream must not be used until it has been enabled in both Partner Ports. For cases where one of the Partner Ports is a Root Port and Selective IDE for Configuration Requests is enabled, the other Partner Port must be enabled prior to the Root Port. For other scenarios, the mechanisms to satisfy this requirement are implementation-specific.

6.34 Unordered IO (UIO) §

Unordered IO (UIO) is an optional capability, intended to address the limitations of the PCI/PCIe fabric-enforced ordering rules. UIO enables fabrics with multiple paths between a source and destination to be supported, and more closely matches the semantics of common IO fabrics (including on-die fabrics). UIO is suitable for all combinations of Requesters and Completers including Host-to-Device, Device-to-Host, and Device-to-Device (P2P).

UIO provides the ability for hardware to maintain full backwards compatibility with the PCI/PCIe producer-consumer model, shifting the responsibility for enforcing the observed ordering from the fabric to the Requester. All UIO Requests have corresponding UIO Completions, and the UIO Completions provide the Requester with the ability (and responsibility) to enforce ordering requirements. UIO can be used only when the entire path from Requester to Completer uses Flit Mode, supports UIO, and has UIO enabled.

6.34.1 UIO Rules §

For the path between a UIO Requester and Completer, UIO must be enabled end-to-end through all intermediate routing elements. For a given operation, the Requester is permitted to select, using implementation-specific means, between using UIO Requests or non-UIO Requests.

Non-tree topologies and multi-path support are permitted for UIO.

- The mechanism used to enable and manage such topologies is outside the scope of this specification.
- The mechanisms required to avoid deadlocks and loops for such topologies are outside the scope of this specification.
- A tree topology must exist as a subset of any non-tree topologies for enumeration and configuration operations and other non-UIO traffic.
 - Until enabled by implementation specific software, any Links outside of this tree topology must not carry any TLPs other than Messages with Local (r[2:0] = 100b) Message routing.

When a VC is configured for UIO, Posted credits are used for UIO Memory Write Requests and Non-Posted credits are used for all other UIO Memory Requests.

A Requester, Completer, or intermediate routing element advertises UIO support through the SVC VC Protocols Supported field in the SVC Resource Capability Register. For UIO functionality that has specific capability and control configuration (see § Section 7.7.9.2 and § Section 7.7.9.3), all UIO-supporting VCs implemented by a Port must have the same capabilities. It is not required for software to enable all implemented UIO-supporting VCs identically.

UIO, as with other PCIe traffic, does not provide protection against address hazarding, that is, the fabric ordering does not consider Request addresses. If such protection is required, it must be implemented outside the scope of this specification.

6.35 MMIO Register Blocks §

MMIO Register Blocks are optional mechanisms for exchanging various types of data structures between system software and a Function. Because all runtime operations are performed using Memory Space, the performance is generally much better than mechanisms such as DOE that use Configuration Space, and the use of Memory Space is better suited to direct assignment of the hardware resources to the appropriate software element.

MMIO Register blocks are discovered using the MMIO Register Block Locator (MRBL) Extended Capability (§ Section 7.9.30). The registers are mapped in Memory Space allocated via a BAR. Each MRBL Locator Register (§ Section 7.9.30.3) entry in the MRBL Extended Capability structure defines the type of MMIO Register Block and the BAR number and the offset within the BAR where these registers are mapped. It is permitted that the BAR contains other items besides the MMIO Register Blocks described in this section.

All accesses to offsets within the MMB Memory Space should be aligned to a boundary equal to the size of the access (e.g., a 1-byte access must be aligned to a 1-byte boundary, a 2-byte access must be aligned to a 2-byte boundary, etc.). If an access is not aligned to a boundary equal to the size of the access, then the request is permitted to be handled as a restricted programming model violation as defined in § Section 2.3.1.

§ Figure 6-83 portrays the relationship between the MRBL Extended Capability and the MMIO Register Blocks described in this section.

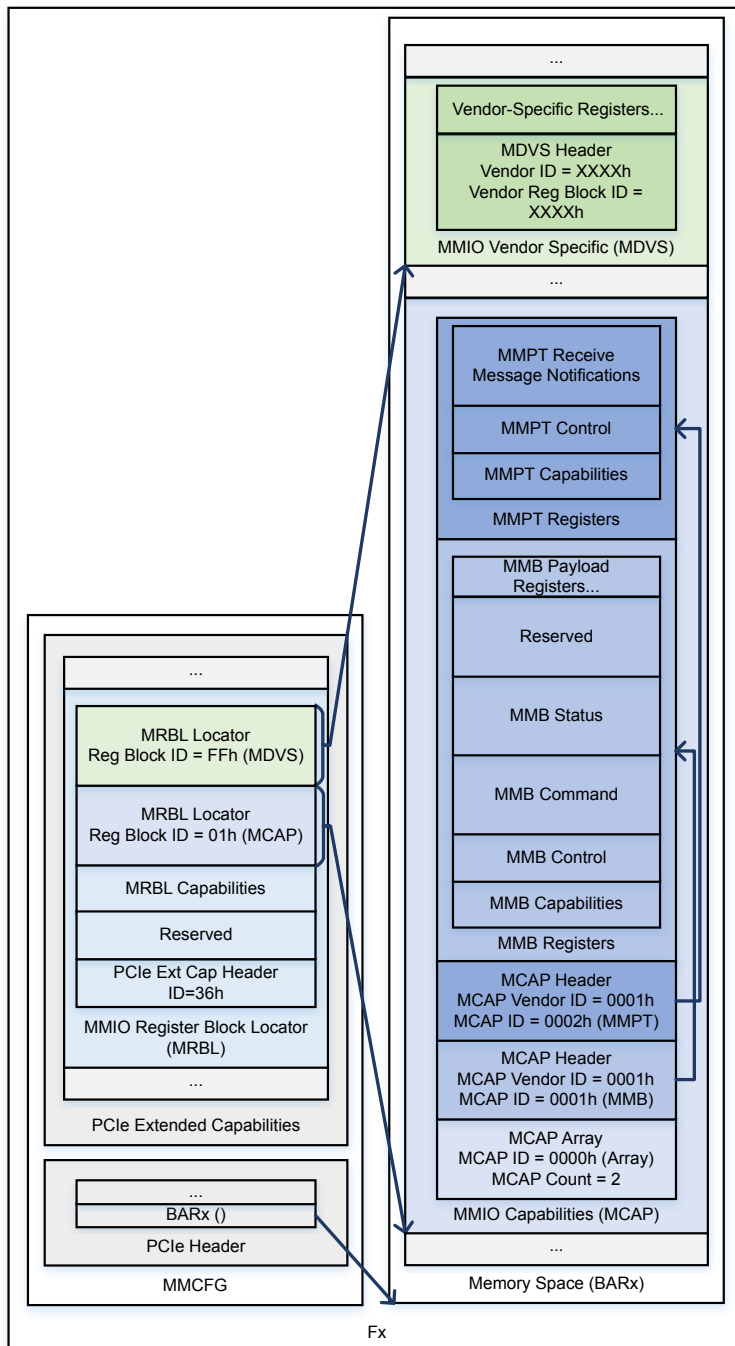

Figure 6-83 MMIO Register Blocks §

6.35.1 MMIO Capabilities Register Block (MCAP) §

The MMIO Capabilities Register Block is an array of capability structures. Each capability in the MCAP array is described by an MCAP Header Register that identifies the specific capability and points to the capability register structure in Memory Space. At the beginning of the MCAP Register Block is the MCAP Array Register (see § Section 6.35.1.1) that defines the size of the array followed by a list of MCAP Header Registers (See § Section 6.35.1.2).

The MCAP Register Block is discovered using the MMIO Register Block Locator Extended Capability (MRBL) (see § Section 7.9.30). The MCAP BAR shall be marked as prefetchable.

§ Figure 6-84 illustrates the MCAP Register Block.

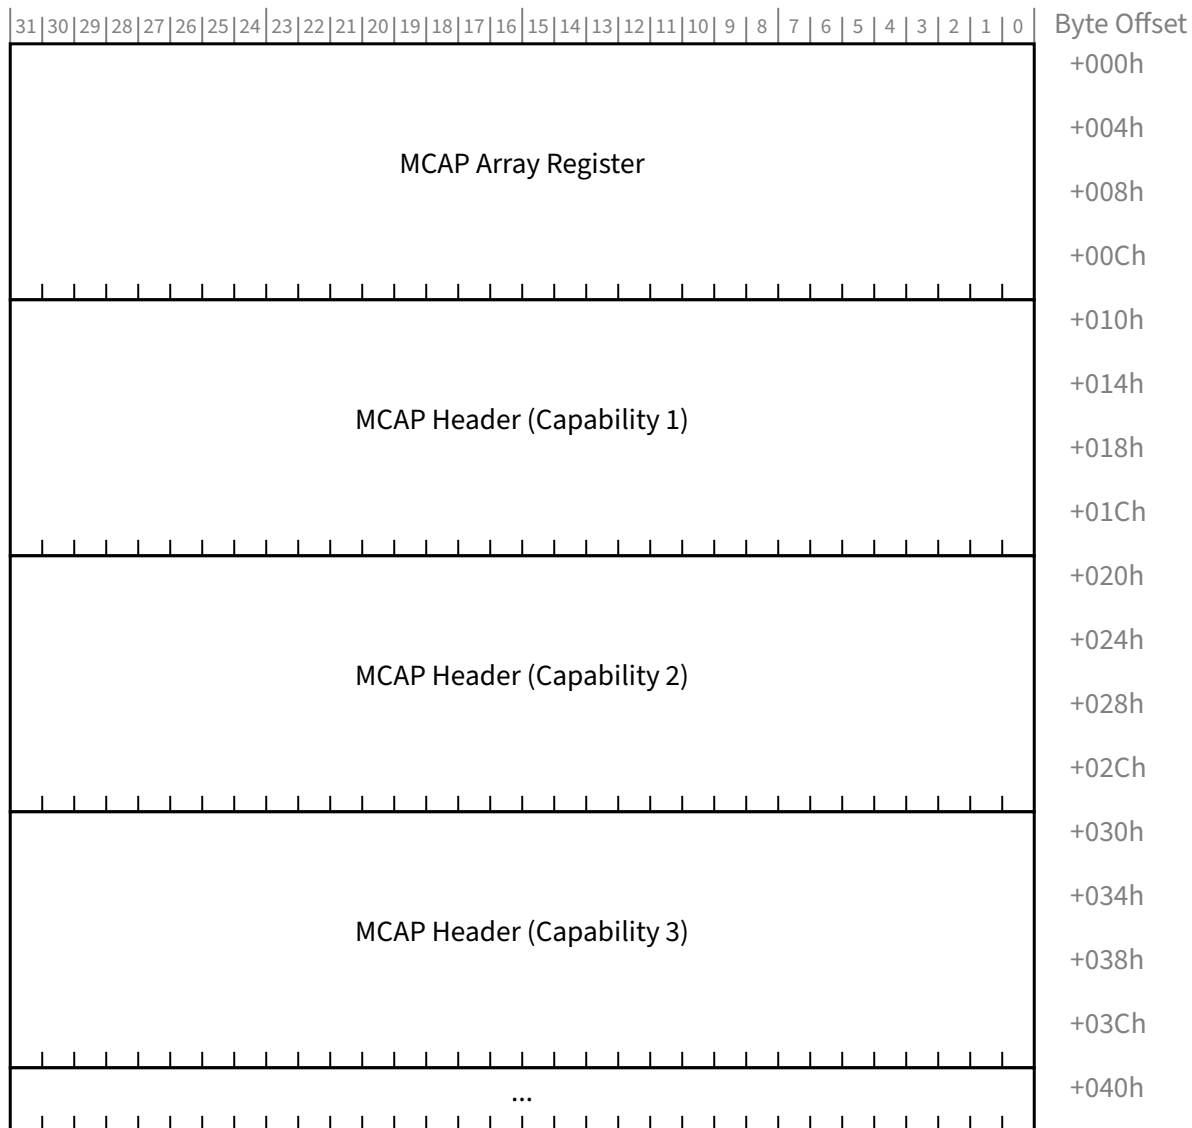

Figure 6-84 MCAP Register Block §

§ Figure 6-85 detail allocation of register fields in the MCAP Array Register Block.

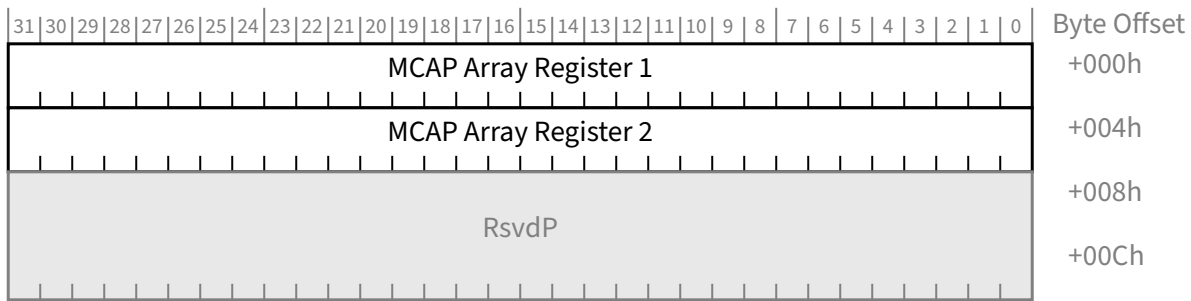

Figure 6-85 MCAP Array Register Block §

§ Figure 6-86 and § Figure 6-87 detail allocation of register fields registers that form the MCAP Array Register Block; § Table 6-38 and § Table 6-39 provide the respective bit definitions.

Figure 6-86 MCAP Array Register 1 §

Table 6-38 MCAP Array Register 1 §

Bit Location	Description	Attributes
15:0	MCAP ID – The MCAP array identifier. For the <u>MCAP Array Register</u> , this field shall be set to 0000h.	<u>RO</u>
23:16	MCAP Array Version – Defines the format of the MCAP Header Registers (see § Section 6.35.1.2 and § Table 6-40 through § Table 6-43) in the <u>MCAP Register Block</u> . Encodings are: 01h The MCAP Header format is defined in § Figure 6-88. Others All other encodings are reserved.	<u>RO</u>
27:24	MCAP Type – Defines the type associated with any type-specific capabilities (MCAP IDs in the range 4000h-7FFFh) in the <u>MCAP Register Block</u> . Encodings are: 0h The type is inferred from the 24-bit value corresponding to the Class Code of the Function. If the Class Code is not associated with any type-specific capabilities, then no type-specific capabilities shall be present. 1h-7h 1h-7h Reserved – Allocated for [CXL]. Others All other encodings are reserved.	<u>RO</u>

Figure 6-87 MCAP Array Register 2 §

Table 6-39 MCAP Array Register 2 §

Bit Location	Description	Attributes
15:0	MCAP Count – The number of capabilities in the MCAP Register Block, not including the MCAP Array Register. Each MCAP Header Register (see § Section 6.35.1.2) is contiguous to previous MCAP Header Register.	RO

6.35.1.2 MCAP Header Register Block (Offset Varies) §

§ Figure 6-89 through § Figure 6-92 detail allocation of register fields in the MCAP Header Register Block; § Table 6-40 through § Table 6-43 provides the respective bit definitions.

Figure 6-89 MCAP Header Register 1 §

Table 6-40 MCAP Header Register 1 §

Bit Location	Register Description	Attributes
15:0	MCAP ID – The capability identifier.	RO
23:16	<p>MCAP Version – Defines the version of the capability register structure.</p> <p>The MCAP Version is incremented whenever the capability register structure is extended to add more functionality. Backward compatibility shall be maintained during this process. For all values of n, version n+1 may extend version n by replacing fields that are marked as reserved in version n but must not redefine the meaning of existing fields. Software that was written for a lower version may continue to operate on capability structures with a higher version but will not be able to take advantage of new functionality. If backwards compatibility cannot be maintained, a new MCAP ID shall be created. Each field in a capability register structure is assumed to be introduced in version 1 of that structure unless specified otherwise in the field's definition.</p>	RO

Figure 6-90 MCAP Header Register 2 §

Table 6-41 MCAP Header Register 2 §

Bit Location	Register Description	Attributes
31:0	<p>MCAP Offset – Offset of the capability register structure from the start of the MCAP Register Block in bytes. The offset of performance sensitive MCAPs and security sensitive MCAPs shall be 4 KB aligned within Memory Space.</p>	RO

Figure 6-91 MCAP Header Register 3 §

Table 6-42 MCAP Header Register 3 §

Bit Location	Register Description	Attributes
31:0	MCAP Length – Size of the capability register structure in bytes.	RO

Figure 6-92 MCAP Header Register 4 §

Table 6-43 MCAP Header Register 4 §

Bit Location	Register Description	Attributes
15:0	MCAP Vendor ID – The PCI-SIG assigned Vendor ID for the entity that defined the capability register structure. A value of 0000h in this field is reserved for legacy compatibility with existing [CXL] defined register structures only.	RO

Table 6-44 PCI-SIG Defined MCAP Identifiers (MCAP Vendor ID = 0001h) §

MCAP Vendor ID	MCAP ID	Description
N/A	0000h	MCAP Array Register – Describes the MCAP Array Register. See § Section 6.35.1.1 .
0001h	0001h	MMIO Mailbox (MMB) – Describes the MMIO mailbox capability registers (MMB). At most one instance of this register structure can exist per Function. See § Section 6.35.1.3 .
0001h	0002h	Management Message Passthrough (MMPT) – Describes the registers required for a Function that supports the Management Message Passthrough (MMPT) command set (§ Section 6.36.1). At most one instance of this register structure can exist per Function (See § Section 6.35.1.4.1).
0001h	0003h-3FFFh	Reserved
N/A	4000h-7FFFh	Type-Specific – Identifies type-specific capabilities associated with the MCAP Type specified in the MCAP Array Register (see § Section 6.35.1.1).
0001h	8000h-FFFFh	Reserved

6.35.1.3 MMIO Mailbox Capability (MMB) (Offset: Varies) §

The MMIO Mailbox Capability (MMB) provides the ability to issue a command to a Function.

The MMB interface shall only be used in a single-threaded manner. It is software’s responsibility to avoid simultaneous, uncoordinated access to the MMB Registers using techniques such as locking.

The MMB command timeout is 2 seconds. This is the maximum permitted time after the Doorbell is Set in the MMB Control Register (see § Section 6.35.1.3.2.2) for the Function to complete the command, Clear the Doorbell, and optionally signal the Command Ready Interrupt, if configured.

MMB commands do not continue to execute across Conventional Resets. It is not required that FLR results in any type of reset to the internal processing engine for MMB operations, although such behavior is permitted, and may be required or forbidden by specific commands.

The optional MMB Attention Mechanism supports improved power management of MMB implementations, by enabling an MMB instance to temporarily enter an unresponsive state, and providing software, a mechanism to direct the instance back to a responsive state. If MMB Attention Mechanism Support is Set, for backwards compatibility, the default is that the MMB instance must remain in a responsive state. System software is recommended to Set MMB Attention Not Needed when it is acceptable for the MMB instance to enter and stay in a state where it is not immediately available for use. When Clear, the MMB instance must remain in a state where it is ready to respond in a timely way to system software. MMB At Attention, when Set, indicates the MMB interface is presently in a state of readiness. This bit must only be Cleared if MMB Attention Not Needed is Set. It is permitted for this bit to remain Clear for up to 50 ms following the Clearing of MMB Attention Not Needed.

Functions may support sending MSI/MSI-X interrupts to indicate MMB command status. Support for MMB interrupts is enumerated in the MMB Capabilities Register (see § Section 6.35.1.3.2.1) and enabled in the MMB Control Register (see § Section 6.35.1.3.2.2).

Unless specified otherwise in the field definitions for the MMB Registers, each field is present in version 1 and later of these structures. The Function must report the version of these structures in the MCAP Version field of the MCAP Header Register (see § Section 6.35.1.2).

6.35.1.3.1 MMB Operation §

The flow for executing a command is described below. The term “caller” represents the entity submitting the command.

- The caller ensures the Function is ready to accept a new command on the MMB.
 - After a Conventional Reset, the caller ensures the MMB is initialized.
 - The caller polls for MMB Ready to be Set in the MMB Status Register (see § Section 6.35.1.3.2.4).
 - The caller ensures the MMB is in a state of readiness.
 - If MMB Attention Mechanism Support in the MMB Capabilities Register (see § Section 6.35.1.3.2.1) is Set, the caller reads MMB At Attention in the MMB Status Register (see § Section 6.35.1.3.2.4). If Clear:
 - The caller Clears MMB Attention Not Needed in the MMB Control Register (see § Section 6.35.1.3.2.2).
 - The caller either polls for MMB At Attention to be Set in the MMB Status Register (see § Section 6.35.1.3.2.4) or waits for the Command Ready Interrupt if configured.
 - The caller ensures the Function is ready to accept a new command.
 - The caller polls for the Doorbell to be Cleared in the MMB Control Register (see § Section 6.35.1.3.2.2).
- The caller issues a new command.
 - The caller writes the MMB Command Register (see § Section 6.35.1.3.2.3).
 - The caller writes the MMB Payload Registers (see § Section 6.35.1.3.2.5) if the input payload is non-empty.
 - The caller Sets the Doorbell in the MMB Control Register (see § Section 6.35.1.3.2.2).
- The caller waits for the command to complete.
 - The caller either polls for the Doorbell to be Cleared in the MMB Control Register (see § Section 6.35.1.3.2.2) or waits for the Command Ready Interrupt if configured.
 - In case of a command timeout, the caller may attempt to recover the Function by issuing a Conventional reset to the Function.

- The caller retrieves the result of the command.
 - The caller reads the Return Code in the MMB Status Register (see § Section 6.35.1.3.2.4).
 - The caller reads the MMB Payload Length in the MMB Command Register (see § Section 6.35.1.3.2.3). If non-zero, the caller reads the MMB Payload Registers (see § Section 6.35.1.3.2.5) to retrieve the output payload.

6.35.1.3.2 MMB Registers §

§ Figure 6-93 illustrates the MMB Registers structure.

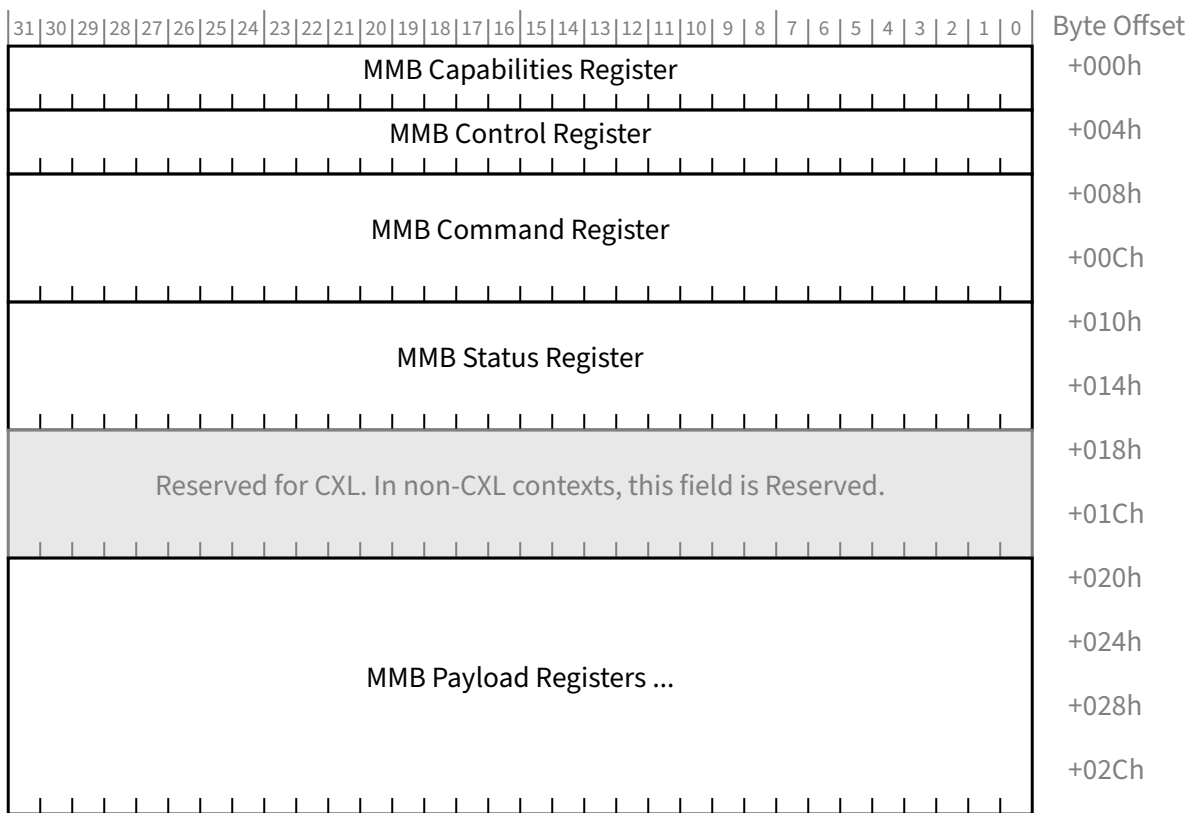

Figure 6-93 MMB Registers §

6.35.1.3.2.1 MMB Capabilities Register (Offset 00h) §

§ Figure 6-94 details allocation of register fields in the MMB Capabilities Register; § Table 6-45 provides the respective bit definitions.

Figure 6-94 MMB Capabilities Register §

Table 6-45 MMB Capabilities Register §

Bit Location	Register Description	Attributes
4:0	MMB Payload Registers Size – Size of the MMB Payload Registers (see § Section 6.35.1.3.2.5) in bytes, expressed as 2^n . The minimum size is 256 bytes (n=8) and the maximum size is 1 MB (n=20).	HWInit
5	Command Ready Interrupt Capable – This field indicates if the MMB supports signaling an MSI/MSI-X interrupt when the Doorbell in the MMB Control Register (see § Section 6.35.1.3.2.2) transitions from Set to Clear or MMB At Attention in the MMB Status Register (see § Section 6.35.1.3.2.4) transitions from Clear to Set. 0 Not supported 1 Supported	HWInit
6	Reserved for CXL – This field is assigned for use by [CXL]. In non-CXL contexts, this field is Reserved.	RsvdP
10:7	Interrupt Message Number – This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with this MMB instance. For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the Message Control register for MSI. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry shall be one of the first 16 entries even if the Function implements more than 16 entries. The value in this field shall be within the range configured by system software to the Function. For a given MSI-X implementation, the entry shall remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field shall indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field indicates the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined.	RO/RsvdP
18:11	MMB Ready Time – This field indicates the maximum amount of time in seconds after a Conventional Reset for MMB Ready in the MMB Status Register (see § Section 6.35.1.3.2.4) to become Set. A value of 0 indicates 2 seconds.	HWInit
22:19	Type – This field identifies the type-specific commands supported by the MMB. 0h The type is inferred from the 24-bit value corresponding to the Class Code of the Function. If the Class Code is not associated with any type-specific commands, then no type-specific commands are present. 1h-7h Reserved – Allocated for [CXL]. Others All other encodings are reserved.	HWInit

Bit Location	Register Description	Attributes
23	<p>MMB Attention Mechanism Capable – This field indicates if the MMB supports the optional MMB Attention Mechanism.</p> <p>0 Not supported</p> <p>1 Supported</p>	HWInit

0	<p>Doorbell – When MMB Ready is Set, this bit, when Clear, indicates that the Function is ready to accept a new command. Set by the caller to notify the Function that the command inputs are ready. Read-only when Set. Cleared by the Function when the command completes.</p> <p>0 Ready to accept a command</p> <p>1 Busy executing a command or initializing</p> <p>Default value of this field is 1b. Cleared by the Function when <u>MMB Ready</u> is Set in the <u>MMB Status Register</u>.</p>	RW
1	<p>Command Ready Interrupt Enable – When <u>Command Ready Interrupt Capable</u> is Set, this bit, when Set, enables the MMB to signal an MSI/MSI-X interrupt when the <u>Doorbell</u> transitions from Set to Cleared or <u>MMB At Attention</u> in the <u>MMB Status Register</u> (see § Section 6.35.1.3.2.4) transitions from Clear to Set. Read-only when the <u>Doorbell</u> is Set.</p> <p>When <u>Command Ready Interrupt Capable</u> is Clear, this bit is permitted to be <u>RsvdP</u>.</p> <p>0 Disabled</p> <p>1 Enabled</p> <p>Default value of this field is 0b.</p>	RW/RsvdP
2	<p>Reserved for CXL – This field is assigned for use by [CXL]. In non-CXL contexts, this field is Reserved.</p>	RsvdP
3	<p>MMB Attention Not Needed – If MMB Attention Mechanism Capable is Set, this bit, when Set, enables the MMB to enter and stay in a state where it is not immediately available for use. When Clear the MMB must remain in a responsive state.</p>	RW/RsvdP

Bit Location	Register Description	Attributes
	<p>When MMB Attention Mechanism Support is Clear, this bit is permitted to be RsvdP.</p> <p>0 Attention needed</p> <p>1 Attention not needed</p> <p>Default value of this bit is 0b.</p>	

6.35.1.3.2.3 MMB Command Register (Offset 08h) §

The MMB Command Register shall only be used by the caller when the Doorbell in the MMB Control Register (see § Section 6.35.1.3.2.2) is Cleared.

§ Figure 6-96 details allocation of register fields in the MMB Command Register; § Table 6-47 provides the respective bit definitions.

Figure 6-96 MMB Command Register §

Table 6-47 MMB Command Register §

Bit Location	Register Description	Attributes
15:0	<p>MMB Command Opcode – The command identifier.</p> <p>Default value of this field is 0000h.</p>	RW
36:16	<p>MMB Payload Length – The size of the data in the MMB Payload Registers (see § Section 6.35.1.3.2.5) in bytes. Valid values for this field are less than or equal to the MMB Payload Registers Size specified in the <u>MMB Capabilities Register</u> (see § Section 6.35.1.3.2.1). Written by the caller to provide the command input payload size to the Function prior to setting the <u>Doorbell</u> in the <u>MMB Control Register</u> (see § Section 6.35.1.3.2.2). Values specified by the caller that are greater than the <u>MMB Payload Registers Size</u> result in an error of Invalid Payload Length being returned in the <u>MMB Return Code</u> field. Written by the Function to provide the command output payload size to the caller when the <u>Doorbell</u> is Cleared in the <u>MMB Control Register</u> (see § Section 6.35.1.3.2.2).</p> <p>Default value of this field is 00000h.</p>	RW
63:48	<p>MMB Command Opcode Vendor ID – The PCI-SIG assigned Vendor ID for the entity that defined the MMB Command Opcode. A value of 0000h in this field is reserved for legacy compatibility with existing [CXL] defined commands only.</p> <p>Default value of this field is 0000h.</p>	RW

IMPLEMENTATION NOTE: MMB COMMAND OPCODE VENDOR ID LEGACY COMPATIBILITY §

For legacy compatibility with OS software, platform firmware should clear the MMB Command Opcode Vendor ID to 0000h prior to OS hand off.

6.35.1.3.2.4 MMB Status Register (Offset 10h) §

Reports information about the state of the MMB and the last command executed since Conventional Reset.

§ Figure 6-97 details allocation of register fields in the MMB Status Register; § Table 6-48 provides the respective bit definitions.

Figure 6-97 MMB Status Register §

Table 6-48 MMB Status Register §

Bit Location	Register Description	Attributes
0	Reserved for CXL – This field is assigned for use by [CXL]. In non-CXL contexts, this field is Reserved.	RsvdP
1	MMB Ready – This bit, when Set, indicates that the Function is ready to accept commands through the MMB interface. Functions that report a non-zero MMB Ready Time shall Set this bit after a Conventional Reset within the time reported in the MMB Ready Time field and it shall remain Set until the next Conventional Reset, or the Function encounters an error that prevents any MMB communication. 0 Not ready 1 Ready	RO
2	MMB At Attention – When MMB Attention Mechanism Capable is Set, this bit, when Set, indicates the MMB interface is presently in a state of readiness. The transition of this bit from Clear to Set triggers a Command Ready interrupt if Command Ready Interrupt Enable is Set. When MMB Attention Mechanism Support is Clear, this bit is RsvdP. This bit is Set by the Function when MMB Ready is Set. 0 Not at Attention 1 At Attention	RO/RsvdP
47:32	MMB Return Code – The result of the command. Only valid after the Doorbell is Cleared in the MMB Control Register (see § Section 6.35.1.3.2.2) after a command completes.	RO
64:48	Vendor-Specific Extended Status – The Vendor-Specific extended status information. Only valid after the Doorbell is Cleared in the MMB Control Register (see § Section 6.35.1.3.2.2) after a command completes.	RO

6.35.1.3.2.4.1 MMB Command Return Codes §

Command Return Codes are associated with the entity that defined the command as indicated by the MMB Command Opcode Vendor ID in the MMB Command Register.

The MMB Command Return Code is Set by the Function to indicate to the Caller the result of a command. If more than one MMB Command Return Code applies, the Function chooses which one to return.

In general, retries are not recommended for commands that return an error except when indicated in the return code definition.

PCI-SIG defined command return codes are only valid for PCI-SIG defined commands.

Table 6-49 MMB PCI-SIG Defined Command Return Codes (Vendor ID = 0001h) §

Value	Description
0000h	Success: The command successfully completed.
0001h	Reserved
0002h	Invalid Input: A command input was invalid.
0003h	Unsupported: The MMB Command Opcode is not supported.
0004h	Internal Error: The command was not completed because of an internal error.
0005h	Retry Required: The command was not completed because of a temporary error. An optional single retry may resolve the issue.
0006h-7FFFh	Reserved: Allocated for [CXL].
8000h	Invalid Payload Length: The input payload length specified for the command is not valid.
8001h	Unsupported Management Message: The MMPT Message Type is not supported.
8002h	Transfer in Progress: Only one transfer can occur at a time. Complete or abort the current data transfer before starting a new one.
8003h	Transfer Out of Order: The transfer was aborted because the data was transferred out of order.
8004h	Transfer Aborted: The data transfer was aborted and must be restarted from the beginning.
8005h-FFFFh	Reserved

6.35.1.3.2.5 MMB Payload Registers (Offset 20h) §

The MMB Payload Registers must consist of 256 Bytes – 1 MB, as shown in § Figure 6-98. The size of the MMB Payload Registers is reported in the MMB Capabilities Register (see § Section 6.35.1.3.2.1). Any data beyond the size specified in the MMB Capabilities Register shall be ignored by the caller and the Function.

The MMB Payload Registers are written by the caller to provide the command input payload to the Function prior to Setting the Doorbell in the MMB Control Register (see § Section 6.35.1.3.2.2). They are written by the Function to provide the command output payload back to the caller prior to Clearing the Doorbell.

These registers must only be used by the caller when the Doorbell in the MMB Control Register (see § Section 6.35.1.3.2.2) is Clear.

Figure 6-98 MMB Payload Registers §

6.35.1.4 Management Message Passthrough (MMPT) Capability (Offset: Varies) §

The Management Message Passthrough (MMPT) Capability is required for Functions that support the MMPT command set. Refer to the MMPT command interface for usage of this capability (§ Section 6.36.1).

Unless specified otherwise in the field definitions, each field is present in version 1 and later of this structure. The Function shall report the version of this structure in the MCAP Version field of the MCAP Header Register.

6.35.1.4.1 MMPT Registers §

Table 6-52 MMPT Receive Message Notification Register §

Bit Location	Register Description	Attributes
0	MMPT Receive Message Ready – When Set, a new management message is ready to be transferred from the Function to the host using the MMPT Receive Message command (see § Section 6.36.1.2).	RO
23:16	MMPT Receive Message Type – This field indicates the nature and format of the management message ready to be transferred from the Function to the host using the MMPT Receive Message command (see § Section 6.36.1.2). Encodings for this field are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.	RO
63:32	MMPT Receive Message Length – This field indicates the length of the management message in bytes ready to be transferred from the Function to the host using the MMPT Receive Message command (see § Section 6.36.1.2).	RO

6.35.2 MMIO Designated Vendor-Specific Register Block (MDVS) §

The MMIO Designated Vendor-Specific Register Block (MDVS) allows a Vendor-Specific Memory Space register block to be discovered by utilizing the MRBL Extended Capability (§ Section 7.9.30). The format of the MDVS Register Block starts with the MDVS Register Block Header Register (see § Section 6.35.2.1 and § Section 6.35.3) as illustrated in § Figure 6-103. The remainder of the MDVS Register Block MDVS Register Block is vendor defined. A single Function is permitted to implement more than one in a MDVS Register Block.

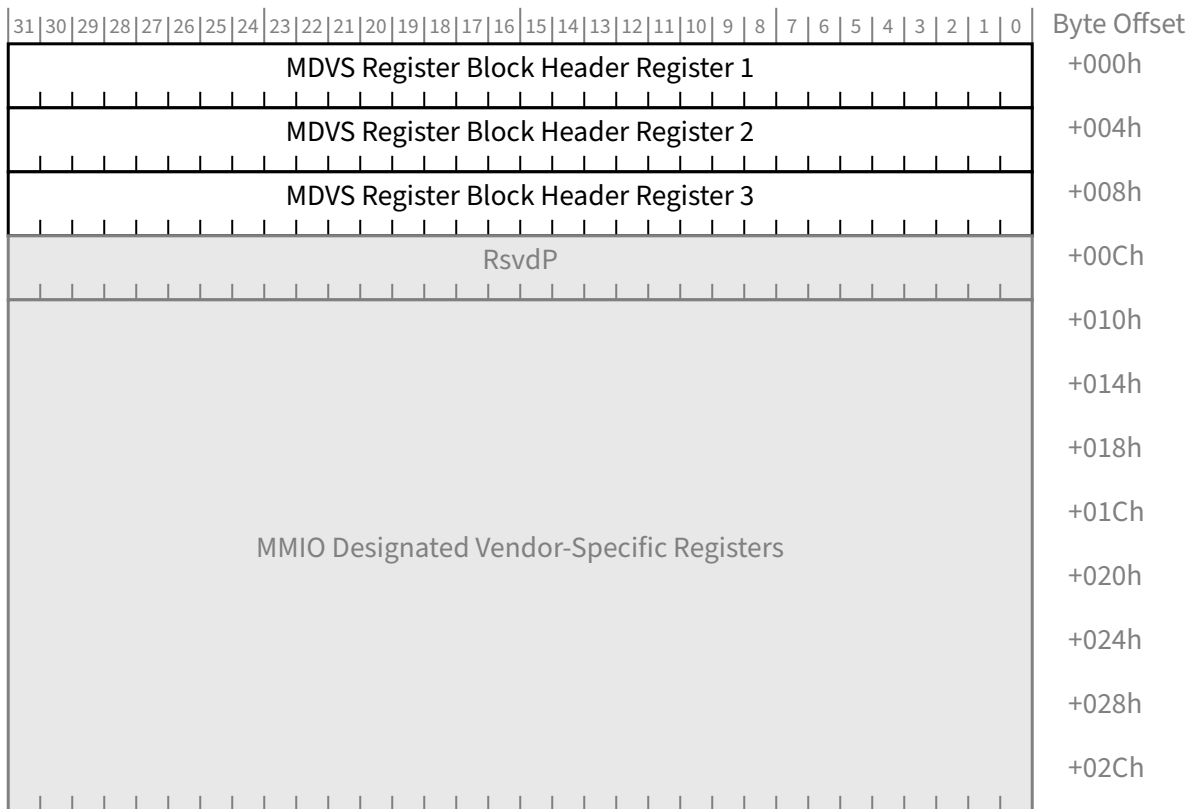

Figure 6-103 MDVS Register Block §

6.35.2.1 MDVS Register Block Header Register 1 (Offset 00h) §

§ Figure 6-104 details allocation of register fields in the MDVS Register Block Header Register 1; § Table 6-53 provides the respective bit definitions.

6.36 MMB Command Interface §

MMB commands are identified by a MMB Command Opcode. MMB Command Opcodes also provide an implicit version number, which means a command's definition shall not change in an incompatible way in future revisions of this specification. Instead, if an incompatible change is required, the specification defining the change shall define a new MMB Command Opcode for the changed command. Commands may evolve by defining new fields in areas of the payload definitions that were originally defined as Reserved, but only in a way where software written using the earlier definition will continue to work correctly, and software written to the new definition can use the 0 value or the payload size to detect Function components that do not support the new field. This implicit versioning allows software to be written with the understanding that a MMB Command Opcode shall only evolve by adding backward compatible changes.

Table 6-56 PCI-SIG Defined MMB Command Opcodes (Vendor ID = 0001h) §

MMB Command Opcode					Input Payload Size (Bytes) (Note 1)	Output Payload Size (Bytes) (Note 1)
Command Set Bits[15:8]		Command Bits[7:0]		Combined Opcode		
00h	Reserved	00h-FFh	Reserved	0000h-00FFh	N/A	N/A
01h	Management Message Passthrough (MMPT)	00h	Send Message (see § Section 6.36.1.1)	0100h	10h+	00h+
		01h	Receive Message (see § Section 6.36.1.2)	0101h	10h	00h+
		02h-FFh	Reserved	0102h-01FFh	N/A	N/A
02h-FFh	Reserved	00h-FFh	Reserved	0200h-FFFFh	N/A	N/A

Notes:

1. Indicates the minimum payload size for a successful completion. Commands with variable payloads sizes are marked with '+'. Actual valid bytes in the output payload are indicated by the MMB Payload Length field in the MMB Command Register (see § Section 6.35.1.3.2.3).

6.36.1 Management Message Passthrough (MMPT) §

The optional Management Message Passthrough (MMPT) command set provides an interface to tunnel management messages defined in other industry standard specifications between the host and the Function using the MMB Command Interface. This enables OS standard class drivers to utilize the same management messages used by the BMC, thus making in-band and out-of-band management more consistent.

Management messages may be initiated from the host to the Function using the Send Message command (see § Section 6.36.1.1) or asynchronously from the Function to the host using the Receive Message command (see § Section 6.36.1.2). The Function notifies the host that a new management message is ready to be retrieved using the Receive Message command (see § Section 6.36.1.2) by setting the MMPT Receive Message Ready bit in the MMPT Receive Message Notification Register (see § Section 6.35.1.4.1.3). If more than one management message is ready to be transferred from the Function to the host, it is the Function's responsibility to queue up the management messages until the host retrieves them.

Management messages may be larger than the MMB Payload Registers Size requiring the management message to be transferred in parts. If a management message is transferred in its entirety, the caller makes one call to Send or Receive Message with Action = Full Data Transfer. The Offset field is not used and shall be ignored. If a management message is transferred in parts, the caller makes one call to Send or Receive Message with Action = Initiate Data Transfer, zero or more calls with Action = Continue Data Transfer, and one call with Action = Finish Data Transfer or Abort Data Transfer. The management message parts shall be transferred in ascending order based on the Offset value, and the Function shall return the Transfer Out of Order return code if the management message parts are not transferred in ascending order. Back-to-back retransmission of any management message part is permitted during a transfer. A Send or Receive Message command with Action = Abort Data Transfer shall be supported for management messages that can be transferred in parts. An attempt to call Send or Receive Message with Action = Abort Data Transfer for a message whose data has been fully transferred shall fail with Invalid Input.

If the management message transfer is interrupted by a Conventional Reset, error condition, or MMB command-specific reason, the management message transfer shall be aborted and the Send or Receive Message command shall return Transfer Aborted. If a management message transfer is aborted prior to the entire management message data being transferred, the Function shall require the management message transfer to be started from the beginning of the message data.

6.36.1.1 MMPT Send Message (Opcode 0100h) §

Transfer all or part of a management message from the host to the Function. If a management message is transferred in parts, the entire management data shall be transferred or aborted prior to transferring a new management message. Otherwise, the function shall return Invalid Input.

Possible MMB Command Return Code values (see § Section 6.35.1.3.2.4.1):

- Success
- Invalid Input
- Internal Error
- Retry Required
- Invalid Payload Length
- Unsupported
- Unsupported Management Message
- Transfer Out of Order
- Transfer in Progress
- Transfer Aborted

Table 6-57 MMPT Send Message Input Payload §

Byte Offset	Length in Bytes	Description
00h	01h	MMPT Message Type – This field indicates the nature and format of the Message Data. Encodings for this field are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.
01h	03h	Reserved
04h	04h	Flags DW Bits[2:0] Action Specifics – Specifies the stage of the Message Data transfer.

Byte Offset	Length in Bytes	Description
		000b Full Data Transfer 001b Initiate Data Transfer 010b Continue Data Transfer 011b Finish Data Transfer 100b Abort Data Transfer Others All other values are reserved Bits[31:3] Reserved
08h	04h	Offset – The Byte Offset in the Message Data.
0Ch	04h	Reserved
10h	variable	Message Data – The management message data, formatted according to the MMPT Message Type specification.

Table 6-58 MMPT Send Message Output Payload §

Byte Offset	Length in Bytes	Description
00h	Varies	Message Data – The management message response, formatted according to the MMPT Message Type specification.

6.36.1.1.1 MMPT Send Message Operation §

The flow for transferring a management message from the host to the Function is described below. Total input payload size refers to the MMPT Send Message Input Payload structure (see § Table 6-57) including the full Message Data.

- The host transfers the management message to the Function using the Send Message command.
 - If the total input payload size is less than or equal to the MMB Payload Registers Size, the host issues the Send Message Command with Action = Full Data Transfer.
 - If the total input payload size is greater than the MMB Payload Registers Size, the host transfers the message to the Function in ordered parts where each part fits in the MMB Payload Registers (§ Section 6.35.1.3.2.5). If any part fails to transfer, the host can retransmit that part before sending the next part or abort the transfer and start over.
 - The host issues the Send Message Command with Action = Initiate Data Transfer.
 - Depending on the size of the Message Data, the host issues zero or more Send Message Commands with Action = Continue Data Transfer.
 - The host issues the Send Message Command with Action = Finish Data Transfer.
- The Function may optionally send a response message back to the host.
 - If the response message size is less than or equal to the MMB Payload Registers Size and the response message data is available when the Send Message command completes, the Function returns the response message in the output payload.
 - Otherwise, the Function sends the response message using the asynchronous Receive Message flow.

6.36.1.2 MMPT Receive Message (Opcode 0101h) §

Transfer all or part of a management message from the Function to the host.

Possible MMB Command Return Code values (§ Section 6.35.1.3.2.4.1):

- Success
- Invalid Input
- Internal Error
- Retry Required
- Invalid Payload Length
- Unsupported
- Unsupported Management Message
- Transfer Out of Order
- Transfer in Progress
- Transfer Aborted

Table 6-59 MMPT Receive Message Input Payload §

Byte Offset	Length in Bytes	Description
00h	01h	MMPT Message Type – This field indicates the nature and format of the Message Data. Encodings for this field are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.

04h	04h	Flags DW: Bits[2:0] Action Specifics – Specifies the stage of the Message Data transfer. 000b Full Data Transfer 001b Initiate Data Transfer 010b Continue Data Transfer 011b Finish Data Transfer 100b Abort Data Transfer Others All other values are reserved Bits[31:3] Reserved
08h	04h	Offset – The Byte Offset in the message data to return in the output payload.
0Ch	04h	Message Length – The Length in Bytes of the message data to return in the output payload.

Table 6-60 MMPT Receive Message Output Payload §

Byte Offset	Length in Bytes	Description
00h	Varies	Message Data – The management message data, formatted according to the MMPT Message Type specification.

6.36.1.2.1 MMPT Receive Message Operation §

The flow for transferring a management message asynchronously from the Function to the Host is described below.

- The Function indicates to the host that a new management message is ready to be retrieved.
 - The Function writes the MMPT Receive Message Notification Register (§ Section 6.35.1.4.1.3) and Sets MMPT Receive Message Ready.
 - The host either polls for MMPT Receive Message Ready to be Set or waits for the MMPT Receive Message Interrupt if configured.
- The host transfers the management message from the Function using the Receive Message command.
 - If the MMPT Receive Message Length is less than or equal to the MMB Payload Registers Size, the host issues the Receive Message Command with Action = Full Data Transfer.
 - If the MMPT Receive Message Length is greater than the MMB Payload Registers Size, the host transfers the management message from the Function in ordered parts where each part fits in the MMB Payload Registers (see § Section 6.35.1.3.2.5). If any part fails to transfer, the host can retransmit that part before receiving the next part or abort the transfer and start over.
 - The host issues the Receive Message Command with Action = Initiate Data Transfer.
 - Depending on MMPT Receive Message Length, the host issues zero or more Receive Message Commands with Action = Continue Data Transfer.
 - The host issues the Receive Message Command with Action = Finish Data Transfer.
- The Function Clears the MMPT Receive Message Notification Register (see § Section 6.35.1.4.1.3).

7. Software Initialization and Configuration §

The PCI Express Configuration model supports two Configuration Space access mechanisms:

- PCI-compatible Configuration Access Mechanism (CAM) (see § Section 7.2.1)
- PCI Express Enhanced Configuration Access Mechanism (ECAM) (see § Section 7.2.2)

The PCI-compatible mechanism supports 100% binary compatibility with Conventional PCI or later aware operating systems and their corresponding bus enumeration and configuration software.

The enhanced mechanism is provided to increase the size of available Configuration Space and to optimize access mechanisms.

7.1 Configuration Topology §

To maintain compatibility with PCI software configuration mechanisms, all PCI Express elements have a PCI-compatible Configuration Space. Each PCI Express Link originates from a logical PCI-PCI Bridge and is mapped into Configuration Space as the secondary bus of this Bridge. The Root Port is a PCI-PCI Bridge structure that originates a PCI Express Link from a PCI Express Root Complex (see § Figure 7-1).

A PCI Express Switch not using FPB Routing ID mechanisms is represented by multiple PCI-PCI Bridge structures connecting PCI Express Links to an internal logical PCI bus (see § Figure 7-2). The Switch Upstream Port is a PCI-PCI Bridge; the secondary bus of this Bridge represents the Switch's internal routing logic. Switch Downstream Ports are PCI-PCI Bridges bridging from the internal bus to buses representing the Downstream PCI Express Links from a PCI Express Switch. Only the PCI-PCI Bridges representing the Switch Downstream Ports may appear on the internal bus. Endpoints, represented by Type 0 Configuration Space Headers, are not permitted to appear on the internal bus.

A PCI Express Endpoint is mapped into Configuration Space as a single Function in a Device, which might contain multiple Functions or just that Function. PCI Express Endpoints and Legacy Endpoints are required to appear within one of the Hierarchy Domains originated by the Root Complex, meaning that they appear in Configuration Space in a tree that has a Root Port as its head. Root Complex Integrated Endpoints (RCiEPs) and Root Complex Event Collectors do not appear within one of the Hierarchy Domains originated by the Root Complex. These appear in Configuration Space as peers of the Root Ports.

Unless otherwise specified, requirements in the Configuration Space definition for a device apply to single Function devices as well as to each Function individually of a Multi-Function Device.

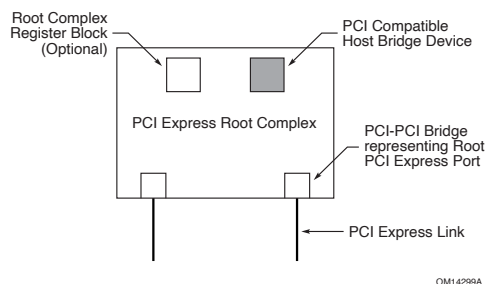

Figure 7-1 PCI Express Root Complex Device Mapping §

Figure 7-2 PCI Express Switch Device Mapping¹⁴⁹ §

IMPLEMENTATION NOTE: CHANGING A DEVICE'S OS DRIVER BINDINGS & RESOURCES §

Under certain circumstances, it is highly useful for a device to change one or more of its architected registers that help determine which OS-managed resources are allocated to the device and which OS drivers get bound to it. Here are two key examples:

- A device might change the Class Code Register value in one or more of its Functions
- Entire Functions might be added or removed after device firmware is updated

Software can direct devices to change their architected registers through a variety of mechanisms outside the scope of this specification, including implementation specific ones and ones defined by external standards bodies. It is recommended that these mechanisms follow the guidance of this Implementation Note.

If a device outside the RC has possibly been enumerated by the OS, it is strongly recommended that software use a mechanism directing the device to change its registers when coming out of a Conventional Reset. From a hardware perspective, this is similar to a hot remove followed by a hot add, providing a clean trigger point for architected registers to change in compliance with this specification, plus it guarantees the architected default hardware state for OS I/O infrastructure software and OS drivers to rely on. It is strongly recommended that software use OS-specific interfaces to perform the Conventional Reset and/or coordinate the reset and subsequent enumeration with the OS. If not feasible via OS-specific interfaces, software may be able to perform a Conventional Reset directly via several ways, including the Secondary Bus Reset bit or the Link Disable bit in the Downstream Port above the device.

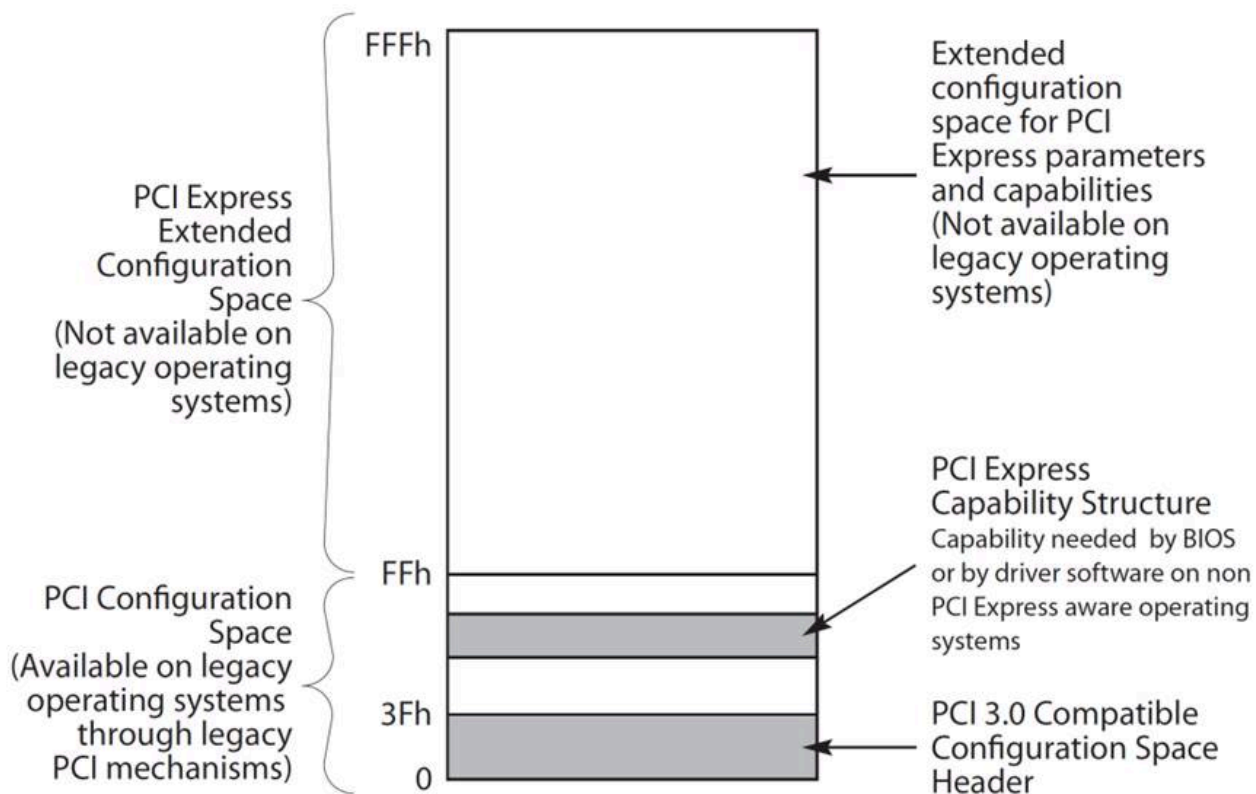

If software knows that a device outside the RC has not been enumerated by the OS, software may choose to direct the device to change its registers without undergoing a reset, thus avoiding unnecessary delay.

7.2 PCI Express Configuration Mechanisms §

PCI Express extends the Configuration Space to 4096 bytes per Function as compared to 256 bytes allowed by [PCI]. PCI Express Configuration Space is divided into a PCI-compatible region, which consists of the first 256 bytes of a Function's Configuration Space, and a PCI Express Extended Configuration Space which consists of the remaining Configuration Space (see § Figure 7-3). The PCI-compatible Configuration Space can be accessed using either the mechanism defined

149. Future PCI Express Switches may be implemented as a single Switch device component (without the PCI-PCI Bridges) that is not limited by legacy compatibility requirements imposed by existing PCI software.

in § Section 7.2.1 or § Section 7.2.2 . Accesses made using either access mechanism are equivalent. The PCI Express Extended Configuration Space can only be accessed by using the ECAM mechanism defined in § Section 7.2.2 .¹⁵⁰

OM14301A

Figure 7-3 PCI Express Configuration Space Layout §

7.2.1 PCI-compatible Configuration Mechanism §

The PCI-compatible PCI Express Configuration Mechanism supports the PCI Configuration Space programming model defined in the [PCI]. By adhering to this model, systems incorporating PCI Express interfaces remain compliant with conventional PCI bus enumeration and configuration software.

In the same manner as PCI device Functions, PCI Express device Functions are required to provide a Configuration Space for software-driven initialization and configuration. Except for the differences described in this chapter, the PCI Express Configuration Space headers are organized to correspond with the format and behavior defined in the [PCI] (Section 6.1).

The PCI-compatible Configuration Access Mechanism uses the same Request format as the ECAM. For PCI-compatible Configuration Requests, the Extended Register Address field must be all zeros.

150. The mechanism defined in § Section 7.2.1 and the ECAM mechanism defined in § Section 7.2.2 and operate independently from each other; there is no implied ordering between the two.

7.2.2 PCI Express Enhanced Configuration Access Mechanism (ECAM) §

For systems that are PC-compatible, or that do not implement a processor-architecture-specific firmware interface standard that allows access to the Configuration Space, the **Enhanced Configuration Access Mechanism (ECAM)** is required as defined in this section.

For systems that implement a processor-architecture-specific firmware interface standard that allows access to the Configuration Space, the operating system uses the standard firmware interface, and the hardware access mechanism defined in this section is not required.

In all systems, device drivers are encouraged to use the application programming interface (API) provided by the operating system to access the Configuration Space of its device and not directly use the hardware mechanism.

The ECAM utilizes a flat memory-mapped address space to access device configuration registers. In this case, the memory address determines the configuration register accessed and the memory data updates (for a write) or returns the contents of (for a read) the addressed register. The mapping from memory address space to PCI Express Configuration Space address is defined in § Table 7-1.

The size and base address for the range of memory addresses mapped to the Configuration Space are determined by the design of the host bridge and the firmware. They are reported by the firmware to the operating system in an implementation specific manner. The size of the range is determined by the number of bits that the host bridge maps to the Bus Number field in the configuration address. In § Table 7-1, this number of bits is represented as n , where $1 \leq n \leq 8$. A host bridge that maps n memory address bits to the Bus Number field supports Bus Numbers from 0 to $2^n - 1$, inclusive, and the base address of the range is aligned to a $2^{(n+20)}$ -byte memory address boundary. Any bits in the Bus Number field that are not mapped from memory address bits must be Clear.

For example, if a system maps three memory address bits to the Bus Number field, the following are all true:

- $n = 3$.
- Address bits A[63:23] are used for the base address, which is aligned to a 2^{23} -byte (8 MB) boundary.
- Address bits A[22:20] are mapped to bits [2:0] in the Bus Number field.
- Bits [7:3] in the Bus Number field are set to Clear.
- The system is capable of addressing Bus Numbers between 0 and 7, inclusive.

A minimum of one memory address bit ($n = 1$) must be mapped to the Bus Number field. Systems are encouraged to map additional memory address bits to the Bus Number field as needed to support a larger number of buses. Systems that support more than 4 GB of memory addresses are encouraged to map eight bits of memory address ($n = 8$) to the Bus Number field. Note that in systems that include multiple host bridges with different ranges of Bus Numbers assigned to each host bridge, the highest Bus Number for the system is limited by the number of bits mapped by the host bridge to which the highest bus number is assigned. In such a system, the highest Bus Number assigned to a particular host bridge would be greater, in most cases, than the number of buses assigned to that host bridge. In other words, for each host bridge, the number of bits mapped to the Bus Number field, n , must be large enough that the highest Bus Number assigned to each particular bridge must be less than or equal to $2^n - 1$ for that bridge.

In some processor architectures, it is possible to generate memory accesses that cannot be expressed in a single Configuration Request, for example due to crossing a DW aligned boundary, or because a locked access is used. A Root Complex implementation is not required to support the translation to Configuration Requests of such accesses.

Table 7-1 Enhanced Configuration Address Mapping [§]

Memory Address ¹⁵¹	PCI Express Configuration Space
A[(20+n-1):20]	Bus Number $1 \leq n \leq 8$
A[19:15]	Device Number
A[14:12]	Function Number
A[11:8]	Extended Register Number
A[7:2]	Register Number
A[1:0]	Along with size of the access, used to generate Byte Enables

Note: for Requests targeting Extended Functions in an ARI Device, A[19:12] represents the (8-bit) Function Number, which replaces the (5-bit) Device Number and (3-bit) Function Number fields above.

The system hardware must provide a method for the system software to guarantee that a write transaction using the ECAM is completed by the completer before system software execution continues.

¹⁵¹. This address refers to the byte-level address from a software point of view.

IMPLEMENTATION NOTE: ORDERING CONSIDERATIONS FOR THE ENHANCED CONFIGURATION ACCESS MECHANISM §

The ECAM converts memory transactions from the host CPU into Configuration Requests on the PCI Express fabric. This conversion potentially creates ordering problems for the software, because writes to memory addresses are typically posted transactions but writes to Configuration Space are not posted on the PCI Express fabric.

Generally, software does not know when a posted transaction is completed by the completer. In those cases in which the software must know that a posted transaction is completed by the completer, one technique commonly used by the software is to read the location that was just written. For systems that follow the PCI ordering rules throughout, the read transaction will not complete until the posted write is complete. However, since the PCI ordering rules allow non-posted write and read transactions to be reordered with respect to each other, the CPU must wait for a non-posted write to complete on the PCI Express fabric to be guaranteed that the transaction is completed by the completer.

As an example, software may wish to configure a device Function's Base Address register by writing to the device using the ECAM, and then read a location in the memory-mapped range described by this Base Address register. If the software were to issue the memory-mapped read before the ECAM write was completed, it would be possible for the memory-mapped read to be re-ordered and arrive at the device before the Configuration Write Request, thus causing unpredictable results.

To avoid this problem, processor and host bridge implementations must ensure that a method exists for the software to determine when the write using the ECAM is completed by the completer.

This method may simply be that the processor itself recognizes a memory range dedicated for mapping ECAM accesses as unique, and treats accesses to this range in the same manner that it would treat other accesses that generate non-posted writes on the PCI Express fabric, i.e., that the transaction is not posted from the processor's viewpoint. An alternative mechanism is for the host bridge (rather than the processor) to recognize the memory-mapped Configuration Space accesses and not to indicate to the processor that this write has been accepted until the non-posted Configuration Transaction has completed on the PCI Express fabric. A third alternative would be for the processor and host bridge to post the memory-mapped write to the ECAM and for the host bridge to provide a separate register that the software can read to determine when the Configuration Write Request has completed on the PCI Express fabric. Other alternatives are also possible.

IMPLEMENTATION NOTE: GENERATING CONFIGURATION REQUESTS §

Because Root Complex implementations are not required to support the generation of Configuration Requests from accesses that cross DW boundaries, or that use locked semantics, software should take care not to cause the generation of such accesses when using the memory-mapped ECAM unless it is known that the Root Complex implementation being used will support the translation.

7.2.2.1 Host Bridge Requirements §

For those systems that implement the ECAM, the PCI Express Host Bridge is required to translate the memory-mapped PCI Express Configuration Space accesses from the host processor to PCI Express configuration transactions. The use of Host Bridge PCI class code is Reserved for backwards compatibility; Host Bridge Configuration Space is opaque to standard PCI Express software and may be implemented in an implementation specific manner that is compatible with PCI Host Bridge Type 0 Configuration Space. A PCI Express Host Bridge is not required to signal errors through a Root Complex Event Collector. This support is optional for PCI Express Host Bridges.

7.2.2.2 PCI Express Device Requirements §

Devices must support an additional 4 bits for decoding configuration register access, i.e., they must decode the Extended Register Address[3:0] field of the Configuration Request header.

IMPLEMENTATION NOTE: DEVICE-SPECIFIC REGISTERS IN CONFIGURATION SPACE §

It is strongly recommended that PCI Express devices place no registers in Configuration Space other than those in headers or Capability structures architected by applicable PCI specifications.

Device-specific registers that have legitimate reasons to be placed in Configuration Space (e.g., they need to be accessible before Memory Space is allocated) should be placed in a Vendor-Specific Capability structure (§ Section 7.9.4), a Vendor-Specific Extended Capability structure (§ Section 7.9.5, or § Section 7.9.6).

Device-specific registers accessed in the run-time environment by drivers should be placed in Memory Space that is allocated by one or more Base Address registers. Even though PCI-compatible or PCI Express Extended Configuration Space may have adequate room for run-time device-specific registers, placing them there is highly discouraged for the following reasons:

- Not all Operating Systems permit drivers to access Configuration Space directly.
- Some platforms provide access to Configuration Space only via firmware calls, which typically have substantially lower performance compared to mechanisms for accessing Memory Space.
- Even on platforms that provide direct access to a memory-mapped PCI Express Enhanced Configuration Mechanism, performance for accessing Configuration Space will typically be significantly lower than for accessing Memory Space since:
 - Configuration Reads and Writes must usually be DWORD or smaller in size,
 - Configuration Writes are usually not posted by the platform, and
 - Some platforms support only one outstanding Configuration Write at a time.

IMPLEMENTATION NOTE:

CONFIGURATION SPACE READ SIDE EFFECTS §

During a read access, any observable interaction that occurs besides the desired value being returned is called a read side effect. System software that has no specific knowledge of the Function being accessed may issue read requests to anywhere within the Function's Configuration Space. It is highly undesirable that any such access has any read side effects. No such side effects are required in any of the Configuration Space registers defined in this specification. It is strongly recommended that any implementation of those registers, as well as any vendor-defined Configuration Space registers, be free of any read side effects.

7.2.3 Root Complex Register Block (RCRB) §

A Root Port or RCiEP may be associated with an optional 4096-byte block of memory mapped registers referred to as the Root Complex Register Block (RCRB). These registers are used in a manner similar to Configuration Space and can include PCI Express Extended Capabilities and other implementation specific registers that apply to the Root Complex. The structure of the RCRB is described in § Section 7.6.2 .

Multiple Root Ports or internal devices are permitted to be associated with the same RCRB. The RCRB memory-mapped registers must not reside in the same address space as the memory-mapped Configuration Space or Memory Space.

A Root Complex implementation is not required to support accesses to an RCRB that cross DWORD aligned boundaries or accesses that use locked semantics.

IMPLEMENTATION NOTE:

ACCESSING ROOT COMPLEX REGISTER BLOCK §

Because Root Complex implementations are not required to support accesses to a RCRB that cross DW boundaries, or that use locked semantics, software should take care not to cause the generation of such accesses when accessing a RCRB unless the Root Complex will support the access.

7.3 Configuration Transaction Rules §

7.3.1 Device Number §

With non-ARI Devices, PCI Express components are restricted to implementing a single Device Number on their primary interface (Upstream Port), but are permitted to implement up to eight independent Functions within that Device Number. Each internal Function is selected based on decoded address information that is provided as part of the address portion of Configuration Request packets.

Except when FPB Routing ID mechanisms are used (see § Section 6.26), Downstream Ports that do not have ARI Forwarding enabled must associate only Device 0 with the device attached to the Logical Bus representing the Link from the Port. Configuration Requests targeting the Bus Number associated with a Link specifying Device Number 0 are delivered to the device attached to the Link; Configuration Requests specifying all other Device Numbers (1-31) must be terminated by the Switch Downstream Port or the Root Port with an Unsupported Request Completion Status (equivalent to Master Abort in PCI).

Non-ARI Devices must capture their assigned Device Number as discussed in § Section 2.2.6.2 . Non-ARI Devices must respond to all Type 0 Configuration Read Requests, regardless of the Device Number specified in the Request.

Switches, and components wishing to incorporate more than eight Functions at their Upstream Port, are permitted to implement one or more “virtual switches” represented by multiple Type 1 Configuration Space Headers (PCI-PCI Bridge) as illustrated in § Figure 7-2. These virtual switches serve to allow fan-out beyond eight Functions. FPB provides a “flattening” mechanism that, when enabled, causes the virtual bridges of the Downstream Ports to appear in configuration space at RID addresses following the RID of the Upstream Port (see § Section 6.26). Since Switch Downstream Ports are permitted to appear on any Device Number, in this case all address information fields (Bus, Device, and Function Numbers) must be completely decoded to access the correct register. Any Configuration Request targeting an unimplemented Bus, Device, or Function must return a Completion with Unsupported Request Completion Status.

With an ARI Device, its Device Number is implied to be 0 rather than specified by a field within an ID. The traditional 5-bit Device Number and 3-bit Function Number fields in its associated Routing IDs, Requester IDs, and Completer IDs are interpreted as a single 8-bit Function Number. See § Section 6.13 . Any Type 0 Configuration Request targeting an unimplemented Function in an ARI Device must be handled as an Unsupported Request.

If an ARI Downstream Port has ARI Forwarding enabled, the logic that determines when to turn a Type 1 Configuration Request into a Type 0 Configuration Request no longer enforces a restriction on the traditional Device Number field being 0.

The following section provides details of the Configuration Space addressing mechanism.

7.3.2 Configuration Transaction Addressing §

PCI Express Configuration Requests use the following addressing fields:

- Destination Segment (Flit Mode only) - Selects one of multiple Segments that may be implemented within a Root Complex. See § Section 2.2.1.2 for a list of Segment rules.
- Bus Number - PCI Express maps logical PCI Bus Numbers onto PCI Express Links such that PCI-compatible configuration software views the Configuration Space of a PCI Express Hierarchy as a PCI hierarchy including multiple bus segments.
- Device Number - Device Number association is discussed in § Section 7.3.1 and in § Section 6.26 . When an ARI Device is targeted and the Downstream Port immediately above it is enabled for ARI Forwarding, the Device Number is implied to be 0, and the traditional Device Number field is used instead as part of an 8-bit Function Number field. See § Section 6.13 .
- Function Number - PCI Express also supports Multi-Function Devices using the same discovery mechanism as PCI. A Multi-Function Device must fully decode the Function Number field. A single-Function Device *MUST@FLIT* also fully decode the Function Number field. With ARI Devices, discovery and enumeration of Extended Functions require ARI-aware software. See § Section 6.13 .
- Extended Register Number and Register Number - Specify the Configuration Space address of the register being accessed (concatenated such that the Extended Register Number forms the more significant bits).

7.3.3 Configuration Request Routing Rules §

For Endpoints, the following rules apply:

- If Configuration Request Type is 1,
 - and the TLP is not an IDE TLP

- and it is targeting a Device's captured Bus Number (See § [Section 9.2.1.2](#) for SRIOV devices that consume multiple Bus numbers)
 - Follow the rules for handling Unsupported Requests
- If Configuration Request Type is 0, or if Configuration Request Type is 1 and the TLP is an IDE TLP associated with a Selective IDE Stream in the Secure state,
 - Determine if the Request addresses a valid local Configuration Space of an implemented Function
 - If so, process the Request
 - If not, follow rules for handling Unsupported Requests

For Root Ports, Switches, and PCI Express-PCI Bridges, the following rules apply:

- Propagation of Configuration Requests from Downstream to Upstream as well as peer-to-peer are not supported
 - Configuration Requests are initiated only by the Host Bridge, including those passed through the [SFI CAM](#) mechanism
- If Configuration Request Type is 0,
 - Determine if the Request addresses a valid local Configuration Space of an implemented Function
 - If so, process the Request
 - If not, follow rules for handling Unsupported Requests
- If Configuration Request Type is 1, apply the following tests, in sequence, to the Bus Number and Device Number fields:
 - If in the case of a PCI Express-PCI Bridge, equal to the Bus Number assigned to secondary PCI bus or, in the case of a Switch or Root Complex, equal to the Bus Number and decoded Device Numbers assigned to one of the Root (Root Complex) or Downstream Ports (Switch), or if required based on the FPB Routing ID mechanism,
 - Transform the Request to Type 0 by changing the value in the Type[4:0] field of the Request (see § [Table 2-3](#)) - all other fields of the Request remain unchanged
 - Forward the Request to that Downstream Port (or PCI bus, in the case of a PCI Express-PCI Bridge)
 - If not equal to the Bus Number of any of Downstream Ports or secondary PCI bus, but in the range of Bus Numbers assigned to either a Downstream Port or a secondary PCI bus, or if required based on the FPB Routing ID mechanism,
 - Forward the Request to that Downstream Port interface without modification
 - Else (none of the above)
 - The Request is invalid - follow the rules for handling Unsupported Requests
- PCI Express-PCI Bridges must terminate as Unsupported Requests any Configuration Requests for which the Extended Register Address field is non-zero that are directed towards a PCI bus that does not support Extended Configuration Space.

Note: This type of access is a consequence of a programming error.

Additional rule specific to Root Complexes:

- Configuration Requests addressing a Destination Segment and Bus Numbers assigned to devices within the Root Complex are processed by the Root Complex
 - The assignment of Segment Numbers and Bus Numbers to the devices within a Root Complex may be done in an implementation specific way.

For all types of devices:

Configuration Reads and Writes to unimplemented registers are not considered to be errors. Unless errors defined elsewhere in this specification are detected and need to be reported, such Requests must return a Completion with Successful Completion status, with reads returning a data value of all 0's and writes discarding the write data without effect.

All other Configuration Space addressing fields are decoded as described elsewhere in this specification.

7.3.4 PCI Special Cycles §

PCI Special Cycles (see the [PCI] for details) are not directly supported by PCI Express. PCI Special Cycles may be directed to PCI bus segments behind PCI Express-PCI Bridges using Type 1 configuration cycles as described in the [PCI].

7.4 Configuration Register Types §

Configuration register fields are assigned one of the attributes described in § Table 7-2. All PCI Express components, with the exception of the Root Complex and system-integrated devices, initialize register fields to specified default values. Root Complexes and system-integrated devices initialize register fields as required by the firmware for a particular system implementation.

Table 7-2 Register and Register Bit-Field Types §

Register Attribute	Description
Hwlnit	Hardware Initialized - Register bits are permitted, as an implementation option, to be hard-coded, initialized by system/device firmware, or initialized by hardware mechanisms such as pin strapping or nonvolatile storage. ¹⁵² Initialization by system firmware is permitted only for system-integrated devices. Bits must be fixed in value and read-only after initialization. After Initialization, values are only permitted to change following Conventional Reset (see § Section 6.6.1) and subsequent re-initialization. <u>Hwlnit</u> register bits are not modified by an <u>FLR</u> .
RO	Read-only - Register bits are read-only and cannot be altered by software. Where explicitly defined, these bits are used to reflect changing hardware state, and as a result bit values can be observed to change at run time. ¹⁵³ Register bit default values and bits that cannot change value at run time, are permitted to be hard-coded, initialized by system/device firmware, or initialized by hardware mechanisms such as pin strapping or nonvolatile storage. Initialization by system firmware is permitted only for system-integrated devices. If the optional feature that would Set the bits is not implemented, the bits must be hardwired to Zero.
RW	Read-Write - Register bits are read-write and are permitted to be either Set or Cleared by software to the desired state. If the optional feature that is associated with the bits is not implemented, the bits are permitted to be hardwired to Zero.
RW1C	Write-1-to-clear status - Register bits indicate status when read. A Set bit indicates a status event which is Cleared by writing a 1b. Writing a 0b to <u>RW1C</u> bits has no effect. If the optional feature that would Set the bit is not implemented, the bit must be read-only and hardwired to Zero.

152. For historical reasons, readers may observe inconsistencies in this document in the use of Hwlnit and RO. As this document is revised we will attempt to ensure that new definitions conform to the definitions given here.

153. For historical reasons, readers may observe inconsistencies in this document in the use of Hwlnit and RO. As this document is revised we will attempt to ensure that new definitions conform to the definitions given here.

Register Attribute	Description
ROS	<p>Sticky - Read-only - Register bits are read-only and cannot be altered by software. If the optional feature that would Set the bit is not implemented, the bit is hardwired to Zero. Bits are neither initialized nor modified by hot reset or FLR.¹⁵⁴</p> <p>Where noted, devices that consume auxiliary power must preserve sticky register bit values when auxiliary power consumption (via either Aux Power PM Enable or PME_En) is enabled. In these cases, register bits are neither initialized nor modified by Hot, Warm, or Cold Reset (see § Section 6.6).</p>
RWS	<p>Sticky - Read-Write - Register bits are read-write and are Set or Cleared by software to the desired state. Bits are neither initialized nor modified by hot reset or FLR.¹⁵⁵</p> <p>If the optional feature that is associated with the bits is not implemented, the bits are permitted to be hardwired to Zero.</p> <p>Where noted, devices that consume auxiliary power must preserve sticky register bit values when auxiliary power consumption (via either Aux Power PM Enable or PME_En) is enabled. In these cases, register bits are neither initialized nor modified by Hot, Warm, or Cold Reset (see § Section 6.6).</p>
RW1CS	<p>Sticky - Write-1-to-clear status - Register bits indicate status when read. A Set bit indicates a status event which is Cleared by writing a 1b. Writing a 0b to RW1CS bits has no effect. If the optional feature that would Set the bit is not implemented, the bit is read-only and hardwired to Zero. Bits are neither initialized nor modified by hot reset or FLR.¹⁵⁶</p> <p>Where noted, devices that consume auxiliary power must preserve sticky register bit values when auxiliary power consumption (via either Aux Power PM Enable or PME_En) is enabled. In these cases, register bits are neither initialized nor modified by Hot, Warm, or Cold Reset (see § Section 6.6).</p>
RsvdP	<p>Reserved and Preserved - Reserved for future RW implementations. Register bits are read-only and must return zero when read. Software must preserve the value read for writes to bits.</p>
RsvdZ	<p>Reserved and Zero - Reserved for future RW1C implementations. Register bits are read-only and must return zero when read. Software must use 0b for writes to bits.</p>

For SR-IOV devices, many registers or fields in VFs are required to be reserved or hardwired to Zero. Before the Single Root I/O Virtualization and Sharing (SR-IOV) Specification was merged into the PCI Express Base Specification, the SR-IOV specification contained many tables summarizing requirements differences for PFs and VFs, relative to the Base specification. These tables contained dedicated columns for PF attributes and VF attributes, though there were relatively few differences for PF attributes.

To provide a clear, consolidated, and concise indication of PF and VF attribute differences from other Function types, this specification eliminated most of those tables. Instead, special field types from the following table indicate VF attribute differences, and any additional attribute or semantic differences with PFs and VFs are covered within the register description column or elsewhere.

154. Bits/fields with the “Sticky” attribute must be implemented such that no Function-specific software or firmware is required to maintain the observed state of the bit/field. Particularly for power management scenarios, it is permitted, but not recommended, to use Function-specific software or firmware to restore the correct values, provided this is done before the system hardware or system software could observe incorrect values. How this could be done is outside the scope of this document.
155. Bits/fields with the “Sticky” attribute must be implemented such that no Function-specific software or firmware is required to maintain the observed state of the bit/field. Particularly for power management scenarios, it is permitted, but not recommended, to use Function-specific software or firmware to restore the correct values, provided this is done before the system hardware or system software could observe incorrect values. How this could be done is outside the scope of this document.
156. Bits/fields with the “Sticky” attribute must be implemented such that no Function-specific software or firmware is required to maintain the observed state of the bit/field. Particularly for power management scenarios, it is permitted, but not recommended, to use Function-specific software or firmware to restore the correct values, provided this is done before the system hardware or system software could observe incorrect values. How this could be done is outside the scope of this document.

Table 7-3 Special Field Types to Indicate VF Attributes §

Register Attribute	Description
VF ROZ	VF RO-Zero - VF register bits must have <u>RO</u> semantics and be hardwired to Zero.
VF RsvdP	VF RsvdP - VF register bits must have <u>RsvdP</u> semantics.
VF RsvdZ	VF RsvdZ - VF register bits must have <u>RsvdZ</u> semantics.

7.5 PCI and PCIe Capabilities Required by the Base Spec for all Ports §

The following registers and capabilities are required by this specification in all Functions, including PFs and VFs.

Except where noted, VF register fields and bits have the same attributes as other Functions. For VF fields marked RsvdP, the associated PF's setting applies to the VF.

7.5.1 PCI-Compatible Configuration Registers §

The first 256 bytes of a Function's Configuration Space form the PCI-compatible region. This region completely aliases the conventional PCI Configuration Space of the Function. Legacy PCI devices can also be accessed with the ECAM without requiring any modifications to the device hardware or device driver software.

Layout of the Configuration Space and format of individual configuration registers are depicted following the little-endian convention.

7.5.1.1 Type 0/1 Common Configuration Space §

§ Figure 7-4 details allocation for common register fields of Type 0 and Type 1 Configuration Space Headers for PCI Express Device Functions. Fields labeled Type Specific vary between different Configuration Space header types.

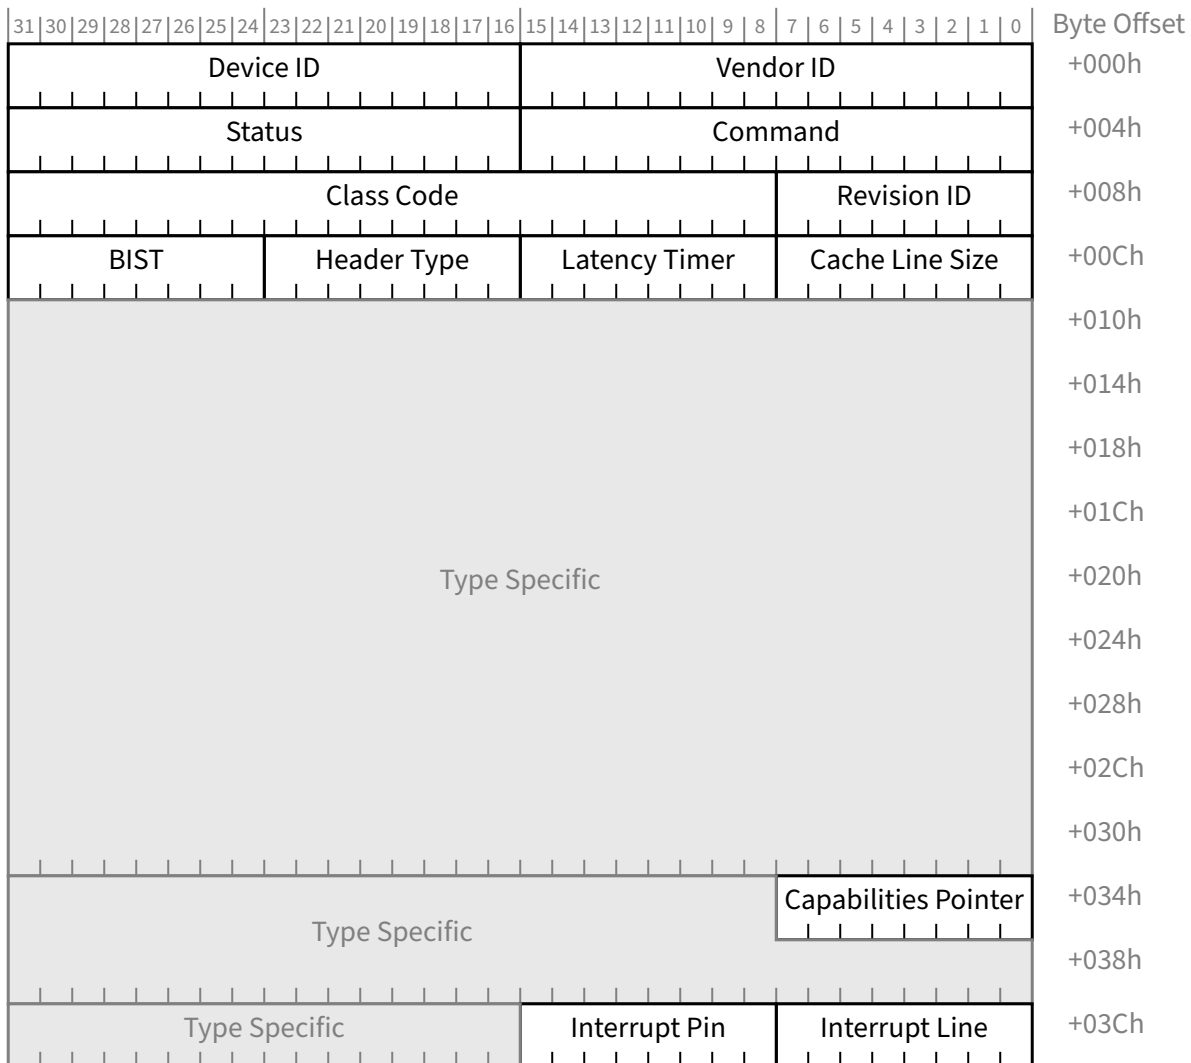

Figure 7-4 Common Configuration Space Header §

These registers are defined for both Type 0 and Type 1 Configuration Space Headers. The PCI Express-specific interpretation of these registers is defined in this section.

7.5.1.1.1 Vendor ID Register (Offset 00h) §

For non-VFs, the Vendor ID register is HwInit and the value in this register identifies the manufacturer of the Function. In keeping with PCI-SIG procedures, valid vendor identifiers must be allocated by the PCI-SIG to ensure uniqueness. Each vendor must have at least one Vendor ID. It is recommended that software read the Vendor ID register to determine if a Function is present, where a value of FFFFh indicates that no Function is present.

For VFs, this field must return FFFFh when read. VI software should return the Vendor ID value from the associated PF as the Vendor ID value for the VF.

7.5.1.1.2 Device ID Register (Offset 02h) §

For non-VFs, the Device ID register is `Hwlnit` and the value in this register identifies the particular Function. The Device ID must be allocated by the vendor. The Device ID, in conjunction with the Vendor ID and Revision ID, are used as one mechanism for software to determine which driver should be loaded. The vendor must ensure that the chosen values do not result in the use of an incompatible device driver.

For VFs, this field must return `FFFFh` when read. VI software should return the VF Device ID (see § Section 9.3.3.11) value from the associated PF as the Device ID for the VF.

IMPLEMENTATION NOTE: LEGACY PCI PROBING SOFTWARE §

Returning `FFFFh` for Device ID and Vendor ID values allows some legacy software to ignore VFs. See § Section 7.5.1.1.1.

7.5.1.1.3 Command Register (Offset 04h) §

§ Table 7-4 defines the Command Register and the layout of the register is shown in § Figure 7-5. Individual bits in the Command Register may or may not be implemented depending on the feature set supported by the Function. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-X-Bridge] for requirements for this register.

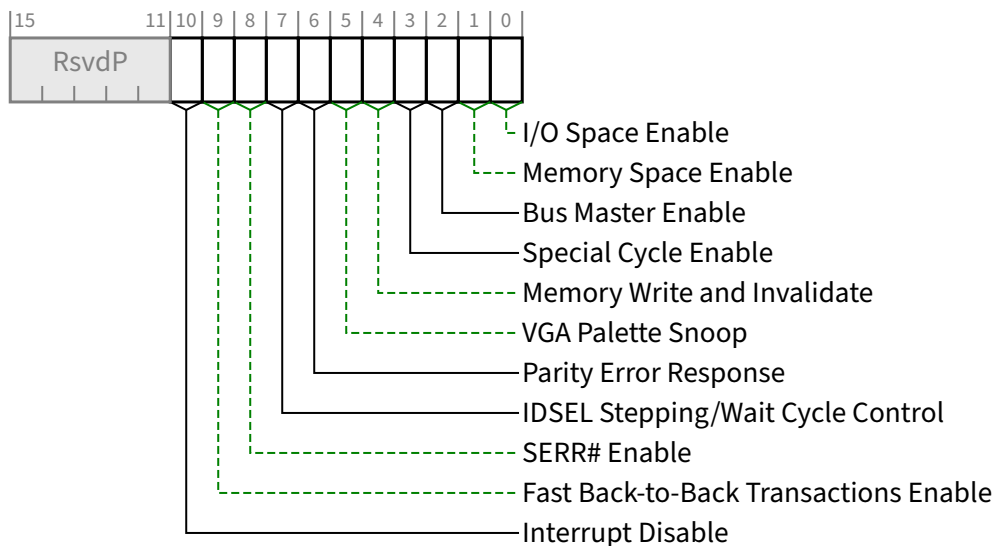

Figure 7-5 Command Register §

Table 7-4 Command Register [§]

Bit Location	Register Description	Attributes
0	<p>I/O Space Enable - Controls a Function's response to I/O Space accesses. When this bit is Clear, all received I/O accesses are caused to be handled as Unsupported Requests. When this bit is Set, the Function is enabled to decode the address and further process I/O Space accesses. For a Function with a <u>Type 1 Configuration Space Header</u>, this bit controls the response to I/O Space accesses received on its <u>Primary Side</u>.</p> <p>Default value of this bit is 0b.</p> <p>This bit is permitted to be hardwired to Zero if a Function does not support I/O Space accesses.</p> <p>This bit does not apply to VFs and must be hardwired to Zero.</p>	<p><u>RW</u></p> <p><u>VF ROZ</u></p>
1	<p>Memory Space Enable - Controls a Function's response to Memory Space accesses. When this bit is Clear, all received Memory Space accesses are caused to be handled as Unsupported Requests. When this bit is Set, the Function is enabled to decode the address and further process Memory Space accesses. For a Function with a <u>Type 1 Configuration Space Header</u>, this bit controls the response to Memory Space accesses received on its <u>Primary Side</u>.</p> <p>Default value of this bit is 0b.</p> <p>This bit is permitted to be hardwired to 0b if a Function does not support Memory Space accesses.</p> <p>This bit does not apply to VFs and must be hardwired to <u>Zero</u>. VF Memory Space is controlled by the VF MSE bit in the <u>SR-IOV Control Register</u>.</p>	<p><u>RW</u></p> <p><u>VF ROZ</u></p>
2	<p>Bus Master Enable - Controls the ability of a Function to issue Memory ¹⁵⁷ and I/O Read/Write Requests, and the ability of a Port to forward Memory and I/O Read/Write Requests in the Upstream direction</p> <ul style="list-style-type: none"> <p>Functions with a Type 0 Configuration Space Header:</p> <p>When this bit is Set, the Function is allowed to issue Memory or I/O Requests.</p> <p>When this bit is Clear, the Function is not allowed to issue any Memory or I/O Requests.</p> <p>Note that as MSI/MSI-X interrupt Messages are in-band memory writes, setting the <u>Bus Master Enable</u> bit to 0b disables MSI/MSI-X interrupt Messages as well.</p> <p>Transactions for a VF that has its Bus Master Enable Set must not be blocked by transactions for VFs that have their Bus Master Enable Cleared.</p> <p>Requests other than Memory or I/O Requests are not controlled by this bit.</p> <p>Default value of this bit is 0b.</p> <p>This bit is hardwired to 0b if a Function does not generate Memory or I/O Requests.</p> <p>Functions with a Type 1 Configurations Space Header:</p> <p>This bit controls the initiating of and the forwarding of Memory or I/O Requests by a Port in the Upstream direction. When this bit is 0b, Memory and I/O Requests received at a Root Port or the Downstream side of a Switch Port must be handled as Unsupported Requests (UR), and for Non-Posted Requests a Completion with UR Completion Status must be returned. This bit does not affect forwarding of Completions in either the Upstream or Downstream direction.</p> <p>The forwarding of Requests other than Memory or I/O Requests is not controlled by this bit.</p> <p>Default value of this bit is 0b.</p> 	<p><u>RW</u></p>
3	<p>Special Cycle Enable - This bit was originally described in the <u>[PCI]</u>. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.</p>	<p><u>RO</u></p>

157. The AtomicOp Requester Enable bit in the Device Control 2 register must also be Set in order for an AtomicOp Requester to initiate AtomicOp Requests, which are Memory Requests.

Bit Location	Register Description	Attributes
4	Memory Write and Invalidate - This bit was originally described in the [PCI] and the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-PCI-X-Bridge] for requirements for this register.	RO
5	VGA Palette Snoop - This bit was originally described in the [PCI] and the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
6	Parity Error Response - See § Section 7.5.1.1.14 . This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status Register. An RCiEP that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b. Default value of this bit is 0b.	RW VF RsvdP
7	IDSEL Stepping/Wait Cycle Control - This bit was originally described in the [PCI]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
8	SERR# Enable - See § Section 7.5.1.1.14 . When Set, this bit enables reporting upstream of Non-fatal and Fatal errors detected by the Function. Note that errors are reported if enabled either through this bit or through the PCI Express specific bits in the Device Control Register (see § Section 7.5.3.4). In addition, for Functions with Type 1 Configuration Space Headers, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error Messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages. An RCiEP that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b. Default value of this bit is 0b.	RW VF RsvdP
9	Fast Back-to-Back Transactions Enable - This bit was originally described in the [PCI]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
10	Interrupt Disable - Controls the ability of a Function to generate INTx emulation interrupts. When Set, Functions are prevented from asserting INTx interrupts. Any INTx emulation interrupts already asserted by the Function must be deasserted when this bit is Set. As described in § Section 2.2.8.1 , INTx interrupts use virtual wires that must, if asserted, be deasserted using the appropriate Deassert_INTx message(s) when this bit is Set. Only the INTx virtual wire interrupt(s) associated with the Function(s) for which this bit is Set are affected. For Functions with a Type 0 Configuration Space Header that generate INTx interrupts, this bit is required. For Functions with a Type 0 Configuration Space Header that do not generate INTx interrupts, this bit is optional. If not implemented, this bit must be hardwired to 0b. For Functions with a Type 1 Configuration Space Header that generate INTx interrupts on their own behalf, this bit is required. This bit has no effect on interrupts forwarded from the secondary side. For Functions with a Type 1 Configuration Space Header that do not generate INTx interrupts on their own behalf this bit is optional. If not implemented, this bit must be hardwired to 0b. Default value of this bit is 0b. This bit does not apply to VFs and must be hardwired to Zero.	RW VF ROZ

7.5.1.1.4 Status Register (Offset 06h) §

§ Table 7-5 defines the Status Register and the layout of the register is shown in § Figure 7-6. Functions may not need to implement all bits, depending on the feature set supported by the Function. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-PCI-X-Bridge] for requirements for this register.

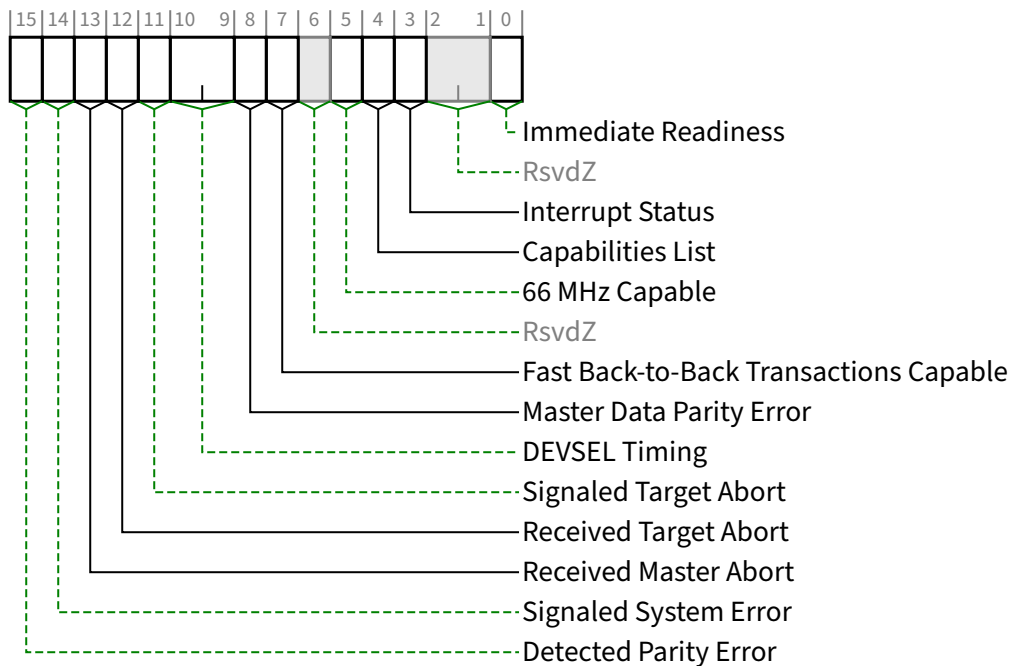

Figure 7-6 Status Register §

Table 7-5 Status Register §

Bit Location	Register Description	Attributes
0	<p>Immediate Readiness - This optional bit, when Set, indicates the Function is guaranteed to be ready to successfully complete valid Configuration Requests at any time. It is permitted for this indication to be based on implementation specific knowledge of how long it takes the host to become ready to issue Configuration Requests.</p> <p>When this bit is Set, for accesses to this Function, software is exempt from all requirements to delay configuration accesses following any type of reset, including but not limited to the timing requirements defined in § Section 6.6 .</p> <p>How this guarantee is established is beyond the scope of this document.</p> <p>It is permitted that system software/firmware provide mechanisms that supersede the indication provided by this bit, however such software/firmware mechanisms are outside the scope of this specification.</p>	RO
3	<p>Interrupt Status - When Set, indicates that an INTx emulation interrupt is pending internally in the Function.</p>	RO VF ROZ

Bit Location	Register Description	Attributes
	<p>Note that INTx emulation interrupts forwarded by Functions with a <u>Type 1 Configuration Space Header</u> from the secondary side are not reflected in this bit.</p> <p>Setting the Interrupt Disable bit has no effect on the state of this bit.</p> <p>Functions that do not generate INTx interrupts are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p> <p>This bit does not apply to VFs and must be hardwired to Zero.</p>	
4	<p>Capabilities List - Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, this bit must be hardwired to 1b.</p>	RO
5	<p>66 MHz Capable - This bit was originally described in the [PCI]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.</p>	RO
7	<p>Fast Back-to-Back Transactions Capable - This bit was originally described in the [PCI]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.</p>	RO
8	<p>Master Data Parity Error - See § Section 7.5.1.1.14</p> <p>This bit is Set by a Function with a <u>Type 0 Configuration Space Header</u> if the <u>Parity Error Response</u> bit in the <u>Command Register</u> is 1b and either of the following two conditions occurs:</p> <ul style="list-style-type: none"> Function receives a Poisoned Completion Function transmits a Poisoned Request <p>This bit is Set by a Function with a <u>Type 1 Configuration Space Header</u> if the <u>Parity Error Response</u> bit in the <u>Command Register</u> is 1b and either of the following two conditions occurs:</p> <ul style="list-style-type: none"> Port receives a Poisoned Completion going Downstream Port transmits a Poisoned Request Upstream <p>If the <u>Parity Error Response</u> bit is 0b, this bit is never Set.</p> <p>Default value of this bit is 0b.</p>	RW1C
10:9	<p>DEVSEL Timing - This field was originally described in the [PCI]. Its functionality does not apply to PCI Express and the field must be hardwired to 00b.</p>	RO
11	<p>Signaled Target Abort - See § Section 7.5.1.1.14 .</p> <p>This bit is Set when a Function completes a Posted or Non-Posted Request as a Completer Abort error. This applies to a Function with a <u>Type 1 Configuration Space Header</u> when the Completer Abort was generated by its Primary Side.</p> <p>Functions with a <u>Type 0 Configuration Space Header</u> that do not signal Completer Abort are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW1C
12	<p>Received Target Abort - See § Section 7.5.1.1.14 .</p> <p>On a Function with a <u>Type 0 Configuration Space Header</u>, this bit is Set when a Requester receives a Completion with Completer Abort Completion Status.</p> <p>On a Function with a <u>Type 1 Configuration Space Header</u>, this bit is Set when its Primary Side receives a Completion with Completer Abort Completion Status.</p> <p>Functions with a <u>Type 0 Configuration Space Header</u> that do not make Non-Posted Requests on their own behalf are permitted to hardwire this bit to 0b.</p>	RW1C

Bit Location	Register Description	Attributes
	Default value of this bit is 0b.	
13	<p>Received Master Abort - See § Section 7.5.1.1.14 .</p> <p>On a Function with a Type 0 Configuration Space Header, this bit is Set when a Requester receives a Completion with Unsupported Request Completion Status.</p> <p>On a Function with a Type 1 Configuration Space Header, the bit is Set when its Primary Side receives a Completion with Unsupported Request Completion Status.</p> <p>Functions with a Type 0 Configuration Space Header that do not make Non-Posted Requests on their own behalf are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW1C
14	<p>Signaled System Error - See § Section 7.5.1.1.14 .</p> <p>This bit is Set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the SERR# Enable bit in the Command Register is 1b.</p> <p>Functions with a Type 0 Configuration Space Header that do not send ERR_FATAL or ERR_NONFATAL Messages are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW1C
15	<p>Detected Parity Error - See § Section 7.5.1.1.14 .</p> <p>This bit is Set by a Function whenever it receives a Poisoned TLP, regardless of the state of the Parity Error Response bit in the Command Register. On a Function with a Type 1 Configuration Space Header, the bit is Set when the Poisoned TLP is received by its Primary Side.</p> <p>Default value of this bit is 0b.</p>	RW1C

7.5.1.1.5 Revision ID Register (Offset 08h) §

The Revision ID Register is HwInit and the value in this register specifies a Function specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. The Device ID, in conjunction with the Vendor ID and Revision ID, are used as one mechanism for software to determine which driver should be loaded. The vendor must ensure that the chosen values do not result in the use of an incompatible device driver.

The value reported in the VF may be different than the value reported in the PF.

7.5.1.1.6 Class Code Register (Offset 09h) §

The Class Code Register is read-only and is used to identify the generic operation of the Function and, in some cases, a specific register level programming interface. The register layout is shown in § Figure 7-7 and described in § Table 7-6. Encodings for base class, sub-class, and programming interface are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.

The field in a PF and its associated VFs must return the same value when read.

Figure 7-7 Class Code Register §

Table 7-6 Class Code Register §

Bit Location	Register Description	Attributes
7:0	Programming Interface - This field identifies a specific register-level programming interface (if any) so that device independent software can interact with the Function. Encodings for this field are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.	RO
15:8	Sub-Class Code - Specifies a base class sub-class, which identifies more specifically the operation of the Function. Encodings for sub-class are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.	RO
23:16	Base Class Code - A code that broadly classifies the type of operation the Function performs. Encodings for base class, are provided in the [PCI-Code-and-ID]. All unspecified encodings are Reserved.	RO

7.5.1.1.7 Cache Line Size Register (Offset 0Ch) §

The Cache Line Size register is programmed by the system firmware or the operating system to system cache line size. However, note that legacy PCI-compatible software may not always be able to program this register correctly especially in the case of Hot-Plug devices. This read-write register is implemented for legacy compatibility purposes but has no effect on any PCI Express device behavior. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-PCI-X-Bridge] for requirements for this register. The default value of this register is 00h.

This bit does not apply to VFs and must be hardwired to Zero.

7.5.1.1.8 Latency Timer Register (Offset 0Dh) §

This register is also referred to as Primary Latency Timer for Type 1 Configuration Space Header Functions. The Latency Timer was originally described in the [PCI] and the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express. This register must be hardwired to 00h.

7.5.1.1.9 Header Type Register (Offset 0Eh) §

This register identifies the layout of the second part of the predefined header (beginning at byte 10h in Configuration Space) and also whether or not the Device might contain multiple Functions. The register layout is shown in § Figure 7-8 and § Table 7-7 describes the bits in the register.

This entire register does not apply to VFs and must be hardwired to Zero.

Figure 7-8 Header Type Register §

Table 7-7 Header Type Register §

Bit Location	Register Description	Attributes
6:0	<p>Header Layout - This field identifies the layout of the second part of the predefined header.</p> <p>For Functions that implement a <u>Type 0 Configuration Space Header</u> the encoding 000 0000b must be used.</p> <p>For Functions that implement a <u>Type 1 Configuration Space Header</u> the encoding 000 0001b must be used.</p> <p>The encoding 000 0010b is Reserved. This encoding was originally described in the [PC-Card] and is used in previous versions of the programming model. Careful consideration should be given to any attempt to repurpose it.</p> <p>All other encodings are Reserved.</p>	<p>RO</p> <p>VF ROZ</p>
7	<p>Multi-Function Device - When Set, indicates that the Device may contain multiple Functions, but not necessarily. Software is permitted to probe for Functions other than Function 0. When Clear, software must not probe for Functions other than Function 0 unless explicitly indicated by another mechanism, such as an ARI or SR-IOV Extended Capability structure. Except where stated otherwise, it is recommended that this bit be Set if there are multiple Functions, and Clear if there is only one Function.</p> <p>The presence of Shadow Functions does not affect this bit.</p> <p>For an SR-IOV device, this bit is Set in non-VFs only if there are multiple non-VFs. VFs do not affect the value of bit 7.</p>	<p>RO</p> <p>VF ROZ</p>

7.5.1.1.10 BIST Register (Offset 0Fh) §

This register is used for control and status of BIST. Functions that do not support BIST must hardwire the register to 00h. VFs shall not support BIST. A Function whose BIST is invoked must not prevent normal operation of the PCI Express Link. § Table 7-8 describes the bits in the register and § Figure 7-9 shows the register layout.

For an SR-IOV device, if the VF Enable bit is Set in any PF, then software should not invoke BIST in any Function associated with that device.

Figure 7-9 BIST Register §

Table 7-8 BIST Register §

Bit Location	Register Description	Attributes
3:0	<p>Completion Code - This field encodes the status of the most recent test. A value of 0000b means that the Function has passed its test. Non-zero values mean the Function failed. Function-specific failure codes can be encoded in the non-zero values.</p> <p>This field's value is only meaningful when BIST Capable is Set and Start BIST is Clear.</p> <p>Default value of this field is 0000b.</p> <p>This field must be hardwired to 0000b if BIST Capable is Clear.</p>	<p><u>RO</u></p> <p><u>VF ROZ</u></p>
6	<p>Start BIST - If BIST Capable is Set, Set this bit to invoke BIST. The Function resets the bit when BIST is complete. Software is permitted to fail the device if this bit is not Clear (BIST is not complete) 2 seconds after it had been Set.</p> <p>Writing this bit to 0b has no effect.</p> <p>This bit must be hardwired to 0b if BIST Capable is Clear.</p>	<p><u>RW/RO</u></p> <p>(see description)</p> <p><u>VF ROZ</u></p>
7	<p>BIST Capable - When Set, this bit indicates that the Function supports BIST. When Clear, the Function does not support BIST.</p>	<p><u>HwInit</u></p> <p><u>VF ROZ</u></p>

7.5.1.1.11 Capabilities Pointer (Offset 34h) §

This register is used to point to a linked list of capabilities implemented by this Function. Since all PCI Express Functions are required to implement the PCI Express Capability structure, which must be included somewhere in this linked list; this register must be non-zero. The bottom two bits are Reserved and must be set to 00b. Software must mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. This register is HwInit.

7.5.1.1.12 Interrupt Line Register (Offset 3Ch) §

The Interrupt Line register communicates interrupt line routing information. The register is read/write and must be implemented by any Function that uses an interrupt pin (see following description). Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems. If Interrupt Pin Register is 00h, this register is permitted to be hardwired to 0b. Otherwise, the default value is implementation specific.

For VFs, this register does not apply and must be hardwired to Zero.

7.5.1.1.13 Interrupt Pin Register (Offset 3Dh) §

The Interrupt Pin register is a read-only register that identifies the legacy interrupt Message(s) the Function uses (see § Section 6.1 for further details). Valid values are 01h, 02h, 03h, and 04h that map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. A value of 00h indicates that the Function uses no legacy interrupt Message(s). The values 05h through FFh are Reserved.

PCI Express defines one legacy interrupt Message for a single Function device and up to four legacy interrupt Messages for a Multi-Function Device. For a single Function device, only INTA may be used.

Any Function on a Multi-Function Device can use any of the INTx Messages. If a device implements a single legacy interrupt Message, it must be INTA; if it implements two legacy interrupt Messages, they must be INTA and INTB; and so forth. For a Multi-Function Device, all Functions may use the same INTx Message or each may have its own (up to a maximum of four Functions) or any combination thereof. A single Function can never generate an interrupt request on more than one INTx Message.

For VFs, this register does not apply and must be hardwired to Zero.

7.5.1.1.14 Error Registers §

The Error Control/Status register bits in the Command and Status registers (see § Section 7.5.1.1.3 and § Section 7.5.1.1.4 respectively) and the Bridge Control Register and Secondary Status Register of Type 1 Configuration Space Header Functions (see § Section 7.5.1.3.10 and § Section 7.5.1.3.7 respectively) control PCI-compatible error reporting for both PCI and PCI Express device Functions. Mapping of PCI Express errors onto PCI errors is also discussed in § Section 6.2.7.1 . In addition to the PCI-compatible error control and status, PCI Express error reporting may be controlled separately from PCI device Functions through the PCI Express Capability structure described in § Section 7.5.3 . The PCI-compatible error control and status register fields do not have any effect on PCI Express error reporting enabled through the PCI Express Capability structure. PCI Express device Functions may implement optional advanced error reporting as described in § Section 7.8.4 .

For PCI Express Root Ports represented by a Type 1 Configuration Space Header:

- The primary side Error Control/Status registers apply to errors detected on the internal logic associated with the Root Complex.
- The secondary side Error Control/Status registers apply to errors detected on the Link originating from the Root Port.

For PCI Express Switch Upstream Ports represented by a Type 1 Configuration Space Header:

- The primary side Error Control/Status registers apply to errors detected on the Upstream Link of the Switch.
- The secondary side Error Control/Status registers apply to errors detected on the internal logic of the Switch.

For PCI Express Switch Downstream Ports represented by a Type 1 Configuration Space Header:

- The primary side Error Control/Status registers apply to errors detected on the internal logic of the Switch.
- The secondary side Error Control/Status registers apply to errors detected on the Downstream Link originating from the Switch Port.

7.5.1.2 Type 0 Configuration Space Header §

§ Figure 7-10 details allocation for register fields of Type 0 Configuration Space Header for PCI Express device Functions.

Figure 7-10 Type 0 Configuration Space Header §

§ Section 7.5.1.1 details the PCI Express-specific registers that are valid for all Configuration Space Header types. The PCI Express-specific interpretation of registers specific to Type 0 Configuration Space Header is defined in this section.

7.5.1.2.1 Base Address Registers (Offset 10h - 24h) §

System software must build a consistent address map before booting the machine to an operating system. This means it has to determine how much memory is in the system, and how much address space the Functions in the system require. After determining this information, system software can map the Functions into reasonable locations and proceed with

system boot. In order to do this mapping in a device-independent manner, the base registers for this mapping are placed in the predefined header portion of Configuration Space. It is strongly recommended that power-up firmware/software also support the optional Enhanced Configuration Access Mechanism (ECAM).

For VFs, these registers must be hardwired to Zero. See § Section 9.2.1.1.1 and § Section 9.3.3.14.

Bit 0 in all Base Address registers is read-only and used to determine whether the register maps into Memory or I/O Space. Base Address registers that map to Memory Space must return a 0b in bit 0 (see § Figure 7-11). Base Address registers that map to I/O Space must return a 1b in bit 0 (see § Figure 7-12).

Figure 7-11 Base Address Register for Memory §

Figure 7-12 Base Address Register for I/O §

Base Address registers that map into I/O Space are always 32 bits wide with bit 0 hardwired to 1b. Bit 1 is Reserved and must return 0b on reads and the other bits are used to map the Function into I/O Space.

Base Address registers that map into Memory Space can be 32 bits or 64 bits wide (to support mapping into a 64-bit address space) with bit 0 hardwired to 0b. For Memory Base Address registers, bits 2 and 1 have an encoded meaning as shown in § Table 7-9. Bit 3 should be set to 1b if the data is prefetchable and set to 0b otherwise. A Function is permitted to mark a range as prefetchable if there are no side effects on reads, the Function returns all bytes on reads regardless of the byte enables, and host bridges can merge processor writes into this range¹⁵⁸ without causing errors. Bits 3-0 are read-only.

Table 7-9 Memory Base Address Register Bits 2:1 Encoding §

Bits 2:1(b)	Meaning
00	Base register is 32 bits wide and can be mapped anywhere in the 32 address bit Memory Space.
01	Reserved ¹⁵⁹
10	Base register is 64 bits wide and can be mapped anywhere in the 64 address bit Memory Space.

158. Any device that has a range that behaves like normal memory should mark the range as prefetchable. A linear frame buffer in a graphics device is an example of a range that should be marked prefetchable.

159. The encoding to support memory space below 1 MB was supported in an earlier version of the PCI Local Bus Specification. System software should recognize this encoding and handle it appropriately.

Bits 2:1(b)	Meaning
11	Reserved

The number of upper bits that a Function actually implements depends on how much of the address space the Function will respond to. A 32-bit Base Address register supports a single, implementation specific, memory size that is a power of 2, from 16 bytes to 256 Bytes (I/O Space) or 128 Bytes to 2 GB (Memory Space). Each BAR must implement all appropriate upper address bits as Read-Write (i.e., a BAR must be able to be configured to any appropriately aligned address in the associated address space). A Function that wants a 1 MB memory address space (using a single 32-bit Base Address register) must implement the top 12 bits of the Address register as Read-Write, hardwiring the other address bits to 0's. The default value of Read-Write bits in BARs is implementation specific. The attributes for some of the bits in the BAR are affected by the Resizable BAR Capability, if it is implemented.

To determine how much address space a Function requires, system software should write a value of all 1's to each BAR register and then read the value back. Low-order bits of the Base Address field in each BAR must return 0's to indicate how much address space is required. Unimplemented Base Address registers must be hardwired to zero.

This design implies that all address spaces used are a power of two in size and are naturally aligned. Functions are free to consume more address space than required, but decoding down to a 4 KB space for memory is suggested for Functions that need less than that amount. For instance, a Function that has 64 bytes of registers to be mapped into Memory Space may consume up to 4 KB of address space in order to minimize the number of bits in the address decoder. Functions that do consume more address space than they use are not required to respond to the unused portion of that address space if the Function's programming model never accesses the unused space. The Function is permitted to return Unsupported Request for accesses targetting the unused locations. Functions that map control functions into I/O Space must not consume more than 256 bytes per I/O Base Address register or per each entry in the Enhanced Allocation Capability. The upper 16 bits of the I/O Base Address register may be hardwired to zero for Functions intended for 16-bit I/O systems, such as PC compatibles. However, a full 32-bit decode of I/O addresses must still be done.

IMPLEMENTATION NOTE:

SIZING A 32-BIT BASE ADDRESS REGISTER EXAMPLE §

Decode (I/O or memory) of the appropriate address space is disabled via the Command Register before sizing a Base Address register. Software saves the original value of the Base Address register, writes a value of all 1's to the register, then reads it back. Size calculation can be done from the 32 bit value read by first clearing encoding information bits (bits 1:0 for I/O, bits 3:0 for memory), inverting all 32 bits (logical NOT), then incrementing by 1. The resultant 32-bit value is the memory/I/O range size decoded by the register. Note that the upper 16 bits of the result is ignored if the Base Address register is for I/O and bits 31:16 returned zero upon read. The original value in the Base Address register is restored before re-enabling decode in the Command Register of the Function.

64-bit (memory) Base Address registers can be handled the same, except that the second 32 bit register is considered an extension of the first (i.e., bits 63:32). Software writes a value of all 1's to both registers, reads them back, and combines the result into a 64-bit value. Size calculation is done on the 64-bit value.

A Type 0 Configuration Space Header has six DWORD locations allocated for Base Address registers starting at offset 10h in Configuration Space. A Type 1 Configurations Space Header has only two DWORD locations. A Function may use any of the locations to implement Base Address registers. An implemented 64-bit Base Address register consumes two consecutive DWORD locations. Software looking for implemented Base Address registers must start at offset 10h and continue upwards through offset 24h. A typical Function requires one memory range for its control functions. Some graphics Functions use two ranges, one for control functions and another for a frame buffer. A Function that wants to map control functions into both memory and I/O Spaces at the same time must implement two Base Address registers

(one memory and one I/O). The driver for that Function might only use one space in which case the other space will be unused. Functions are recommended to always map control functions into Memory Space.

A PCI Express Function requesting Memory Space through a BAR must set the BAR's Prefetchable bit unless the range contains locations with read side effects or locations in which the Function does not tolerate write merging. It is strongly encouraged that resources mapped into Memory Space be designed as prefetchable whenever possible. PCI Express Functions other than Legacy Endpoints must support 64-bit addressing for any Base Address register that requests prefetchable Memory Space. The minimum Memory Space address range requested by a BAR is 128 bytes. The attributes for some of the bits in the BAR are affected by the Resizable BAR Capability, if it is implemented.

IMPLEMENTATION NOTE: ADDITIONAL GUIDANCE ON THE PREFETCHABLE BIT IN MEMORY SPACE BARS §

PCI Express adapters with Memory Space BARs that request a large amount of non-prefetchable Memory Space (e.g., over 64 MB) may cause shortages of that Space on certain scalable platforms, since many platforms support a total of only 1 GB or less of non-prefetchable Memory Space. This may limit the number of such adapters that can be supported on those platforms. For this reason, it is especially encouraged for BARs requesting large amounts of Memory Space to have their Prefetchable bit Set, since prefetchable Memory Space is more bountiful on most scalable platforms.

While a Memory Space BAR is required to have its Prefetchable bit Set if none of the locations within its range have read side effects and all of the locations tolerate write merging, there are system configurations where having the Prefetchable bit Set will still allow correct operation even if those conditions are not met. For those cases, it may make sense for the adapter to have the Prefetchable bit Set in certain candidate BARs so that the system can map those BARs into prefetchable Memory Space in order to avoid non-prefetchable Memory Space shortages.

On PCI Express systems that meet the criteria enumerated below, setting the Prefetchable bit in a candidate BAR will still permit correct operation even if the BAR's range includes some locations that have read side-effects or cannot tolerate write merging. This is primarily due to the fact that PCI Express Memory Reads always contain an explicit length, and PCI Express Switches never prefetch or do byte merging. Generally only 64-bit BARs are good candidates, since only Legacy Endpoints are permitted to set the Prefetchable bit in 32-bit BARs, and most scalable platforms map all 32-bit Memory BARs into non-prefetchable Memory Space regardless of the Prefetchable bit value.

Here are criteria that are sufficient to guarantee correctness for a given candidate BAR:

- The entire path from the host to the adapter is over PCI Express.
- No conventional PCI or PCI-X devices do peer-to-peer reads to the range mapped by the BAR.
- The PCI Express Host Bridge does no byte merging. (This is believed to be true on most platforms.)
- Any locations with read side-effects are never the target of Memory Reads with the TH bit Set. See § Section 2.2.5.
- The range mapped by the BAR is never the target of a speculative Memory Read, either Host initiated or peer-to-peer.

The above criteria are a simplified set that are sufficient to guarantee correctness. Other less restrictive but more complex criteria may also guarantee correctness, but are outside the scope of this specification.

7.5.1.2.2 *Cardbus CIS Pointer Register (Offset 28h)* §

This register was originally described in the [\[PC-Card\]](#). This register does not apply to PCI Express and must be hardwired to Zero.

7.5.1.2.3 *Subsystem Vendor ID Register/Subsystem ID Register (Offset 2Ch/2Eh)* §

The Subsystem Vendor ID and Subsystem ID registers are used to uniquely identify the adapter or subsystem where the PCI Express component resides. They provide a mechanism for vendors to distinguish their products from one another even though the assemblies may have the same PCI Express component on them (and, therefore, the same Vendor ID and Device ID).

Implementation of these registers is required for all Functions except those that have a Base Class 06h with Sub Class 00h-04h (00h, 01h, 02h, 03h, 04h), or a Base Class 08h with Sub Class 00h-03h (00h, 01h, 02h, 03h). Subsystem Vendor IDs can be obtained from the PCI SIG and are used to identify the vendor of the adapter, motherboard, or subsystem¹⁶⁰. A Subsystem Vendor ID (SVID) must be a Vendor ID assigned by the PCI-SIG to the vendor of the subsystem. In keeping with PCI-SIG procedures, valid vendor identifiers must be obtained from the PCI-SIG to ensure uniqueness.

Values for the Subsystem ID are vendor assigned. Subsystem ID values, in conjunction with the Subsystem Vendor ID, form a unique identifier for the PCI product. Subsystem ID and Device ID values are distinct and unrelated to each other, and software should not assume any relationship between them.

Values in these registers must be loaded before the Function becomes Configuration-Ready. How these values are loaded is not specified but could be done during the manufacturing process or loaded from external logic (e.g., strapping options, serial ROMs, etc.). These values must not be loaded using Expansion ROM software because Expansion ROM software is not guaranteed to be run during POST in all systems.

If a device is designed to be used exclusively on the system board, the system vendor may use system specific software to initialize these registers after each power-on.

The Subsystem Vendor ID register in a PF and its associated VFs must return the same value when read.

The Subsystem ID register in a PF and its associated VFs are permitted to return different values when read.

IMPLEMENTATION NOTE: SUBSYSTEM VENDOR ID AND SUBSYSTEM ID §

The Subsystem Vendor ID and Subsystem ID fields, taken together, allow software to uniquely identify a PCI circuit board product. Vendors should therefore not reuse Subsystem ID values across multiple product types that share a common Subsystem Vendor ID. It is acceptable, although not preferred, to reuse the Subsystem ID value on products with the same Subsystem Vendor ID in cases where the products are in the same family and generation, and differ only in capacity or performance. Note also that it is acceptable for vendors to use multiple unique Subsystem ID values over time for a single product type, such as to indicate some internal difference such as component selection.

160. A company requires only one Vendor ID. That value can be used in either the Vendor ID register of Configuration Space (e.g., offset 00h) or the Subsystem Vendor ID register of Configuration Space (e.g., offset 2Ch). It is used in the Vendor ID register (e.g., offset 00h) if the company built the silicon. It is used in the Subsystem Vendor ID register (e.g., offset 2Ch) if the company built the assembly. If a company builds both the silicon and the assembly, then the same value would be used in both registers.

7.5.1.2.4 Expansion ROM Base Address Register (Offset 30h) §

Some Functions, especially those that are intended for use on add-in cards, require local EPROMs for Expansion ROM (refer to the [Firmware] for a definition of ROM contents). This register is defined to handle the base address and size information for this Expansion ROM. The register layout is shown in § Figure 7-13 and § Table 7-10 describes the bits in the register.

For VFs, the Expansion ROM Base Address register is not supported and must be hardwired to Zero. The VI may choose to provide access to a PF's Expansion ROM Base Address register for its associated VFs via emulation.

Functions that support an expansion ROM must allow that ROM to be accessed with any combination of byte enables.

Figure 7-13 Expansion ROM Base Address Register §

Table 7-10 Expansion ROM Base Address Register §

Bit Location	Description	Attributes
0	<p>Expansion ROM Enable - This bit controls whether or not the Function accepts accesses to its Expansion ROM via the Expansion ROM Base Address Register. Functions that support an Expansion ROM accessible through this register must implement this bit. If the Function has an Enhanced Allocation Capability that includes an EA entry for an Expansion ROM, this bit must be hardwired to 0b (see § Section 7.5.1.2.4). Functions that do not support an Expansion ROM are permitted to hardwire this bit to 0b. When this bit is 0b, the Function's Expansion ROM address space via the Expansion ROM Base Address Register is disabled. When the bit is 1b, address decoding is enabled using the Expansion ROM Base Address field in this register. This optionally allows a Function to be used with or without an Expansion ROM depending on system configuration. The Memory Space Enable bit in the Command register has precedence over the Expansion ROM Enable bit. A Function must claim accesses to its Expansion ROM via the Expansion ROM Base Address Register only if both the Memory Space Enable bit and the Expansion ROM Enable bit are Set. The default value of this bit is 0b.</p> <p>In order to minimize the number of address decoders needed, a Function is permitted to share a decoder between the Expansion ROM Base Address Register and other Base Address registers or entries in the Enhanced Allocation Capability¹⁶¹. When Expansion ROM Enable is Set, the decoder is used for accesses to the Expansion ROM and device independent software must not access the Function through any other Base Address Registers or entries in the Enhanced Allocation Capability. Address decode sharing is not permitted for PFs or if the Function contains an Enhanced Allocation Capability with an EA entry for an Expansion ROM.</p>	RO/RW
3:1	<p>Expansion ROM Validation Status - Expansion ROM Validation is optional. When this field is non-zero, it indicates the status of hardware validation of the Expansion ROM contents.</p>	HwInit/ROS

161. Note that it is the address decoder that is shared, not the registers themselves. The Expansion ROM Base Address Register and other Base Address Registers or entries in the Enhanced Allocation Capability must be able to hold unique values at the same time.

Bit Location	Description	Attributes
	<ul style="list-style-type: none"> • An Expansion ROM is considered valid if it passes an implementation specific integrity check. • An Expansion ROM is considered valid-warn if the implementation specific integrity check passes but indicates an implementation specific warning condition. • A valid or valid-warn Expansion ROM is also considered trusted if passes an optional implementation specific trust test (e.g., signed by a trusted certificate). • Hardware validation must include the contents of the Expansion ROM. This validation status is also permitted to cover additional internal information (e.g., internal firmware). Validation does not include Vital Product Data (see § Section 6.27). • It is optional whether an implementation is capable of returning Validation Status values 011b, 101b, 110b, or 111b. <p>Defined encodings are:</p> <p>000b Validation not supported</p> <p>001b Validation in Progress</p> <p>010b Validation Pass Valid contents, trust test was not performed</p> <p>011b Validation Pass Valid and trusted contents</p> <p>100b Validation Fail Invalid contents</p> <p>101b Validation Fail Valid but untrusted contents (e.g., Out of Date, Expired or Revoked Certificate)</p> <p>110b Warning Pass Validation Passed with implementation specific warning. Valid contents, trust test was not performed</p> <p>111b Warning Pass Validation Passed with implementation specific warning. Valid and trusted contents</p> <ul style="list-style-type: none"> • If the Function does not support validation, this field must be hardwired to 000b. • If the Function supports validation and has an <u>Enhanced Allocation Capability</u> with an EA entry for an Expansion ROM, this field is <u>Hwlnit</u> and its value must be between 010b and 111b (see § Section 7.8.5.3). • Otherwise, this field is Read Only Sticky and has a default value of 001b. When validation completes, this field must contain a value between 010b and 111b inclusive. • Software is permitted to assume validation will never complete if this field contains 001b and 1 minute has passed after de-assertion of Fundamental Reset. This field is only reset by Fundamental Reset, and is not affected by other resets. 	
7:4	<p>Expansion ROM Validation Details - contains optional, implementation specific details associated with Expansion ROM Validation.</p> <ul style="list-style-type: none"> • If the Function does not support validation, this field is <u>RsvdP</u>. • This field is optional. When validation is supported and this field is not implemented, this field must be hardwired to 0000b. Any unused bits in this field are permitted to be hardwired to 0b. • If validation is in progress (<u>Expansion ROM Validation Status</u> is 001b), non-zero values of this field represent implementation specific indications of the phase of the validation progress (e.g., 50% complete). The value 0000b indicates that no validation progress information is provided. 	<u>Hwlnit/ROS/RsvdP</u>

Bit Location	Description	Attributes
	<ul style="list-style-type: none"> • If validation is completed (Expansion ROM Validation Status 010b to 111b inclusive), non-zero values in this field represent additional implementation specific information. The value 0000b indicates that no information is provided. • If the Function supports validation and has an <u>Enhanced Allocation Capability</u> with an EA entry for an Expansion ROM, this field is <u>HwInit</u>. • Otherwise, this field is Read Only Sticky. This field is only reset by Fundamental Reset, and is not affected by other resets. • This field must not change value once the validation process completes. • It is recommended that system software include the value of this field when it reports validation status (e.g., error log). 	
31:11	<p>Expansion ROM Base Address - contains the upper bits 21 bits of the starting memory address of the Expansion ROM. The lower 11 bits of the Expansion ROM Base Address Register are masked off (set to zero) by software to form a 32-bit address.</p> <p>This field functions like the address portion of a 32-bit Base Address register. This field corresponds to the upper 21 bits of the <u>Expansion ROM Base Address</u>. The number of bits (out of these 21) that a Function actually implements depends on how much Expansion ROM address space the Function requires. For instance, a Function that requires a 64 KB area to map its Expansion ROM would implement the top 16 bits in this field as writeable, leaving the bottom 5 bits (out of these 21) hardwired to 0b. The amount of address space a Function requests must not be greater than 16 MB. Functions that support an Expansion ROM accessible through this register must implement this field. If the Function has an <u>Enhanced Allocation Capability</u> that includes an EA entry for an Expansion ROM, this field must be hardwired to 0 (see § Section 7.8.5.3) Functions that do not support an Expansion ROM are permitted to hardwire this field to 0.</p> <p>Device independent configuration software can determine how much address space the Function requires by writing a value of all 1's to this field and then reading the value back. Low order bits of this field must return 0's in all don't-care bits, effectively specifying the size and alignment requirements. The amount of address space a Function requests must not be greater than 16 MB.</p>	<u>RW/RO</u>

7.5.1.2.5 Min_Gnt Register/Max_Lat Register (Offset 3Eh/3Fh) §

These registers do not apply to PCI Express and must be hardwired to Zero.

7.5.1.3 Type 1 Configuration Space Header §

§ Figure 7-14 details allocation for register fields of Type 1 Configuration Space Header for Switch and Root Ports.

Figure 7-14 Type 1 Configuration Space Header §

§ Section 7.5.1.1 details the PCI Express-specific registers that are valid for all Configuration Space Header types. The PCI Express-specific interpretation of registers specific to Type 1 Configuration Space Header is defined in this section. Register interpretations described in this section apply to PCI-PCI Bridge structures representing Switch and Root Ports; other device Functions such as PCI Express to PCI/PCI-X Bridges with Type 1 Configuration Space headers are not covered by this section.

7.5.1.3.1 Type 1 Base Address Registers (Offset 10h-14h) §

These registers are defined in § Section 7.5.1.2.1. However the number of BARs available within the Type 1 Configuration Space Header is different than that of the Type 0 Configuration Space Header.

7.5.1.3.2 Primary Bus Number Register (Offset 18h) §

Except as noted, this register is not used by PCI Express Functions but must be implemented as read-write and the default value must be 00h, for compatibility with legacy software. PCI Express Functions capture the Bus (and Device) Number as described (including exceptions) in § Section 2.2.6 . Refer to [PCIe-to-PCI-PCI-X-Bridge] for exceptions to this requirement.

7.5.1.3.3 Secondary Bus Number Register (Offset 19h) §

The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this register. The Bridge uses this register to determine when and how to respond to an ID-routed TLP observed on its primary interface, notably when to forward the TLP to its secondary interface, in certain cases after performing some conversion. See § Section 7.3.3 for Configuration Request routing and conversion rules. This register must be implemented as read/write and the default value must be 00h.

7.5.1.3.4 Subordinate Bus Number Register (Offset 1Ah) §

The Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind (or subordinate to) the bridge. Configuration software programs the value in this register. The Bridge uses this register to determine when and how to respond to an ID-routed TLP observed on its primary interface, notably when to forward the TLP to its secondary interface. See § Section 7.3.3 for Configuration Request routing rules. This register must be implemented as read-write and the default value must be 00h.

7.5.1.3.5 Secondary Latency Timer (Offset 1Bh) §

This register does not apply to PCI Express. It must be read-only and hardwired to 00h. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-PCI-X-Bridge] for requirements for this register.

7.5.1.3.6 I/O Base/I/O Limit Registers(Offset 1Ch/1Dh) §

The I/O Base and I/O Limit registers are optional and define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other.

If a bridge does not implement an I/O address range, then both the I/O Base and I/O Limit registers must be implemented as read-only registers that return zero when read. If a bridge supports an I/O address range, then these registers must be initialized by configuration software so default states are not specified.

If a bridge implements an I/O address range, the upper 4 bits of both the I/O Base and I/O Limit registers are writable and correspond to address bits Address[15:12]. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, Address[11:0], of the I/O base address (not implemented in the I/O Base register) are zero. Similarly, the bridge assumes that the lower 12 address bits, Address[11:0], of the I/O limit address (not implemented in the I/O Limit register) are FFFh. Thus, the bottom of the defined I/O address range will be aligned to a 4 KB boundary and the top of the defined I/O address range will be one less than a 4 KB boundary.

The I/O Limit register can be programmed to a smaller value than the I/O Base register, if there are no I/O addresses on the secondary side of the bridge. In this case, the bridge will not forward any I/O transactions from the primary bus to the secondary and will forward all I/O transactions from the secondary bus to the primary bus.

The lower four bits of both the I/O Base and I/O Limit registers are read-only, contain the same value, and encode the I/O addressing capability of the bridge according to § Table 7-11.

Table 7-11 I/O Addressing Capability §

Bits 3:0	I/O Addressing Capability
0h	16-bit I/O addressing
1h	32-bit I/O addressing
2h-Fh	Reserved

If the low four bits of the I/O Base and I/O Limit registers have the value 0000b, then the bridge supports only 16-bit I/O addressing (for ISA compatibility), and, for the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O base and I/O limit address (not implemented in the I/O Base and I/O Limit registers) are zero. Note that the bridge must still perform a full 32-bit decode of the I/O address (i.e., check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh).

If the low four bits of the I/O Base and I/O Limit registers are 0001b, then the bridge supports 32-bit I/O address decoding, and the I/O Base Upper 16 Bits and the I/O Limit Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit I/O Base and I/O Limit addresses respectively. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4 GB I/O Space. Note that the 4 KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing.

These registers must be initialized by configuration software, so default states are not specified.

7.5.1.3.7 Secondary Status Register (Offset 1Eh) §

§ Table 7-12 defines the Secondary Status Register and § Figure 7-15 provides the register layout. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-PCI-X-Bridge] for requirements for this register.

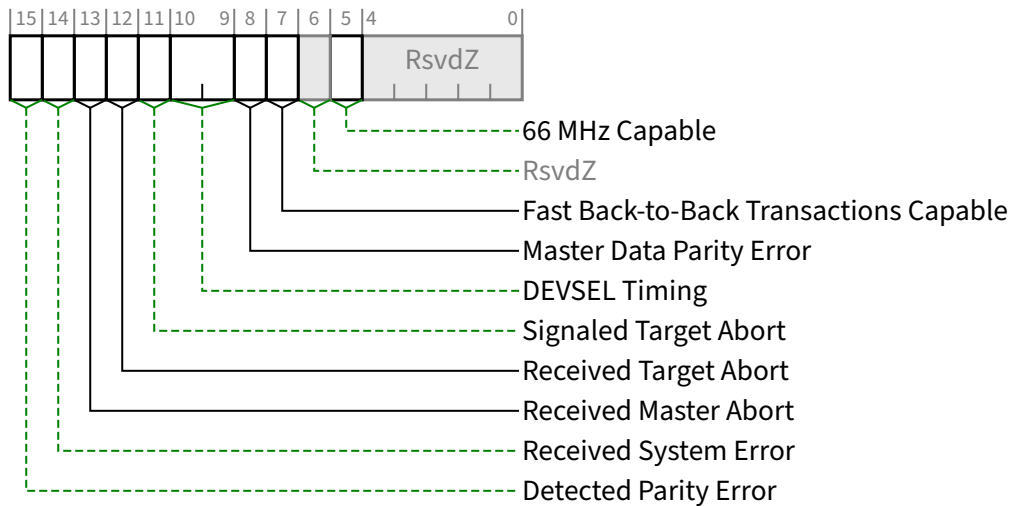

Figure 7-15 Secondary Status Register §

Table 7-12 Secondary Status Register §

Bit Location	Register Description	Attributes
5	66 MHz Capable - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
7	Fast Back-to-Back Transactions Capable - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
8	Master Data Parity Error - See § Section 7.5.1.1.14 . This bit is Set by a Function with a Type 1 Configuration Space Header if the Parity Error Response Enable bit in the Bridge Control Register is Set and either of the following two conditions occurs: Port receives a Poisoned Completion coming Upstream Port transmits a Poisoned Request Downstream If the Parity Error Response Enable bit is Clear, this bit is never Set. Default value of this bit is 0b.	RW1C
10:9	DEVSEL Timing - This field was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the field must be hardwired to 00b.	RO
11	Signaled Target Abort - See § Section 7.5.1.1.14 . This bit is Set when the Secondary Side for Type 1 Configuration Space Header Function (for Requests completed by the Type 1 header Function itself) completes a Posted or Non-Posted Request as a Completer Abort error. Default value of this bit is 0b.	RW1C
12	Received Target Abort - See § Section 7.5.1.1.14 . This bit is Set when the Secondary Side for Type 1 Configuration Space Header Function (for Requests initiated by the Type 1 header Function itself) receives a Completion with Completer Abort Completion Status.	RW1C

Bit Location	Register Description	Attributes
	Default value of this bit is 0b.	
13	<p>Received Master Abort - See § Section 7.5.1.1.14 .</p> <p>This bit is Set when the Secondary Side for Type 1 Configuration Space Header Function (for Requests initiated by the Type 1 header Function itself) receives a Completion with Unsupported Request Completion Status.</p> <p>Default value of this bit is 0b.</p>	RW1C
14	<p>Received System Error - See § Section 7.5.1.1.14 .</p> <p>This bit is Set when the Secondary Side for a Type 1 Configuration Space Header Function receives an ERR_FATAL or ERR_NONFATAL Message.</p> <p>Default value of this bit is 0b.</p>	RW1C
15	<p>Detected Parity Error - See § Section 7.5.1.1.14 .</p> <p>This bit is Set by a Function with a Type 1 Configuration Space Header when a Poisoned TLP is received by its Secondary Side, regardless of the state the Parity Error Response Enable bit in the Bridge Control Register.</p> <p>Default value of this bit is 0b.</p>	RW1C

7.5.1.3.8 Memory Base Register/Memory Limit Register(Offset 20h/22h) §

The Memory Base and Memory Limit registers define a memory mapped address range which is used by the bridge to determine when to forward memory transactions from one interface to the other (see the [PCI-to-PCI-Bridge] for additional details).

The upper 12 bits of both the Memory Base and Memory Limit registers are read/write and correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory base address (not implemented in the Memory Base register) are zero. Similarly, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory limit address (not implemented in the Memory Limit register) are FFFFh. Thus, the bottom of the defined memory address range will be aligned to a 1 MB boundary and the top of the defined memory address range will be one less than a 1 MB boundary.

The Memory Limit register must be programmed to a smaller value than the Memory Base register if there is no memory-mapped address space on the secondary side of the bridge.

If there is no prefetchable memory space, and there is no memory-mapped space on the secondary side of the bridge, then the bridge will not forward any memory transactions from the primary bus to the secondary bus and will forward all memory transactions from the secondary bus to the primary bus.

The bottom four bits of both the Memory Base and Memory Limit registers are read-only and return zeros when read.

These registers must be initialized by configuration software, so default states are not specified.

7.5.1.3.9 Prefetchable Memory Base/Prefetchable Memory Limit Registers (Offset 24h/26h) §

The Prefetchable Memory Base and Prefetchable Memory Limit registers, if implemented, must indicate that 64-bit addresses are supported.

The Prefetchable Memory Base and Prefetchable Memory Limit registers define a prefetchable memory address range that is used by the bridge to determine when to forward memory transactions from one interface to the other.

If a bridge does not implement a prefetchable memory address range, then both Prefetchable Memory Base and Prefetchable Memory Limit registers must be implemented as read-only registers that return zero when read. If a bridge implements a Prefetchable memory address range, then both of these registers must be implemented as read/write registers. If a bridge supports a prefetchable memory address range, then these registers must be initialized by configuration software so default states are not specified.

If the bridge implements a prefetchable memory address range, the upper 12 bits of the register are read/write and correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the prefetchable memory base address (not implemented in the Prefetchable Memory Base register) are zero. Similarly, the bridge assumes that the lower 20 address bits, Address[19:0], of the prefetchable memory limit address (not implemented in the Prefetchable Memory Limit register) are FFFFh. Thus, the bottom of the defined prefetchable memory address range will be aligned to a 1 MB boundary and the top of the defined memory address range will be one less than a 1 MB boundary.

The Prefetchable Memory Limit register must be programmed to a smaller value than the Prefetchable Memory Base register if there is no prefetchable memory on the secondary side of the bridge. If there is no prefetchable memory, and there is no memory-mapped address space (see the [PCI-to-PCI-Bridge]) on the secondary side of the bridge, then the bridge will not forward any memory transactions from the primary bus to the secondary but will forward all memory transactions from the secondary bus to the primary bus.

The bottom 4 bits of both the Prefetchable Memory Base and Prefetchable Memory Limit registers are read-only, contain the same value, and encode whether or not the bridge supports 64-bit addresses. If these four bits have the value 0h, then the bridge supports only 32-bit addresses. If these four bits have the value 01h, then the bridge supports 64-bit addresses and the Prefetchable Base Upper 32 Bits and Prefetchable Limit Upper 32 Bits registers hold the rest of the 64-bit prefetchable base and limit addresses respectively. All other encodings are Reserved.

These registers must be initialized by configuration software, so default states are not specified.

7.5.1.3.10 Prefetchable Base Upper 32 Bits/Prefetchable Limit Upper 32 Bits Registers (Offset 28h/2Ch) §

If a bridge does not implement a prefetchable memory address range, then both Prefetchable Memory Base Upper 32 Bits and Prefetchable Memory Limit Upper 32 Bits registers must be implemented as read-only registers that return zero when read. If a bridge implements a prefetchable memory address range, then both of these registers must be implemented as read/write registers that must be initialized by configuration software. They specify the upper 32 bits, corresponding to Address[63:32], of the 64-bit base and limit addresses that specify the prefetchable memory address range.

These registers must be initialized by configuration software, so default states are not specified.

7.5.1.3.11 I/O Base Upper 16 Bits/I/O Limit Upper 16 Bits Registers (Offset 30h/32h) §

The I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits registers are optional extensions to the I/O Base and I/O Limit registers. If the I/O Base and I/O Limit registers indicate support for 16-bit I/O address decoding, then the I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits registers are implemented as read-only registers which return zero when read.

If the I/O Base and I/O Limit registers indicate support for 32-bit I/O addressing, then the I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits registers must be initialized by configuration software so default states are not specified.

If 32-bit I/O address decoding is supported, the I/O Base Upper 16 Bits and the I/O Limit Upper 16 Bits registers specify the upper 16 bits, corresponding to Address[31:16], of the 32-bit base and limit addresses respectively, that specify the I/O address range (see the [PCI-to-PCI-Bridge] for additional details).

These registers must be initialized by configuration software, so default states are not specified.

7.5.1.3.12 Expansion ROM Base Address Register (Offset 38h) §

This register is defined in § Section 7.5.1.2.4 . However the offset of the register within the Type 1 Configuration Space Header is different than that of the Type 0 Configuration Space Header.

7.5.1.3.13 Bridge Control Register (Offset 3Eh) §

The Bridge Control Register provides extensions to the Command Register that are specific to a Function with a Type 1 Configuration Space Header. The Bridge Control Register provides many of the same controls for the secondary interface that are provided by the Command Register for the primary interface. There are some bits that affect the operation of both interfaces of the bridge.

§ Table 7-13 defines the Bridge Control Register and § Figure 7-16 depicts register layout. For PCI Express to PCI/PCI-X Bridges, refer to the [PCIe-to-PCI-PCI-X-Bridge] for requirements for this register.

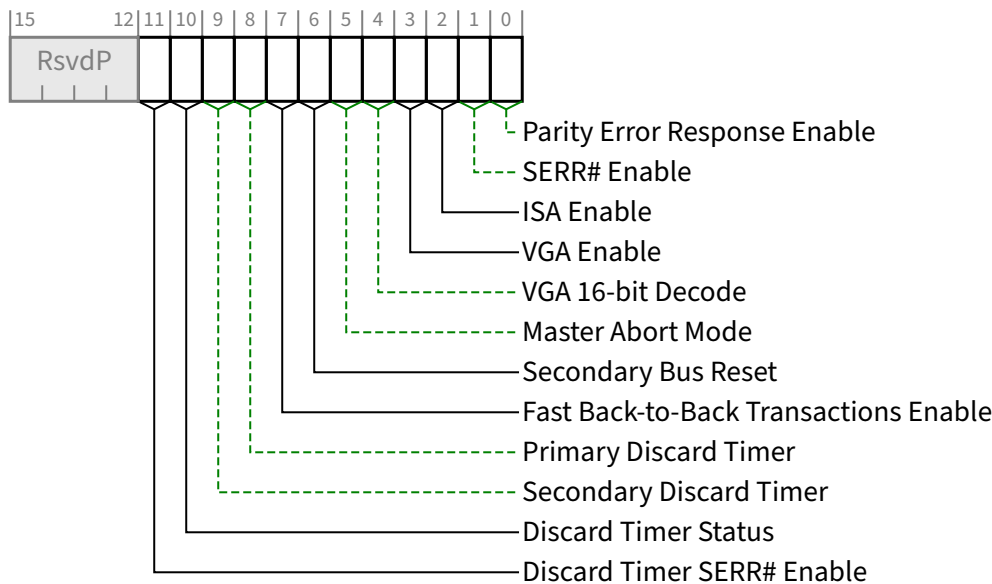

Figure 7-16 Bridge Control Register §

Table 7-13 Bridge Control Register §

Bit Location	Register Description	Attributes
0	<p>Parity Error Response Enable - See § Section 7.5.1.1.14 .</p> <p>This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the <u>Secondary Status Register</u>.</p> <p>Default value of this bit is 0b.</p>	RW
1	<p>SERR# Enable - See § Section 7.5.1.1.14 .</p> <p>This bit controls forwarding of <u>ERR_COR</u>, <u>ERR_NONFATAL</u> and <u>ERR_FATAL</u> from secondary to primary.</p>	RW

Bit Location	Register Description	Attributes
	Default value of this bit is 0b.	
2	<p>ISA Enable - Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the <u>I/O Base</u> and <u>I/O Limit</u> registers and are in the first 64 KB of I/O address space (0000 0000h to 0000 FFFFh). If this bit is Set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1 KB block. In the opposite direction (secondary to primary), I/O transactions will be forwarded if they address the last 768 bytes in each 1 KB block.</p> <p>0b forward downstream all I/O addresses in the address range defined by the <u>I/O Base</u> and <u>I/O Limit</u> registers</p> <p>1b forward upstream ISA I/O addresses in the address range defined by the <u>I/O Base</u> and <u>I/O Limit</u> registers that are in the first 64 KB of PCI I/O address space (top 768 bytes of each 1 KB block)</p> <p>Default value of this bit is 0b.</p>	RW
3	<p>VGA Enable - Modifies the response by the bridge to VGA compatible addresses. If the <u>VGA Enable</u> bit is Set, the bridge will positively decode and forward the following accesses on the primary interface to the secondary interface (and, conversely, block the forwarding of these addresses from the secondary to primary interface):</p> <ul style="list-style-type: none"> • Memory accesses in the range 000A 0000h to 000B FFFFh • I/O addresses in the first 64 KB of the I/O address space (Address[31:16] are 0000h) where Address[9:0] are in the ranges 3B0h to 3BBh and 3C0h to 3DFh (inclusive of ISA address aliases determined by the setting of <u>VGA 16-bit Decode</u>) <p>If the <u>VGA Enable</u> bit is Set, forwarding of these accesses is independent of the <u>I/O address range</u> and <u>memory address ranges</u> defined by the <u>I/O Base</u> and <u>Limit</u> registers, the <u>Memory Base</u> and <u>Limit</u> registers, and the <u>Prefetchable Memory Base</u> and <u>Limit</u> registers of the bridge. Forwarding of these accesses is also independent of the setting of the <u>ISA Enable</u> bit (in the <u>Bridge Control Register</u>) when the <u>VGA Enable</u> bit is Set. Forwarding of these accesses is qualified by the <u>I/O Space Enable</u> and <u>Memory Space Enable</u> bits in the <u>Command Register</u>.</p> <p>0b do not forward VGA compatible memory and I/O addresses from the primary to the secondary interface (addresses defined above) unless they are enabled for forwarding by the defined I/O and memory address ranges</p> <p>1b forward VGA compatible memory and I/O addresses (addresses defined above) from the primary interface to the secondary interface (if the <u>I/O Space Enable</u> and <u>Memory Space Enable</u> bits are set) independent of the <u>I/O</u> and <u>memory address ranges</u> and independent of the <u>ISA Enable</u> bit</p> <p>Functions that do not support VGA are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW
4	<p>VGA 16-bit Decode - This bit only has meaning if bit 3 (<u>VGA Enable</u>) of this register is also Set, enabling VGA I/O decoding and forwarding by the bridge.</p> <p>This bit enables system configuration software to select between 10-bit and 16-bit I/O address decoding for all VGA I/O register accesses that are forwarded from primary to secondary.</p> <p>0b execute 10-bit address decodes on VGA I/O accesses</p> <p>1b execute 16-bit address decodes on VGA I/O accesses</p> <p>Functions that do not support VGA are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW

Bit Location	Register Description	Attributes
5	Master Abort Mode - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
6	Secondary Bus Reset - Setting this bit triggers a hot reset on the corresponding PCI Express Port. Software must ensure a minimum reset duration of 1 ms, (corresponding to T_{rst} in [PCI]). Software and systems must honor first-access-following-reset timing requirements defined in § Section 6.6., unless the Readiness Notifications mechanism (see § Section 6.22) is used or if the Immediate Readiness bit in the relevant Function's Status register is Set. Port configuration registers must not be changed, except as required to update Port status. See Implementation Note: <u>Delays in Data Link Layer Link Active Reflecting Link Control Operations</u> for related information. Default value of this bit is 0b.	RW
7	Fast Back-to-Back Transactions Enable - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
8	Primary Discard Timer - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
9	Secondary Discard Timer - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
10	Discard Timer Status - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and the bit must be hardwired to 0b.	RO
11	Discard Timer SERR# Enable - This bit was originally described in the [PCI-to-PCI-Bridge]. Its functionality does not apply to PCI Express and must be hardwired to 0b.	RO

7.5.2 PCI Power Management Capability Structure §

This section describes the registers making up the PCI Power Management Interface structure.

§ Figure 7-17 illustrates the organization of the PCI Power Management Capability structure. This structure is required for all PCI Express Functions.

Figure 7-17 PCI Power Management Capability Structure §

Note: The 8-bit Power Management Data Register (Offset 07h) is optional for both Type 0 and Type 1 Functions.

PCI Express device Functions are required to support D0 and D3 device states; PCI-PCI Bridge structures representing PCI Express Ports as described in § Section 7.1 are required to indicate PME Message passing capability due to the in-band nature of PME messaging for PCI Express.

The `PME_Status` bit for the PCI-PCI Bridge structure representing PCI Express Ports, however, is only Set when the PCI-PCI Bridge Function is itself generating a PME. The `PME_Status` bit is not Set when the Bridge is propagating a PME Message but the PCI-PCI Bridge Function itself is not internally generating a PME.

7.5.2.1 Power Management Capabilities Register (Offset 00h) §

§ Figure 7-18 details allocation of register fields for Power Management Capabilities Register and § Table 7-14 describes the requirements for this register.

Figure 7-18 Power Management Capabilities Register §

Table 7-14 Power Management Capabilities Register §

Bit Location	Register Description	Attributes
7:0	Capability_ID - This field returns 01h to indicate that this is the PCI Power Management Capability. Each Function may have only one item in its capability list with <code>Capability_ID</code> set to 01h.	RO
15:8	Next Capability Pointer - This field provides an offset into the Function's Configuration Space pointing to the location of next item in the capabilities list. If there are no additional items in the capabilities list, this field is set to 00h.	RO
18:16	Version - Must be hardwired to 011b for Functions compliant to this specification.	RO
19	PME Clock - Does not apply to PCI Express and must be hardwired to 0b.	RO
20	Immediate_Readiness_on_Return_to_D0 - If this bit is a "1", this Function is guaranteed to be ready to successfully complete valid accesses immediately after being set to <code>D0</code> . These accesses include Configuration cycles, and if the Function returns to <code>D0_{active}</code> , they also include Memory and I/O Cycles. When this bit is "1", for accesses to this Function, software is exempt from all requirements to delay accesses following a transition to <code>D0</code> , including but not limited to the 10 ms delay; the delays described in § Section 5.9. How this guarantee is established is beyond the scope of this document. It is permitted that system software/firmware provide mechanisms that supersede the indication provided by this bit, however such software/firmware mechanisms are outside the scope of this specification.	RO
21	Device Specific Initialization - The DSI bit indicates whether special initialization of this Function is required.	RO

Bit Location	Register Description	Attributes																
	When Set indicates that the Function requires a device specific initialization sequence following a transition to the <u>D0_{uninitialized}</u> state.																	
24:22	<p>Aux_Current¹⁶² - This 3 bit field reports the <u>Vaux</u> auxiliary current requirements for the Function. If this Function implements the <u>Power Management Data Register</u>, this field must be hardwired to 000b. bit(29) X X1XXb	PME can be generated from <u>D2</u>																	
bit(30) X 1XXXb	PME can be generated from <u>D3_{Hot}</u>																	
bit(31) 1 XXXXb	PME can be generated from <u>D3_{Cold}</u>																	

162. Earlier versions of this specification defined power levels as current (mA) at 3.3 V (hence the field name “Aux_Current”). To support form factors with different Aux Power voltage levels, the definition was changed to the equivalent wattage values (mW).

Bit Location	Register Description	Attributes
	<p>Bit 31 (PME can be asserted from <u>D3Cold</u>) represents a special case. Functions that Set this bit require some sort of auxiliary power source. Implementation specific mechanisms are recommended to validate that the power source is available before setting this bit.</p> <p>Each bit that corresponds to a supported D-state must be Set for PCI-PCI Bridge structures representing Ports on Root Complexes/Switches to indicate that the Bridge will forward PME Messages. Bit 31 must only be Set if the Port is still able to forward PME Messages when main power is not available.</p>	

7.5.2.2 Power Management Control/Status Register (Offset 04h) §

This register is used to manage the PCI Function's power management state as well as to enable/monitor PMEs.

The PME Context includes the value of the PME_Status and PME_En bits, implementation specific state needed during D3Cold to implement the wakeup functionality (e.g., recognized a Wake on LAN packet and generate a PME Message), as well as any additional implementation specific state that must be preserved during a transition to the D0uninitialized state.

If a Function supports PME generation from D3Cold, its PME Context is not affected by Reset. This is because the Function's PME functionality itself may have been responsible for the wake event which caused the transition back to D0. Therefore, the PME Context must be preserved for the system software to process.

If PME generation is not supported from D3Cold, then all PME Context is initialized with the assertion of Reset.

§ Figure 7-19 details allocation of the register fields for the Power Management Control/Status Register and § Table 7-15 describes the requirements for this register.

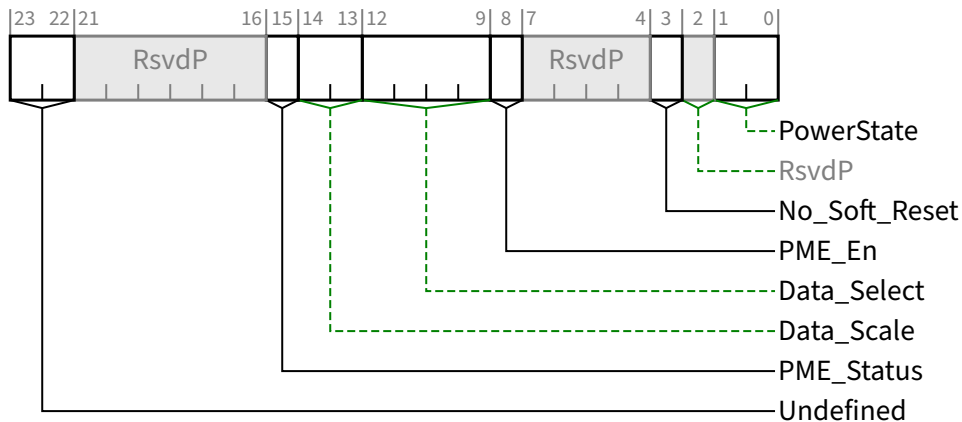

Figure 7-19 Power Management Control/Status Register §

Table 7-15 Power Management Control/Status Register §

Bit Location	Register Description	Attributes
1:0	PowerState - This 2-bit field is used both to determine the current power state of a Function and to set the Function into a new power state. The definition of the field values is given below.	<u>RW</u>

Bit Location	Register Description	Attributes
	<p>00b D0</p> <p>01b D1</p> <p>10b D2</p> <p>11b <u>D3_{Hot}</u></p> <p>If software attempts to write an unsupported, optional state to this field, the write operation must complete normally; however, the data is discarded and no state change occurs.</p> <p>Default value of this field is 00b.</p>	
3	<p>No_Soft_Reset - This bit indicates the state of the Function after writing the PowerState field to transition the Function from <u>D3_{Hot}</u> to <u>D0</u>. This bit <i>MUST@FLIT</i> be Set.</p> <p>When Set, this transition preserves internal Function state. The Function is in <u>D0_{Active}</u> and no additional software intervention is required.</p> <p>When Clear, this transition results in undefined internal Function state.</p> <p>Regardless of this bit, Functions that transition from <u>D3_{Hot}</u> to <u>D0</u> by Fundamental Reset must return to <u>D0_{uninitialized}</u> with only PME context preserved if PME is supported and enabled.</p> <p>If a VF implements the <u>PCI Power Management Capability</u>, the VF's value of this field must be identical to the associated PF's value.</p>	<u>RO</u>
8	<p>PME_En - When Set, the Function is permitted to generate a PME. When Clear, the Function is not permitted to generate a PME.</p> <p>If <u>PME_Support</u> is 1 xxxxb (PME generation from <u>D3_{Cold}</u>) or the Function consumes auxiliary power and auxiliary power is available this bit is <u>RWS</u> and the bit is not modified by Conventional Reset or <u>FLR</u></p> <p>If <u>PME_Support</u> is 0 xxxxb, this field is not sticky (<u>RW</u>) and defaults to 0b in response to a Conventional Reset or an <u>FLR</u>.</p> <p>If <u>PME_Support</u> is 0 0000b, this bit is permitted to be hardwired to 0b.</p>	<u>RW/RWS</u>
12:9	<p>Data_Select - This 4-bit field is used to select which data is to be reported through the <u>Power Management Data Register</u> and <u>Data_Scale</u> field.</p> <p>If the <u>Power Management Data Register</u> is not implemented, this field must be hardwired to Zero.</p> <p>Refer to § Section 7.5.2.3 for more details.</p> <p>The default of this field is Zero.</p>	<u>RW</u> <u>VF ROZ</u>
14:13	<p>Data_Scale - This field indicates the scaling factor to be used when interpreting the value of the Data register. The value and meaning of this field will vary depending on which data value has been selected by the <u>Data_Select</u> field.</p> <p>This field is a required component of the <u>Power Management Data Register</u> (offset 7) and must be implemented if the <u>Power Management Data Register</u> is implemented.</p> <p>If the <u>Power Management Data Register</u> is not implemented, this field must be hardwired to Zero.</p> <p>Refer to § Section 7.5.2.3 for more details.</p>	<u>RO</u> <u>VF ROZ</u>
15	<p>PME_Status - This bit is Set when the Function would normally generate a PME signal. The value of this bit is not affected by the value of the <u>PME_En</u> bit.</p> <p>If <u>PME_Support</u> bit 31 of the <u>Power Management Capabilities Register</u> is Clear, this bit is permitted to be hardwired to 0b.</p> <p>Functions that consume auxiliary power must preserve the value of this sticky register when auxiliary power is available. In such Functions, this register value is not modified by Conventional Reset or <u>FLR</u>.</p>	<u>RW1CS</u>

Bit Location	Register Description	Attributes
23:22	Undefined Undefined - these bits were defined in previous specifications. They should be ignored by software.	RO

7.5.2.3 Power Management Data Register (Offset 07h) §

The Power Management Data Register is an optional, 8-bit read-only register that provides a mechanism for the Function to report state dependent operating power consumed or dissipation.

If the Power Management Data Register is implemented, then the Data_Select and Data_Scale fields must also be implemented. If this register is not implemented, it must be hardwired to 00h.

Software may check for the presence of the Power Management Data Register by writing different values into the Data_Select field, looking for non-zero return data in the Power Management Data Register and/or Data_Scale field. Any non-zero Power Management Data Register/Data_Select read data indicates that the Power Management Data Register complex has been implemented.

Figure 7-20 Power Management Data Register §

Table 7-16 Power Management Data Register §

Bit Location	Register Description	Attributes
7:0	Data - This register is used to report the state dependent data requested by the <u>Data_Select</u> field. The value of this register is scaled by the value reported by the <u>Data_Scale</u> field. For VFs, this register is not supported and must be hardwired to Zero.	RO VF ROZ

The Power Management Data Register is used by writing the proper value to the Data_Select field in the PMCSR and then reading the Data_Scale field and the Power Management Data Register. The binary value read from Data is then multiplied by the scaling factor indicated by Data_Scale to arrive at the value for the desired measurement. § Table 7-17 shows which measurements are defined and how to interpret the values of each register.

Table 7-17 Power Consumption/Dissipation Reporting §

Value in <u>Data_Select</u>	Data Reported	<u>Data_Scale</u> Interpretation	Units/ Accuracy
0	<u>D0</u> Power Consumed	0 = Unknown 1 = 0.1x 2 = 0.01x 3 = 0.001x	Watts
1	<u>D1</u> Power Consumed		
2	<u>D2</u> Power Consumed		
3	<u>D3</u> Power Consumed		
4	<u>D0</u> Power Dissipated		

Value in Data_Select	Data Reported	Data_Scale Interpretation	Units/ Accuracy
5	D1 Power Dissipated		
6	D2 Power Dissipated		
7	D3 Power Dissipated		
8	Common logic power consumption (<u>Multi-Function Devices</u> , Function 0 only) Function 0 of a Multi-Function Device: Power consumption that is not associated with a specific Function. All other Functions: Reserved		
9-15	Reserved	Reserved	TBD

The “Power Consumed” values defined above must include all power consumed from the power planes through the connector pins. If the add-in card provides power to external devices, that power must be included as well. It must not include any power derived from a battery or an external source. This information is useful for management of the power supply or battery.

The “Power Dissipated” values must provide the amount of heat which will be released into the interior of the computer chassis. This excludes any power delivered to external devices but must include any power derived from a battery or external power source and dissipated inside the computer chassis. This information is useful for fine grained thermal management.

Multi-Function Devices are recommended to report the power consumed by each Function in each corresponding Function’s Configuration Space. In a Multi-Function Device, power consumption for circuitry common to multiple Functions is reported in Function 0’s Configuration Space through the Power Management Data Register once the Data_Select field of Function 0’s Power Management Control/Status Register has been programmed to 1000b. For a Multi-Function Device, power consumption of the device is the sum of this value and, for every Function of the device, the reported value associated with the Function’s current Power State.

Multiple component add-in cards implementing power reporting (i.e., multiple components behind a switch or bridge) must have the switch/bridge report the power it uses by itself. Each Function of each component on the add-in card is responsible for reporting the power consumed by that Function.

IMPLEMENTATION NOTE: NEW DESIGNS SHOULD USE POWER BUDGETING EXTENDED CAPABILITY §

Both the Power Budgeting Extended Capability and the PCI Power Management Capability report power consumption. The Power Budgeting Extended Capability mechanism is required in some situations (by this specification or the associated form factor specification). The Power Budgeting Extended Capability mechanism provides additional information beyond that which is provided by the Data register of the PCI Power Management Capability. It is strongly recommended that designs implement the Power Budgeting Extended Capability instead of the mechanism in this section, and that new designs hardwire the Data, Data_Select, and Data_Scale fields to 0.

7.5.3 PCI Express Capability Structure §

PCI Express defines a Capability structure in PCI-compatible Configuration Space (first 256 bytes) as shown in § Figure 7-3. This structure allows identification of a PCI Express device Function and indicates support for new PCI Express features. The PCI Express Capability structure is required for PCI Express device Functions. The Capability structure is a mechanism for enabling PCI software transparent features requiring support on legacy operating systems. In addition to identifying a PCI Express device Function, the PCI Express Capability structure is used to provide access to PCI Express specific Control/Status registers and related Power Management enhancements.

§ Figure 7-21 details allocation of register fields in the PCI Express Capability structure.

The PCI Express Capabilities, Device Capabilities, Device Status, and Device Control registers are required for all PCI Express device Functions. Device Capabilities 2, Device Status 2, and Device Control 2 registers are required for all PCI Express device Functions that implement capabilities requiring those registers. For device Functions that do not implement the Device Capabilities 2, Device Status 2, and Device Control 2 registers, these spaces must be hardwired to 0b.

The Link Capabilities, Link Status, and Link Control registers are required for all Root Ports, Switch Ports, Bridges, and Endpoints that are not RCiEPs. For Functions that do not implement the Link Capabilities, Link Status, and Link Control registers, these spaces must be hardwired to 0. Link Capabilities 2, Link Status 2, and Link Control 2 registers are required for all Root Ports, Switch Ports, Bridges, and Endpoints (except for RCiEPs) that implement capabilities requiring those registers. For Functions that do not implement the Link Capabilities 2, Link Status 2, and Link Control 2 registers, these spaces must be hardwired to 0b.

The Slot Capabilities, Slot Status, and Slot Control registers are required in certain Switch Downstream and Root Ports. The Slot Capabilities Register is required if the Slot Implemented bit is Set (see § Section 7.5.3.2). The Slot Status and Slot Control registers are required if Slot Implemented is Set or if Data Link Layer Link Active Reporting Capable is Set (see § Section 7.5.3.6). Switch Downstream and Root Ports are permitted to implement these registers, even when they are not required, and in this case the behavior of most of the fields in these registers is undefined. See § Section 7.5.3.9 , § Section 7.5.3.10 , and § Section 7.5.3.11 for details. For Functions that do not implement the Slot Capabilities, Slot Status, and Slot Control registers, these spaces must be hardwired to 0b, with the exception of the Presence Detect State bit in the Slot Status Register of Downstream Ports, which must be hardwired to 1b (see § Section 7.5.3.11). Slot Capabilities 2, Slot Status 2, and Slot Control 2 registers are required for Switch Downstream and Root Ports if the Function implements capabilities requiring those registers. For Functions that do not implement the Slot Capabilities 2, Slot Status 2, and Slot Control 2 registers, these spaces must be hardwired to 0b.

Root Ports and Root Complex Event Collectors must implement the Root Capabilities, Root Status, and Root Control registers. For Functions that do not implement the Root Capabilities, Root Status, and Root Control registers, these spaces must be hardwired to 0b.

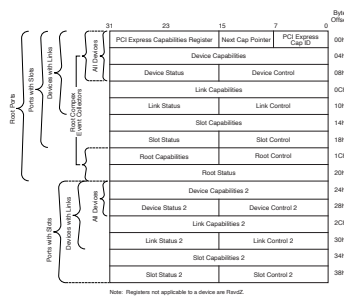

Figure 7-21 PCI Express Capability Structure §

7.5.3.1 PCI Express Capability List Register (Offset 00h) §

The PCI Express Capability List Register enumerates the PCI Express Capability structure in the PCI Configuration Space Capability list. § Figure 7-22 details allocation of register fields in the PCI Express Capability List Register; § Table 7-18 provides the respective bit definitions.

Figure 7-22 PCI Express Capability List Register §

Table 7-18 PCI Express Capability List Register §

Bit Location	Register Description	Attributes
7:0	Capability ID - Indicates the PCI Express Capability structure. This field must return a Capability ID of 10h indicating that this is a PCI Express Capability structure.	RO
15:8	Next Capability Pointer - This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities.	RO

7.5.3.2 PCI Express Capabilities Register (Offset 02h) §

The PCI Express Capabilities Register identifies PCI Express device Function type and associated capabilities. § Figure 7-23 details allocation of register fields in the PCI Express Capabilities Register; § Table 7-19 provides the respective bit definitions.

Figure 7-23 PCI Express Capabilities Register §

Table 7-19 PCI Express Capabilities Register [§]

Bit Location	Register Description	Attributes
3:0	<p>Capability Version - Indicates PCI-SIG defined PCI Express Capability structure version number.</p> <p>A version of the specification that changes the PCI Express Capability structure in a way that is not otherwise identifiable (e.g., through a new Capability field) is permitted to increment this field. All such changes to the PCI Express Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a PCI Express Capability structure that is compatible with that piece of software.</p> <p>Must be hardwired to 2h for Functions compliant to this specification.</p>	<u>RO</u>
7:4	<p>Device/Port Type ¹⁶³ - Indicates the specific type of this PCI Express Function. Note that different Functions in a Multi-Function Device can generally be of different types.</p> <p>Defined encodings for Functions that implement a Type 00h PCI Configuration Space header are:</p> <p>0000b PCI Express Endpoint</p> <p>0001b Legacy PCI Express Endpoint</p> <p>1001b RCiEP</p> <p>1010b Root Complex Event Collector</p> <p>Defined encodings for Functions that implement a Type 01h PCI Configuration Space header are:</p> <p>0100b Root Port of PCI Express Root Complex</p> <p>0101b Upstream Port of PCI Express Switch</p> <p>0110b Downstream Port of PCI Express Switch</p> <p>0111b PCI Express to PCI/PCI-X Bridge</p> <p>1000b PCI/PCI-X to PCI Express Bridge</p> <p>All other encodings are Reserved.</p> <p>Note that the different Endpoint types have notably different requirements in § Section 1.3.2 regarding I/O resources, Extended Configuration Space, and other capabilities.</p>	<u>RO</u>
8	<p>Slot Implemented - When Set, this bit indicates that the Link associated with this Port is connected to a slot (as compared to being connected to a system-integrated device or being disabled).</p> <p>This bit is valid for Downstream Ports. This bit is undefined for Upstream Ports.</p>	<u>HwInit</u>
13:9	<p>Interrupt Message Number - This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability structure. This vector is also used for:</p> <ul style="list-style-type: none"> Native PME Software Model (see § Section 6.1.6 and § Section 6.7.3.4) Link Activation (see § Section 5.5.6) Flit Error Counter Interrupts (see § Section 7.7.8.4) <p>For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the Message Control Register for MSI.</p> <p>For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant.</p>	<u>RO</u>

163. This field would be better named 'Function Type' but for historical reasons is named Device/Port Type.

Bit Location	Register Description	Attributes
	If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined.	
14	Undefined - The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate support for TCS Routing. System software should ignore the value read from this bit. System software is permitted to write any value to this bit.	RO
15	Flit Mode Supported - When Set, indicates support for Flit Mode. Must be Set by all implementations that support Flit Mode. Must be Clear by implementations that do not support Flit Mode. See Flit Mode Supported .	HwInit

7.5.3.3 Device Capabilities Register (Offset 04h) §

The Device Capabilities Register identifies PCI Express device Function specific capabilities. § Figure 7-24 details allocation of register fields in the Device Capabilities Register; § Table 7-20 provides the respective bit definitions.

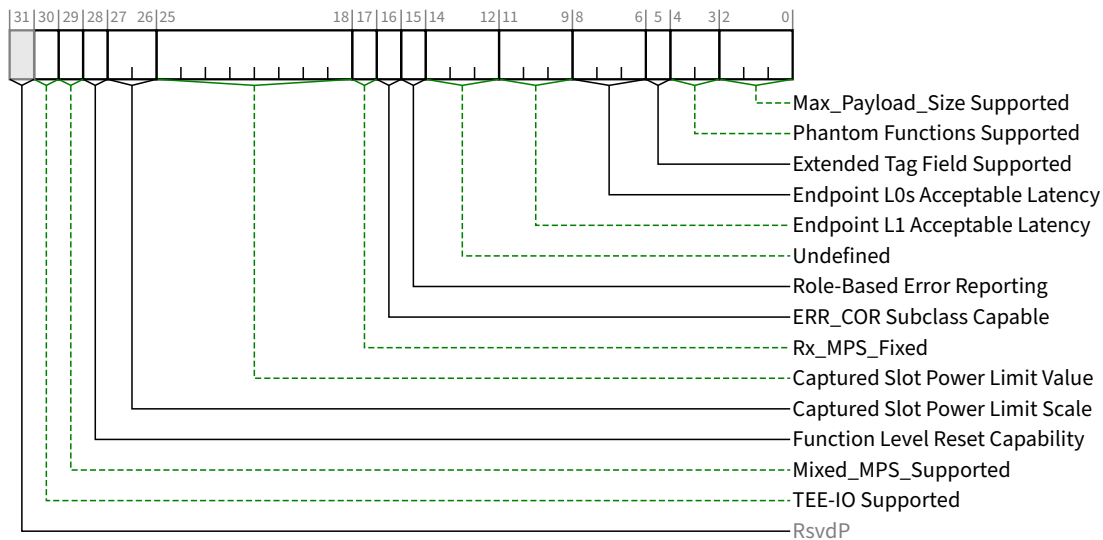

Figure 7-24 Device Capabilities Register §

Table 7-20 Device Capabilities Register §

Bit Location	Register Description	Attributes
2:0	Max_Payload_Size Supported - This field indicates the maximum payload size that the Function can support for TLPs. This field <i>MUST@FLIT</i> indicate a minimum of 512 bytes. If the Rx_MPS_Fixed bit is Set, the Function's Rx_MPS_Limit is fixed with the value indicated by this (Max_Payload_Size Supported) field. Otherwise, the Rx_MPS_Limit is determined by the	RO

Bit Location	Register Description	Attributes																
	<p>Max_Payload_Size field (the "MPS setting") in one or more Functions. See § Section 2.2.2 for important details regarding <u>Multi-Function Devices</u>.</p> <p>Defined encodings are:</p> <table border="0"> <tr> <td>000b</td> <td>128 bytes max payload size</td> </tr> <tr> <td>001b</td> <td>256 bytes max payload size</td> </tr> <tr> <td>010b</td> <td>512 bytes max payload size</td> </tr> <tr> <td>011b</td> <td>1024 bytes max payload size</td> </tr> <tr> <td>100b</td> <td>2048 bytes max payload size</td> </tr> <tr> <td>101b</td> <td>4096 bytes max payload size</td> </tr> <tr> <td>110b</td> <td>Reserved</td> </tr> <tr> <td>111b</td> <td>Reserved</td> </tr> </table> <p>The Functions of a <u>Multi-Function Device</u> are permitted to report different values for this field.</p>	000b	128 bytes max payload size	001b	256 bytes max payload size	010b	512 bytes max payload size	011b	1024 bytes max payload size	100b	2048 bytes max payload size	101b	4096 bytes max payload size	110b	Reserved	111b	Reserved

Function 1 is permitted to use Function Numbers 3, 5, and 7 as Phantom Functions.	11b	All 3 bits of Function Number in Requester ID used for Phantom Functions. The device must have a single Function 0 that is permitted to use all other Function Numbers as Phantom Functions.	<p><u>RO</u> <u>VF ROZ</u></p>								
00b	No Function Number bits are used for Phantom Functions. <u>Multi-Function Devices</u> are permitted to implement up to 8 independent Functions.																	
01b	The most significant bit of the Function number in Requester ID is used for Phantom Functions; a <u>Multi-Function Device</u> is permitted to implement Functions 0-3. Functions 0, 1, 2, and 3 are permitted to use Function Numbers 4, 5, 6, and 7 respectively as Phantom Functions.																	
10b	The two most significant bits of Function Number in Requester ID are used for Phantom Functions; a <u>Multi-Function Device</u> is permitted to implement Functions 0-1. Function 0 is permitted to use Function Numbers 2, 4, and 6 for Phantom Functions. Function 1 is permitted to use Function Numbers 3, 5, and 7 as Phantom Functions.																	
11b	All 3 bits of Function Number in Requester ID used for Phantom Functions. The device must have a single Function 0 that is permitted to use all other Function Numbers as Phantom Functions.																	
5	<p><i>Extended Tag Field Supported</i> - This bit, in combination with the <u>10-Bit Tag Requester Supported</u> bit and the <u>14-Bit Tag Requester Supported</u> bit, indicates the maximum supported size of the Tag field as a Requester. This bit must be Set if the <u>10-Bit Tag Requester Supported</u> bit or the <u>14-Bit Tag Requester Supported</u> bit is Set.</p>	<p><u>RO</u></p>																

Bit Location	Register Description	Attributes
	<p>Defined encodings are:</p> <p>0b 5-bit Tag Requester capability supported</p> <p>1b 8-bit Tag Requester capability supported</p> <p>Note that 8-bit Tag field generation must be enabled by the <u>Extended Tag Field Enable</u> bit in the <u>Device Control Register</u> of the <u>Requester Function</u> before 8-bit Tags can be generated by the Requester. See § <u>Section 2.2.6.2</u> for interactions with enabling the use of 10-Bit or 14-Bit Tags.</p>	
8:6	<p>Endpoint L0s Acceptable Latency - This field indicates the acceptable total latency that an Endpoint can withstand due to the transition from <u>L0s</u> state to the <u>L0</u> state. It is essentially an indirect measure of the Endpoint's internal buffering.</p> <p>Power management software uses the reported L0s Acceptable Latency number to compare against the <u>L0s</u> exit latencies reported by all components comprising the data path from this Endpoint to the <u>Root Complex Root Port</u> to determine whether ASPM L0s entry can be used with no loss of performance.</p> <p>Defined encodings are:</p> <p>000b Maximum of 64 ns</p> <p>001b Maximum of 128 ns</p> <p>010b Maximum of 256 ns</p> <p>011b Maximum of 512 ns</p> <p>100b Maximum of 1 μs</p> <p>101b Maximum of 2 μs</p> <p>110b Maximum of 4 μs</p> <p>111b No limit</p> <p>For Functions other than Endpoints, this field is Reserved and must be hardwired to 000b.</p>	RO
11:9	<p>Endpoint L1 Acceptable Latency - This field indicates the acceptable latency that an Endpoint can withstand due to the transition from <u>L1</u> state to the <u>L0</u> state. It is essentially an indirect measure of the Endpoint's internal buffering.</p> <p>Power management software uses the reported L1 Acceptable Latency number to compare against the <u>L1</u> Exit Latencies reported (see below) by all components comprising the data path from this Endpoint to the <u>Root Complex Root Port</u> to determine whether ASPM L1 entry can be used with no loss of performance.</p> <p>Defined encodings are:</p> <p>000b Maximum of 1 μs</p> <p>001b Maximum of 2 μs</p> <p>010b Maximum of 4 μs</p> <p>011b Maximum of 8 μs</p> <p>100b Maximum of 16 μs</p> <p>101b Maximum of 32 μs</p> <p>110b Maximum of 64 μs</p> <p>111b No limit</p> <p>For Functions other than Endpoints, this field is Reserved and must be hardwired to 000b.</p>	RO
14:12	<p>Undefined - The value read from these bits are undefined. In previous versions of this specification, this bit was used to indicate that a <u>Attention Button</u>, <u>Attention Indicator</u>, or <u>Power Indicator</u>, is implemented on the adapter and electrically controlled by the component on the adapter. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.</p>	RO

Bit Location	Register Description	Attributes
15	Role-Based Error Reporting - When Set, this bit indicates that the Function implements the functionality originally defined in the Error Reporting ECN for [PCIe-1.0a], and later incorporated into [PCIe-1.1]. This bit must be Set by all Functions conforming to the ECN, [PCIe-1.1], or subsequent [PCIe] revisions.	RO
16	ERR_COR Subclass Capable - When Set, this bit indicates that the Function supports the ERR_COR Subclass field in ERR_COR Messages, allowing different subclasses to be distinguished. See § Section 2.2.8.3. Downstream Ports that implement the System Firmware Intermediary (SFI) capability must Set this bit. Downstream Ports that implement Downstream Port Containment (DPC) are strongly encouraged to Set this bit.	RO
17	Rx_MPS_Fixed - When Set, the Function's Rx_MPS_Limit is fixed with the value indicated by the Max_Payload_Size Supported field. Otherwise, the Rx_MPS_Limit is determined by the Max_Payload_Size field (the "MPS setting") in one or more Functions. See § Section 2.2.2 for important details regarding Multi-Function devices. This bit <i>MUST@FLIT</i> be Set.	HwInit
25:18	Captured Slot Power Limit Value (Upstream Ports only) - In combination with the Captured Slot Power Limit Scale value, specifies the upper limit on power available to the adapter. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Captured Slot Power Limit Scale field except when the Captured Slot Power Limit Scale field equals 00b (1.0x) and the Captured Slot Power Limit Value exceeds EFh, then alternative encodings are used (see § Section 7.5.3.9). This value is set by the Set_Slot_Power_Limit Message or hardwired to 00h (see § Section 6.9). The default value is 00h. For VFs, the field value when read is undefined.	RO
27:26	Captured Slot Power Limit Scale (Upstream Ports only) - Specifies the scale used for the Slot Power Limit Value. Range of Values: 00b 1.0x 01b 0.1x 10b 0.01x 11b 0.001x This value is set by the Set_Slot_Power_Limit Message or hardwired to 00b (see § Section 6.9). The default value is 00b. For VFs, the field value when read is undefined.	RO
28	Function Level Reset Capability - A value of 1b indicates the Function supports the optional Function Level Reset mechanism described in § Section 6.6.2. This bit applies to Endpoints only. For all other Function types this bit must be hardwired to <u>Zero</u> . For PFs and VFs, the feature is mandatory and this bit must be Set.	RO
29	Mixed_MPS_Supported - When Set, the Function must have an implementation specific mechanism capable of supporting different MPS settings for different targets. This bit <i>MUST@FLIT</i> be Set if the Function supports P2P Memory Transactions and the Function's Max_Payload_Size Supported field indicates an MPS value greater than 512 bytes. If not mandatory, supporting Mixed MPS capability may still be beneficial if this Function does P2P with targets or over paths whose supported MPS is significantly less than this Function's supported MPS; e.g., 128 bytes vs. 512 bytes. The implementation specific mechanism must handle both Request and Completion TLPs, and is permitted to base its determination of P2P targets on Memory Space ranges, Bus Number ranges, or implementation specific means; e.g., data mover channels.	HwInit

Bit Location	Register Description	Attributes
	For SR-IOV devices, this field in each VF must have the same value its associated PF. If this field is Set, the implementation specific mechanism must use the same P2P target-specific MPS setting for each VF as its associated PF. This parallels the requirement for the <u>Max_Payload_Size</u> field in the <u>Device Control Register</u> .	
30	TEE-IO Supported – When Set, this bit indicates that the Function implements the TEE-IO functionality as described by the <u>TEE Device Interface Security Protocol (TDISP)</u> . See § Chapter 11. .	<u>HwInit</u>

7.5.3.4 Device Control Register (Offset 08h) §

The Device Control Register controls PCI Express device specific parameters. § Figure 7-25 details allocation of register fields in the Device Control Register; § Table 7-21 provides the respective bit definitions.

For VF fields indicated as RsvdP, the PF setting applies to the VF.

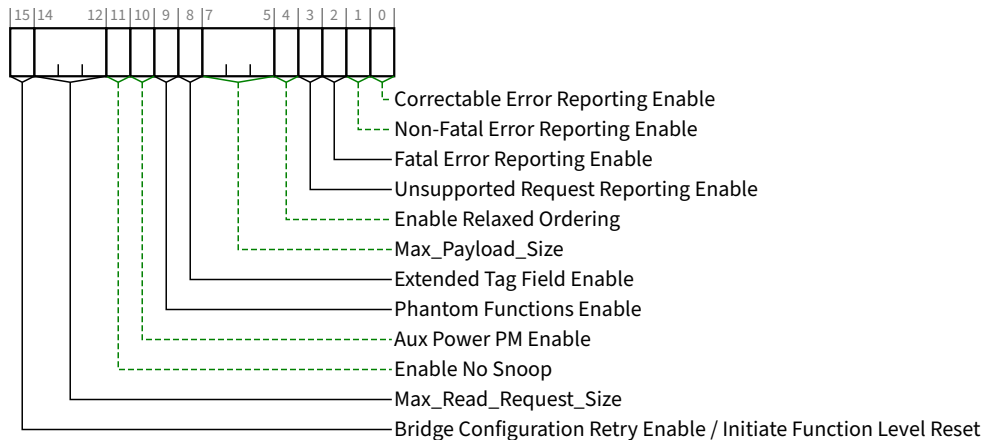

Figure 7-25 Device Control Register §

Table 7-21 Device Control Register §

Bit Location	Register Description	Attributes
0	<p>Correctable Error Reporting Enable - This bit, in conjunction with other bits, controls sending <u>ERR_COR</u> Messages (see § Section 6.2.5 , § Section 6.2.6 , and § Section 6.2.11.2 for details). For a <u>Multi-Function Device</u>, this bit controls error reporting for each Function from point-of-view of the respective Function.</p> <p>For a Root Port, the reporting of correctable errors is internal to the root. No external <u>ERR_COR</u> Message is generated.</p> <p>An <u>RCiEP</u> that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<u>RW</u> <u>VF RsvdP</u>

Bit Location	Register Description	Attributes										
1	<p>Non-Fatal Error Reporting Enable - This bit, in conjunction with other bits, controls sending <u>ERR_NONFATAL</u> Messages (see § Section 6.2.5 and § Section 6.2.6 for details). For a Multi-Function Device, this bit controls error reporting for each Function from point-of-view of the respective Function.</p> <p>For a Root Port, the reporting of Non-fatal errors is internal to the root. No external <u>ERR_NONFATAL</u> Message is generated.</p> <p>An RCiEP that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>										
2	<p>Fatal Error Reporting Enable - This bit, in conjunction with other bits, controls sending <u>ERR_FATAL</u> Messages (see § Section 6.2.5 and § Section 6.2.6 for details). For a Multi-Function Device, this bit controls error reporting for each Function from point-of-view of the respective Function.</p> <p>For a Root Port, the reporting of Fatal errors is internal to the root. No external <u>ERR_FATAL</u> Message is generated.</p> <p>An RCiEP that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>										
3	<p>Unsupported Request Reporting Enable - This bit, in conjunction with other bits, controls the signaling of Unsupported Request Errors by sending error Messages (see § Section 6.2.5 and § Section 6.2.6 for details). For a Multi-Function Device, this bit controls error reporting for each Function from point-of-view of the respective Function.</p> <p>An RCiEP that is not associated with a Root Complex Event Collector is permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>										
4	<p>Enable Relaxed Ordering - If this bit is Set, the Function is permitted to set the <u>Relaxed Ordering</u> bit in the Attributes field of transactions it initiates that do not require strong write ordering (see § Section 2.2.6.4 and § Section 2.4).</p> <p>A Function is permitted to hardwire this bit to 0b if it never sets the <u>Relaxed Ordering</u> attribute in transactions it initiates as a Requester.</p> <p>When not hardwired to 0b, the default value of this bit is 1b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>										
7:5	<p>Max_Payload_Size - For specified cases, this field determines the maximum TLP payload size (the MPS setting) for the Function. Values permitted to be programmed are indicated by the <u>Max_Payload_Size Supported</u> field.</p> <p>As a Receiver, if the <u>Rx_MPS_Fixed</u> bit is Set, the <u>Rx_MPS_Limit</u> is fixed with the value indicated by the <u>Max_Payload_Size Supported</u> field. Otherwise, the <u>Rx_MPS_Limit</u> is determined by the MPS setting in one or more Functions. See § Section 2.2.2 for important details regarding Multi-Function Devices.</p> <p>As a Transmitter, the Function must not generate TLPs with payloads exceeding the MPS setting, with the exception of Functions in a Multi-Function Device, or Functions with implementation-specific mechanisms capable of supporting different MPS settings for different targets. See § Section 2.2.2 for important details.</p> <p>Defined encodings for this field are:</p> <table> <tbody> <tr> <td>000b</td> <td>128 bytes MPS</td> </tr> <tr> <td>001b</td> <td>256 bytes MPS</td> </tr> <tr> <td>010b</td> <td>512 bytes MPS</td> </tr> <tr> <td>011b</td> <td>1024 bytes MPS</td> </tr> <tr> <td>100b</td> <td>2048 bytes MPS</td> </tr> </tbody> </table>	000b	128 bytes MPS	001b	256 bytes MPS	010b	512 bytes MPS	011b	1024 bytes MPS	100b	2048 bytes MPS	<p><u>RW</u> <u>VF RsvdP</u></p>
000b	128 bytes MPS											
001b	256 bytes MPS											
010b	512 bytes MPS											
011b	1024 bytes MPS											
100b	2048 bytes MPS											

Bit Location	Register Description	Attributes
	<p>101b 4096 bytes MPS</p> <p>110b Reserved</p> <p>111b Reserved</p> <p>Functions that support only the 128-byte MPS are permitted to hardwire this field to 000b.</p> <p>System software is not required to program the same value for this field for all the Functions of a Multi-Function Device.</p> <p>Default value of this field is 000b.</p>	
8	<p>Extended Tag Field Enable - This bit, in combination with the 10-Bit Tag Requester Enable bit and the 14-Bit Tag Requester Enable bit, determines how many Tag field bits a Requester is permitted to use.</p> <p>The following applies when the 10-Bit Tag Requester Enable bit and the 14-Bit Tag Requester Enable bit are both Clear. If the Extended Tag Field Enable bit is Set, the Function is permitted to use an 8-bit Tag field as a Requester. If the bit is Clear, the Function is restricted to using a 5-bit Tag field.</p> <p>See § Section 2.2.6.2 for required behavior when one or both of these larger-Tag Requester Enable bits are Set.</p> <p>If software changes the value of the Extended Tag Field Enable bit while the Function has outstanding Non-Posted Requests, the result is undefined.</p> <p>Functions that do not implement this capability hardwire this bit to 0b.</p> <p>Default value of this bit is implementation specific.</p>	<p>RW</p> <p>VF RsvdP</p>
9	<p>Phantom Functions Enable - This bit, in combination with the 10-Bit Tag Requester Enable bit and the 14-Bit Tag Requester Enable bit, determines how many outstanding Non-Posted Requests a Requester is permitted to generate. See § Section 2.2.6.2 for complete details.</p> <p>When Set, this bit enables a Function to use unclaimed Functions as Phantom Functions to extend the number of outstanding transaction identifiers. If the bit is Clear, the Function is not allowed to use Phantom Functions.</p> <p>Behavior is undefined when this bit is Set in Functions with enabled Shadow Functions.</p> <p>Software should not change the value of this bit while the Function has outstanding Non-Posted Requests; otherwise, the result is undefined.</p> <p>Functions that do not implement this capability hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<p>RW</p> <p>VF RsvdP</p>
10	<p>Aux Power PM Enable - When Set this bit, enables a Function to draw auxiliary power independent of PME Aux power. Functions that require auxiliary power on legacy operating systems should continue to indicate PME Aux power requirements. Auxiliary power is allocated as requested in the Aux_Current field of the Power Management Capabilities Register (PMC), independent of the PME_En bit in the Power Management Control/Status Register (PMCSR) (see § Chapter 5.). For Multi-Function Devices, a component is allowed to draw auxiliary power if at least one of the Functions has this bit set.</p> <p>Note: Functions that consume auxiliary power must preserve the value of this sticky register when auxiliary power is available. In such Functions, this bit is not modified by Conventional Reset.</p> <p>Functions that do not implement this capability hardwire this bit to 0b.</p> <p>Additional Aux power is permitted to be allocated using the firmware based mechanism (see the Request D3_{Cold} Aux Power Limit _DSM call as defined in [Firmware]).</p> <p>Additional Aux power is also permitted to be allocated by selecting a PM Sub State in the Power Limit mechanism (see § Section 7.8.1.3).</p>	<p>RWS</p> <p>VF RsvdP</p>
11	<p>Enable No Snoop - If this bit is Set, the Function is permitted to Set the No Snoop bit in the Requester Attributes of transactions it initiates that do not require hardware enforced cache coherency (see</p>	<p>RW</p> <p>VF RsvdP</p>

Bit Location	Register Description	Attributes																
	<p>§ Section 2.2.6.5). Note that setting this bit to 1b should not cause a Function to Set the No Snoop attribute on all transactions that it initiates. Even when this bit is Set, a Function is only permitted to Set the No Snoop attribute on a transaction when it can guarantee that the address of the transaction is not stored in any cache in the system.</p> <p>This bit is permitted to be hardwired to 0b if a Function would never Set the No Snoop attribute in transactions it initiates.</p> <p>Default value of this bit is 1b.</p>																	
14:12	<p>Max_Read_Request_Size - This field sets the maximum Read Request size for the Function as a Requester. The Function must not generate Read Requests with a size exceeding the set value. Defined encodings for this field are:</p> <table border="0"> <tr> <td>000b</td> <td>128 bytes maximum Read Request size</td> </tr> <tr> <td>001b</td> <td>256 bytes maximum Read Request size</td> </tr> <tr> <td>010b</td> <td>512 bytes maximum Read Request size</td> </tr> <tr> <td>011b</td> <td>1024 bytes maximum Read Request size</td> </tr> <tr> <td>100b</td> <td>2048 bytes maximum Read Request size</td> </tr> <tr> <td>101b</td> <td>4096 bytes maximum Read Request size</td> </tr> <tr> <td>110b</td> <td>Reserved</td> </tr> <tr> <td>111b</td> <td>Reserved</td> </tr> </table> <p>Functions that do not generate Read Requests larger than 128 bytes and Functions that do not generate Read Requests on their own behalf are permitted to implement this field as Read Only (RO) with a value of 000b.</p> <p>Default value of this field is 010b.</p>	000b	128 bytes maximum Read Request size	001b	256 bytes maximum Read Request size	010b	512 bytes maximum Read Request size	011b	1024 bytes maximum Read Request size	100b	2048 bytes maximum Read Request size	101b	4096 bytes maximum Read Request size	110b	Reserved	111b	Reserved	<p>RW VF RsvdP</p>
000b	128 bytes maximum Read Request size																	
001b	256 bytes maximum Read Request size																	
010b	512 bytes maximum Read Request size																	
011b	1024 bytes maximum Read Request size																	
100b	2048 bytes maximum Read Request size																	
101b	4096 bytes maximum Read Request size																	
110b	Reserved																	
111b	Reserved																	
15	<p>Bridge Configuration Retry Enable / Initiate Function Level Reset - this bit has a different meaning based on Function type:</p> <ul style="list-style-type: none"> <p>PCI Express to PCI/PCI-X Bridges:</p> <p>Bridge Configuration Retry Enable - When Set, this bit enables PCI Express to PCI/PCI-X bridges to return Request Retry Status (RRS) in response to Configuration Requests that target devices below the bridge. Refer to [PCIe-to-PCI-PCI-X-Bridge] for further details.</p> <p>Default value of this bit is 0b.</p> <p>Endpoints with Function Level Reset Capability set to 1b:</p> <p>Initiate Function Level Reset - A write of 1b initiates Function Level Reset to the Function. The value read by software from this bit is always 0b.</p> <p>PFs and VFs must support FLR. Note: performing FLR on a PF Clears its VF Enable bit, which causes its VFs no longer to exist after the FLR completes.</p> <p>All others:</p> <p>Reserved - Must hardwire the bit to 0b.</p> 	<p>PCI Express to PCI/PCI-X Bridges: RW FLR Capable Endpoints: RW All others: RsvdP</p>																

IMPLEMENTATION NOTE: SOFTWARE UR REPORTING COMPATIBILITY WITH 1.0A DEVICES §

With [PCIe-1.0a] device Functions,¹⁶⁴ if the Unsupported Request Reporting Enable bit is Set, the Function when operating as a Completer will send an uncorrectable error Message (if enabled) when a UR error is detected. On platforms where an uncorrectable error Message is handled as a System Error, this will break PC-compatible Configuration Space probing, so software/firmware on such platforms may need to avoid setting the Unsupported Request Reporting Enable bit.

With device Functions implementing Role-Based Error Reporting, setting the Unsupported Request Reporting Enable bit will not interfere with PC-compatible Configuration Space probing, assuming that the severity for UR is left at its default of non-fatal. However, setting the Unsupported Request Reporting Enable bit will enable the Function to report UR errors¹⁶⁵ detected with posted Requests, helping avoid this case for potential silent data corruption.

On platforms where robust error handling and PC-compatible Configuration Space probing is required, it is suggested that software or firmware have the Unsupported Request Reporting Enable bit Set for Role-Based Error Reporting Functions, but clear for [PCIe-1.0a] Functions. Software or firmware can distinguish the two classes of Functions by examining the Role-Based Error Reporting bit in the Device Capabilities Register.

164. In this context, [PCIe-1.0a] devices Functions are devices that do not implement Role-Based Error Reporting.

165. With Role-Based Error Reporting devices, setting the SERR# Enable bit in the Command Register also implicitly enables UR reporting.

IMPLEMENTATION NOTE: USE OF MAX_PAYLOAD_SIZE §

The `Max_Payload_Size` (MPS) mechanism enables software to control the maximum payload in TLPs sent by Endpoints to balance latency versus bandwidth trade-offs, particularly for isochronous traffic.

If software chooses to program the MPS of various System Elements to non-default values, it must take care to ensure that each TLP with a data payload does not exceed the MPS setting of any System Element along the TLP's path. Otherwise, the TLP will be rejected by the System Element whose MPS setting is too small.

No specific algorithm to configure MPS is required by this specification, but software should base its algorithm upon factors such as the following:

- the MPS capability of each System Element within a Hierarchy
- awareness of when System Elements are added or removed through Hot-Plug operations
- knowing which System Elements send TLPs to each other, what type of traffic is carried, what type of transactions are used, and if TLP sizes are constrained by other mechanisms

For the case of system firmware that configures System Elements in preparation for running legacy operating system environments, system firmware may need to avoid programming MPS settings above the default of 128 bytes, which is the minimum supported by Endpoints.

For example, if the operating system environment does not implement services for optimizing MPS settings, system firmware probably should not program a non-default MPS for a Hierarchy that supports Hot-Plug operations. Otherwise, if no software is present to manage MPS settings when a new element is added, improper operation may result. Note that a newly added element may not even support a MPS setting as large as the rest of the Hierarchy, in which case software may need to deny enabling the new element or reduce the MPS settings of other elements, which may require quiescing all traffic carrying data payloads.

For ARI Devices and other MFDs, it's challenging to describe concisely what determines a Function's MPS limit for received TLPs. For this reason, the formal term `Rx_MPS_Limit` was introduced. It is used in many instances where former revisions of this specification used `Max_Payload_Size` in the context of a Receiver. It covers several special cases where the MPS limit is determined by the MPS settings in other Functions of an MFD. See § [Section 2.2.2](#) for details.

For ARI Devices and other MFDs, it's also challenging to describe concisely what determines a Function's MPS limit for *transmitted* TLPs. For this reason, the formal term `Tx_MPS_Limit` was introduced. It is used in several instances where former revisions of this specification used `Max_Payload_Size` in the context of a Transmitter. It covers several special cases where the MPS limit is determined by the MPS settings in other Functions of an MFD. See § [Section 2.2.2](#) for details.

IMPLEMENTATION NOTE:

RX_MPS_FIXED ENHANCEMENT FOR MAX_PAYLOAD_SIZE §

The `Rx_MPS_Fixed` field was added to the Device Capabilities Register in the 6.0 Revision of this specification. As required in § Section 7.5.3.3, the `Rx_MPS_Fixed` capability bit *MUST@FLIT* be Set.

When `Rx_MPS_Fixed` is Set, the Receiver MPS limit for that Function is the value of the Function's `Max_Payload_Size Supported capability` field, the highest MPS setting that the Function supports. The `Rx_MPS_Fixed` mechanism enables the MPS limit for the Function's Receiver and Transmitter to be independent, which in certain cases enables software to change MPS settings without having to quiesce all traffic carrying data payloads.

For example, in configurations where active Functions lack this enhancement, if software increases the MPS setting of a given Function, any TLPs with data payloads that the Function sends to another Function may exceed its MPS setting, resulting in Malformed TLP errors. Similarly, if software decreases the MPS setting of a given Function, any TLPs with data payloads that other Functions send to it may exceed its MPS setting, again resulting in Malformed TLP errors. Without `Rx_MPS_Fixed`, the only general solution is to quiesce said traffic during reconfiguration.

IMPLEMENTATION NOTE:

MIXED MAX_PAYLOAD_SIZE CONFIGURATIONS §

The simplest way for System Software to configure a non-default `Max_Payload_Size (MPS)` setting for a Hierarchy is to scan all Functions, determine the smallest `Max_Payload_Size Supported capability`, and configure the MPS setting in all Functions to this value. This guarantees that no Function will send a TLP with a payload size that the target Function can't handle. However, this simple policy may be unnecessarily restrictive, given that not all Functions send each other Memory Space transactions. In fact, many Endpoints only exchange Memory Space transactions with the host, and don't exchange any P2P TLPs with other Endpoints.

To support the use case for "mixed MPS configurations", a Function that has its `Mixed_MPS_Supported` bit Set is permitted to transmit TLPs with payloads exceeding its MPS setting, though it must never exceed its `Max_Payload_Size Supported capability`. For the case where host memory supports `Rx_MPS_Fixed`, System Software may configure the MPS setting in each Endpoint based solely on its path to host memory and the `Max_Payload_Size Supported capability` of host memory. Then, for any Endpoints that support P2P with other Endpoints, driver software can make adjustments necessary for the P2P traffic, including routing element MPS capability along P2P paths. If the Endpoint's `Mixed_MPS_Supported` bit is Set, indicating that it supports an implementation specific mechanism capable of supporting different MPS settings for different targets, the driver software may configure that mechanism to optimize the MPS setting for P2P target Endpoints. If the Endpoint does not support this type of mechanism, or if the mechanism is unable to accommodate all of the Endpoint's P2P MPS requirements, the driver software may reduce its MPS setting if needed to accommodate its P2P traffic.

Mixed MPS configurations are especially useful for cases where a set of Endpoints exchange a high volume of very large P2P TLPs between each other; e.g., a set of high-end accelerators or SSDs connected by one or more high-end switches. Such configurations might use a much larger MPS setting (e.g., 2048 bytes) for the high-end switches and accelerators/SSDs than supported by most hosts (e.g., 512 bytes).

IMPLEMENTATION NOTE: USE OF MAX_READ_REQUEST_SIZE §

The Max_Read_Request_Size mechanism allows improved control of bandwidth allocation in systems where Quality of Service (QoS) is important for the target applications. For example, an arbitration scheme based on counting Requests (and not the sizes of those Requests) provides imprecise bandwidth allocation when some Requesters use much larger sizes than others. The Max_Read_Request_Size mechanism can be used to force more uniform allocation of bandwidth, by restricting the upper size of Read Requests.

7.5.3.5 Device Status Register (Offset 0Ah) §

The Device Status Register provides information about PCI Express device (Function) specific parameters. § Figure 7-26 details allocation of register fields in the Device Status Register; § Table 7-22 provides the respective bit definitions.

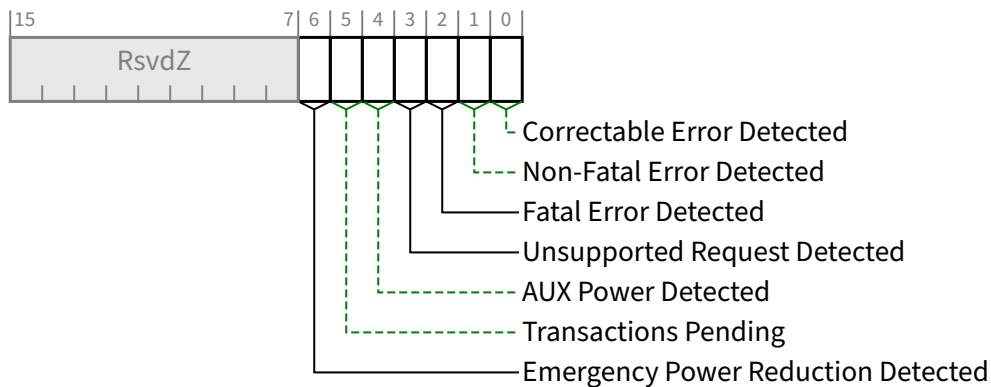

Figure 7-26 Device Status Register §

Table 7-22 Device Status Register §

Bit Location	Register Description	Attributes
0	<p>Correctable Error Detected - This bit indicates status of correctable errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. For a Multi-Function Device, each Function indicates status of errors as perceived by the respective Function.</p> <p>For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Correctable Error Mask register.</p> <p>Default value of this bit is 0b.</p>	RW1C
1	<p>Non-Fatal Error Detected - This bit indicates status of Non-fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. For a Multi-Function Device, each Function indicates status of errors as perceived by the respective Function.</p> <p>For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register.</p> <p>Default value of this bit is 0b.</p>	RW1C

Bit Location	Register Description	Attributes
2	<p>Fatal Error Detected - This bit indicates status of Fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. For a Multi-Function Device, each Function indicates status of errors as perceived by the respective Function.</p> <p>For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register.</p> <p>Default value of this bit is 0b.</p>	RW1C
3	<p>Unsupported Request Detected - This bit indicates that the Function received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. For a Multi-Function Device, each Function indicates status of errors as perceived by the respective Function.</p> <p>Default value of this bit is 0b.</p>	RW1C
4	<p>AUX Power Detected - Functions that require auxiliary power report this bit as Set if auxiliary power is detected by the Function.</p> <p>For VFs, this bit is not supported and must be hardwired to Zero.</p>	RO VF ROZ
5	<p>Transactions Pending -</p> <p><i>Endpoints:</i></p> <p>When Set, this bit indicates that the Function has issued Non-Posted Requests that have not been completed. A Function reports this bit cleared only when all outstanding Non-Posted Requests have completed or have been terminated by the Completion Timeout mechanism. This bit must also be cleared upon the completion of an FLR.</p> <p><i>Root and Switch Ports:</i></p> <p>When Set, this bit indicates that a Port has issued Non-Posted Requests on its own behalf (using the Port's own, or its Shadow Function's, Requester ID) which have not been completed. The Port reports this bit cleared only when all such outstanding Non-Posted Requests have completed or have been terminated by the Completion Timeout mechanism. Note that Root and Switch Ports implementing only the functionality required by this document do not issue Non-Posted Requests on their own behalf, and therefore are not subject to this case. Root and Switch Ports that do not issue Non-Posted Requests on their own behalf hardwire this bit to 0b.</p>	RO
6	<p>Emergency Power Reduction Detected - This bit is Set when the Function is in the Emergency Power Reduction State. Whenever any condition is present that would cause the Emergency Power Reduction State to be entered, the Function remains in the Emergency Power Reduction State and writes to this bit have no effect. See § Section 6.24 for additional details.</p> <p>Multi-Function Devices associated with an Upstream Port must Set this bit in all Functions that support Emergency Power Reduction State.</p> <p>For VFs, this bit is not supported and must be hardwired to Zero.</p> <p>Except for VFs, this bit is RsvdZ if the Emergency Power Reduction Supported field is 00b (see § Section 7.5.3.15).</p> <p>This bit is RsvdZ in Functions that are not associated with an Upstream Port.</p> <p>Default value is 0b.</p>	RW1C VF ROZ

7.5.3.6 Link Capabilities Register (Offset 0Ch) §

The Link Capabilities Register identifies PCI Express Link specific capabilities. § Figure 7-27 details allocation of register fields in the Link Capabilities Register; § Table 7-23 provides the respective bit definitions.

Figure 7-27 Link Capabilities Register §

Table 7-23 Link Capabilities Register §

Bit Location	Register Description	Attributes
3:0	<p>Max Link Speed - This field indicates the maximum Link speed of the associated Port.</p> <p>The encoded value specifies a Bit Location in the Supported Link Speeds Vector (in the <u>Link Capabilities 2 Register</u>) that corresponds to the maximum Link speed.</p> <p>Defined encodings are:</p> <p>0001b Supported Link Speeds Vector field bit 0</p> <p>0010b Supported Link Speeds Vector field bit 1</p> <p>0011b Supported Link Speeds Vector field bit 2</p> <p>0100b Supported Link Speeds Vector field bit 3</p> <p>0101b Supported Link Speeds Vector field bit 4</p> <p>0110b Supported Link Speeds Vector field bit 5</p> <p>0111b Supported Link Speeds Vector field bit 6</p> <p>All other encodings are reserved.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	RO
9:4	<p>Maximum Link Width - This field indicates the maximum Link width (xN - corresponding to N Lanes) implemented by the component. This value is permitted to exceed the number of Lanes routed to the slot (Downstream Port), adapter connector (Upstream Port), or in the case of component-to-component connections, the actual wired connection width.</p> <p>Defined encodings are:</p> <p>00 0001b x1</p> <p>00 0010b x2</p> <p>00 0100b x4</p> <p>00 1000b x8</p> <p>01 0000b x16</p> <p>All other encodings are Reserved.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	RO

Bit Location	Register Description	Attributes
11:10	<p>ASPM Support / Active State Power Management Support - This field indicates the level of ASPM supported on the given PCI Express Link. See § Section 5.4.1 for ASPM support requirements.</p> <p>Defined encodings are:</p> <p>00b No ASPM Support</p> <p>01b L0s Supported</p> <p>10b L1 Supported</p> <p>11b L0s and L1 Supported</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	RO
14:12	<p>L0s Exit Latency - This field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L0s to L0. If L0s is not supported, the value is undefined; however, see the Implementation Note “Potential Issues With Legacy Software When L0s is Not Supported” in § Section 5.4.1.1 for the recommended value.</p> <p>Defined encodings are:</p> <p>000b Less than 64 ns</p> <p>001b 64 ns to less than 128 ns</p> <p>010b 128 ns to less than 256 ns</p> <p>011b 256 ns to less than 512 ns</p> <p>100b 512 ns to less than 1 μs</p> <p>101b 1 μs to less than 2 μs</p> <p>110b 2 μs-4 μs</p> <p>111b More than 4 μs</p> <p>Note that exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	RO
17:15	<p>L1 Exit Latency - This field indicates the L1 Exit Latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from ASPM L1 to L0. If ASPM L1 is not supported, the value is undefined.</p> <p>Defined encodings are:</p> <p>000b Less than 1 μs</p> <p>001b 1 μs to less than 2 μs</p> <p>010b 2 μs to less than 4 μs</p> <p>011b 4 μs to less than 8 μs</p> <p>100b 8 μs to less than 16 μs</p> <p>101b 16 μs to less than 32 μs</p> <p>110b 32 μs-64 μs</p> <p>111b More than 64 μs</p> <p>Note that exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	RO

Bit Location	Register Description	Attributes
18	<p>Clock Power Management - For Upstream Ports, a value of 1b in this bit indicates that the component tolerates the removal of any reference clock(s) via the “clock request” (CLKREQ#) mechanism when the Link is in the L1 and L2/L3 Ready Link states. A value of 0b indicates the component does not have this capability and that reference clock(s) must not be removed in these Link states.</p> <p>L1 PM Substates defines other semantics for the CLKREQ# signal, which are managed independently of Clock Power Management.</p> <p>This Capability is applicable only in form factors that support “clock request” (CLKREQ#) capability.</p> <p>For a Multi-Function Device associated with an Upstream Port, each Function indicates its capability independently. Power Management configuration software must only permit reference clock removal if all Functions of the Multi-Function Device indicate a 1b in this bit. For ARI Devices, all Functions must indicate the same value in this bit.</p> <p>For Downstream Ports, this bit must be hardwired to 0b.</p>	RO
19	<p>Surprise Down Error Reporting Capable - For a Downstream Port, this bit must be Set if the component supports the optional capability of detecting and reporting a Surprise Down error condition.</p> <p>For Upstream Ports and components that do not support this optional capability, this bit must be hardwired to 0b.</p>	RO
20	<p>Data Link Layer Link Active Reporting Capable - For a Downstream Port, this bit must be hardwired to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable Downstream Port (as indicated by the Hot-Plug Capable bit of the Slot Capabilities Register) or a Downstream Port that supports Link speeds greater than 5.0 GT/s, this bit must be hardwired to 1b.</p> <p>For Upstream Ports and components that do not support this optional capability, this bit must be hardwired to 0b.</p>	RO
21	<p>Link Bandwidth Notification Capability - A value of 1b indicates support for the Link Bandwidth Notification status and interrupt mechanisms. This capability is required for all Root Ports and Switch Downstream Ports supporting Links wider than x1 and/or multiple Link speeds.</p> <p>This field is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches.</p> <p>Functions that do not implement the Link Bandwidth Notification Capability must hardwire this bit to 0b.</p>	RO
22	<p>ASPM Optionality Compliance - This bit must be set to 1b in all Functions. Components implemented against certain earlier versions of this specification will have this bit set to 0b.</p> <p>Software is permitted to use the value of this bit to help determine whether to enable ASPM or whether to run ASPM compliance tests.</p>	Hwlnit
31:24	<p>Port Number - This field indicates the PCI Express Port number for the given PCI Express Link.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	Hwlnit

IMPLEMENTATION NOTE: USE OF THE ASPM OPTIONALITY COMPLIANCE BIT §

Correct implementation and utilization of ASPM can significantly reduce Link power. However, ASPM feature implementations can be complex, and historically, some implementations have not been compliant to the specification. To address this, some of the ASPM optionality and ASPM entry requirements from earlier revisions of this document have been loosened. However, clear pass/fail compliance testing for ASPM features is also supported and expected.

The ASPM Optionality Compliance bit was created as a tool to establish clear expectations for hardware and software. This bit is Set to indicate hardware that conforms to the current specification, and this bit must be Set in components compliant to this specification.

System software as well as compliance software can assume that if this bit is Set, that the associated hardware conforms to the current specification. Hardware should be fully capable of supporting ASPM configuration management without needing component-specific treatment by system software.

For older hardware that does not have this bit Set, it is strongly recommended for system software to provide mechanisms to enable ASPM on components that work correctly with ASPM, and to disable ASPM on components that don't.

7.5.3.7 Link Control Register (Offset 10h) §

The Link Control Register controls PCI Express Link specific parameters. § Figure 7-28 details allocation of register fields in the Link Control Register; § Table 7-24 provides the respective bit definitions.

For VF fields indicated as RsvdP, the associated PF's setting applies to the VF.

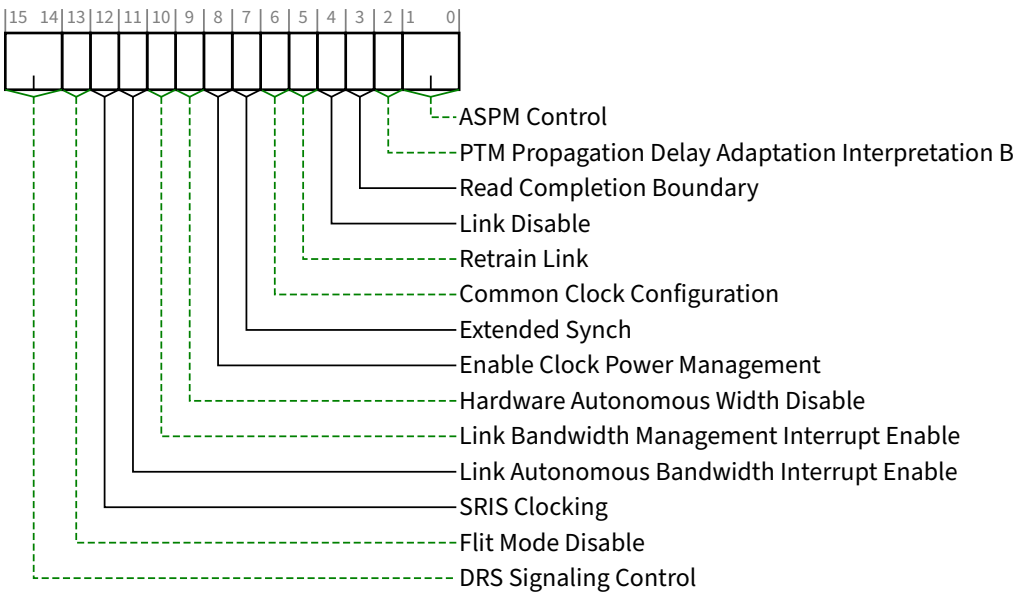

Figure 7-28 Link Control Register §

Table 7-24 Link Control Register §

Bit Location	Register Description	Attributes
1:0	<p>ASPM Control / Active State Power Management Control - This field controls the level of ASPM enabled on the given PCI Express Link. See § Section 5.4.1.4 for requirements on when and how to enable ASPM.</p> <p>Defined encodings are:</p> <p>00b Disabled</p> <p>01b L0s Entry Enabled</p> <p>10b L1 Entry Enabled</p> <p>11b L0s and L1 Entry Enabled</p> <p>Note: “L0s Entry Enabled” enables the Transmitter to enter L0s. If L0s is supported, the Receiver must be capable of entering L0s even when the Transmitter is disabled from entering L0s (00b or 10b).</p> <p>In Flit Mode, L0s is not supported, bit 0 of this field is ignored and has no effect (i.e., encodings 01b and 00b are equivalent as are encodings 11b and 10b).</p> <p>ASPM L1 must be enabled by software in the Upstream component on a Link prior to enabling ASPM L1 in the Downstream component on that Link. When disabling ASPM L1, software must disable ASPM L1 in the Downstream component on a Link prior to disabling ASPM L1 in the Upstream component on that Link. ASPM L1 must only be enabled on the Downstream component if both components on a Link support ASPM L1.</p> <p>For Multi-Function Devices (including ARI Devices), it is recommended that software program the same value for this field in all Functions. For non-ARI Multi-Function Devices, only capabilities enabled in all Functions are enabled for the component as a whole.</p> <p>For ARI Devices, ASPM Control is determined solely by the setting in Function 0, regardless of Function 0’s D-state. The settings in the other Functions always return whatever value software programmed for each, but otherwise are ignored by the component.</p>	<p>RW</p> <p>VF RsvdP</p>

Bit Location	Register Description	Attributes
	Default value of this field is 00b unless otherwise required by a particular form factor.	
2	PTM Propagation Delay Adaptation Interpretation B – For a device that supports PTM, if PTM Propagation Delay Adaptation Capable in the PTM Capability Register is Set, then, for an Upstream Port, this bit when Set selects interpretation B of the Propagation Delay[31:0] field for received PTM ResponseD Messages, and for a Downstream Port, this bit when Set selects interpretation B of the Propagation Delay[31:0] field for PTM ResponseD Messages transmitted by the Port; otherwise this bit when Clear selects interpretation A for both cases. For a device that supports PTM, if its PTM Propagation Delay Adaptation Capable in the PTM Capability Register is Clear, Ports must hardwire this bit to 0b. For Multi-Function Devices associated with an Upstream Port of a device that supports PTM, this bit must be implemented in the same Function that contains the PTM Extended Capability structure and RsvdP in all other Functions. Default value is implementation specific, but is recommended to be 0b. For a device that does not support PTM, for all Ports in that device this bit must be RsvdP.	<u>RW / RsvdP</u>
3	<p>Read Completion Boundary (RCB) - field is meaningful in Root Ports, Endpoints and Bridges. When meaningful, defined encodings are:</p> <p>0b 64 byte</p> <p>1b 128 byte</p> <p>Root Ports: RCB contains the RCB value for the Root Port. Refer to § Section 2.3.1.1 for the definition of the parameter RCB.</p> <p> This bit is hardwired for a Root Port and returns its <u>RCB</u> support capabilities.</p> <p>Endpoints and Bridges: Read Completion Boundary (RCB) - Optionally Set by configuration software to indicate the RCB value of the Root Port Upstream from the Endpoint or Bridge. Refer to § Section 2.3.1.1 for the definition of the parameter RCB.</p> <p> Configuration software must only Set this bit if the Root Port Upstream from the Endpoint or Bridge reports an <u>RCB</u> value of 128 bytes (a value of 1b in the <u>Read Completion Boundary</u> bit).</p> <p> Default value of this bit is 0b.</p> <p> Functions that do not implement this feature must hardwire the bit to 0b.</p> <p>Switch Ports: Not applicable - must hardwire the bit to 0b</p>	<p>Root Ports:</p> <p><u>RO</u></p> <p>Endpoints and Bridges:</p> <p><u>RW</u></p> <p><u>VF RsvdP</u></p> <p>Switch Ports:</p> <p><u>RO</u></p>
4	<p>Link Disable - This bit disables the Link by directing the LTSSM to the Disabled state when Set; this bit is Reserved on Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches.</p> <p>See <u>Implementation Note: Delays in Data Link Layer Link Active Reflecting Link Control Operations</u> for related information.</p> <p>Writes to this bit are immediately reflected in the value read from the bit, regardless of actual Link state.</p> <p>After clearing this bit, software must honor timing requirements defined in § Section 6.6.1 with respect to the first Configuration Read following a Conventional Reset.</p> <p>Default value of this bit is 0b.</p>	<u>RW</u>
5	<p>Retrain Link - A write of 1b to this bit initiates Link retraining by directing the Physical Layer LTSSM to the Recovery state. If the LTSSM is already in Recovery or Configuration, re-entering Recovery is permitted but not required. If the Port is in DPC when a write of 1b to this bit occurs, the result is undefined. Reads of this bit always return 0b.</p> <p>It is permitted to write 1b to this bit while simultaneously writing modified values to other fields in this register. If the LTSSM is not already in Recovery or Configuration, the resulting Link training must</p>	<u>RW</u>

Bit Location	Register Description	Attributes
	<p>use the modified values. If the LTSSM is already in Recovery or Configuration, the modified values are not required to affect the Link training that's already in progress.</p> <p>This bit is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches.</p> <p>This bit always returns 0b when read.</p>	
6	<p>Common Clock Configuration - When Set, this bit indicates that this component and the component at the opposite end of this Link are operating with a distributed common reference clock.</p> <p>A value of 0b indicates that this component and the component at the opposite end of this Link are operating with asynchronous reference clock.</p> <p>For non-ARI Multi-Function Devices, software must program the same value for this bit in all Functions. If not all Functions are Set, then the component must as a whole assume that its reference clock is not common with the Upstream component.</p> <p>For ARI Devices, Common Clock Configuration is determined solely by the setting in Function 0. The settings in the other Functions always return whatever value software programmed for each, but otherwise are ignored by the component.</p> <p>Components utilize this <u>Common Clock Configuration</u> information to report the correct <u>L0s</u> and <u>L1 Exit Latencies</u>.</p> <p>After changing the value in this bit in both components on a Link, software must trigger the Link to retrain by writing a 1b to the <u>Retrain Link</u> bit of the Downstream Port.</p> <p>Default value of this bit is 0b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>
7	<p>Extended Synch - When Set, this bit forces the transmission of additional Ordered Sets when exiting the L0s state (see § Section 4.2.5.6) and when in the Recovery state (see § Section 4.2.7.4.1). This mode provides external devices (e.g., logic analyzers) monitoring the Link time to achieve bit and Symbol lock before the Link enters the L0 state and resumes communication.</p> <p>For Multi-Function Devices if any Function has this bit Set, then the component must transmit the additional Ordered Sets when exiting <u>L0s</u> or when in Recovery.</p> <p>Default value for this bit is 0b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>
8	<p>Enable Clock Power Management - Applicable only for Upstream Ports and with form factors that support a “Clock Request” (CLKREQ#) mechanism, this bit operates as follows:</p> <p>0b Clock power management is disabled and device must hold CLKREQ# signal low.</p> <p>1b When this bit is Set, the device is permitted to use CLKREQ# signal to power manage Link clock according to protocol defined in appropriate form factor specification.</p> <p>For a non-ARI Multi-Function Device, power-management-configuration software must only Set this bit if all Functions of the Multi-Function Device indicate a 1b in the Clock Power Management bit of the <u>Link Capabilities Register</u>. The component is permitted to use the CLKREQ# signal to power manage Link clock only if this bit is Set for all Functions.</p> <p>For ARI Devices, Clock Power Management is enabled solely by the setting in Function 0. The settings in the other Functions always return whatever value software programmed for each, but otherwise are ignored by the component.</p> <p>The CLKREQ# signal may also be controlled via the <u>L1 PM Substates</u> mechanism. Such control is not affected by the setting of this bit.</p> <p>Downstream Ports and components that do not support Clock Power Management (as indicated by a 0b value in the <u>Clock Power Management</u> bit of the <u>Link Capabilities Register</u>) must hardwire this bit to 0b.</p> <p>Default value of this bit is 0b, unless specified otherwise by the form factor specification.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>

Bit Location	Register Description	Attributes												
9	<p>Hardware Autonomous Width Disable - When Set, this bit disables hardware from changing the Link width for reasons other than attempting to correct unreliable Link operation by reducing Link width.</p> <p>For a Multi-Function Device associated with an Upstream Port, the bit in Function 0 is of type RW, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is of type RsvdP.</p> <p>Components that do not implement the ability autonomously to change Link width are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<p>RW/RsvdP (see description)</p> <p>VF RsvdP</p>												
10	<p>Link Bandwidth Management Interrupt Enable - When Set, this bit enables the generation of an interrupt to indicate that the <u>Link Bandwidth Management Status</u> bit has been Set.</p> <p>This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches.</p> <p>Functions that do not implement the <u>Link Bandwidth Notification Capability</u> must hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW												
11	<p>Link Autonomous Bandwidth Interrupt Enable - When Set, this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been Set.</p> <p>This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches.</p> <p>Functions that do not implement the <u>Link Bandwidth Notification Capability</u> must hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW												
12	<p>SRIS Clocking - This bit, in conjunction with <u>Common Clock Configuration</u>, indicates the clocking mode used on the Link.</p> <p>This bit is meaningful in Downstream Ports that support Flit Mode. In all other Functions, this bit is RsvdP.</p> <p>If <u>Common Clock Configuration</u> is Set, this bit has no effect and the SRIS Clocking bit in the <u>TS1s</u> must be 0b (Symbol 4, bit 7).</p> <p>If <u>Common Clock Configuration</u> is Clear, this bit is sent in the SRIS Clocking bit of <u>TS1s</u> (Symbol 4, bit 7).</p> <table border="1" data-bbox="467 1270 1101 1497"> <thead> <tr> <th>Clocking Mode</th> <th>Common Clock Configuration</th> <th>SRIS Clocking</th> </tr> </thead> <tbody> <tr> <td>Common Clock</td> <td>1</td> <td>x</td> </tr> <tr> <td><u>SRNS</u></td> <td>0</td> <td>0</td> </tr> <tr> <td><u>SRIS</u></td> <td>0</td> <td>1</td> </tr> </tbody> </table> <p>Default is 0b.</p>	Clocking Mode	Common Clock Configuration	SRIS Clocking	Common Clock	1	x	<u>SRNS</u>	0	0	<u>SRIS</u>	0	1	RW
Clocking Mode	Common Clock Configuration	SRIS Clocking												
Common Clock	1	x												
<u>SRNS</u>	0	0												
<u>SRIS</u>	0	1												
13	<p>Flit Mode Disable - when Set, the Port is not permitted to set the Flit Mode Supported bit in training sets it sends. This bit has no effect on the Flit Mode Supported bit in the <u>PCI Express Capabilities Register</u> and thus has no effect on behavior required by <u>MUST@FLIT</u>.</p> <p>Since Flit Mode is required at 64.0 GT/s or higher, disabling Flit Mode also has the effect of disabling data rates of 64.0 GT/s or higher.</p> <p>This bit is mandatory in Downstream Ports where <u>Flit Mode Supported</u> is Set.</p> <p>For Functions associated with an Upstream Port, this bit is optionally implemented in Function 0 and is not implemented in all other Functions. When not implemented, this bit must be hardwired to <u>Zero</u>.</p>	RW												

Bit Location	Register Description	Attributes
	<p>Changing this bit while the Link is Up has no effect. The updated value will take effect on the next transition to Link Up.</p> <p>This bit can be used as a workaround for faulty Flit Mode implementations. As such, it might be set by System Firmware, Device Firmware. As such, System Software should not clear this bit.</p> <p>This bit is not implemented in RCiEPs.</p> <p>In Downstream Ports, the default is Zero. In Upstream Ports, the default is implementation specific (e.g., it might be Set by device firmware).</p>	
15:14	<p>DRS Signaling Control - Indicates the mechanism used to report reception of a DRS message. Must be implemented for Downstream Ports with the <u>DRS Supported</u> bit Set in the <u>Link Capabilities 2 Register</u>. Encodings are:</p> <p>00b DRS not Reported: If <u>DRS Supported</u> is Set, receiving a <u>DRS Message</u> will set <u>DRS Message Received</u> in the <u>Link Status 2 Register</u> but will otherwise have no effect</p> <p>01b DRS Interrupt Enabled: If the <u>DRS Message Received</u> bit in the <u>Link Status 2 Register</u> transitions from 0 to 1, and either <u>MSI</u> or <u>MSI-X</u> is enabled, an <u>MSI</u> or <u>MSI-X</u> interrupt is generated using the vector in <u>Interrupt Message Number</u> (§ Section 7.5.3.2)</p> <p>10b DRS to FRS Signaling Enabled: If the <u>DRS Message Received</u> bit in the <u>Link Status 2 Register</u> transitions from 0 to 1, the Port must send an <u>FRS Message Upstream</u> with the <u>FRS Reason</u> field set to <u>DRS Message Received</u>.</p> <p>Behavior is undefined if this field is set to 10b and the <u>FRS Supported</u> bit in the <u>Device Capabilities 2 Register</u> is Clear.</p> <p>Behavior is undefined if this field is set to 11b.</p> <p>Downstream Ports with the <u>DRS Supported</u> bit Clear in the <u>Link Capabilities 2 Register</u> must hardwire this field to 00b.</p> <p>This field is Reserved for Upstream Ports.</p> <p>Default value of this field is 00b.</p>	RW/RsvdP

IMPLEMENTATION NOTE: SOFTWARE COMPATIBILITY WITH ARI DEVICES §

With the ASPM Control field, Common Clock Configuration bit, and Enable Clock Power Management bit in the Link Control Register, there are potential software compatibility issues with ARI Devices since these controls operate strictly off the settings in Function 0 instead of the settings in all Functions.

With compliant software, there should be no issues with the Common Clock Configuration bit, since software is required to set this bit the same in all Functions.

With the Enable Clock Power Management bit, there should be no compatibility issues with software that sets this bit the same in all Functions. However, if software does not set this bit the same in all Functions, and relies on each Function having the ability to prevent Clock Power Management from being enabled, such software may have compatibility issues with ARI Devices.

With the ASPM Control field, there should be no compatibility issues with software that sets this bit the same in all Functions. However, if software does not set this bit the same in all Functions, and relies on each Function in D0 state having the ability to prevent ASPM from being enabled, such software may have compatibility issues with ARI Devices.

IMPLEMENTATION NOTE: AVOIDING RACE CONDITIONS WHEN USING THE RETRAIN LINK BIT §

When software changes Link control parameters and writes a 1b to the Retrain Link bit in order to initiate Link training using the new parameter settings, special care is required in order to avoid certain race conditions. At any instant the LTSSM may transition to the Recovery or Configuration state due to normal Link activity, without software awareness. If the LTSSM is already in Recovery or Configuration when software writes updated parameters to the Link Control Register, as well as a 1b, to the Retrain Link bit, the LTSSM might not use the updated parameter settings with the current Link training, and the current Link training might not achieve the results that software intended.

To avoid this potential race condition, it is strongly recommended that software use the following algorithm or something similar:

1. Software sets the relevant Link control parameters to the desired settings without writing a 1b to the Retrain Link bit.
2. Software polls the Link Training bit in the Link Status Register until the value returned is 0b.
3. Software writes a 1b to the Retrain Link bit without changing any other fields in the Link Control Register.

The above algorithm guarantees that Link training will be based on the Link control parameter settings that software intends.

IMPLEMENTATION NOTE: USE OF THE SLOT CLOCK CONFIGURATION AND COMMON CLOCK CONFIGURATION BITS §

In order to determine the common clocking configuration of components on opposite ends of a Link that crosses a connector, two pieces of information are required. The following description defines these requirements.

The first necessary piece of information is whether the Downstream Port that connects to the slot uses a clock that has a common source and therefore constant phase relationship to the clock signal provided on the slot. This information is provided by the system side component through a hardware initialized bit (Slot Clock Configuration) in its Link Status Register. Note that some electromechanical form factor specifications may require the Port that connects to the slot use a clock that has a common source to the clock signal provided on the slot.

The second necessary piece of information is whether the component on the adapter uses the clock supplied on the slot or one generated locally on the adapter. The adapter design and layout will determine whether the component is connected to the clock source provided by the slot. A component going onto this adapter should have some hardware initialized method for the adapter design/designer to indicate the configuration used for this particular adapter design. This information is reported by Slot Clock Configuration in the Link Status Register of each Function in the Upstream Port. Note that some electromechanical form factor specifications may require the Port on the adapter to use the clock signal provided on the connector.

System firmware or software will read the Slot Clock Configuration from the components on both ends of a physical Link. If the Slot Clock Configuration bit is Set for both components, this firmware/software will Set the Common Clock Configuration bit on both components connected to the Link. Each component uses this bit to determine the length of time required to re-synch its Receiver to the opposing component's Transmitter when exiting L0s.

The time required to re-synch is reported as a time value in the L0s Exit Latency in the Link Capabilities Register (offset 0Ch) and is sent to the opposing Transmitter as part of the initialization process as N_FTS. Components would be expected to require much longer synch times without common clocking and would therefore report a longer L0s Exit Latency in bits 12-14 of the Link Capabilities Register and would send a larger number for N_FTS during training. This forces a requirement that whatever software changes this bit should force a Link retrain in order to get the correct N_FTS set for the Receivers at both ends of the Link.

7.5.3.8 Link Status Register (Offset 12h) §

The Link Status Register provides information about PCI Express Link specific parameters. § Figure 7-29 details allocation of register fields in the Link Status Register; § Table 7-26 provides the respective bit definitions.

For a VF, all fields are RsvdZ and the associated PF's setting for each field applies to the VF.

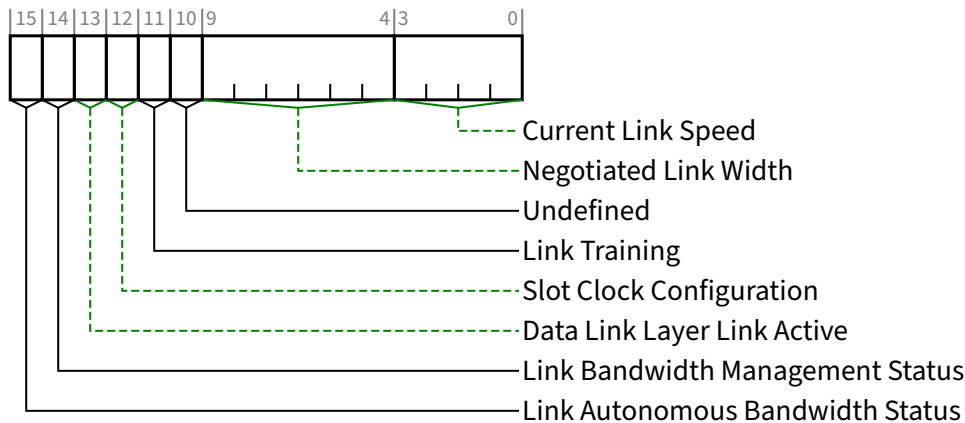

Figure 7-29 Link Status Register §

Table 7-26 Link Status Register §

Bit Location	Register Description	Attributes
3:0	<p>Current Link Speed - This field indicates the negotiated Link speed of the given PCI Express Link. The encoded value specifies a Bit Location in the Supported Link Speeds Vector (in the <u>Link Capabilities 2 Register</u>) that corresponds to the current Link speed.</p> <p>Defined encodings are:</p> <ul style="list-style-type: none"> 0001b Supported Link Speeds Vector field bit 0 0010b Supported Link Speeds Vector field bit 1 0011b Supported Link Speeds Vector field bit 2 0100b Supported Link Speeds Vector field bit 3 0101b Supported Link Speeds Vector field bit 4 0110b Supported Link Speeds Vector field bit 5 0111b Supported Link Speeds Vector field bit 6 <p>All other encodings are Reserved.</p> <p>The value in this field is undefined when the Link is not up.</p>	<p>RO</p> <p>VF RsvdZ</p>
9:4	<p>Negotiated Link Width - This field indicates the negotiated width of the given PCI Express Link. This includes the Link Width determined during initial link training as well changes that occur after initial link training (e.g., L0p).</p> <p>Defined encodings are:</p> <ul style="list-style-type: none"> 00 0001b x1 00 0010b x2 00 0100b x4 00 1000b x8 01 0000b x16 <p>All other encodings are Reserved. The value in this field is undefined when the Link is not up.</p>	<p>RO</p> <p>VF RsvdZ</p>

Bit Location	Register Description	Attributes
10	Undefined - The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate a Link Training Error. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.	<u>RO</u> <u>VF RsvdZ</u>
11	Link Training - This read-only bit indicates that the Physical Layer LTSSM is in the Configuration or Recovery state, or that 1b was written to the Retrain Link bit but Link training has not yet begun. Hardware clears this bit when the LTSSM exits the Configuration/Recovery state. This bit is not applicable and Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches, and must be hardwired to 0b.	<u>RO</u> <u>VF RsvdZ</u>
12	Slot Clock Configuration - This bit indicates that the component uses the same physical reference clock that the platform provides on the connector. If the device uses an independent clock irrespective of the presence of a reference clock on the connector, this bit must be clear. For a Multi-Function Device, each Function must report the same value for this bit.	<u>HwInit</u> <u>VF RsvdZ</u>
13	Data Link Layer Link Active - This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1b to indicate the <u>DL_Active</u> state, 0b otherwise. See Implementation Note: <u>Delays in Data Link Layer Link Active Reflecting Link Control Operations</u> for related information. This bit must be implemented if the <u>Data Link Layer Link Active Reporting Capable</u> bit is 1b. Otherwise, this bit must be hardwired to 0b.	<u>RO</u> <u>VF RsvdZ</u>
14	Link Bandwidth Management Status - This bit is Set by hardware to indicate that either of the following has occurred without the Port transitioning through <u>DL_Down</u> status: <ul style="list-style-type: none"> A Link retraining has completed following a write of 1b to the <u>Retrain Link</u> bit. Note: This bit is Set following any write of 1b to the <u>Retrain Link</u> bit, including when the Link is in the process of retraining for some other reason. Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was not indicated as an autonomous change. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. Functions that do not implement the <u>Link Bandwidth Notification Capability</u> must hardwire this bit to 0b. The default value of this bit is 0b.	<u>RW1C</u> <u>VF RsvdZ</u>
15	Link Autonomous Bandwidth Status - This bit is Set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through <u>DL_Down</u> status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was indicated as an autonomous change. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. Functions that do not implement the <u>Link Bandwidth Notification Capability</u> must hardwire this bit to 0b. The default value of this bit is 0b.	<u>RW1C</u> <u>VF RsvdZ</u>

IMPLEMENTATION NOTE: DELAYS IN DLL LINK ACTIVE REFLECTING LINK CONTROL OPERATIONS §

When software changes Link control parameters such as Setting the Secondary Bus Reset bit in the Bridge Control Register or the Link Disable bit in the Link Control Register, the Downstream Port will eventually transition to the DL_Down state, but there may be a significant delay with this occurring and being reflected by the Data Link Layer Link Active bit in the Link Status Register being Cleared. Often this occurs within a few ms, but in certain cases it may take tens of ms or longer. When software is waiting for Data Link Layer Link Active to become Clear, in some environments it may be best for software to set up a Data Link Layer State Changed interrupt instead of polling Data Link Layer Link Active continuously until it Clears

7.5.3.9 Slot Capabilities Register (Offset 14h) §

The Slot Capabilities Register identifies PCI Express slot specific capabilities. § Figure 7-30 details allocation of register fields in the Slot Capabilities Register; § Table 7-27 provides the respective bit definitions.

If this register is implemented but the Slot Implemented bit is Clear, the field behavior of this entire register is undefined.

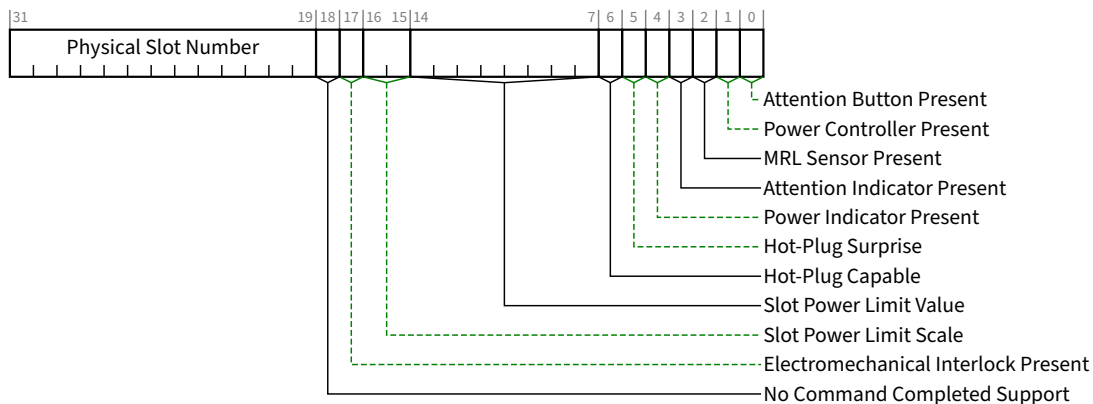

Figure 7-30 Slot Capabilities Register §

Table 7-27 Slot Capabilities Register §

Bit Location	Register Description	Attributes
0	Attention Button Present - When Set, this bit indicates that an Attention Button for this slot is electrically controlled by the chassis.	<u>HwInit</u>
1	Power Controller Present - When Set, this bit indicates that a software programmable Power Controller is implemented for this slot/adaptor (depending on form factor).	<u>HwInit</u>
2	MRL Sensor Present - When Set, this bit indicates that an MRL Sensor is implemented on the chassis for this slot.	<u>HwInit</u>

Bit Location	Register Description	Attributes																																
3	Attention Indicator Present - When Set, this bit indicates that an Attention Indicator is electrically controlled by the chassis.	<u>HwInit</u>																																
4	Power Indicator Present - When Set, this bit indicates that a Power Indicator is electrically controlled by the chassis for this slot.	<u>HwInit</u>																																
5	Hot-Plug Surprise - When Set, this bit indicates that an adapter present in this slot might be removed from the system without any prior notification. This is a form factor specific capability. This bit is an indication to the operating system to allow for such removal without impacting continued software operation. If the <u>SFI HPS Suppress</u> bit in the SFI Control Register is Clear, a read of the <u>Hot-Plug Surprise</u> bit returns the <u>HwInit</u> value. If the <u>SFI HPS Suppress</u> bit is Set, a read returns 0b. See <u>Section 7.9.22.3</u> .	<u>HwInit/RO</u> (see description)																																
6	Hot-Plug Capable - When Set, this bit indicates that this slot is capable of supporting hot-plug operations.	<u>HwInit</u>																																
14:7	Slot Power Limit Value - In combination with the Slot Power Limit Scale value, specifies the upper limit on power supplied by the slot (see <u>Section 6.9</u>) or by other means to the adapter. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field except when the Slot Power Limit Scale field equals 00b (1.0x) and Slot Power Limit Value exceeds EFh, the following alternative encodings are used: <table border="0"> <tr><td>F0h</td><td>> 239 W and ≤ 250 W Slot Power Limit</td></tr> <tr><td>F1h</td><td>> 250 W and ≤ 275 W Slot Power Limit</td></tr> <tr><td>F2h</td><td>> 275 W and ≤ 300 W Slot Power Limit</td></tr> <tr><td>F3h</td><td>> 300 W and ≤ 325 W Slot Power Limit</td></tr> <tr><td>F4h</td><td>> 325 W and ≤ 350 W Slot Power Limit</td></tr> <tr><td>F5h</td><td>> 350 W and ≤ 375 W Slot Power Limit</td></tr> <tr><td>F6h</td><td>> 375 W and ≤ 400 W Slot Power Limit</td></tr> <tr><td>F7h</td><td>> 400 W and ≤ 425 W Slot Power Limit</td></tr> <tr><td>F8h</td><td>> 425 W and ≤ 450 W Slot Power Limit</td></tr> <tr><td>F9h</td><td>> 450 W and ≤ 475 W Slot Power Limit</td></tr> <tr><td>FAh</td><td>> 475 W and ≤ 500 W Slot Power Limit</td></tr> <tr><td>FBh</td><td>> 500 W and ≤ 525 W Slot Power Limit</td></tr> <tr><td>FCh</td><td>> 525 W and ≤ 550 W Slot Power Limit</td></tr> <tr><td>FDh</td><td>> 550 W and ≤ 575 W Slot Power Limit</td></tr> <tr><td>FEh</td><td>> 575 W and ≤ 600 W Slot Power Limit</td></tr> <tr><td>FFh</td><td>Reserved for Slot Power Limit Values above 600 W</td></tr> </table> This register must be implemented if the <u>Slot Implemented</u> bit is Set. Writes to this register also cause the Port to send the <u>Set_Slot_Power_Limit</u> Message. The default value prior to hardware/firmware initialization is 0000 0000b.	F0h	> 239 W and ≤ 250 W Slot Power Limit	F1h	> 250 W and ≤ 275 W Slot Power Limit	F2h	> 275 W and ≤ 300 W Slot Power Limit	F3h	> 300 W and ≤ 325 W Slot Power Limit	F4h	> 325 W and ≤ 350 W Slot Power Limit	F5h	> 350 W and ≤ 375 W Slot Power Limit	F6h	> 375 W and ≤ 400 W Slot Power Limit	F7h	> 400 W and ≤ 425 W Slot Power Limit	F8h	> 425 W and ≤ 450 W Slot Power Limit	F9h	> 450 W and ≤ 475 W Slot Power Limit	FAh	> 475 W and ≤ 500 W Slot Power Limit	FBh	> 500 W and ≤ 525 W Slot Power Limit	FCh	> 525 W and ≤ 550 W Slot Power Limit	FDh	> 550 W and ≤ 575 W Slot Power Limit	FEh	> 575 W and ≤ 600 W Slot Power Limit	FFh	Reserved for Slot Power Limit Values above 600 W	<u>HwInit</u>

FEh	> 575 W and ≤ 600 W Slot Power Limit																																	
FFh	Reserved for Slot Power Limit Values above 600 W																																	
16:15	Slot Power Limit Scale - Specifies the scale used for the <u>Slot Power Limit Value</u> (see <u>Section 6.9</u>). Range of Values: <table border="0"> <tr><td>00b</td><td>1.0x</td></tr> <tr><td>01b</td><td>0.1x</td></tr> <tr><td>10b</td><td>0.01x</td></tr> </table>	00b	1.0x	01b	0.1x	10b	0.01x	<u>HwInit</u>																										
00b	1.0x																																	
01b	0.1x																																	
10b	0.01x																																	

Bit Location	Register Description	Attributes
	<p>11b 0.001x</p> <p>This register must be implemented if the <u>Slot Implemented</u> bit is Set.</p> <p>Writes to this register also cause the Port to send the <u>Set_Slot_Power_Limit</u> Message.</p> <p>The default value prior to hardware/firmware initialization is 00b.</p>	
17	<p>Electromechanical Interlock Present - When Set, this bit indicates that an Electromechanical Interlock is implemented on the chassis for this slot.</p>	<u>HwInit</u>
18	<p>No Command Completed Support - When Set, this bit indicates that this slot does not generate software notification when an issued command is completed by the Hot-Plug Controller. This bit is only permitted to be Set if the hot-plug capable Port is able to accept writes to all fields of the <u>Slot Control Register</u> without delay between successive writes.</p>	<u>HwInit</u>
31:19	<p>Physical Slot Number - This field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is unique within the chassis, regardless of the form factor associated with the slot. This field must be initialized to Zero for Ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port.</p>	<u>HwInit</u>

7.5.3.10 Slot Control Register (Offset 18h) §

The Slot Control Register controls PCI Express Slot specific parameters. § Figure 7-31 details allocation of register fields in the Slot Control Register; § Table 7-28 provides the respective bit definitions.

Attention Indicator Control, Power Indicator Control, and Power Controller Control fields of the Slot Control Register do not have a defined default value. If these fields are implemented, it is the responsibility of either system firmware or operating system software to (re)initialize these fields after a reset of the Link.

In hot-plug capable Downstream Ports, a write to the Slot Control Register must cause a hot-plug command to be generated (see § Section 6.7.3.2 for details on hot-plug commands). A write to the Slot Control Register in a Downstream Port that is not hot-plug capable must not cause a hot-plug command to be executed.

If this register is implemented but the Slot Implemented bit is Clear, the field behavior of this entire register with the exception of the Data Link Layer State Changed Enable bit is undefined.

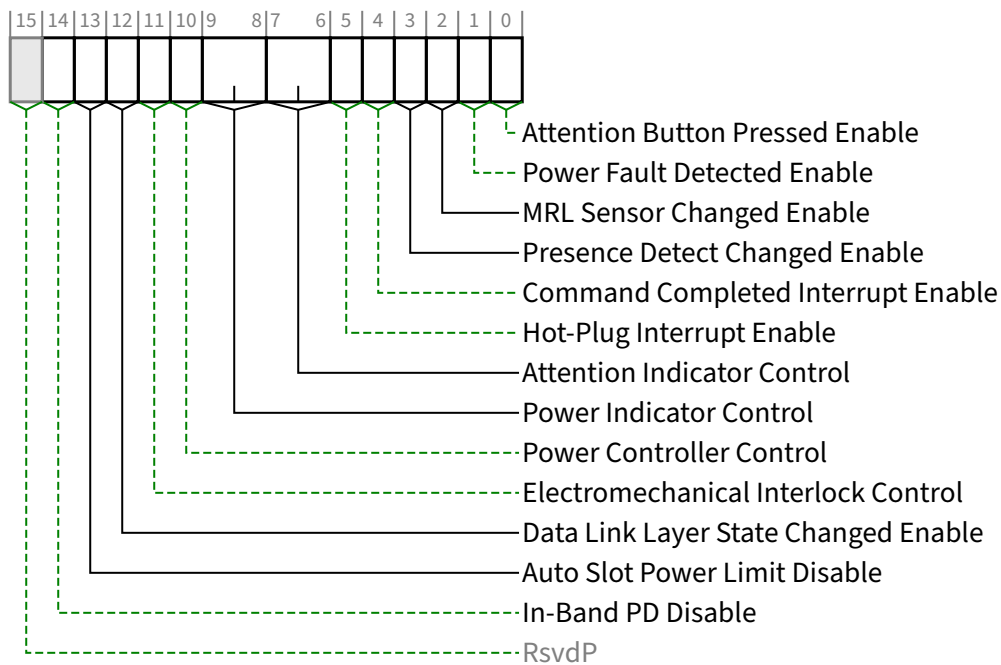

Figure 7-31 Slot Control Register §

Table 7-28 Slot Control Register §

Bit Location	Register Description	Attributes
0	<p>Attention Button Pressed Enable - When Set to 1b, this bit enables software notification on an attention button pressed event (see § Section 6.7.3).</p> <p>If the Attention Button Present bit in the <u>Slot Capabilities Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b.</p>	RW
1	<p>Power Fault Detected Enable - When Set, this bit enables software notification on a power fault event (see § Section 6.7.3).</p> <p>If a Power Controller that supports power fault detection is not implemented, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b.</p>	RW
2	<p>MRL Sensor Changed Enable - When Set, this bit enables software notification on a MRL sensor changed event (see § Section 6.7.3).</p> <p>If the MRL Sensor Present bit in the <u>Slot Capabilities Register</u> is Clear, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b.</p>	RW
3	<p>Presence Detect Changed Enable - When Set, this bit enables software notification on a presence detect changed event (see § Section 6.7.3).</p> <p>If the Hot-Plug Capable bit in the <u>Slot Capabilities Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p>	RW

Bit Location	Register Description	Attributes								
	Default value of this bit is 0b.									
4	<p>Command Completed Interrupt Enable - If Command Completed notification is supported (if the <u>No Command Completed Support</u> bit in the <u>Slot Capabilities Register</u> is 0b), when Set, this bit enables software notification when a hot-plug command is completed by the Hot-Plug Controller.</p> <p>If <u>Command Completed</u> notification is not supported, this bit must be hardwired to 0b.</p> <p>Default value of this bit is 0b.</p>	RW								
5	<p>Hot-Plug Interrupt Enable - When Set, this bit enables generation of an interrupt on enabled hot-plug events.</p> <p>If the <u>Hot-Plug Capable</u> bit in the <u>Slot Capabilities Register</u> is Clear, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b.</p>	RW								
7:6	<p>Attention Indicator Control - If an Attention Indicator is implemented, writes to this field set the Attention Indicator to the written state.</p> <p>Reads of this field must reflect the value from the latest write, even if the corresponding hot-plug command is not complete, unless software issues a write without waiting, if required to, for the previous command to complete in which case the read value is undefined.</p> <p>Defined encodings are:</p> <table> <tr> <td>00b</td> <td>Reserved</td> </tr> <tr> <td>01b</td> <td>On</td> </tr> <tr> <td>10b</td> <td>Blink</td> </tr> <tr> <td>11b</td> <td>Off</td> </tr> </table> <p>Note: The default value of this field must be one of the non-Reserved values. If the <u>Attention Indicator Present</u> bit in the <u>Slot Capabilities Register</u> is 0b, this bit is permitted to be read-only with a value of 00b.</p>	00b	Reserved	01b	On	10b	Blink	11b	Off	RW
00b	Reserved									
01b	On									
10b	Blink									
11b	Off									
9:8	<p>Power Indicator Control - If a Power Indicator is implemented, writes to this field set the Power Indicator to the written state. Reads of this field must reflect the value from the latest write, even if the corresponding hot-plug command is not complete, unless software issues a write without waiting, if required to, for the previous command to complete in which case the read value is undefined.</p> <p>Defined encodings are:</p> <table> <tr> <td>00b</td> <td>Reserved</td> </tr> <tr> <td>01b</td> <td>On</td> </tr> <tr> <td>10b</td> <td>Blink</td> </tr> <tr> <td>11b</td> <td>Off</td> </tr> </table> <p>Note: The default value of this field must be one of the non-Reserved values. If the <u>Power Indicator Present</u> bit in the <u>Slot Capabilities Register</u> is 0b, this bit is permitted to be read-only with a value of 00b.</p>	00b	Reserved	01b	On	10b	Blink	11b	Off	RW
00b	Reserved									
01b	On									
10b	Blink									
11b	Off									
10	<p>Power Controller Control - If a Power Controller is implemented, this bit when written sets the power state of the slot per the defined encodings. Reads of this bit must reflect the value from the latest write, even if the corresponding hot-plug command is not complete, unless software issues a write, if required to, without waiting for the previous command to complete in which case the read value is undefined.</p> <p>Note that in some cases the power controller may autonomously remove slot power or not respond to a power-up request based on a detected fault condition, independent of the <u>Power Controller Control</u> setting.</p> <p>The defined encodings are:</p> <table> <tr> <td>0b</td> <td>Power On</td> </tr> </table>	0b	Power On	RW						
0b	Power On									

Bit Location	Register Description	Attributes
	<p>1b Power Off</p> <p>If the Power Controller Present bit in the Slot Capabilities Register is Clear, then writes to this bit have no effect and the read value of this bit is undefined.</p>	
11	<p>Electromechanical Interlock Control - If an Electromechanical Interlock is implemented, a write of 1b to this bit causes the state of the interlock to toggle. A write of 0b to this bit has no effect. A read of this bit always returns a 0b.</p>	RW
12	<p>Data Link Layer State Changed Enable - If the Data Link Layer Link Active Reporting Capable is 1b, this bit enables software notification when Data Link Layer Link Active bit is changed.</p> <p>If the Data Link Layer Link Active Reporting Capable bit is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b.</p>	RW
13	<p>Auto Slot Power Limit Disable - When Set, this disables the automatic sending of a Set_Slot_Power_Limit Message when a Link transitions from a non-DL_Up status to a DL_Up status.</p> <p>Downstream ports that don't support DPC are permitted to hardwire this bit to 0.</p> <p>Default value of this bit is implementation specific.</p>	RW
14	<p>In-Band PD Disable - When Set, this bit disables the in-band presence detect mechanism from affecting the Presence Detect State bit, allowing that bit to report out-of-band presence detect exclusively. Otherwise, the Presence Detect State bit reflects the logical OR of the in-band and out-of-band presence detect mechanisms.</p> <p>In addition, the In-Band PD Disable bit governs the Component Presence state for the Downstream Component Presence field in the Link Status 2 Register. See § Section 7.5.3.20 .</p> <p>This bit must be implemented if the In-Band PD Disable Supported bit is 1b. Otherwise, this bit must be hardwired to 0b.</p> <p>Default value of this bit is 0b.</p>	RW

7.5.3.11 Slot Status Register (Offset 1Ah) §

The Slot Status Register provides information about PCI Express Slot specific parameters. § Figure 7-32 details allocation of register fields in the Slot Status Register; § Table 7-29 provides the respective bit definitions. Register fields for status bits not implemented by the device have the RsvdZ attribute.

If this register is implemented but the Slot Implemented bit is Clear, the field behavior of this entire register with the exception of the Data Link Layer State Changed bit is undefined.

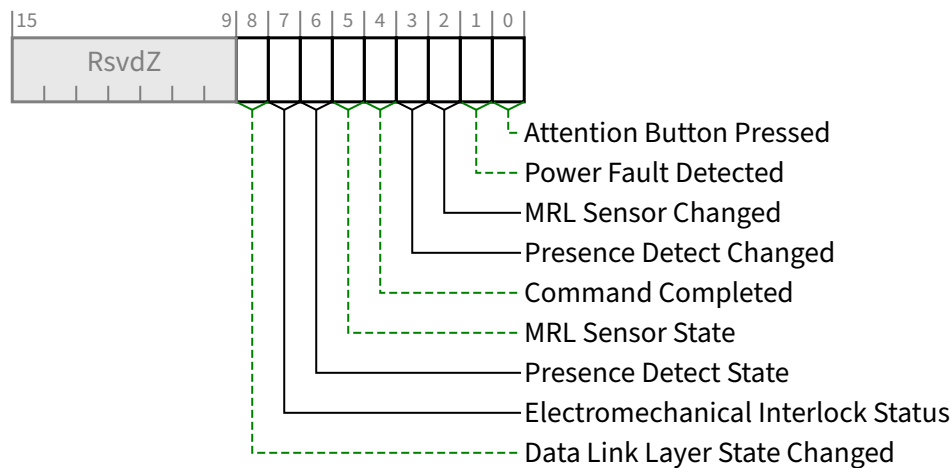

Figure 7-32 Slot Status Register §

Table 7-29 Slot Status Register §

Bit Location	Register Description	Attributes
0	Attention Button Pressed - If an Attention Button is implemented, this bit is Set when the attention button is pressed. If an Attention Button is not supported, this bit must not be Set.	<u>RW1C</u>
1	Power Fault Detected - If a Power Controller that supports power fault detection is implemented, this bit is Set when the Power Controller detects a power fault at this slot. Note that, depending on hardware capability, it is possible that a power fault can be detected at any time, independent of the Power Controller Control setting or the occupancy of the slot. If power fault detection is not supported, this bit must not be Set.	<u>RW1C</u>
2	MRL Sensor Changed - If an MRL sensor is implemented, this bit is Set when a <u>MRL Sensor State</u> change is detected. If an MRL sensor is not implemented, this bit must not be Set.	<u>RW1C</u>
3	Presence Detect Changed - This bit is Set when the value reported in the <u>Presence Detect State</u> bit is changed.	<u>RW1C</u>
4	Command Completed - If Command Completed notification is supported (if the <u>No Command Completed Support</u> bit in the Slot Capabilities Register is 0b), this bit is Set when a hot-plug command has completed and the Hot-Plug Controller is ready to accept a subsequent command. The <u>Command Completed</u> status bit is Set as an indication to host software that the Hot-Plug Controller has processed the previous command and is ready to receive the next command; it provides no guarantee that the action corresponding to the command is complete. If <u>Command Completed</u> notification is not supported, this bit must be hardwired to 0b.	<u>RW1C</u>
5	MRL Sensor State - This bit reports the status of the MRL sensor if implemented. Defined encodings are: 0b MRL Closed 1b MRL Open	<u>RO</u>
6	Presence Detect State - This bit indicates the presence of an adapter in the slot. When the <u>In-Band PD Disable</u> bit is Clear, this is reflected by the logical “OR” of the Physical Layer in-band presence detect	<u>RO</u>

Bit Location	Register Description	Attributes
	<p>mechanism and, if present, any out-of-band presence detect mechanism defined for the slot's corresponding form factor. Note that the in-band presence detect mechanism requires that power be applied to an adapter for its presence to be detected. Consequently, form factors that require a power controller for hot-plug must implement an out-of-band presence detect mechanism. When the <u>In-Band PD Disable</u> bit is Set, the in-band presence detect mechanism has no effect on this bit.</p> <p>Defined encodings are:</p> <p>0b Adapter not Present</p> <p>1b Adapter Present</p> <p>This bit must be implemented on all Downstream Ports that implement slots. For Downstream Ports not connected to slots (where the <u>Slot Implemented</u> bit of the <u>PCI Express Capabilities Register</u> is 0b), this bit must be hardwired to 1b.</p>	
7	<p>Electromechanical Interlock Status - If an Electromechanical Interlock is implemented, this bit indicates the status of the Electromechanical Interlock.</p> <p>Defined encodings are:</p> <p>0b Electromechanical Interlock Disengaged</p> <p>1b Electromechanical Interlock Engaged</p>	RO
8	<p>Data Link Layer State Changed - This bit is Set when the value reported in the <u>Data Link Layer Link Active</u> bit of the <u>Link Status Register</u> is changed.</p> <p>In response to a Data Link Layer State Changed event, software must read the <u>Data Link Layer Link Active</u> bit of the <u>Link Status Register</u> to determine if the Link is active before initiating <u>configuration cycles</u> to the hot plugged device.</p>	RW1C

IMPLEMENTATION NOTE: NO SLOT POWER CONTROLLER §

For slots that do not implement a power controller, software must ensure that system power planes are enabled to provide power to slots prior to reading Presence Detect State.

7.5.3.12 Root Control Register (Offset 1Ch) §

The Root Control Register controls PCI Express Root Complex specific parameters. § Figure 7-33 details allocation of register fields in the Root Control Register; § Table 7-30 provides the respective bit definitions.

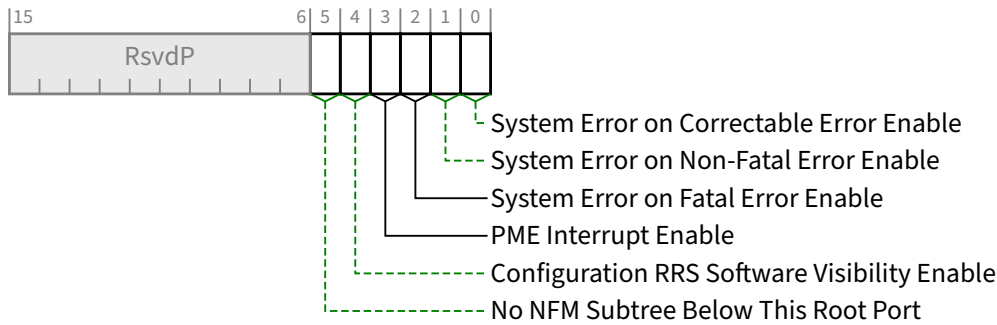

Figure 7-33 Root Control Register §

Table 7-30 Root Control Register §

Bit Location	Register Description	Attributes
0	<p>System Error on Correctable Error Enable - If Set, this bit indicates that a System Error should be generated if a correctable error (ERR_COR) is reported by any of the devices in the Hierarchy Domain associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific.</p> <p>Root Complex Event Collectors provide support for the above-described functionality for RCiEPs.</p> <p>Default value of this bit is 0b.</p>	RW
1	<p>System Error on Non-Fatal Error Enable - If Set, this bit indicates that a System Error should be generated if a Non-fatal error (ERR_NONFATAL) is reported by any of the devices in the Hierarchy Domain associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific.</p> <p>Root Complex Event Collectors provide support for the above-described functionality for RCiEPs.</p> <p>Default value of this bit is 0b.</p>	RW
2	<p>System Error on Fatal Error Enable - If Set, this bit indicates that a System Error should be generated if a Fatal error (ERR_FATAL) is reported by any of the devices in the Hierarchy Domain associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific.</p> <p>Root Complex Event Collectors provide support for the above-described functionality for RCiEPs.</p> <p>Default value of this bit is 0b.</p>	RW
3	<p>PME Interrupt Enable - When Set, this bit enables PME interrupt generation upon receipt of a PME Message as reflected in the PME Status bit (see § Table 7-32). A PME interrupt is also generated if the PME Status bit is Set when this bit is changed from Clear to Set (see § Section 5.3.3).</p> <p>Default value of this bit is 0b.</p>	RW
4	<p>Configuration RRS Software Visibility Enable - When Set, this bit enables the Root Port to indicate to software when Request Retry Status (RRS) Completion Status is received in response to a Configuration Request (see § Section 2.3.1).</p> <p>Root Ports that do not implement this capability must hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW

Bit Location	Register Description	Attributes
5	<p>No NFM Subtree Below This Root Port - When Clear, indicates that the RC must take ownership of non-UIO Non-Posted Requests passing peer-to-peer through the RC targeting this RP as the Egress Port. It is strongly recommended that system software Set this bit if it is determined that no NFM subtree(s) exist below this Root Port. RC implementations are strongly recommended to avoid taking ownership when not required to do so.</p> <p>Root Ports must handle the Clearing of this bit without disruption to Non-Posted Requests the RC has taken ownership of.</p> <p>Root Ports that do not implement this capability must hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW

7.5.3.13 Root Capabilities Register (Offset 1Eh) §

The Root Capabilities Register identifies PCI Express Root Port specific capabilities. § Figure 7-34 details allocation of register fields in the Root Capabilities Register; § Table 7-31 provides the respective bit definitions.

Figure 7-34 Root Capabilities Register §

Table 7-31 Root Capabilities Register §

Bit Location	Register Description	Attributes
0	<p>Configuration RRS Software Visibility - When Set, this bit indicates that the Root Port is capable of indicating to software when Request Retry Status (RRS) Completion Status is received in response to a Configuration Request (see § Section 2.3.1).</p>	RO

7.5.3.14 Root Status Register (Offset 20h) §

The Root Status Register provides information about PCI Express device specific parameters. § Figure 7-35 details allocation of register fields in the Root Status Register; § Table 7-32 provides the respective bit definitions.

Figure 7-35 Root Status Register §

Table 7-32 Root Status Register §

Bit Location	Register Description	Attributes
15:0	PME Requester ID - This field indicates the PCI Requester ID of the last PME Requester. This field is only valid when the <u>PME Status</u> bit is Set.	<u>RO</u>
16	PME Status - This bit indicates that PME was asserted by the PME Requester indicated in the PME Requester ID field. Subsequent PMEs are kept pending until the status register is cleared by software by writing a 1b. Default value of this bit is 0b.	<u>RW1C</u>
17	PME Pending - This bit indicates that another PME is pending when the PME Status bit is Set. When the <u>PME Status</u> bit is cleared by software; the PME is delivered by hardware by setting the <u>PME Status</u> bit again and updating the <u>PME Requester ID</u> field appropriately. The <u>PME Pending</u> bit is cleared by hardware if no more PMEs are pending.	<u>RO</u>

7.5.3.15 Device Capabilities 2 Register (Offset 24h) §

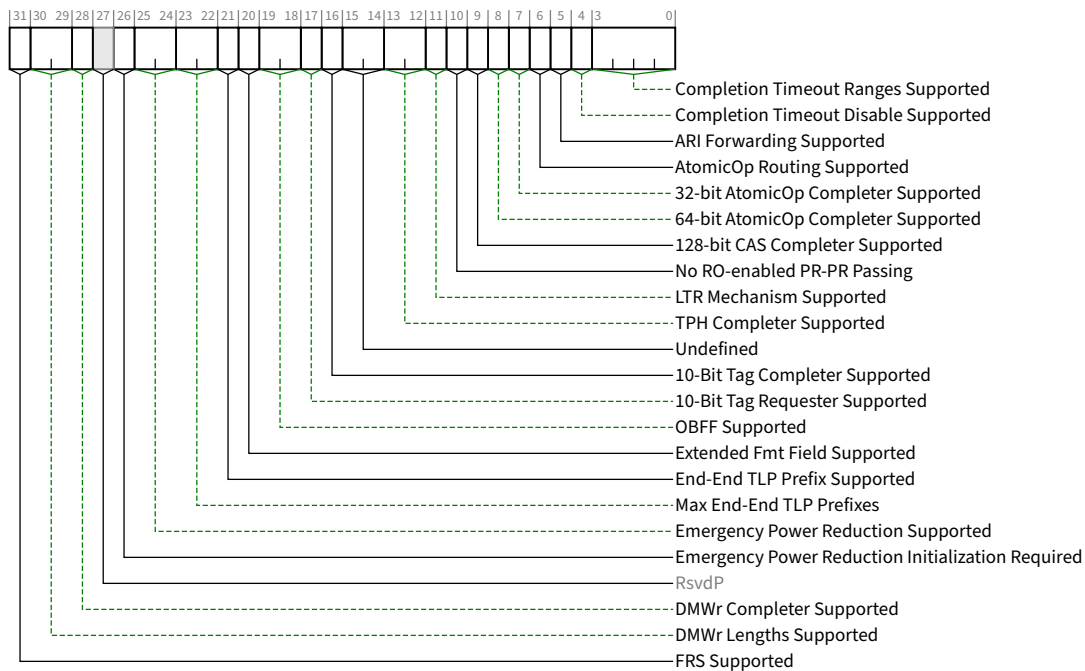

Figure 7-36 Device Capabilities 2 Register §

Table 7-33 Device Capabilities 2 Register §

Bit Location	Register Description	Attributes
3:0	<p>Completion Timeout Ranges Supported - This field indicates device Function support for the optional Completion Timeout programmability mechanism. This mechanism allows system software to modify the <u>Completion Timeout Value</u>.</p> <p>This field is applicable only to Root Ports, Endpoints that issue Non-Posted Requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of Non-Posted Requests issued on PCI Express. For all other Functions this field is Reserved and must be hardwired to 0000b.</p> <p>Four time value ranges are defined (A, B, C, D), each with two selectable sub-ranges (for which the time ranges are defined in the description of the <u>Completion Timeout Value</u> field in the <u>Device Control 2</u> register):</p> <p>The value in this field indicates the timeout value ranges supported:</p> <p>0000b Completion Timeout programming not supported - See § Section 2.8 for requirements.</p> <p>0001b Range A</p> <p>0010b Range B</p> <p>0011b Ranges A and B</p> <p>0110b Ranges B and C</p> <p>0111b Ranges A, B, and C</p> <p>1110b Ranges B, C, and D</p> <p>1111b Ranges A, B, C, and D</p>	<p><u>HwInit</u></p>

Bit Location	Register Description	Attributes
	<p>All other values are Reserved.</p> <p>For VFs, this field value must be identical to the associated PF's field value.</p>	
4	<p>Completion Timeout Disable Supported - A value of 1b indicates support for the Completion Timeout Disable mechanism.</p> <p>The Completion Timeout Disable mechanism is required for Endpoints that issue Non-Posted Requests on their own behalf and PCI Express to PCI/PCI-X Bridges that take ownership of Non-Posted Requests issued on PCI Express.</p> <p>For VFs, this bit value must be identical to the associated PF's bit value.</p> <p>This mechanism is optional for Root Ports.</p> <p>For all other Functions this field is Reserved and must be hardwired to 0b.</p>	<u>RO</u>
5	<p>ARI Forwarding Supported - Applicable only to Switch Downstream Ports and Root Ports; must be 0b for other Function types. This bit must be set to 1b if a Switch Downstream Port or Root Port supports this optional capability. See § Section 6.13 for additional details.</p>	<u>RO</u>
6	<p>AtomicOp Routing Supported - Applicable only to Switch Upstream Ports, Switch Downstream Ports, and Root Ports; must be 0b for other Function types. This bit must be set to 1b if the Port supports this optional capability. See § Section 6.15 for additional details.</p>	<u>RO</u>
7	<p>32-bit AtomicOp Completer Supported - Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1b if the Function supports this optional capability. See § Section 6.15.3.1 for additional RC requirements.</p> <p>For VFs, this bit value must be identical to the associated PF's bit value.</p>	<u>RO</u>
8	<p>64-bit AtomicOp Completer Supported - Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1b if the Function supports this optional capability. See § Section 6.15.3.1 for additional RC requirements.</p> <p>For VFs, this bit value must be identical to the associated PF's bit value.</p>	<u>RO</u>
9	<p>128-bit CAS Completer Supported - Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. This bit must be set to 1b if the Function supports this optional capability. See § Section 6.15 for additional details.</p> <p>For VFs, this bit value must be identical to the associated PF's bit value.</p>	<u>RO</u>
10	<p>No RO-enabled PR-PR Passing - If this bit is Set, the routing element never carries out the passing permitted by § Table 2-42 entry A2b that is associated with the <u>Relaxed Ordering Attribute</u> field being Set.</p> <p>This bit applies only for Switches and RCs that support peer-to-peer traffic between Root Ports. This bit applies only to Posted Requests being forwarded through the Switch or RC and does not apply to traffic originating or terminating within the Switch or RC itself. All Ports on a Switch or RC must report the same value for this bit.</p> <p>For all other functions, this bit must be 0b.</p>	<u>HwInit</u>
11	<p>LTR Mechanism Supported - A value of 1b indicates support for the optional Latency Tolerance Reporting (LTR) mechanism.</p> <p>Root Ports, Switches and Endpoints are permitted to implement this capability.</p> <p>For a <u>Multi-Function Device</u> associated with an Upstream Port, each Function must report the same value for this bit.</p>	<u>RO</u>

Bit Location	Register Description	Attributes
	For Bridges and other Functions that do not implement this capability, this bit must be hardwired to 0b.	
13:12	<p>TPH Completer Supported - Value indicates Completer support for TPH or Extended TPH. Applicable only to Root Ports and Endpoints. For all other Functions, this field is Reserved.</p> <p>Defined Encodings are:</p> <p>00b TPH and Extended TPH Completer not supported.</p> <p>01b TPH Completer supported; Extended TPH Completer not supported.</p> <p>10b Reserved.</p> <p>11b Both TPH and Extended TPH Completer supported.</p> <p>See § Section 6.17 for details.</p>	<u>RO</u>
15:14	Undefined - formerly used for Lightweight Notification (LN), which is now deprecated	<u>RO</u>
16	<p>10-Bit Tag Completer Supported - If this bit is Set, the Function supports 10-Bit Tag Completer capability; otherwise, the Function does not. See § Section 2.2.6.2 .</p> <p>For VFs, this bit value must be identical to the associated PF's bit value.</p>	<u>HwInit</u>
17	<p>10-Bit Tag Requester Supported - If this bit is Set, the Function supports 10-Bit Tag Requester capability; otherwise, the Function does not.</p> <p>This bit must not be Set if the 10-Bit Tag Completer Supported bit is Clear.</p> <p>If the Function is an RCiEP, this bit must be Clear if the RC does not support 10-Bit Tag Completer capability for Requests coming from this RCiEP.</p> <p>For VFs, this bit value must equal the <u>VF 10-Bit Tag Requester Supported</u> bit value in the <u>SR-IOV Capabilities Register</u>.</p> <p>Note that 10-Bit Tag field generation must be enabled by the <u>10-Bit Tag Requester Enable</u> bit in the <u>Device Control 2 Register</u> of the Requester Function before 10-Bit Tags can be generated by the Requester. See § Section 2.2.6.2 .</p>	<u>HwInit</u>
19:18	<p>OBFF Supported - This field indicates if OBFF is supported and, if so, what signaling mechanism is used.</p> <p>00b OBFF Not Supported</p> <p>01b OBFF supported using Message signaling only</p> <p>10b OBFF supported using WAKE# signaling only</p> <p>11b OBFF supported using WAKE# and Message signaling</p> <p>The value reported in this field must indicate support for WAKE# signaling only if:</p> <ul style="list-style-type: none"> for a Downstream Port, driving the WAKE# signal for OBFF is supported and the connector or component connected Downstream is known to receive that same WAKE# signal for an Upstream Port, receiving the WAKE# signal for OBFF is supported and, if the component is on an add-in-card, that the component is connected to the WAKE# signal on the connector. <p>Root Ports, Switch Ports, and Endpoints are permitted to implement this capability.</p> <p>For a <u>Multi-Function Device</u> associated with an Upstream Port, each Function must report the same value for this field.</p> <p>For Bridges and Ports that do not implement this capability, this field must be hardwired to 00b.</p>	<u>HwInit</u>

Bit Location	Register Description	Attributes
20	<p>Extended Fmt Field Supported - If Set, the Function supports the 3-bit definition of the Fmt field when operating in Non-Flit Mode. If Clear, the Function supports a 2-bit definition of the Fmt field. See § Section 2.2 .</p> <p>Must be Set for Functions that support End-End TLP Prefixes (NFM) or OHC-E (FM). All Functions in an Upstream Port must have the same value for this bit. Each Downstream Port of a component may have a different value for this bit.</p> <p><i>MUST@FLIT</i> be Set.</p>	<u>RO</u>
21	<p>End-End TLP Prefix Supported - Indicates whether End-End TLP Prefix support (NFM) / <u>OHC-E</u> (FM) is offered by a Function. Values are:</p> <p>0b No Support</p> <p>1b Support is provided to receive TLPs containing End-End TLP Prefixes (NFM) and optionally OHC-E (FM).</p> <p>All Ports of a Switch must have the same value for this bit.</p> <p>The definition of this bit is ambiguous for designs that choose only to support End-End TLP Prefixes in NFM and do not support OHC-E in FM. This bit is static and does not change value with current link operation (FM vs. NFM). Software cannot rely on this bit to infer if <u>OHC-E</u> is support by a Function.</p> <p>The definition of this bit is also ambiguous for RPs that choose to support End-End TLP Prefixes (NFM) / OHC-E (FM) as a terminus only without forwarding. Software cannot rely on this bit to infer if End-End TLP Prefix forwarding / <u>OHC-E</u> forwarding is supported in a RP or not.</p>	<u>HwInit</u>
23:22	<p>Max End-End TLP Prefixes - Indicates the maximum number of End-End TLP Prefixes supported by this Function (NFM) or the maximum size of <u>OHC-E</u> supported (FM). See § Section 2.2.10.4 for important details. Values are:</p> <p>01b 1 End-End TLP Prefix / OHC-E1</p> <p>10b 2 End-End TLP Prefixes / OHC-E2</p> <p>11b 3 End-End TLP Prefixes / OHC-E4</p> <p>00b 4 End-End TLP Prefixes / OHC-E4</p> <p>If <u>End-End TLP Prefix Supported</u> is Clear, this field is <u>RsvdP</u>.</p> <p>Different Root Ports that have the <u>End-End TLP Prefix Supported</u> bit Set are permitted to report different values for this field.</p> <p>For Switches where <u>End-End TLP Prefix Supported</u> is Set, this field must be 00b indicating support for up to four End-End TLP Prefixes.</p> <p>The definition of this bit is ambiguous for designs that only chose to support End-End TLP Prefixes in NFM and do not support OHC-E in FM. This bit is static and does not change value based on current link operation (FM vs. NFM). Refer to § Section 2.2.11 for how hardware must handle received TLPs with <u>OHC-E</u> in the scenario that they don't support it.</p>	<u>HwInit</u>
25:24	<p>Emergency Power Reduction Supported - Indicates support level of the optional Emergency Power Reduction State feature. A Function can enter Emergency Power Reduction State <u>autonomously</u>, or based on one of two mechanisms defined by the associated Form Factor Specification. Functions that are in the Emergency Power Reduction State consume less power. The Emergency Power Reduction mechanism permits a chassis to request add-in cards to rapidly enter <u>Emergency Power Reduction State</u> without involving system software. See § Section 6.24 for additional details.</p> <p>Values are:</p> <p>00b Emergency Power Reduction State not supported</p> <p>01b <u>Emergency Power Reduction State</u> is supported and is triggered by Device Specific mechanism(s)</p>	<u>HwInit</u>

Bit Location	Register Description	Attributes
	<p>10b Emergency Power Reduction State is supported and is triggered either by the mechanism defined in the corresponding Form Factor specification or by Device Specific mechanism(s)</p> <p>11b Reserved</p> <p>This field is RsvdP in Functions that are not associated with an Upstream Port.</p> <p>For Multi-Function Devices associated with an Upstream Port, all Functions that report a non-Zero value for this field, must report the same non-Zero value for this field.</p> <p>For VFs, this field value must be identical to the associated PF's field value.</p> <p>Default value is 00b.</p> <p>After reset, once this field returns a non-Zero value, it must continue to return the same non-Zero value, until the next reset.</p>	
26	<p>Emergency Power Reduction Initialization Required - If Set, the Function requires complete or partial initialization upon exit from the Emergency Power Reduction State. If Clear, the Function requires no software intervention to return to normal operation upon exit from the Emergency Power Reduction State. See § Section 6.24 for additional details.</p> <p>For Multi-Function Devices associated with an Upstream Port, all Functions must report the same value for this bit.</p> <p>For VFs, this bit value must be identical to the associated PF's bit value.</p> <p>This bit is RsvdP in Functions that are not associated with an Upstream Port.</p> <p>Default value is 0b.</p> <p>After reset, when this field returns a non-Zero value, it must continue to return the same non-Zero value.</p>	HwInit
28	<p>DMWr Completer Supported – Applicable to Functions with Memory Space BARs as well as all Root Ports; This bit must be Set if the Function can serve as a DMWr Completer. See § Section 6.32 for additional details.</p>	HwInit
30:29	<p>DMWr Lengths Supported – Applicable to Functions with either the DMWr Request Routing Supported bit Set or the DMWR Completer Supported bit Set (or both). This field indicates the largest DMWr TLP that this Function can receive.</p> <p>Defined Encodings are:</p> <p>00b DMWr TLPs up to 64 bytes are supported</p> <p>01b DMWr TLPs up to 128 bytes are supported</p> <p>10b Reserved</p> <p>11b Reserved</p> <p>When applicable, all Functions in a Multi-Function Device associated with an Upstream Port must report the same value in this field.</p> <p>This field is RsvdP if both DMWr Completer Supported and DMWr Request Routing Supported are Clear.</p>	HwInit/RsvdP
31	<p>FRS Supported - When Set, indicates support for the optional Function Readiness Status (FRS) capability.</p> <p>Must be Set for all Functions that support generation or reception capabilities of FRS Messages.</p> <p>Must not be Set by Switch Functions that do not generate FRS Messages on their own behalf.</p>	HwInit

IMPLEMENTATION NOTE: USE OF THE NO RO-ENABLED PR-PR PASSING BIT §

The No RO-enabled PR-PR Passing bit allows platforms to utilize PCI Express switching elements on the path between a requester and completer for requesters that could benefit from a slightly less relaxed ordering model. An example is a device that cannot ensure that multiple overlapping posted writes to the same address are outstanding at the same time. The method by which such a device is enabled to utilize this mode is beyond the scope of this specification.

7.5.3.16 Device Control 2 Register (Offset 28h) §

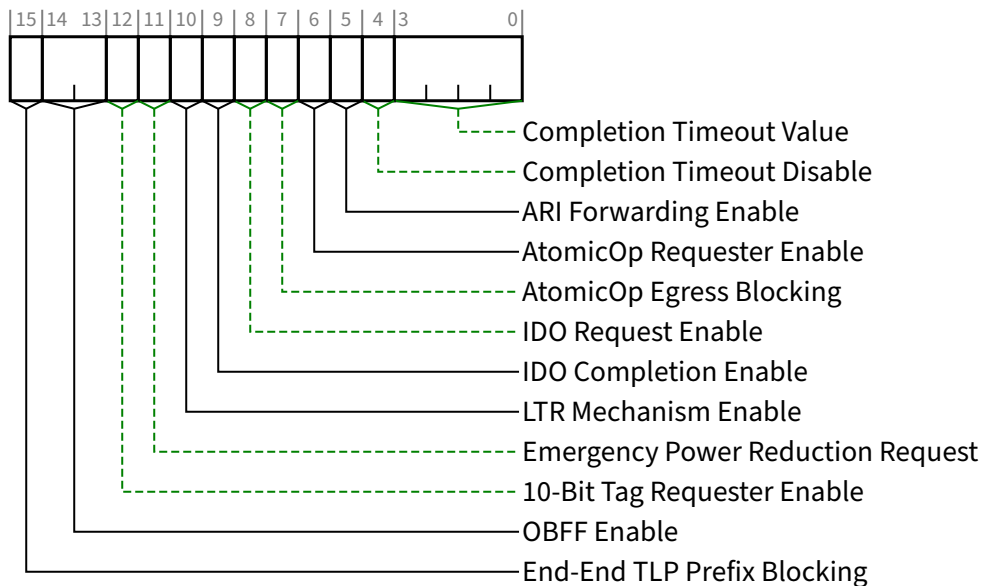

Figure 7-37 Device Control 2 Register §

Table 7-34 Device Control 2 Register §

Bit Location	Register Description	Attributes
3:0	<p>Completion Timeout Value - In device Functions that support Completion Timeout programmability, this field allows system software to modify the Completion Timeout Value.</p> <p>This field is applicable to Root Ports, Endpoints that issue Non-Posted Requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of Non-Posted Requests issued on PCI Express. For VFs, the associated PF's value applies, and this field must be RsvdP. For all other Functions, this field must be hardwired to Zero.</p> <p>A Function that does not support this optional capability must hardwire this field to 0000b. Functions that support Completion Timeout programmability must support the values given below corresponding to the programmability ranges indicated in the <u>Completion Timeout Ranges Supported</u> field.</p>	<p>RW</p> <p>VF RsvdP</p>

Bit Location	Register Description	Attributes
	<p>Defined encodings:</p> <p>0000b Default range: 50 μs to 50 ms; the Function <i>MUST@FLIT</i> implement a timeout value in the range 40 ms to 50 ms.</p> <p>For Functions that do not support Flit Mode, it is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms.</p> <p>Values available if Range A is supported:</p> <p>0001b 50 μs to 100 μs</p> <p>0010b 1 ms to 10 ms</p> <p>Values available if Range B is supported:</p> <p>0101b 16 ms to 55 ms ; <i>MUST@FLIT</i> 40 ms to 55 ms</p> <p>0110b 65 ms to 210 ms</p> <p>Values available if Range C is supported:</p> <p>1001b 260 ms to 900 ms</p> <p>1010b 1 s to 3.5 s</p> <p>Values available if the Range D is supported:</p> <p>1101b 4 s to 13 s</p> <p>1110b 17 s to 64 s</p> <p>Values not defined above are Reserved.</p> <p>Software is permitted to change the value in this field at any time. For Requests already pending when the Completion Timeout Value is changed, hardware is permitted to use either the new or the old value for the outstanding Requests, and is permitted to base the start time for each Request either on when this value was changed or on when each request was issued.</p> <p>The default value for this field is 0000b.</p>	
4	<p>Completion Timeout Disable - When Set, this bit disables the Completion Timeout mechanism.</p> <p>For non-VFs, this bit is required for all Functions that support the Completion Timeout Disable capability. For VFs, the associated PF's value applies, and this field must be RsvdP. Otherwise, Functions that do not support this optional capability are permitted to hardwire this bit to Zero.</p> <p>Software is permitted to Set or Clear this bit at any time. When Set, the Completion Timeout detection mechanism is disabled. If there are outstanding Requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding Requests. If this is done, it is permitted to base the start time for each Request on either the time this bit was cleared or the time each Request was issued.</p> <p>The default value for this bit is 0b.</p>	<p><u>RW</u></p> <p><u>VF RsvdP</u></p>
5	<p>ARI Forwarding Enable - When set, the Downstream Port disables its traditional Device Number field being 0 enforcement when turning a Type 1 Configuration Request into a Type 0 Configuration Request, permitting access to Extended Functions in an <u>ARI Device</u> immediately below the Port. See <u>§ Section 6.13</u> .</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ARI Forwarding Supported</u> bit is 0b.</p> <p>This bit is not applicable and Reserved for Upstream Ports.</p>	<p><u>RW / RsvdP</u></p>
6	<p>AtomicOp Requester Enable - Applicable only to Endpoints and Root Ports; must be hardwired to 0b for other Function types. The Function is allowed to initiate AtomicOp Requests only if this bit and the Bus Master Enable bit in the Command register are both Set.</p>	<p><u>RW</u></p> <p><u>VF RsvdP</u></p>

Bit Location	Register Description	Attributes
	<p>For VFs, the associated PF's value applies, and this bit must be RsvdP. For non-VFs, this bit is required to be RW if the Endpoint or Root Port is capable of initiating AtomicOp Requests, but otherwise is permitted to be hardwired to Zero.</p> <p>This bit does not serve as a capability bit. This bit is permitted to be RW even if no AtomicOp Requester capabilities are supported by the Endpoint or Root Port.</p> <p>Default value of this bit is 0b.</p>	
7	<p>AtomicOp Egress Blocking - Applicable and mandatory for Switch Upstream Ports, Switch Downstream Ports, and Root Ports that implement AtomicOp routing capability; otherwise must be hardwired to 0b.</p> <p>When this bit is Set, AtomicOp Requests that target going out this Egress Port must be blocked. See § Section 6.15.2 .</p> <p>Default value of this bit is 0b.</p>	RW
8	<p>IDO Request Enable - If this bit is Set, the Function is permitted to set the ID-Based Ordering (IDO) bit (Attr[2]) of Requests it initiates (see § Section 2.2.6.3 and § Section 2.4).</p> <p>Endpoints, including RC Integrated Endpoints, and Root Ports are permitted to implement this capability.</p> <p>For VFs, the associated PF's value applies, and this bit must be RsvdP. Otherwise, a Function is permitted to hardwire this bit to Zero if it never sets the IDO attribute in Requests.</p> <p>Default value of this bit is 0b.</p>	RW VF RsvdP
9	<p>IDO Completion Enable - If this bit is Set, the Function is permitted to set the ID-Based Ordering (IDO) bit (Attr[2]) of Completions it returns (see § Section 2.2.6.3 and § Section 2.4).</p> <p>Endpoints, including RC Integrated Endpoints, and Root Ports are permitted to implement this capability.</p> <p>For VFs, the associated PF's value applies, and this bit must be RsvdP. Otherwise, a Function is permitted to hardwire this bit to Zero if it never sets the IDO attribute in Completions.</p> <p>Default value of this bit is 0b.</p>	RW VF RsvdP
10	<p>LTR Mechanism Enable - When Set to 1b, this bit enables Upstream Ports to send LTR messages and Downstream Ports to process LTR Messages.</p> <p>For a Multi-Function Device associated with an Upstream Port of a device that implements LTR, the bit in Function 0 is RW, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is RsvdP.</p> <p>Functions that do not implement the LTR mechanism are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p> <p>For Downstream Ports, this bit must be reset to the default value if the Port goes to DL_Down status.</p>	RW/RsvdP
11	<p>Emergency Power Reduction Request - If Set, all Functions in the component that support Emergency Power Reduction State must enter the Emergency Power Reduction State. If Clear these Functions must exit the Emergency Power Reduction State if no other reasons exist to preclude exiting this state. See § Section 6.24 for additional details.</p> <p>This bit is implemented in the lowest numbered (non-VF) Function associated with an Upstream Port that has a non-Zero value in the Emergency Power Reduction Supported field. This bit is RsvdP in all other Functions, including VFs.</p> <p>Default is 0b.</p>	RW/RsvdP VF RsvdP

Bit Location	Register Description	Attributes
12	<p>10-Bit Tag Requester Enable - This bit, in combination with the <u>Extended Tag Field Enable</u> bit and the <u>14-Bit Tag Requester Enable</u> bit, determines how many Tag field bits a Requester is permitted to use. When the <u>10-Bit Tag Requester Enable</u> bit is Set, the Requester is permitted to use 10-Bit Tags. See § Section 2.2.6.2 for complete details.</p> <p>If software changes the value of this bit while the Function has outstanding Non-Posted Requests, the result is undefined.</p> <p>For VFs, the value in the <u>VF 10-Bit Tag Requester Enable</u> bit in the associated PF's <u>SR-IOV Control Register</u> applies, and this bit must be <u>RsvdP</u>.</p> <p>Non-VF Functions that do not implement 10-Bit Tag Requester capability are permitted to hardwire this bit to <u>Zero</u>.</p> <p>Default value of this bit is 0b.</p>	<p><u>RW</u> <u>VF RsvdP</u></p>
14:13	<p>OBFF Enable - This field enables the OBFF mechanism and selects the signaling method.</p> <p>00b Disabled</p> <p>01b Enabled using Message signaling [Variation A]</p> <p>10b Enabled using Message signaling [Variation B]</p> <p>11b Enabled using WAKE# signaling</p> <p>See § Section 6.19 for an explanation of the above encodings.</p> <p>This field is required for all Ports that support the OBFF Capability.</p> <p>For a Multi-Function Device associated with an Upstream Port of a Device that implements OBFF, the field in Function 0 is of type <u>RW</u>, and only Function 0 controls the Component's behavior. In all other Functions of that Device, this field is of type <u>RsvdP</u>.</p> <p>Ports that do not implement OBFF are permitted to hardwire this field to 00b.</p> <p>Default value of this field is 00b.</p>	<p><u>RW/RsvdP</u> (see description)</p>
15	<p>End-End TLP Prefix Blocking - Controls whether the routing function is permitted to forward TLPs containing an End-End TLP Prefix (NFM) / <u>OHC-E</u> (FM). Values are:</p> <p>0b Forwarding Enabled - Function is permitted to send TLPs with End-End TLP Prefixes (NFM) or <u>OHC-E</u> (FM).</p> <p>1b Forwarding Blocked - Function is not permitted to send TLPs with End-End TLP Prefixes (NFM) or <u>OHC-E</u> (FM).</p> <p>This bit affects TLPs that exit the Switch/Root Complex using the associated Port. It does not affect TLPs forwarded internally within the Switch/Root Complex. It does not affect TLPs that enter through the associated Port, that originate in the associated Port or originate in a Root Complex Integrated Device integrated with the associated Port. As described in § Section 2.2.10.4, blocked TLPs are reported by the TLP Prefix Blocked Error.</p> <p>The default value of this bit is 0b.</p> <p>This bit is hardwired to 1b in Root Ports that support End-End TLP Prefixes/<u>OHC-E</u> but do not support forwarding of End-End TLP Prefixes/<u>OHC-E</u>.</p> <p>This bit is applicable to Root Ports and Switch Ports where the <u>End-End TLP Prefix Supported</u> bit is Set. This bit is not applicable and is <u>RsvdP</u> in all other cases.</p>	<p><u>RW</u> (see description)</p>

7.5.3.17 Device Status 2 Register (Offset 2Ah) §

This section is a placeholder. There are no capabilities that require this register.

This register must be treated by software as RsvdZ.

7.5.3.18 Link Capabilities 2 Register (Offset 2Ch) §

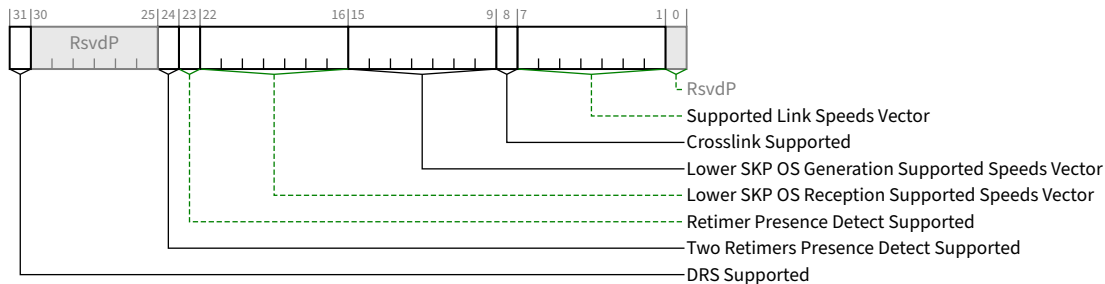

Figure 7-38 Link Capabilities 2 Register §

Table 7-35 Link Capabilities 2 Register §

Bit Location	Register Description	Attributes
7:1	<p>Supported Link Speeds Vector - This field indicates the supported Link speed(s) of the associated Port. For each bit, a value of 1b indicates that the corresponding Link speed is supported; otherwise, the Link speed is not supported. See § Section 8.2.1 for further requirements.</p> <p>Bit definitions within this field are:</p> <ul style="list-style-type: none"> Bit 0 2.5 GT/s Bit 1 5.0 GT/s Bit 2 8.0 GT/s Bit 3 16.0 GT/s Bit 4 32.0 GT/s Bit 5 64.0 GT/s Bit 6 RsvdP <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	HwInit/RsvdP
8	<p>Crosslink Supported - When set to 1b, this bit indicates that the associated Port supports crosslinks (see § Section 4.2.7.3.1). When set to 0b on a Port that supports Link speeds of 8.0 GT/s or higher, this bit indicates that the associated Port does not support crosslinks. When set to 0b on a Port that only supports Link speeds of 2.5 GT/s or 5.0 GT/s, this bit provides no information regarding the Port's level of crosslink support.</p> <p>It is recommended that this bit be Set in any Port that supports crosslinks even though doing so is only required for Ports that also support operating at 8.0 GT/s or higher Link speeds.</p> <p>Note: Software should use this bit when referencing fields whose definition depends on whether or not the Port supports crosslinks (see § Section 7.7.3.4).</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	RO
15:9	<p>Lower SKP OS Generation Supported Speeds Vector - If this field is non-Zero, it indicates that the Port, when operating at the indicated speed(s) supports SRIS and also supports software control of the SKP Ordered Set transmission scheduling rate.</p> <p>Bit definitions within this field are:</p>	HwInit/RsvdP

Bit Location	Register Description	Attributes
	<p>Bit 0 2.5 GT/s</p> <p>Bit 1 5.0 GT/s</p> <p>Bit 2 8.0 GT/s</p> <p>Bit 3 16.0 GT/s</p> <p>Bit 4 32.0 GT/s</p> <p>Bit 5 64.0 GT/s</p> <p>Bit 6 RsvdP</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p> <p>Behavior is undefined if a bit is Set in this field and the corresponding bit is not Set in the Supported Link Speeds Vector.</p>	
22:16	<p>Lower SKP OS Reception Supported Speeds Vector - If this field is non-Zero, it indicates that the Port, when operating at the indicated speed(s) supports <u>SRIS</u> and also supports receiving SKP OS at the rate defined for <u>SRNS</u> while running in <u>SRIS</u>.</p> <p>Bit definitions within this field are:</p> <p>Bit 0 2.5 GT/s</p> <p>Bit 1 5.0 GT/s</p> <p>Bit 2 8.0 GT/s</p> <p>Bit 3 16.0 GT/s</p> <p>Bit 4 32.0 GT/s</p> <p>Bit 5 64.0 GT/s</p> <p>Bit 6 RsvdP</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p> <p>Behavior is undefined if a bit is Set in this field and the corresponding bit is not Set in the Supported Link Speeds Vector.</p>	<u>HwInit/RsvdP</u>
23	<p>Retimer Presence Detect Supported - When set to 1b, this bit indicates that the associated Port supports detection and reporting of Retimer presence.</p> <p>This bit <i>MUST@FLIT</i> be Set.</p> <p>This bit must be set to 1b in a Port when the Supported Link Speeds Vector of the <u>Link Capabilities 2 Register</u> indicates support for a Link speed of 16.0 GT/s or higher.</p> <p>It is permitted to be set to 1b regardless of the supported Link speeds.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	<u>HwInit/RsvdP</u>
24	<p>Two Retimers Presence Detect Supported - When set to 1b, this bit indicates that the associated Port supports detection and reporting of two Retimers presence.</p> <p>This bit <i>MUST@FLIT</i> be Set.</p> <p>This bit must be set to 1b in a Port when the Supported Link Speeds Vector of the <u>Link Capabilities 2 Register</u> indicates support for a Link speed of 16.0 GT/s or higher.</p> <p>It is permitted to be set to 1b regardless of the supported Link speeds if the <u>Retimer Presence Detect Supported</u> bit is also set to 1b.</p> <p>Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.</p>	<u>HwInit/RsvdP</u>

Bit Location	Register Description	Attributes
31	<p>DRS Supported - When Set, indicates support for the optional Device Readiness Status (DRS) capability.</p> <p>Must be Set in Downstream Ports that support DRS.</p> <p>Must be Set in Downstream Ports that support FRS.</p> <p>For Upstream Ports that support DRS, this bit <i>MUST@FLIT</i> be Set in Function 0. For all other Functions associated with an Upstream Port, this bit must be Clear.¹⁶⁶</p> <p>Must be Clear in Functions that are not associated with a Port.</p> <p>RsvdP in all other Functions.</p>	HwInit/RsvdP

IMPLEMENTATION NOTE: SOFTWARE MANAGEMENT OF LINK SPEEDS WITH EARLIER HARDWARE §

Hardware components compliant to versions prior to [PCIe-3.0] either did not implement the Link Capabilities 2 Register, or the register was Reserved.

For software to determine the supported Link speeds for components where the Link Capabilities 2 Register is either not implemented, or the value of its Supported Link Speeds Vector is 0000000b, software can read bits 3:0 of the Link Capabilities Register (now defined to be the Max Link Speed field), and interpret the value as follows:

0001b

2.5 GT/s Link speed supported

0010b

5.0 GT/s and 2.5 GT/s Link speeds supported

For such components, the encoding of the values for the Current Link Speed field (in the Link Status Register) and Target Link Speed field (in the Link Control 2 Register) is the same as above.

IMPLEMENTATION NOTE: SOFTWARE MANAGEMENT OF LINK SPEEDS WITH FUTURE HARDWARE §

It is strongly encouraged that software primarily utilize the Supported Link Speeds Vector instead of the Max Link Speed field, so that software can determine the exact set of supported speeds on current and future hardware. This can avoid software being confused if a future specification defines Links that do not require support for all slower speeds.

166. It is expressly permitted for Upstream Ports to send DRS Messages even when the DRS Supported bit is Clear.

7.5.3.19 Link Control 2 Register (Offset 30h) §

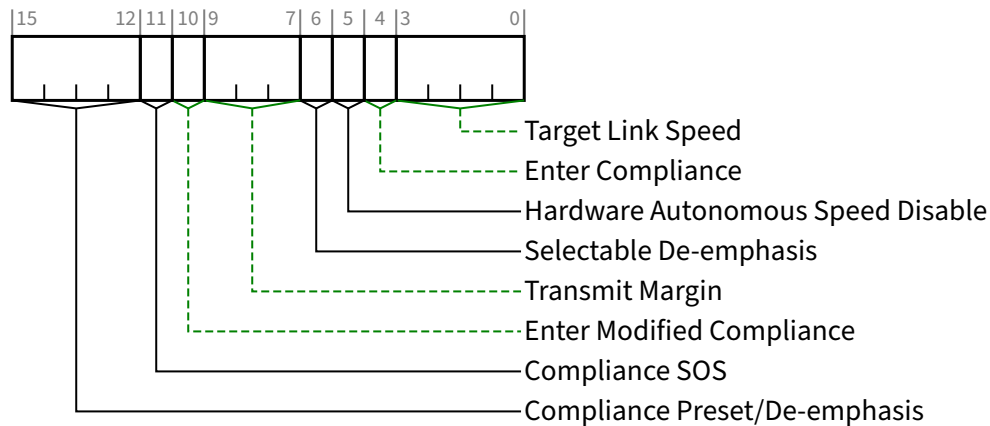

Figure 7-39 Link Control 2 Register §

Table 7-36 Link Control 2 Register §

Bit Location	Register Description	Attributes
3:0	<p>Target Link Speed - For Downstream Ports, this field sets an upper limit on Link operational speed by restricting the values advertised by the Upstream component in its training sequences.</p> <p>The encoded value specifies a Bit Location in the Supported Link Speeds Vector (in the Link Capabilities 2 Register) that corresponds to the desired target Link speed.</p> <p>Defined encodings are:</p> <ul style="list-style-type: none"> 0001b Supported Link Speeds Vector field bit 0 0010b Supported Link Speeds Vector field bit 1 0011b Supported Link Speeds Vector field bit 2 0100b Supported Link Speeds Vector field bit 3 0101b Supported Link Speeds Vector field bit 4 0110b Supported Link Speeds Vector field bit 5 0111b Supported Link Speeds Vector field bit 6 Others All other encodings are Reserved. <p>If a value is written to this field that does not correspond to a supported speed (as indicated by the Supported Link Speeds Vector), the result is undefined.</p> <p>If either of the Enter Compliance or Enter Modified Compliance bits are implemented, then this field must also be implemented.</p> <p>The default value of this field is the highest Link speed supported by the component (as reported in the Max Link Speed field of the Link Capabilities Register) unless the corresponding platform/form factor requires a different default value.</p> <p>For both Upstream and Downstream Ports, this field is used to set the target compliance mode speed when software is using the Enter Compliance bit to force a Link into compliance mode.</p> <p>For Upstream Ports, if the Enter Compliance bit is Clear, this field is permitted to have no effect.</p>	RWS/RsvdP (see description)

Bit Location	Register Description	Attributes				
	<p>For a Multi-Function Device associated with an Upstream Port, the field in Function 0 is of type <u>RWS</u>, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this field is of type <u>RsvdP</u>.</p> <p>Components that support only the 2.5 GT/s speed are permitted to hardwire this field to 0000b.</p>					
4	<p>Enter Compliance - Software is permitted to force a Link to enter Compliance mode (at the speed indicated in the Target Link Speed field and the de-emphasis/preset level indicated by the Compliance Preset/De-emphasis bit) by setting this bit to 1b in both components on a Link and then initiating a <u>Hot Reset</u> on the Link.</p> <p>Default value of this bit following Fundamental Reset is 0b.</p> <p>For a Multi-Function Device associated with an Upstream Port, the bit in Function 0 is of type <u>RWS</u>, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is of type <u>RsvdP</u>.</p> <p>Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b.</p> <p>This bit is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is Set to the default value.</p>	<u>RWS/RsvdP</u> (see description)				
5	<p>Hardware Autonomous Speed Disable - When Set, this bit disables hardware from changing the Link speed for device-specific reasons other than attempting to correct unreliable Link operation by reducing Link speed. Initial transition to the highest supported common link speed is not blocked by this bit.</p> <p>For a Multi-Function Device associated with an Upstream Port, the bit in Function 0 is of type <u>RWS</u>, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is of type <u>RsvdP</u>.</p> <p>Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	<u>RWS/RsvdP</u> (see description)				
6	<p>Selectable De-emphasis - When the Link is operating at 5.0 GT/s speed, this bit is used to control the transmit de-emphasis of the link in specific situations. See § Section 4.2.7 for detailed usage information.</p> <p>Encodings:</p> <table border="0"> <tr> <td>1b</td> <td>-3.5 dB</td> </tr> <tr> <td>0b</td> <td>-6 dB</td> </tr> </table> <p>When the Link is not operating at 5.0 GT/s speed, the setting of this bit has no effect. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b.</p> <p>This bit is not applicable and Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches.</p>	1b	-3.5 dB	0b	-6 dB	<u>HwInit</u>
1b	-3.5 dB					
0b	-6 dB					
9:7	<p>Transmit Margin - This field controls the value of the non-deemphasized voltage level at the Transmitter pins. This field is reset to 000b on entry to the LTSSM Polling.Configuration substate (see § Chapter 4. for details of how the Transmitter voltage level is determined in various states).</p> <p>Encodings:</p> <table border="0"> <tr> <td>000b</td> <td>Normal operating range</td> </tr> <tr> <td>001b-111b</td> <td>As defined in § Section 8.3.4 not all encodings are required to be implemented.</td> </tr> </table> <p>For a Multi-Function Device associated with an Upstream Port, the field in Function 0 is of type <u>RWS</u>, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this field is of type <u>RsvdP</u>.</p>	000b	Normal operating range	001b-111b	As defined in § Section 8.3.4 not all encodings are required to be implemented.	<u>RWS/RsvdP</u> (see description)
000b	Normal operating range					
001b-111b	As defined in § Section 8.3.4 not all encodings are required to be implemented.					

Bit Location	Register Description	Attributes
	<p>Default value of this field is 000b.</p> <p>Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 000b.</p> <p>This field is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value.</p>	
10	<p>Enter Modified Compliance - When this bit is Set to 1b, the device transmits Modified Compliance Pattern if the LTSSM enters <u>Polling.Compliance</u> substate.</p> <p>Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b.</p> <p>For a Multi-Function Device associated with an Upstream Port, the bit in Function 0 is of type RWS, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is of type RsvdP.</p> <p>Default value of this bit is 0b.</p> <p>This bit is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is Set to the default value.</p>	RWS/RsvdP (see description)
11	<p>Compliance SOS - When set to 1b, the LTSSM is required to send SKP Ordered Sets between sequences when sending the Compliance Pattern or Modified Compliance Pattern.</p> <p>For a Multi-Function Device associated with an Upstream Port, the bit in Function 0 is of type RWS, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this bit is of type RsvdP.</p> <p>The default value of this bit is 0b.</p> <p>This bit is applicable when the Link is operating at 2.5 GT/s or 5.0 GT/s data rates only.</p> <p>Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b.</p>	RWS/RsvdP (see description)
15:12	<p>Compliance Preset/De-emphasis -</p> <p>For 8.0 GT/s and higher Data Rate: This field sets the Transmitter Preset in <u>Polling.Compliance</u> state if the entry occurred due to the Enter Compliance bit being 1b. The encodings are defined in § Section 4.2.4.2 . Results are undefined if a reserved preset encoding is used when entering <u>Polling.Compliance</u> in this way.</p> <p>For 5.0 GT/s Data Rate: This field sets the de-emphasis level in <u>Polling.Compliance</u> state if the entry occurred due to the <u>Enter Compliance</u> bit being 1b.</p> <p>Defined Encodings are:</p> <p>0001b -3.5 dB</p> <p>0000b -6 dB</p> <p>When the Link is operating at 2.5 GT/s, the setting of this field has no effect. Components that support only 2.5 GT/s speed are permitted to hardwire this field to 0000b.</p> <p>For a Multi-Function Device associated with an Upstream Port, the field in Function 0 is of type RWS, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this field is of type RsvdP.</p> <p>The default value of this field is 0000b.</p> <p>This field is intended for debug and compliance testing purposes. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value.</p>	RWS/RsvdP (see description)

IMPLEMENTATION NOTE: SELECTABLE DE-EMPHASIS USAGE §

Selectable De-emphasis setting is applicable only to Root Ports and Switch Downstream Ports. The De-emphasis setting is implementation specific and depends on the platform or enclosure in which the Root Port or the Switch Downstream Port is located. System firmware or hardware strapping is used to configure the Selectable De-emphasis value. In cases where system firmware cannot be used to set the de-emphasis value (for example, a hot plugged Switch), hardware strapping must be used to set the de-emphasis value.

7.5.3.20 Link Status 2 Register (Offset 32h) §

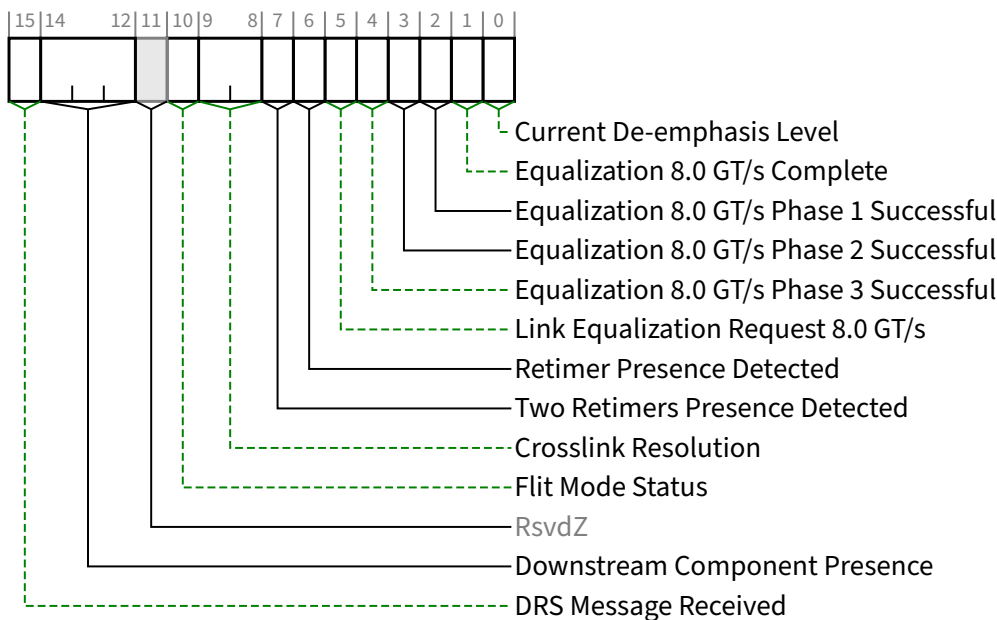

Figure 7-40 Link Status 2 Register §

Table 7-37 Link Status 2 Register §

Bit Location	Register Description	Attributes
0	<p>Current De-emphasis Level - When the Link is operating at 5.0 GT/s speed, this bit reflects the level of de-emphasis.</p> <p>Encodings:</p> <p>1b -3.5 dB</p> <p>0b -6 dB</p> <p>The value in this bit is undefined when the Link is not operating at 5.0 GT/s speed.</p> <p>For VFs, the associated PF's value applies, and this field must be RsvdZ. Otherwise, components that support only the 2.5 GT/s speed are permitted to hardwire this bit to Zero.</p>	<p>RO</p> <p>VF RsvdZ</p>

Bit Location	Register Description	Attributes
	For components that support speeds greater than 2.5 GT/s, Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions of the Port.	
1	<p>Equalization 8.0 GT/s Complete - When set to 1b, this bit indicates that the Transmitter Equalization procedure at the 8.0 GT/s data rate has completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 .</p> <p>The default value of this bit is 0b.</p> <p>For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0b.</p>	<u>ROS</u>
2	<p>Equalization 8.0 GT/s Phase 1 Successful - When set to 1b, this bit indicates that Phase 1 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 .</p> <p>The default value of this bit is 0b.</p> <p>For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0b.</p>	<u>ROS</u>
3	<p>Equalization 8.0 GT/s Phase 2 Successful - When set to 1b, this bit indicates that Phase 2 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 .</p> <p>The default value of this bit is 0b.</p> <p>For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0b.</p>	<u>ROS</u>
4	<p>Equalization 8.0 GT/s Phase 3 Successful - When set to 1b, this bit indicates that Phase 3 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 .</p> <p>The default value of this bit is 0b.</p> <p>For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0b.</p>	<u>ROS</u>
5	<p>Link Equalization Request 8.0 GT/s - This bit is Set by hardware to request the 8.0 GT/s Link equalization process to be performed on the Link. Refer to § Section 4.2.4 and § Section 4.2.7.4.2 for details.</p> <p>The default value of this bit is 0b.</p> <p>For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. Components that only support speeds below 8.0 GT/s are permitted to hardwire this bit to 0b.</p>	<u>RW1CS</u>
6	<p>Retimer Presence Detected - When set to 1b, this bit indicates that a Retimer was present during the most recent Link negotiation. Refer to § Section 4.2.7.3.5.1 for details.</p> <p>The default value of this bit is 0b.</p> <p>This bit is required for Ports that have the Retimer Presence Detect Supported bit of the Link Capabilities 2 Register set to 1b.</p> <p>Ports that have the Retimer Presence Detect Supported bit set to 0b are permitted to hardwire this bit to 0b.</p>	<u>ROS/RsvdZ</u>

Bit Location	Register Description	Attributes
	For Multi-Function Devices associated with an Upstream Port, this bit must be implemented in Function 0 and is <u>RsvdZ</u> in all other Functions.	
7	<p>Two Retimers Presence Detected - When set to 1b, this bit indicates that two Retimers were present during the most recent Link negotiation. Refer to § Section 4.2.7.3.5.1 for details.</p> <p>The default value of this bit is 0b.</p> <p>This bit is required for Ports that have the <u>Two Retimers Presence Detect Supported</u> bit of the <u>Link Capabilities 2 Register</u> set to 1b.</p> <p>Ports that have the <u>Two Retimers Presence Detect Supported</u> bit set to 0b are permitted to hardwire this bit to 0b.</p> <p>For Multi-Function Devices associated with an Upstream Port, this bit must be implemented in Function 0 and <u>RsvdZ</u> in all other Functions.</p>	<u>ROS/RsvdZ</u>
9:8	<p>Crosslink Resolution - This field indicates the state of the Crosslink negotiation. It must be implemented if <u>Crosslink Supported</u> is Set and the Port supports 16.0 GT/s or higher data rate. It is permitted to be implemented in all other Ports. If <u>Crosslink Supported</u> is Clear, this field may be hardwired to 01b or 10b.</p> <p>Encoding is:</p> <p>00b Crosslink Resolution is not supported. No information is provided regarding the status of the Crosslink negotiation.</p> <p>01b Crosslink negotiation resolved as an Upstream Port.</p> <p>10b Crosslink negotiation resolved as a Downstream Port.</p> <p>11b Crosslink negotiation is not completed.</p> <p>Once a value of 01b or 10b is returned in this field, that value must continue to be returned while the Link is Up.</p>	<u>RO</u>
10	<p>Flit Mode Status - When <u>Flit Mode Supported</u> is Set, this bit when Set indicates that the Link is or will be operating in Flit Mode.</p> <p>For Downstream Ports, this bit is only meaningful when <u>Downstream Component Presence</u> is either 011b, 100b, or 101b. In all other states, this bit must contain <u>Zero</u>.</p> <p>For Upstream Ports, this bit is meaningful when the Link is Up. When the Link is Down, the value is implementation specific.</p> <p>This bit is <u>RsvdZ</u> if <u>Flit Mode Supported</u> is Clear.</p>	<u>RO / RsvdZ</u>
14:12	<p>Downstream Component Presence - This field indicates the presence and DRS status for the Downstream Component, if any, connected to the Link; defined values are:</p> <p>000b Link Down - Presence Not Determined</p> <p>001b Link Down - Component Not Present indicates the Downstream Port (DP) has determined that a Downstream Component is not present</p> <p>010b Link Down - Component Present indicates the DP has determined that a Downstream Component is present, but the Data Link Layer is not active</p> <p>011b Link Down - Flit Mode Negotiation Completed indicates that the DP has determined that a Downstream Component, the LTSSM has determined whether or not the Link will be operating in Flit Mode, but the Data Link Layer is not yet active. The <u>Flit Mode Status</u> bit is meaningful in this state.</p> <p>100b Link Up - Component Present indicates the DP has determined that a Downstream Component is present, but no DRS Message has been received since the Data Link Layer became active. The Flit Mode Status bit is meaningful in this state.</p>	<u>RO/RsvdZ</u>

Bit Location	Register Description	Attributes
	<p>101b Link Up - Component Present and DRS Received indicates the DP has received a DRS Message since the Data Link Layer became active. The <u>Flit Mode Status bit</u> is meaningful in this state.</p> <p>110b Reserved</p> <p>111b Reserved</p> <p>Downstream Component Presence state must be determined by the logical “OR” of the Physical Layer in-band presence detect mechanism and, if present, any out-of-band presence detect mechanism implemented for the Link. If no out-of-band presence detect mechanism is implemented, then Downstream Component Presence state must be determined solely by the Physical Layer in-band presence detect mechanism.</p> <p>If the In-Band PD Disable bit in the Slot Control Register is Set, the Physical Layer in-band presence detect mechanism must always indicate that no component is present.</p> <p>Component Presence, Link Up, and DRS Received states indicated by this field must reflect their maskable states, which are controlled by the <u>SFI PD State Mask</u>, <u>SFI DLL State Mask</u>, or <u>SFI DRS Mask bits</u> in the <u>SFI Control Register</u>. See § Section 7.9.22.3.</p> <p>This field must be implemented in any Downstream Port where the <u>DRS Supported bit</u> is Set in the <u>Link Capabilities 2 Register</u>. This field must be implemented in any Downstream Port where the <u>Flit Mode Supported bit</u> is Set.</p> <p>This field is <u>RsvdZ</u> for all other Functions.</p> <p>Default value of this field is 000b.</p>	
15	<p>DRS Message Received - This bit must be Set whenever the Port receives a DRS Message.</p> <p>This bit must be Cleared in <u>DL_Down</u>.</p> <p>This bit must be implemented in any Downstream Port where the <u>DRS Supported bit</u> is Set in the <u>Link Capabilities 2 Register</u>.</p> <p>This bit is <u>RsvdZ</u> for all other Functions.</p> <p>Default value of this bit is 0b.</p>	<u>RW1C/RsvdZ</u>

7.5.3.21 Slot Capabilities 2 Register (Offset 34h) §

Figure 7-41 Slot Capabilities 2 Register §

Table 7-38 Slot Capabilities 2 Register §

Bit Location	Register Description	Attributes
0	<p>In-Band PD Disable Supported - When Set, this bit indicates that this slot supports disabling the reporting of the in-band presence detect state, as controlled by the In-Band PD Disable bit in the Slot Control Register. If the slot does not support an out-of-band presence detect mechanism, this bit must be Clear.</p>	<u>HwInit</u>

7.5.3.22 Slot Control 2 Register (Offset 38h) §

This section is a placeholder. There are no capabilities that require this register.

This register must be treated by software as RsvdP.

7.5.3.23 Slot Status 2 Register (Offset 3Ah) §

This section is a placeholder. There are no capabilities that require this register.

This register must be treated by software as RsvdZ.

7.6 PCI Express Extended Capabilities §

PCI Express Extended Capability registers are located in Configuration Space at offsets 256 or greater as shown in § Figure 7-42 or in the Root Complex Register Block (RCRB). These registers when located in the Configuration Space are accessible using only the PCI Express Enhanced Configuration Access Mechanism (ECAM).

PCI Express Extended Capability structures are allocated using a linked list of optional or required PCI Express Extended Capabilities following a format resembling PCI Capability structures. The first DWORD of the Capability structure identifies the Capability and version and points to the next Capability as shown in § Figure 7-42.

Each Capability structure must be DWORD aligned.

Figure 7-42 PCI Express Extended Configuration Space Layout §

7.6.1 Extended Capabilities in Configuration Space §

Extended Capabilities in Configuration Space always begin at offset 100h with a PCI Express Extended Capability header (§ Section 7.6.3). Absence of any Extended Capabilities is required to be indicated by an Extended Capability header with a Capability ID of 0000h, a Capability Version of 0h, and a Next Capability Offset of 000h.

7.6.2 Extended Capabilities in the Root Complex Register Block §

Extended Capabilities in a Root Complex Register Block always begin at offset 000h with a PCI Express Extended Capability header (§ Section 7.6.3). Absence of any Extended Capabilities is required to be indicated by an Extended Capability header with a Capability ID of FFFFh and a Next Capability Offset of 000h.

7.6.3 PCI Express Extended Capability Header §

All PCI Express Extended Capabilities must begin with a PCI Express Extended Capability Header. § Figure 7-43 details the allocation of register fields of a PCI Express Extended Capability Header; § Table 7-39 provides the respective bit definitions.

Figure 7-43 PCI Express Extended Capability Header §

Table 7-39 PCI Express Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. A version of the specification that changes the Extended Capability in a way that is not otherwise identifiable (e.g., through a new Capability field) is permitted to increment this field. All such changes to the Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a Capability structure that is compatible with that piece of software.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits.	RO

7.7 PCI and PCIe Capabilities Required by the Base Spec in Some Situations §

The following capabilities are required by this specification for some Functions. For example, Functions that support specific data rates, functions that generate interrupts, etc.

7.7.1 MSI Capability Structures §

All PCI Express device Functions that are capable of generating interrupts must implement MSI or MSI-X or both.

The MSI Capability structure is described in this section. The MSI-X Capability structure is described in § Section 7.7.2.

The MSI Capability structure is illustrated in § Figure 7-44 and § Figure 7-45. Each device Function that supports MSI (in a Multi-Function Device) must implement its own MSI Capability structure. More than one MSI Capability structure per Function is prohibited, but a Function is permitted to have both an MSI and an MSI-X Capability structure.

Figure 7-44 MSI Capability Structure for 32-bit Message Address §

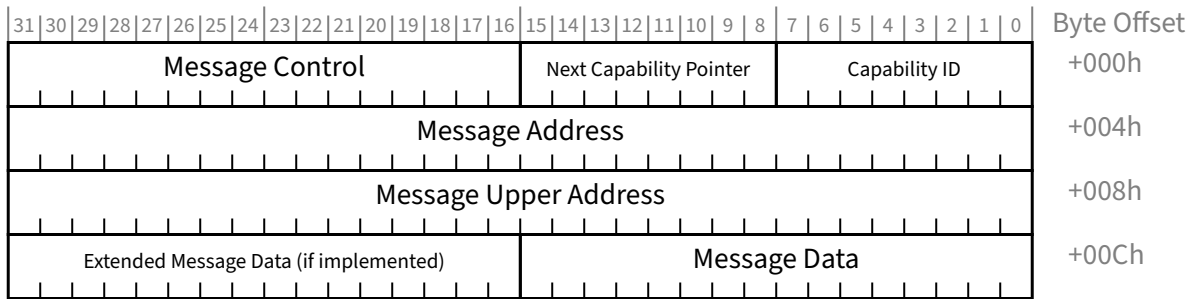

Figure 7-45 MSI Capability Structure for 64-bit Message Address §

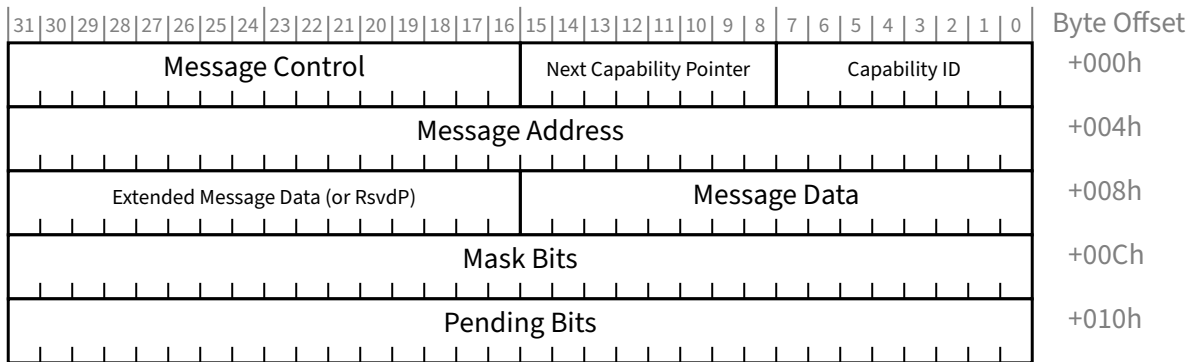

Figure 7-46 MSI Capability Structure for 32-bit Message Address and PVM §

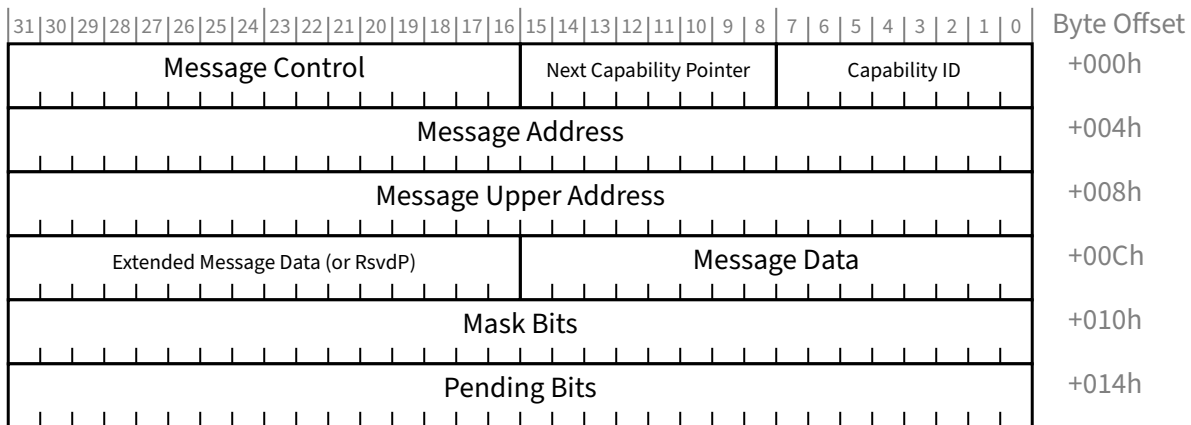

Figure 7-47 MSI Capability Structure for 64-bit Message Address and PVM §

To request service, an MSI Function writes the contents of the Message Data Register for MSI, and if enabled, the Extended Message Data Register for MSI, to the address specified by the contents of the Message Address Register for MSI (and, optionally, when 64-bit message addresses are used, the Message Upper Address Register for MSI). A read of the address specified by the contents of the Message Address register produces undefined results.

A Function supporting MSI implements one of four MSI Capability structure layouts illustrated in § Figure 7-44 to § Figure 7-47, depending upon which optional features are supported. A Legacy Endpoint that implements MSI is required to support either the 32-bit or 64-bit Message Address version of the MSI Capability structure. A PCI Express Endpoint that implements MSI is required to support the 64-bit Message Address version of the MSI Capability structure. The Message Control Register for MSI indicates the Function's capabilities and provides system software control over MSI.

Each field is further described in the following sections.

7.7.1.1 MSI Capability Header (Offset 00h) §

The MSI Capability Header enumerates the MSI Capability structure in the PCI Configuration Space Capability list. § Figure 7-48 details allocation of register fields in the MSI Capability Header; § Table 7-40 provides the respective bit definitions.

Figure 7-48 MSI Capability Header §

Table 7-40 MSI Capability Header §

Bit Location	Register Description	Attributes
7:0	Capability ID - Indicates the MSI Capability structure. This field must return a Capability ID of 05h indicating that this is an MSI Capability structure.	RO
15:8	Next Capability Pointer - This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities.	RO

7.7.1.2 Message Control Register for MSI (Offset 02h) §

This register provides system software control over MSI. By default, MSI is disabled. If MSI and MSI-X are both disabled, the Function requests servicing using INTx interrupts (if supported). System software can enable MSI by Setting bit 0 of this register. System software is permitted to modify the Message Control Register for MSI's read-write bits and fields. A device driver is not permitted to modify the Message Control Register for MSI's read-write bits and fields.

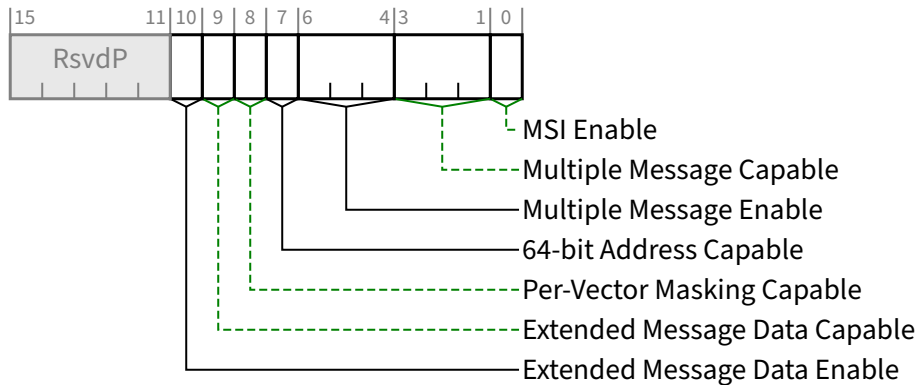

Figure 7-49 Message Control Register for MSI §

Table 7-41 Message Control Register for MSI §

Bit Location	Register Description	Attributes
0	MSI Enable - If Set and the MSI-X Enable bit in the Message Control Register for MSI-X (see § Section 7.7.2.2) is Clear, the Function is permitted to use MSI to request service and is prohibited from using INTx interrupts. System configuration software Sets this bit to enable MSI. Refer to § Section 7.5.1.1.3 for control of INTx interrupts. If Clear, the Function is prohibited from using MSI to request service. Software changing this bit during active operation may result in the Function dropping pending interrupt conditions or failing to recognize new interrupt conditions. See § Section 6.1.4.5. Default value of this bit is 0b.	RW
3:1	Multiple Message Capable - System software reads this field to determine the number of requested vectors. The number of requested vectors must be aligned to a power of two (if a Function requires three vectors, it requests four by initializing this field to 010b). The encoding is defined as: 000b 1 vector requested	RO

Bit Location	Register Description	Attributes
	<p>001b 2 vectors requested</p> <p>010b 4 vectors requested</p> <p>011b 8 vectors requested</p> <p>100b 16 vectors requested</p> <p>101b 32 vectors requested</p> <p>110b Reserved</p> <p>111b Reserved</p>	
6:4	<p>Multiple Message Enable - software writes to this field to indicate the number of allocated vectors. The number of allocated vectors is aligned to a power of two. As an example, if a Function requests four vectors (indicated by a Multiple Message Capable encoding of 010b), software can allocate either four, two, or one vector by writing a 010b, 001b, or 000b to this field, respectively.</p> <p>Behavior is undefined if the number of vectors allocated is greater than the number of vectors requested.</p> <p>Behavior is undefined if this field is changed while <u>MSI Enable</u> is Set.</p> <p>When <u>MSI Enable</u> is Set, a Function will be allocated at least 1 vector. The encoding is defined as:</p> <p>000b 1 vector allocated</p> <p>001b 2 vectors allocated</p> <p>010b 4 vectors allocated</p> <p>011b 8 vectors allocated</p> <p>100b 16 vectors allocated</p> <p>101b 32 vectors allocated</p> <p>110b Reserved</p> <p>111b Reserved</p> <p>Function behavior is undefined if software changes the value of this field while the MSI Enable bit is Set.</p> <p>Default value of this field is 000b.</p>	<u>RW</u>
7	<p>64-bit Address Capable - If Set, the Function is capable of sending a 64-bit Message Address. If Clear, the Function is not capable of sending a 64-bit Message Address. This bit must be Set if the Function is a PCI Express Endpoint, as indicated by the value in the <u>Device/Port Type</u> field. This bit <i>MUST@FLIT</i> be Set.</p>	<u>RO</u>
8	<p>Per-Vector Masking Capable - If Set, the Function supports MSI Per-Vector Masking. If Clear, the Function does not support MSI Per-Vector Masking. This bit must be Set if the Function is a PF or VF within an SR-IOV Device.</p>	<u>RO</u>
9	<p>Extended Message Data Capable - If Set, the Function is capable of providing <u>Extended Message Data</u>. If Clear, the Function does not support providing <u>Extended Message Data</u>.</p>	<u>RO</u>
10	<p>Extended Message Data Enable - If Set, the Function is enabled to provide <u>Extended Message Data</u>. If Clear, the Function is not enabled to provide <u>Extended Message Data</u>.</p> <p>Default value of this bit is 0b.</p> <p>This bit must be read-write if the <u>Extended Message Data Capable</u> bit is 1b; otherwise it must be hardwired to 0b.</p>	<u>RW/RO</u>

7.7.1.3 Message Address Register for MSI (Offset 04h) §

Figure 7-50 Message Address Register for MSI §

Table 7-42 Message Address Register for MSI §

Bit Location	Register Description	Attributes
1:0	Reserved Reserved - Always returns 0 on read. Write operations have no effect.	<u>RsvdP</u>
31:2	Message Address - System-specified message address. If the MSI Enable bit is Set, the contents of this register specify the DWORD-aligned address (Address[31:02]) for the MSI transaction. Address[1:0] are set to 00b. Default value of this field is undefined.	<u>RW</u>

7.7.1.4 Message Upper Address Register for MSI (Offset 08h) §

Figure 7-51 Message Upper Address Register for MSI §

Table 7-43 Message Upper Address Register for MSI §

Bit Location	Register Description	Attributes
31:0	Message Upper Address - System-specified message upper address. This register is implemented only if the Function supports a 64-bit message address (<u>64-bit Address Capable</u> is Set). This register is implemented only if the Function supports a 64-bit message address (64-bit Address Capable is Set). This register is required for PCI Express Endpoints (as indicated by the value in the <u>Device/Port Type</u> field) and is optional for other Function types. If the MSI Enable bit is Set, the contents of this register (if non-zero) specify the upper 32-bits of a 64-bit message address (Address[63:32]). If the contents of this register are zero, the Function uses the 32 bit address specified by the Message Address register. Default value of this field is undefined.	<u>RW</u>

7.7.1.5 Message Data Register for MSI (Offset 08h or 0Ch) §

Figure 7-52 Message Data Register for MSI §

Table 7-44 Message Data Register for MSI §

Bit Location	Register Description	Attributes
15:0	<p>Message</p> <p>Message Data - System-specified message data.</p> <p>If the <u>MSI Enable</u> bit is Set, the Function sends a DWORD Memory Write transaction using Message Data for the lower 16 bits. All 4 Byte Enables are Set.</p> <p>The <u>Multiple Message Enable</u> field defines the number of low order message data bits the Function is permitted to modify to generate its system software allocated vectors. For example, a <u>Multiple Message Enable</u> encoding of 010b indicates the Function has been allocated four vectors and is permitted to modify message data bits 1 and 0 (a Function modifies the lower message data bits to generate the allocated number of vectors). If the <u>Multiple Message Enable</u> field is 000b, the Function is not permitted to modify the message data. When <u>Multiple Message Enable</u> is non-zero, behavior is undefined if the corresponding low order bits of this register are not 0b.</p> <p>Default value of this field is undefined.</p>	RW

7.7.1.6 Extended Message Data Register for MSI (Optional) §

Figure 7-53 Extended Message Data Register for MSI §

Table 7-45 Extended Message Data Register for MSI §

Bit Location	Register Description	Attributes
15:0	<p>Extended Message Data - System-specified message data.</p> <p>This register is optional. For the MSI Capability structures without Per-vector Masking, it must be implemented if the <u>Extended Message Data Capable</u> bit is Set; otherwise, it is outside the MSI Capability structure and undefined. For the MSI Capability structures with Per-vector Masking, it must be implemented if the <u>Extended Message Data Capable</u> bit is Set; otherwise, it is RsvdP.</p> <p>If the <u>Extended Message Data Enable</u> bit is Set, the DWORD Memory Write transaction uses <u>Extended Message Data</u> for the upper 16 bits; otherwise, it uses 0000h for the upper 16 bits.</p>	RW/undefined/ RsvdP

Bit Location	Register Description	Attributes
	Default value of this field is 0000h.	

7.7.1.7 Mask Bits Register for MSI (Offset 0Ch or 10h) §

This register is optional. It is present if Per-Vector Masking Capable is Set (see § Section 7.7.1.2). The offset of this register within the capability depends on the value of the 64-bit Address Capable bit (see § Section 7.7.1.2).

The Mask Bits and Pending Bits registers enable software to disable or defer message sending on a per-vector basis.

MSI vectors are numbered 0 through N-1, where N is the number of vectors allocated by software. Each vector is associated with a correspondingly numbered bit in the Mask Bits and Pending Bits registers.

The Multiple Message Capable field indicates how many vectors (with associated Mask and Pending bits) are implemented. All unimplemented Mask and Pending bits are Reserved.

The Multiple Message Enable field controls how many vectors are allocated for use. The value of each implemented Mask bit and Pending bit that is currently not allocated must be ignored by hardware; i.e., the value must not affect the generation of interrupts.

Figure 7-54 Mask Bits Register for MSI §

Table 7-46 Mask Bits Register for MSI §

Bit Location	Register Description	Attributes
31:0	Mask Bits - For each Mask bit that is Set, the Function is prohibited from sending the associated message. Default is 0.	<u>RW</u>

7.7.1.8 Pending Bits Register for MSI (Offset 10h or 14h) §

This register is optional. It is present if Per-Vector Masking Capable is Set (see § Section 7.7.1.2).

The offset of this register within the capability depends on the value of the 64-bit Address Capable bit (see § Section 7.7.1.2)

See § Section 7.7.1.7 for additional requirements on this register.

Figure 7-55 Pending Bits Register for MSI §

Table 7-47 Pending Bits Register for MSI §

Bit Location	Register Description	Attributes
31:0	Pending Bits - For each Pending bit that is Set, the Function has a pending associated message. Default is 0.	RO

7.7.2 MSI-X Capability and Table Structure §

The MSI-X Capability structure is illustrated in § Figure 7-56. More than one MSI-X Capability structure per Function is prohibited, but a Function is permitted to have both an MSI Capability structure and an MSI-X Capability structure.

In contrast to the MSI Capability structure, which directly contains all of the control/status information for the Function's vectors, the MSI-X Capability structure instead points to an **MSI-X Table** structure and an **MSI-X PBA** structure (Pending Bit Array structure), each residing in Memory Space (see § Figure 7-57 and § Figure 7-58).

Each structure is mapped by a Base Address Register (BAR) belonging to the Function, located beginning at 10h in Configuration Space, or an entry in the Enhanced Allocation capability. A BAR Indicator register (BIR) indicates which BAR(or BEI when using Enhanced Allocation), and a QWORD-aligned Offset indicates where the structure begins relative to the base address associated with the BAR. The BAR is permitted to be either 32-bit or 64-bit, but must map Memory Space. A Function is permitted to map both structures with the same BAR, or to map each structure with a different BAR.

The MSI-X Table structure, illustrated in § Figure 7-57, typically contains multiple entries, each consisting of several fields: Message Address, Message Upper Address, Message Data, and Vector Control. Each entry is capable of specifying a unique vector.

The Pending Bit Array (PBA) structure, illustrated in § Figure 7-58, contains the Function's Pending Bits, one per Table entry, organized as a packed array of bits within QWORDS. The last QWORD will not necessarily be fully populated.

Figure 7-56 MSI-X Capability Structure §

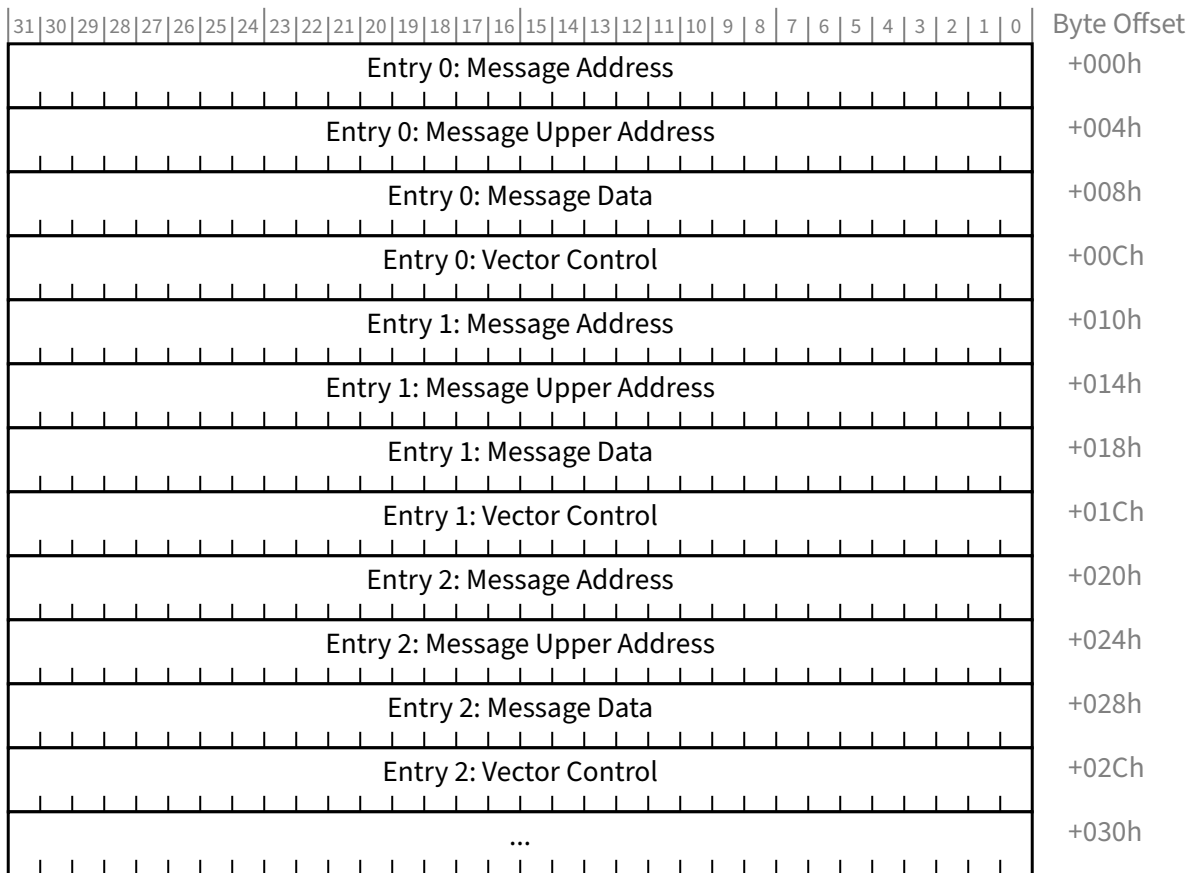

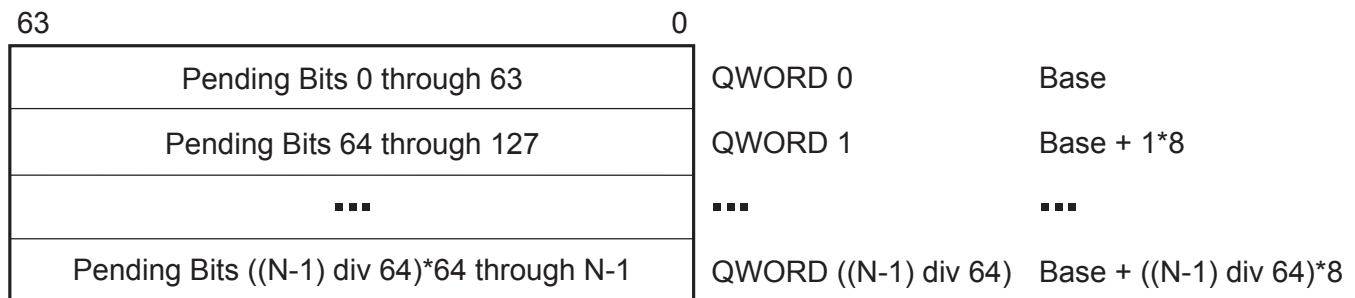

Figure 7-57 MSI-X Table Structure §

A-0385

Figure 7-58 MSI-X PBA Structure §

To request service using a given MSI-X Table entry, a Function performs a DWORD Memory Write transaction using the contents of the Message Data field entry for data, the contents of the Message Upper Address field for the upper 32 bits of address, and the contents of the Message Address field entry for the lower 32 bits of address. A memory read transaction from the address targeted by the MSI-X message produces undefined results.

If a Base Address Register or entry in the Enhanced Allocation capability that maps address space for the MSI-X Table or MSI-X PBA also maps other usable address space that is not associated with MSI-X structures, locations (e.g., for CSRs) used in the other address space must not share any naturally aligned 4-KB address range with one where either MSI-X structure resides. This allows system software where applicable to use different processor attributes for MSI-X structures and the other address space. (Some processor architectures do not support having different processor attributes associated with the same naturally aligned 4-KB physical address range.) The MSI-X Table and MSI-X PBA are permitted to co-reside within a naturally aligned 4-KB address range, though they must not overlap with each other.

With SR-IOV devices, alignment requirements like those in the preceding paragraph still apply, but they must be based on the System Page Size value from the PF's SR-IOV Extended Capability instead using a fixed 4-KB value.

IMPLEMENTATION NOTE: DEDICATED BARS AND ADDRESS RANGE ISOLATION §

To enable system software to map MSI-X structures onto different processor pages for improved access control, it is recommended that a Function dedicate separate Base Address Registers for the MSI-X Table and MSI-X PBA, or else provide more than the minimum required isolation with address ranges.

If dedicated separate Base Address Registers is not feasible, it is recommended that a Function dedicate a single Base Address Register for the MSI-X Table and MSI-X PBA.

If a dedicated Base Address Register is not feasible, it is recommended that a Function isolate the MSI-X structures from the non-MSI-X structures with aligned 8 KB ranges rather than the mandatory aligned 4 KB ranges.

For example, if a Base Address Register needs to map 2 KB for an MSI-X Table containing 128 entries, 16 bytes for an MSI-X PBA containing 128 bits, and 64 bytes for registers not related to MSI-X, the following is an acceptable implementation. The Base Address Register requests 8 KB of total address space, maps the first 64 bytes for the non MSI-X registers, maps the MSI-X Table beginning at an offset of 4 KB, and maps the MSI-X PBA beginning at an offset of 6 KB.

A preferable implementation for a shared Base Address Register is for it to request 16 KB of total address space, map the first 64 bytes for the non MSI-X registers, map the MSI-X Table beginning at an offset of 8 KB, and map the MSI-X PBA beginning at an offset of 12 KB.

IMPLEMENTATION NOTE: MSI-X MEMORY SPACE STRUCTURES IN READ/WRITE MEMORY §

The MSI-X Table and MSI-X PBA structures are defined such that they can reside in general purpose read/write memory on a device, for ease of implementation and added flexibility. To achieve this, none of the contained fields are required to be read-only, and there are also restrictions on transaction alignment and sizes.

For all accesses to MSI-X Table and MSI-X PBA fields, software must use aligned full DWORD or aligned full QWORD transactions; otherwise, the result is undefined.

MSI-X Table entries and Pending bits are each numbered 0 through N-1, where N-1 is indicated by the Table Size field in the Message Control Register for MSI-X. For a given arbitrary MSI-X Table entry k , its starting address can be calculated with the formula:

entry starting address = Table base + $k \times 16$

Equation 7-1 MSI-X Starting Address §

For the associated Pending bit k , its address for QWORD access and bit number within that QWORD can be calculated with the formulas:

$$\text{QWORD address} = \text{PBA base} + (k \text{ div } 64) \times 8$$

$$\text{QWORD bit\#} = k \text{ mod } 64$$

Equation 7-2 MSI-X PBA QWORD Access §

Software that chooses to read Pending bit K with DWORD accesses can use these formulas:

$$\text{DWORD address} = \text{PBA base} + (k \text{ div } 32) \times 4$$

$$\text{DWORD bit\#} = k \text{ mod } 32$$

Equation 7-3 MSI-X PBA DWORD Access §

Each field in the MSI-X Capability, MSI-X Table, and MSI-X PBA structures is further described in the following sections. Within the MSI-X Capability structure, Reserved registers and bits always return 0 when read, and write operations have no effect. Within the MSI-X Table and PBA structures, Reserved fields have special rules.

7.7.2.1 MSI-X Capability Header (Offset 00h) §

The MSI-X Capability Header enumerates the MSI-X Capability structure in the PCI Configuration Space Capability list. § Figure 7-56 details allocation of register fields in the MSI-X Capability Header; § Table 7-48 provides the respective bit definitions.

Figure 7-59 MSI-X Capability Header §

Table 7-48 MSI-X Capability Header §

Bit Location	Register Description	Attributes
7:0	Capability ID - Indicates the MSI-X Capability structure. This field must return a Capability ID of 11h indicating that this is an MSI-X Capability structure.	RO
15:8	Next Capability Pointer - This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities.	RO

7.7.2.2 Message Control Register for MSI-X (Offset 02h) §

By default, MSI-X is disabled. If MSI and MSI-X are both disabled, the Function requests servicing via INTx interrupts (if supported). System software can enable MSI-X by Setting bit 15 of this register. System software is permitted to modify the Message Control register's read-write bits and fields. A device driver is not permitted to modify the Message Control register's read-write bits and fields.

Figure 7-60 Message Control Register for MSI-X §

Table 7-49 Message Control Register for MSI-X §

Bit Location	Register Description	Attributes
10:0	Table Size - System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. For example, a returned value of 000 0000 0011b indicates a table size of 4.	RO
13:11	Reserved Reserved - Always returns 0 on a read, and a write operation has no effect.	RsvdP
14	Function Mask - If Set, all of the vectors associated with the Function are masked, regardless of their per-vector Mask bit values. If Clear, each vector's Mask bit determines whether the vector is masked or not. Setting or Clearing the MSI-X Function Mask bit has no effect on the value of the per-vector Mask bits. Default value of this bit is 0b.	RW
15	MSI-X Enable - If Set and the MSI Enable bit in the Message Control Register for MSI (see § Section 7.7.1.2) is Clear, the Function is permitted to use MSI-X to request service and is prohibited from using INTx interrupts (if implemented). System configuration software Sets this bit to enable MSI-X. If Clear, the Function is prohibited from using MSI-X to request service. Software changing this bit during active operation may result in the Function dropping pending interrupt conditions or failing to recognize new interrupt conditions. See § Section 6.1.4.5 . Default value of this bit is 0b.	RW

7.7.2.3 Table Offset/Table BIR Register for MSI-X (Offset 04h) §

Figure 7-61 Table Offset/Table BIR Register for MSI-X §

Table 7-50 Table Offset/Table BIR Register for MSI-X §

Bit Location	Register Description	Attributes																
2:0	<p>Table BIR - Indicates which one of a Function's Base Address Registers, located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching <u>BAR Equivalent Indicator (BEI)</u>, is used to map the Function's <u>MSI-X Table</u> into Memory Space.</p> <p>Defined encodings are:</p> <table border="0"> <tr><td>0</td><td>Base Address Register 10h</td></tr> <tr><td>1</td><td>Base Address Register 14h</td></tr> <tr><td>2</td><td>Base Address Register 18h</td></tr> <tr><td>3</td><td>Base Address Register 1Ch</td></tr> <tr><td>4</td><td>Base Address Register 20h</td></tr> <tr><td>5</td><td>Base Address Register 24h</td></tr> <tr><td>6</td><td>Reserved</td></tr> <tr><td>7</td><td>Reserved</td></tr> </table> <p>For a 64-bit Base Address Register, the Table BIR indicates the lower DWORD. For Functions with Type 1 Configuration Space headers, BIR values 2 through 5 are also Reserved.</p>	0	Base Address Register 10h	1	Base Address Register 14h	2	Base Address Register 18h	3	Base Address Register 1Ch	4	Base Address Register 20h	5	Base Address Register 24h	6	Reserved	7	Reserved	RO
0	Base Address Register 10h

Bit Location	Register Description	Attributes
31:0	<p>Message Upper Address - System-specified message upper address bits.</p> <p>If this field is zero, 32-bit address messages are used. If this field is non-zero, 64-bit address messages are used.</p> <p>Default value of this field is undefined.</p>	RW

7.7.2.7 Message Data Register for MSI-X Table Entries §

Figure 7-65 Message Data Register for MSI-X Table Entries §

Table 7-54 Message Data Register for MSI-X Table Entries §

Bit Location	Register Description	Attributes
31:0	<p>Message Data - System-specified message data.</p> <p>For MSI-X messages, the contents of this field from an MSI-X Table entry specifies the 32-bit <u>data payload</u> of the DWORD Memory Write transaction. All 4 Byte Enables are Set.</p> <p>In contrast to message data used for MSI messages, the low-order message data bits in MSI-X messages are not modified by the Function.</p> <p>This field is read-write.</p> <p>Default value of this field is undefined.</p>	RW

7.7.2.8 Vector Control Register for MSI-X Table Entries §

If a Function implements a TPH Requester Extended Capability structure and an MSI-X Capability structure, the Function can optionally use the Vector Control Register for MSI-X Table Entries in each entry to store a Steering Tag. See Section 6.17.

Figure 7-66 Vector Control Register for MSI-X Table Entries §

Table 7-55 Vector Control Register for MSI-X Table Entries §

Bit Location	Register Description	Attributes
0	<p>Mask Bit - When this bit is Set, the Function is prohibited from sending a message using this MSI-X Table entry. However, any other MSI-X Table entries programmed with the same vector will still be capable of sending an equivalent message unless they are also masked.</p> <p>Default value of this bit is 1b (entry is masked)</p>	RW
15:1	<p>Reserved</p> <p>Reserved - By default, the value of these bits must be 0. However, for potential future use, software must preserve the value of these Reserved bits when modifying the value of other Vector Control bits. If software modifies the value of these Reserved bits, the result is undefined.</p> <p>These bits are permitted to be RsvdP or read-write.</p>	RW or RsvdP
23:16	<p>ST Lower - If the Function implements a TPH Requester Extended Capability structure, and the ST Table Location indicates a value of 10b, then this field contains the lower 8 bits of a Steering Tag and must be read-write.</p> <p>Otherwise, this field is permitted to be read-write or RsvdP, and for potential future use, software must preserve the value of these Reserved bits when modifying the value of other Vector Control bits, or the result is undefined.</p> <p>Default value of this field is 00h.</p>	RW/RsvdP
31:24	<p>ST Upper - If the Function implements a TPH Requester Extended Capability structure, and the ST Table Location indicates a value of 10b, and the Extended TPH Requester Supported bit is Set, then this field contains the upper 8 bits of a Steering Tag and must be read-write.</p> <p>Otherwise, this field is permitted to be read-write or RsvdP, and for potential future use, software must preserve the value of these Reserved bits when modifying the value of other Vector Control bits, or the result is undefined.</p> <p>Default value of this field is 00h.</p>	RW/RsvdP

Figure 7-67 Pending Bits Register for MSI-X PBA Entries §

Table 7-56 Pending Bits Register for MSI-X PBA Entries §

Bit Location	Register Description	Attributes
63:0	<p>Pending Bits - For each Pending Bit that is Set, the Function has a pending message for the associated MSI-X Table entry.</p> <p>Pending bits that have no associated <u>MSI-X Table</u> entry are Reserved. By default, the value of Reserved Pending bits must be 0b.</p> <p>Software should never write, and should only read Pending Bits. If software writes to Pending Bits, the result is undefined.</p> <p>Default value of each Pending Bit is 0b.</p> <p>These bits are permitted to be read-only or read-write.</p>	RO or RW

7.7.3 Secondary PCI Express Extended Capability §

The Secondary PCI Express Extended Capability structure must be implemented in any Function or RCRB where any of the following are true:

- The Supported Link Speeds Vector field indicates that the Link supports Link Speeds of 8.0 GT/s or higher (see § Section 7.5.3.18 or § Section 7.9.9.2).
- Any bit in the Lower SKP OS Generation Supported Speeds Vector field is Set (see § Section 7.5.3.18).
- When Lane based errors are reported in the Lane Error Status register (discussed in § Section 4.2.7).

To support future additions to this capability, this capability is permitted in any Function or RCRB associated with a Link. For a Multi-Function Device associated with an Upstream Port, this capability is permitted only in Function 0 of the Device.

7.7.3.3 Lane Error Status Register (Offset 08h) §

The Lane Error Status Register consists of a 32-bit vector, where each bit indicates if the Lane with the corresponding Lane number detected an error. This Lane number is the default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

Figure 7-71 Lane Error Status Register §

Table 7-59 Lane Error Status Register §

Bit Location	Register Description	Attributes
31:0	<p>Lane Error Status Bits - Each bit indicates if the corresponding Lane detected a Lane-based error. A value of 1b indicates that a Lane based-error was detected on the corresponding Lane Number (see § Section 4.2.2.3.3, § Section 4.2.7, and § Section 4.2.8.2 for details).</p> <p>The default value of each bit is 0b.</p> <p>For Ports that are narrower than 32 Lanes, the unused upper bits [31: Maximum Link Width] are RsvdZ.</p> <p>For Ports that do not support 8.0 GT/s and do not set these bits based on 8b/10b errors (optional, see § Section 4.2.7), this field is permitted to be hardwired to 0.</p>	RW1CS

7.7.3.4 Lane Equalization Control Register (Offset 0Ch) §

The Lane Equalization Control Register consists of control fields required for per-Lane 8.0 GT/s equalization and the number of entries in this register are sized by Maximum Link Width (see § Section 7.5.3.6). Each entry contains the values for the Lane with the corresponding default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

If the Port does not support 8.0 GT/s, this register is permitted to be hardwired to 0.

C	Upstream Port	1b	Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is HwInit.				
See § Section 4.2.4 and § Chapter 8. for details. The field encodings are defined in § Section 4.2.4.2 . The default value is 111b.							

7.7.4 Data Link Feature Extended Capability §

The Data Link Feature Capability is an optional Extended Capability that is required for Downstream Ports that support one or more of the associated features. Since the Scaled Flow Control Feature is required for Ports that support 16.0 GT/s, this capability is required for Downstream Ports that support 16.0 GT/s (see § Section 3.4.2). It is optional in other Downstream Ports. It is optional in Functions associated with an Upstream Port. In Multi-Function Devices associated with an Upstream Port, this capability is individually optional for each non-VF Function, and all implemented instances of this capability must report identical information in all fields of this capability. It is not applicable in Functions that are not associated with a Port (e.g., RCIEPs, Root Complex Event Collectors). The Data Link Feature Extended Capability is shown in § Figure 7-74.

Figure 7-74 Data Link Feature Extended Capability §

7.7.4.1 Data Link Feature Extended Capability Header (Offset 00h) §

§ Figure 7-75 details allocation of register fields in the Data Link Feature Extended Capability Header; § Table 7-63 provides the respective bit definitions.

Figure 7-75 Data Link Feature Extended Capability Header §

Table 7-63 Data Link Feature Extended Capability Header §

Bit Location	Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for Data Link Feature is 0025h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits.	RO

7.7.4.2 Data Link Feature Capabilities Register (Offset 04h) §

§ Figure 7-76 details allocation of register fields in the Data Link Feature Capabilities register; § Table 7-64 provides the respective bit definitions.

When this Port sends a Data Link Feature DLLP, the Feature Supported field in Symbols 1, 2, and 3 of that DLLP contains bits [22:16], [15:8], and [7:0] of this register respectively (See § Figure 3-14).

Figure 7-76 Data Link Feature Capabilities Register §

Table 7-64 Data Link Feature Capabilities Register §

Bit Location	Description	Attributes
22:0	<p>Local Data Link Feature Supported - This field contains the Feature Supported value used when this Port sends a Data Link Feature DLLP (see § Figure 3-14). Defined features are:</p> <p>Bit 0 Local Scaled Flow Control Supported – Data Link Feature This bit indicates that this Port supports the Scaled Flow Control Feature (see § Section 3.4.2).</p> <p>Bit 1 Local Immediate Readiness – Data Link Parameter This bit indicates that all non-Virtual Functions in this Port have Immediate Readiness Set (see § Section 7.5.1.1.4). This bit <i>MUST@FLIT</i> be meaningful. In Non-Flit Mode, this bit is meaningful when Set, but when Clear indicates either that some non-Virtual Function has Immediate Readiness Clear or that this Port is not providing this information.</p> <p>Bits 4:2 Local Extended VC Count – Data Link Parameter This is the maximum number of Virtual Channels that can simultaneously be enabled, taking into account the Extended VC Count field in the Multi-Function Virtual Channel Extended Capability or the Virtual Channel Extended Capability (with Capability ID 0002h), and the SVC Extended VC Count field in the Streamlined Virtual Channel Extended Capability. This field is meaningful in Flit Mode. In Non-Flit Mode, this field must be zero.</p> <p>Bits 7:5 Local L0p Exit Latency – Data Link Parameter This field indicates this Port's knowledge of L0p Exit Latency. The value reported is the larger of Port L0p Exit Latency and Retimer L0p Exit Latency. The actual time required to widen the Link is the larger of Local L0p Exit Latency and Remote L0p Exit Latency. The Downstream Port's Retimer L0p Exit Latency should include retimers that are part of the “system”. The Upstream Port's Retimer L0p Exit Latency should include retimers that are part of the “add-in card”. Defined encodings are:</p>	HwInit/RsvdP

Bit Location	Description	Attributes
	<p>000b Less than 1µs</p> <p>001b 1 µs to less than 2 µs</p> <p>010b 2 µs to less than 4 µs</p> <p>011b 4 µs to less than 8 µs</p> <p>100b 8 µs to less than 16 µs</p> <p>101b 16 µs to less than 32 µs</p> <p>110b 32 µs-64 µs</p> <p>111b More than 64 µs</p> <p>This field is meaningful in Flit Mode. In Non-Flit Mode, this field must be zero.</p> <p>Bits 22:8 RsvdP</p> <p>Other bits in this field are RsvdP.</p>	
31	Data Link Feature Exchange is Enabled - If Set, indicates that this Port will enter the <u>DL_Feature</u> negotiation state (see § Section 3.2.1).	<u>HwInit</u>

7.7.4.3 Data Link Feature Status Register (Offset 08h) §

§ Figure 7-77 details allocation of register fields in the Data Link Feature Status Register; § Table 7-65 provides the respective bit definitions.

Figure 7-77 Data Link Feature Status Register §

101b	16 µs to less than 32 µs																	
110b	32 µs-64 µs																	
111b	More than 64 µs																	
31	<p>Remote Data Link Feature Supported Valid - This bit indicates that the Port has received a <u>Data Link Feature DLLP</u> in state <u>DL_Feature</u> (see § Section 3.2.1) and that the <u>Remote Data Link Feature Supported</u> field is meaningful. This bit is Cleared on entry to state <u>DL_Inactive</u> (see § Section 3.2.1).</p> <p>Default is 0b.</p>	RO																

7.7.5 Physical Layer 16.0 GT/s Extended Capability §

The Physical Layer 16.0 GT/s Extended Capability structure must be implemented in:

- A Function associated with a Downstream Port where the Supported Link Speeds Vector field indicates support for a Link speed of 16.0 GT/s.
- A Function of a single-Function Device associated with an Upstream Port where the Supported Link Speeds Vector field indicates support for a Link speed of 16.0 GT/s.
- Function 0 (and only Function 0) of a Multi-Function Device associated with an Upstream Port where the Supported Link Speeds Vector field indicates support for a Link speed of 16.0 GT/s.

This capability is permitted to be implemented in any of the Functions listed above even if the 16.0 GT/s Link speed is not supported. Implementing this capability is strongly recommended for 8.0 GT/s only Flit Mode components. In Non-Flit

Mode, when the 16.0 GT/s Link speed is not supported and in Flit Mode, when the 8.0 GT/s Link speed is not supported, the behavior of registers other than the Capability Header is undefined. In Flit Mode, operating at 8.0 GT/s, the Capability Header, 16.0 GT/s Local Data Parity Register, 16.0 GT/s First Retimer Data Parity Register, and 16.0 GT/s Second Retimer Data Parity Register are meaningful.

§ Figure 7-79 details allocation of register fields in the Physical Layer 16.0 GT/s Extended Capability structure.

7.7.5.5 16.0 GT/s Local Data Parity Mismatch Status Register (Offset 10h) §

The Local Data Parity Mismatch Status register is a 32-bit vector where each bit indicates if the local receiver detected a Data Parity mismatch on the Lane with the corresponding Lane number. This Lane number is the default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

This register collects parity errors for 16.0 GT/s and higher data rates as well as 8.0 GT/s data rate in Flit Mode. When tracking errors for a specific Link Speed, software should clear this register on speed changes.

Figure 7-83 16.0 GT/s Local Data Parity Mismatch Status Register §

Table 7-70 16.0 GT/s Local Data Parity Mismatch Status Register §

Bit Location	Register Description	Attributes
31:0	<p>Local Data Parity Mismatch Status - Each bit indicates if the corresponding Lane detected a Data Parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding Lane Number. See § Section 4.2.8.2 for more information.</p> <p>The default value of each bit is 0b.</p> <p>For Ports that are narrower than 32 Lanes, the unused upper bits [31: Maximum Link Width] are RsvdZ.</p>	RW1CS/RsvdZ

7.7.5.6 16.0 GT/s First Retimer Data Parity Mismatch Status Register (Offset 14h) §

The First Retimer Data Parity Status register is a 32-bit vector where each bit indicates if the first Retimer of a Path (see § Figure 4-62 for more information) detected a Data Parity mismatch on the Lane with the corresponding Lane number. This Lane number is the default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

This register collects parity errors for 16.0 GT/s and higher data rates as well as 8.0 GT/s data rate in Flit Mode. When tracking errors for a specific Link Speed, software should clear this register on speed changes.

Figure 7-84 16.0 GT/s First Retimer Data Parity Mismatch Status Register §

Table 7-71 16.0 GT/s First Retimer Data Parity Mismatch Status Register §

Bit Location	Register Description	Attributes
31:0	<p>First Retimer Data Parity Mismatch Status - Each bit indicates if the corresponding Lane detected a Data Parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding Lane Number. See § Section 4.2.8.2 for more information.</p> <p>The default value of each bit is 0b.</p> <p>The value of this field is undefined when no Retimers are present.</p> <p>For Ports that are narrower than 32 Lanes, the unused upper bits [31: Maximum Link Width] are RsvdZ.</p>	RW1CS/RsvdZ

7.7.5.7 16.0 GT/s Second Retimer Data Parity Mismatch Status Register (Offset 18h) §

The 16.0 GT/s Second Retimer Data Parity Mismatch Status Register is a 32-bit vector where each bit indicates if the second Retimer of a Path (see § Figure 4-62 for more information) detected a Data Parity mismatch on the Lane with the corresponding Lane number. This Lane number is the default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

This register collects parity errors for 16.0 GT/s and higher data rates as well as 8.0 GT/s data rate in Flit Mode. When tracking errors for a specific Link Speed, software should clear this register on speed changes.

Figure 7-85 16.0 GT/s Second Retimer Data Parity Mismatch Status Register §

Table 7-72 16.0 GT/s Second Retimer Data Parity Mismatch Status Register §

Bit Location	Register Description	Attributes
31:0	<p>Second Retimer Data Parity Mismatch Status - Each bit indicates if the corresponding Lane detected a Data Parity mismatch. A value of 1b indicates that a mismatch was detected on the corresponding Lane Number. See § Section 4.2.8.2 for more information.</p> <p>The default value of each bit is 0b.</p> <p>The value of this field is undefined when no Retimers are present or only one Retimer is present.</p> <p>For Ports that are narrower than 32 Lanes, the unused upper bits [31: Maximum Link Width] are RsvdZ.</p>	RW1CS/RsvdZ

7.7.5.8 Physical Layer 16.0 GT/s Reserved (Offset 1Ch) §

This register is RsvdP.

7.7.5.9 16.0 GT/s Lane Equalization Control Register (Offsets 20h to 3Ch) §

The Equalization Control register consists of control fields required for per-Lane 16.0 GT/s equalization. It contains entries for at least the number of Lanes defined by the Maximum Link Width (see § Section 7.5.3.6 or § Section 7.9.9.2), must be implemented in whole DW granularity (e.g., if the Maximum Link Width is x1, the register will still contain entries for 4 Lanes with the entries for Lanes 1, 2 and 3 being undefined), and it is permitted to contain up to 32 entries regardless of the Maximum Link Width. The value of entries beyond the Maximum Link Width is undefined.

Each entry contains the values for the Lane with the corresponding default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

Figure 7-86 16.0 GT/s Lane Equalization Control Register Entry §

Table 7-73 16.0 GT/s Lane Equalization Control Register Entry §

Bit Location	Register Description	Attributes
3:0	<p>Downstream Port 16.0 GT/s Transmitter Preset - Transmitter Preset used for 16.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. See § Chapter 8. for details. The field encodings are defined in § Section 4.2.4.2 .</p> <p>For an Upstream Port if Crosslink Supported is 0b, this field is RsvdP. Otherwise, this field is Hwlnit. See § Section 7.5.3.18 .</p> <p>The default value is 1111b.</p>	Hwlnit/RsvdP (see description)

Bit Location	Register Description	Attributes																
7:4	<p>Upstream Port 16.0 GT/s Transmitter Preset - Field contains the Transmit Preset value sent or received during 16.0 GT/s Link Equalization. Field usage varies as follows:</p> <table border="1"> <thead> <tr> <th></th> <th>Operating Port Direction</th> <th>Crosslink Supported</th> <th>Usage</th> </tr> </thead> <tbody> <tr> <td>A</td> <td>Downstream Port</td> <td>Any</td> <td>Field contains the value sent on the associated Lane during Recovery.RcvrCfg. C	Upstream Port	1b	Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A (above) applies. Field is <u>Hwlnit</u> .															
<p>See § Section 4.2.4 and § Chapter 8. for details. The field encodings are defined in § Section 4.2.4.2 . The default value is 1111b.</p>																		

7.7.6 Physical Layer 32.0 GT/s Extended Capability §

The Physical Layer 32.0 GT/s Extended Capability structure must be implemented in Ports where one or more of the following features are supported:

- The Supported Link Speeds Vector field indicates support for a Link speed of 32.0 GT/s.
- The Function supports sending and/or receiving Modified TS1/TS2 Ordered Sets.

When implemented, this structure must be implemented in:

- A Function associated with a Downstream Port

- A Function of a single-Function Device associated with an Upstream Port
- Function 0 (and only Function 0) of a Multi-Function Device associated with an Upstream Port

This capability is permitted to be implemented in any of the Functions listed above even if the 32.0 GT/s Link speed is not supported. When the 32.0 GT/s Link speed is not supported, the behavior of registers other than the Capability Header is undefined.

§ Figure 7-87 details allocation of register fields in the Physical Layer 32.0 GT/s Extended Capability structure.

Note that parity errors for 32.0 GT/s are recorded in 16.0 GT/s Local Data Parity Mismatch Status Register, 16.0 GT/s First Retimer Data Parity Mismatch Status Register, and 16.0 GT/s Second Retimer Data Parity Mismatch Status Register. When tracking errors for a specific Link Speed, software should clear those registers on speed changes.

Figure 7-88 Physical Layer 32.0 GT/s Extended Capability Header §

Table 7-75 Physical Layer 32.0 GT/s Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Physical Layer 32.0 GT/s Capability is 002Ah.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.7.6.2 32.0 GT/s Capabilities Register (Offset 04h) §

Figure 7-89 32.0 GT/s Capabilities Register §

Table 7-76 32.0 GT/s Capabilities Register §

Bit Location	Register Description	Attributes
0	Equalization Bypass to Highest NRZ Rate Supported - When Set, this Port supports controlling whether the Port negotiates to skip equalization for speeds other than the highest common supported speed. See Section § Section 4.2.4 for details. Must be 1b for Ports that support 32.0 GT/s or higher data rates.	HwInit

Bit Location	Register Description	Attributes
1	No Equalization Needed Supported - When Set, this Port supports controlling whether or not Equalization is needed.	<u>HwInIt</u>
8	Modified TS Usage Mode 0 Supported - PCI Express - This bit indicates that this Port supports PCI Express (Modified TS Usage 000b). This bit must be 1b.	<u>RO</u>
9	Modified TS Usage Mode 1 Supported - Training Set Message - This bit indicates that this Port supports sending and receiving vendor specific Training Set Messages (Modified TS Usage 001b). See § Section 4.2.5.2 for details.	<u>HwInIt</u>
10	Modified TS Usage Mode 2 Supported - Alternate Protocol - This bit indicates that this Port supports negotiating to use alternate protocols (Modified TS Usage 010b). See § Section 4.2.5.2 for details.	<u>HwInIt</u>
15:11	Modified TS Reserved Usage Modes - Reserved bits for future Usage Modes defined by the PCISIG. Must be 0 0000b.	<u>RO</u>

7.7.6.3 32.0 GT/s Control Register (Offset 08h) §

Figure 7-90 32.0 GT/s Control Register §

Table 7-77 32.0 GT/s Control Register §

Bit Location	Register Description	Attributes
0	Equalization Bypass to Highest NRZ Rate Disable - When Clear, this Port is permitted to indicate during Link Training that it wishes to train to the highest common link NRZ data rate and skip equalization of intermediate data rates. See § Section 4.2.4 for details. If Equalization Bypass to Highest NRZ Rate Supported is Set, this bit is <u>RWS</u> with a default value of 0b. If Equalization Bypass to Highest NRZ Rate Supported is Clear, this bit is permitted to be hardwired to 0b.	<u>RWS/RO</u>
1	No Equalization Needed Disable - When Clear, this Port is permitted to indicate that it does not require equalization. When Set, this Port must always indicate that it requires equalization. See § Section 4.2.4 for details. If No Equalization Needed Supported is Set, this bit is <u>RWS</u> with a default value of 0b. If No Equalization Needed Supported is Clear, this bit is permitted to be hardwired to 0b.	<u>RWS/RO</u>
10:8	Modified TS Usage Mode Selected - This field indicates which Usage Mode will be used by this Downstream Port the next time the Link enters L0 LTSSM State. See § Section 4.2.5.2 for details. Behavior is undefined if this field indicates a Usage Mode that is not supported (i.e., associated Modified TS Usage Mode Supported bit is Clear). Unused bits in this field are permitted to be hardwired to 0b. If the only supported usage mode is PCI Express, this field is permitted to be hardwired to 000b.	<u>RWS/RO/RsvdP</u>

Bit Location	Register Description	Attributes
	This field is present in Downstream Ports. In Upstream Ports, this field is <u>RsvdP</u> . Default is 000b.	

7.7.6.4 32.0 GT/s Status Register (Offset 0Ch) §

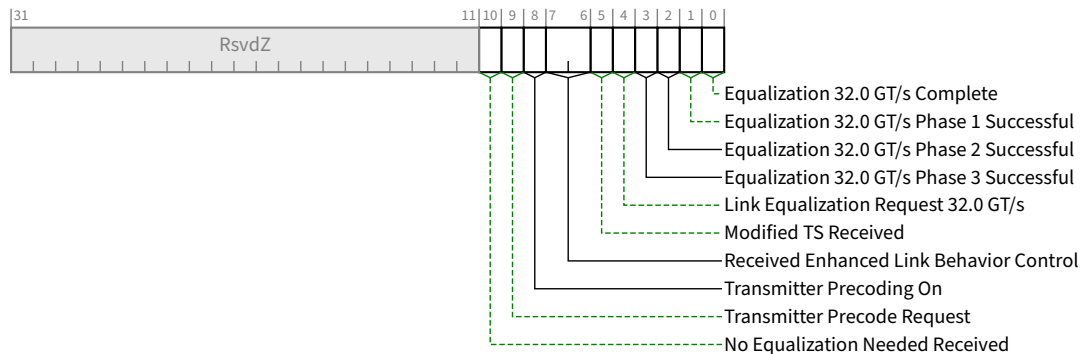

Figure 7-91 32.0 GT/s Status Register §

Table 7-78 32.0 GT/s Status Register §

Bit Location	Register Description	Attributes
0	Equalization 32.0 GT/s Complete - When Set, this bit indicates that the 32.0 GT/s Transmitter Equalization procedure has completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 . The default value of this bit is 0b. For a Multi-Function Upstream Port, this bit must be implemented in Function 0 and <u>RsvdZ</u> in other Functions.	<u>ROS/RsvdZ</u>
1	Equalization 32.0 GT/s Phase 1 Successful - When set to 1b, this bit indicates that Phase 1 of the 32.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 . The default value of this bit is 0b. For a Multi-Function Upstream Port, this bit must be implemented in Function 0 and <u>RsvdZ</u> in other Functions.	<u>ROS/RsvdZ</u>
2	Equalization 32.0 GT/s Phase 2 Successful - When set to 1b, this bit indicates that Phase 2 of the 32.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 . The default value of this bit is 0b. For a Multi-Function Upstream Port, this bit must be implemented in Function 0 and <u>RsvdZ</u> in other Functions.	<u>ROS/RsvdZ</u>
3	Equalization 32.0 GT/s Phase 3 Successful - When set to 1b, this bit indicates that Phase 3 of the 32.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in § Section 4.2.7.4.2 .	<u>ROS/RsvdZ</u>

Bit Location	Register Description	Attributes
	<p>The default value of this bit is 0b.</p> <p>For a Multi-Function Upstream Port, this bit must be implemented in Function 0 and <u>RsvdZ</u> in other Functions.</p>	
4	<p>Link Equalization Request 32.0 GT/s - This bit is Set by hardware to request the 32.0 GT/s Link equalization process to be performed on the Link. Refer to § Section 4.2.4 and § Section 4.2.7.4.2 for details.</p> <p>The default value of this bit is 0b.</p> <p>For a Multi-Function Upstream Port, this bit must be implemented in Function 0 and <u>RsvdZ</u> in other Functions.</p>	<u>RW1CS/RsvdZ</u>
5	<p>Modified TS Received - If Set, Received Modified TS Data 1 Register and Received Modified TS Data 2 Register contain meaningful data.</p> <p>This bit is Cleared when the Link is Down. This bit is Set when the Modified TS1/TS2 Ordered Set is received (See § Section 4.2.7.3.3). Default is 0b.</p>	<u>RO</u>
7:6	<p>Received Enhanced Link Behavior Control - This field contains the Enhanced Link Behavior Control bits from the most recent TS1 or TS2 received in the <u>Polling</u> or <u>Configuration</u> states. See § Section 4.2.5.1 , § Table 4-25 and § Table 4-26.</p> <p>This field is Cleared on <u>DL_Down</u>.</p> <p>Default is 00b.</p>	<u>RO</u>
8	<p>Transmitter Precoding On - This field indicates whether the Receiver asked this transmitter to enable Precoding. See § Section 4.2.2.5 . This bit is cleared on <u>DL_Down</u>.</p> <p>Default is 0b.</p>	<u>RO</u>
9	<p>Transmitter Precode Request - When Set, this Port will request the transmitter to use Precoding by setting the Transmitter Precode Request bit in the TS1s/TS2s it transmits prior to entry to <u>Recovery.Speed</u> (see § Section 4.2.2.5).</p> <p>Default is Implementation Specific.</p>	<u>RO</u>
10	<p>No Equalization Needed Received - When Set, this Port either received a Modified TS1/TS2 with the No Equalization Needed bit Set or received a non-modified TS1/TS2 was received with the No Equalization Needed encoding (also reported in the <u>Received Enhanced Link Behavior Control</u> field).</p> <p>Default is 0b.</p>	<u>RO</u>

7.7.6.5 Received Modified TS Data 1 Register (Offset 10h) §

This register contains the values received in the Modified TS1/TS2 Ordered Set (see § Table 4-27).

If PCI Express (Usage Mode 0) is the only one supported by a Port, this register is permitted to be hardwired to 0000 0000h.

Figure 7-92 Received Modified TS Data 1 Register §

Table 7-79 Received Modified TS Data 1 Register §

Bit Location	Description	Attributes
2:0	<p>Received Modified TS Usage Mode - If Modified TS Received is Set, this field contains the Modified TS Usage field from the Modified TS1/TS2 Ordered Set (see § Section 4.2.7.3.6). If Modified TS Received is Clear, this field contains 000b.</p> <p>Unused bits in this field are permitted to be hardwired to 0b. If PCI Express (Usage Mode 0) is the only one supported, this field is permitted to be hardwired to 000b.</p> <p>Default is 000b.</p>	RO
15:3	<p>Received Modified TS Information 1 - If Modified TS Received is Set, this field contains the Modified TS Information 1 field from the Modified TS1/TS2 Ordered Set (see § Section 4.2.7.3.6). If Modified TS Received is Clear, this field contains 0 0000 0000 0000b.</p> <p>Bits 15:8 contain the value of Symbol 9.</p> <p>Bits 7:3 contain bits 7:3 of Symbol 8.</p> <p>If PCI Express (Usage Mode 0) is the only one supported, this field is permitted to be hardwired to 0 0000 0000 0000b.</p> <p>Default is 0 0000 0000 0000b.</p>	RO
31:16	<p>Received Modified TS Vendor ID - If Modified TS Received is Set, this field contains the Training Set Message Vendor ID or Alternate Protocol Vendor ID field from the Modified TS1/TS2 Ordered Set received (see § Section 4.2.7.3.6). If Modified TS Received is Clear, this field contains 0000h.</p> <p>Bits 15:8 contain the value of Symbol 11.</p> <p>Bits 7:0 contain the value of Symbol 10.</p> <p>If PCI Express (Usage Mode 0) is the only one supported, this field is permitted to be hardwired to 0000h.</p> <p>Default is 0000h.</p>	RO

7.7.6.6 Received Modified TS Data 2 Register (Offset 14h) §

This register contains the values received in Symbols 12 through 14 of the Modified TS1/TS2 (see § Table 4-27).

If Modified TS Usage Mode 1 Supported - Training Set Message and Modified TS Usage Mode 2 Supported - Alternate Protocol are both Clear, this register is permitted to be hardwired to 0000 0000h.

Figure 7-93 Received Modified TS Data 2 Register §

Table 7-80 Received Modified TS Data 2 Register §

Bit Location	Description	Attributes
23:0	<p>Received Modified TS Information 2 - If Modified TS Received is Set, this field contains the Modified TS Information 2 field from the received Modified TS1/TS2 Ordered Set (§ Section 4.2.7.3.6). If Modified TS Received is Clear, this field contains 00 0000h.</p> <p>Bits 23:16 contain the value of Symbol 14.</p> <p>Bits 16:8 contain the value of Symbol 13.</p> <p>Bits 7:0 contain the value of Symbol 12.</p> <p>If PCI Express (Usage Mode 0) is the only one supported, this field is permitted to be hardwired to 00 0000h.</p> <p>Default is 00 0000h.</p>	RO
25:24	<p>Alternate Protocol Negotiation Status - Indicates the status of the Alternate Protocol Negotiation. Encodings are:</p> <p>00b Alternate Protocol Negotiation not supported</p> <p>01b Alternate Protocol Negotiation disabled</p> <p>10b Alternate Protocol Negotiation failed - Alternate Protocol Negotiation was attempted and did not locate a protocol that was supported on both ends of the Link.</p> <p>11b Alternate Protocol Negotiation succeeded - Alternate Protocol Negotiation located one or more protocols that were supported on both ends of the Link and the Downstream Port selected one of those protocols for use.</p> <p>If 11b, Alternate Protocol Negotiation completed successfully. If not 11b, Alternate Protocol Negotiation has not completed successfully. If Modified TS Usage Mode 1 Supported - Training Set Message and Modified TS Usage Mode 2 Supported - Alternate Protocol are both Clear, this field is permitted to be hardwired to 00b.</p> <p>If Modified TS Usage Mode 2 Supported - Alternate Protocol is Clear, this field is hardwired to 00b.</p> <p>If Modified TS Usage Mode 2 Supported - Alternate Protocol is Set and Modified TS Usage Mode Selected does not equal 2, this field must return a non-11b value. This field is cleared to 00b on entering Detect.</p> <p>Default is 00b.</p>	RO

7.7.6.7 Transmitted Modified TS Data 1 Register (Offset 18h) §

This register contains the values transmitted in the Modified TS1/TS2 Ordered Set (see § Table 4-27).

If PCI Express (Usage Mode 0) is the only one supported by a Port, this register is permitted to be hardwired to 0000 0000h.

Figure 7-94 Transmitted Modified TS Data 1 Register §

7.7.6.9 32.0 GT/s Lane Equalization Control Register (Offset 20h) §

The 32.0 GT/s Equalization Control register consists of control fields required for per-Lane 32.0 GT/s equalization. It contains entries for at least the number of Lanes defined by the Maximum Link Width (see § Section 7.5.3.6 or § Section 7.9.9.2), must be implemented in whole DW granularity (e.g., if the Maximum Link Width is x1, the register will still contain entries for 4 Lanes with the entries for Lanes 1, 2 and 3 being undefined), and it is permitted to contain up to 32 entries regardless of the Maximum Link Width. The value of entries beyond the Maximum Link Width is undefined.

Each entry contains the values for the Lane with the corresponding default Lane number which is invariant to Link width and Lane reversal negotiation that occurs during Link training.

	See § Section 4.2.4 and § Chapter 8. for details. The field encodings are defined in § Section 4.2.4.2 . The default value is 1111b.	

7.7.7 Physical Layer 64.0 GT/s Extended Capability §

The Physical Layer 64.0 GT/s Extended Capability structure must be implemented in Ports where one or more of the following features are supported:

- The Supported Link Speeds Vector field indicates support for a Link speed of 64.0 GT/s.

When implemented, this structure must be implemented in:

- A Function associated with a Downstream Port
- A Function of a single-Function Device associated with an Upstream Port
- Function 0 (and only Function 0) of a Multi-Function Device associated with an Upstream Port

This capability is permitted to be implemented in any of the Functions listed above even if the 64.0 GT/s Link speed is not supported. When the 64.0 GT/s Link speed is not supported, the behavior of registers other than the Capability Header is undefined.

§ Figure 7-97 details allocation of register fields in the Physical Layer 64.0 GT/s Extended Capability structure.

Note that parity errors for 64.0 GT/s are recorded in 16.0 GT/s Local Data Parity Mismatch Status Register, 16.0 GT/s First Retimer Data Parity Mismatch Status Register, and 16.0 GT/s Second Retimer Data Parity Mismatch Status Register. When tracking errors for a specific Link Speed, software should clear those registers on speed changes.

7.7.8 Flit Logging Extended Capability §

This capability *MUST* be implemented in Ports and RCRBs that support Flit Mode. For Functions associated with an Upstream Port, this capability *MUST* be implemented in Function 0 and *MUST* not be implemented in any other Function of that Upstream Port.

This capability is only used in Flit Mode. The capability has no effect in Non-Flit Mode.

§ Figure 7-103 details allocation of the register bits in the Flit Logging Extended Capability structure.

Bit Location	Register Description	Attributes
15:0	Flit Logging Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Flit Logging Extended Capability is 0032h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.7.8.2 Flit Error Log 1 Register (Offset 04h) §

The Flit Error Log 1 Register and Flit Error Log 2 Register are Link level registers and contain information about the Flit errors corrected and/or detected by the FEC and/or CRC in a received Flit. The Flit Error Log is a FIFO of an implementation specific and unspecified size (size 1 is permitted). These registers contain the oldest log entry. Clearing the Flit Error Log Valid removes the oldest log entry from the FIFO and loads these registers with the next oldest log entry (if there is one). See § Section 4.2.3.1.2 , § Section 4.2.3.1.3 , § Appendix J , and § Appendix K. for details.

Figure 7-105 Flit Error Log 1 Register §

Table 7-92 Flit Error Log 1 Register §

Bit Location	Register Description	Attributes												
0	<p>Flit Error Log Valid – This bit is Set to 1b when an error is logged in this register.</p> <p>Writing 1b to this bit either clears this bit or, if More Entries for Flit Error Log Register are Valid (i.e., Bit 13) is Set, loads the <u>Flit Error Log 1 Register</u> and <u>Flit Error Log 2 Register</u> with the next oldest log entry</p> <p>Default <u>Zero</u>.</p>	<u>RW1CS</u>												
3:1	<p>Flit Error Link Width – Link Width when error was logged (taking into account any narrowing due to L0p). Encoding is:</p> <table> <tr> <td>000b</td> <td>x1</td> </tr> <tr> <td>001b</td> <td>x2</td> </tr> <tr> <td>010b</td> <td>x4</td> </tr> <tr> <td>011b</td> <td>x8</td> </tr> <tr> <td>100b</td> <td>x16</td> </tr> <tr> <td>Others</td> <td>Reserved</td> </tr> </table> <p>Default is <u>Zero</u>.</p>	000b	x1	001b	x2	010b	x4	011b	x8	100b	x16	Others	Reserved	<u>ROS</u>
000b	x1													
001b	x2													
010b	x4													
011b	x8													
100b	x16													
Others	Reserved													
7:4	<p>Flit Offset from the Last Logged Flit in Error – This is the offset from the last Flit whose error has been recorded in the prior entry of the Flit Error Log Register, if any.</p> <ul style="list-style-type: none"> • If this is the very first error that gets logged or this is the only copy of the Flit Error Log Register, this value must be 0h. • If the previous flit was in error and logged, this value must be 1h. • If the last logged Flit was more than 15 Flits away, this value must be Fh. <p>This field only reflects errors that were logged. If the previous flit was in error but was not logged, that error has no effect on this value.</p> <p>Default is <u>Zero</u>.</p>	<u>ROS</u>												
12:8	<p>Consecutive Flit Error after the Last Flit Error – Initially, this field is Zero. If there are any errors (either correctable or uncorrectable by FEC) in any of the 5 consecutive Flits immediately following the Flit recorded in this log entry, the corresponding bits are set to 1b; otherwise they remain 0b. This field can change value after Flit Error Log Valid is Set and more Flits are received. If More Entries for Flit Error Log Register is Set, some bits of this field may not be meaningful and the actual value of this field needs to be computed from this field and from subsequent log entries.</p> <p>Consider consecutive log entries A, B and C, where A is older than B and B is older than C:</p> <ul style="list-style-type: none"> • If <u>Flit Offset from the Last Logged Flit in Error</u> in B is >5, then this field in log entry A is accurate (since there were more than 5 intervening flits between A and B). • If <u>Flit Offset from the Last Logged Flit in Error</u> in B is ≤ 5, then some bits of this field in A must be computed from B (and C, if applicable, depending on the distance between A and C). • If <u>Flit Offset from the Last Logged Flit in Error</u> in B = 2h, then entry A is for two flits earlier. For entry A: <ul style="list-style-type: none"> ◦ Bit 0 represents the intervening Flit (which might have been in error but not logged) and ◦ Bits 4:1 are not meaningful and must be computed from B (and C, if applicable, depending on the distance between A and C). Computed bit 1 is 1b (because B exists), and computed bits 4:2 are bits 2:0 of B. 	<u>ROS</u>												

Bit Location	Register Description	Attributes
	<ul style="list-style-type: none"> If in turn, Flit Offset from the Last Logged Flit in Error in C is ≤ 5, some of the bits in B are not meaningful and must be computed from C (and possibly the next entry D, if applicable and available). <p>Default is <u>Zero</u>.</p>	
13	<p>More Entries for Flit Error Log Register are Valid – when Set, it indicates that the Port has additional valid copies of the Flit Error Log Register for subsequent Flits. A port that implements only one set of Flit Error Log Register is permitted to hardwire this to <u>Zero</u>.</p> <p>If this bit is Set, clearing the Flit Error Log Valid bit loads the next oldest Flit Error Log Register entry. This bit can change value when Flit Error Log Valid bit is Set and an additional error is being logged.</p> <p>Default is <u>Zero</u>.</p>	<u>ROS</u>
14	<p>Unrecognized Flit – when Set indicates receipt of a Flit that passes CRC after FEC decode but uses a Reserved encoding in the <u>Flit Usage</u> or <u>Flit Status</u> fields.</p> <p>Default is <u>Zero</u></p>	<u>ROS</u>
15	<p>FEC Uncorrectable Error in Flit – When set to 1b indicates either a CRC mismatch or one of the three FEC groups detecting an error it could not correct</p>	<u>ROS</u>
23:16	<p>Syndrome Parity for ECC Group 0 – Synd_Parity in § Chapter 4. .</p> <p>Default is <u>Zero</u>.</p>	<u>ROS</u>

7.7.8.6 FBER Measurement Control Register (Offset 10h) §

The FBER Measurement Control register enables direct FBER measurement with status reported in the FBER Measurement Status Registers. For Retimers, the control is provided through Margin Command in the Control SKP Ordered Set from the Downstream Port (see § Chapter 4.).

Figure 7-109 FBER Measurement Control Register §

Table 7-96 FBER Measurement Control Register §

0	<p>FBER Measurement Enable – Setting this bit enables and starts the FBER measurement in the Link. Clearing this bit stops FBER measurement.</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>
1	<p>Clear FBER Counters – Writing a 1b to this bit clears the FBER counters.</p> <p>This bit always return <u>Zero</u> when read</p>	<u>RW</u>
3:2	<p>Granularity of per-Lane Error reported –</p> <p>00b count all bit errors corrected by FEC in valid Flits,</p> <p>01b count all even bit errors in each UI corrected by FEC in valid Flits,</p> <p>10b count all odd bit errors in each UI corrected by FEC in valid Flits,</p> <p>11b count only mismatches in the Control SKP OS as a single correctable bit error</p> <p>FBER measurement results are undefined if this field contains 01b or 10b and the Link is not operating in PAM4.</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>

Bit Location	Register Description	Attributes
4	Report Longest Burst vs First Burst – This bit is now deprecated. Behavior is undefined if this bit is Set. Default is <u>Zero</u> .	<u>RW</u>

7.7.8.7 FBER Measurement Status 1 Register (Offset 14h) §

FBER Measurement Status 1 Register through FBER Measurement Status 10 Register contain a collection of per-Link and per-Lane counters:

- Flit Counter – per-Link
- Invalid Flit Counter – per-Link
- Correctable Error Counters – per-Lane (Adding these together produces a per-Link counter)

A write of 1b to either the Clear FBER Counters or the FBER Measurement Enable bit of the FBER Measurement Control Register resets the value of all of these counters to their default values. All of these counters saturate (i.e., when they reach their maximum value, they do not roll over).

Figure 7-110 FBER Measurement Status 1 Register §

Table 7-97 FBER Measurement Status 1 Register §

10	UIO Mem RdWr Completer Supported – When Set, indicates the Function supports UIO Memory Read and UIO Memory Write as a Completer.	<u>HwInit</u>
11	UIO Mem RdWr Requester Supported – When Set, indicates the Function supports UIO Memory Read and/or UIO Memory Write as a Requester.	<u>HwInit</u>

7.7.9.3 Device Control 3 Register (Offset 08h) §

§ Figure 7-123 details the allocation of register bits of the Device Control 3 register; § Table 7-109 provides the respective bit definitions.

IMPLEMENTATION NOTE:

USE OF UIO REQUEST 256B BOUNDARY DISABLE §

UIO is intended to be suitable for routing its Requests directly to memory controllers. For memory architectures that support interleaving, it is intended that a single UIO Request not target multiple memory controllers. When Clear, the UIO Request 256B Boundary Disable bit prevents UIO Requests from crossing naturally aligned 256-byte address boundaries, supporting interleaving granularities of that size and integer multiples of it.

Flit Mode Link efficiency for 256-byte UIO Requests is relatively high, and it increases only a few percent when maximum-sized 4-KB Requests are used. However, for cases where using larger UIO Requests is desired in order to increase Link efficiency and/or lower TLP rates, software may Set the UIO Request 256B Boundary Disable bit to enable larger Requests. Software should only do this if it knows there is no requirement for this Requester to honor 256-byte boundaries.

Figure 7-123 Device Control 3 Register §

Table 7-109 Device Control 3 Register §

Bit Location	Register Description	Attributes
0	<p>DMWr Requester Enable - Applicable only to Endpoints, Root Ports and RCRBs; must be hardwired to 0b for other Function types. The Function is allowed to initiate DMWr Requests only if this bit and the Bus Master Enable bit in the Command register are both Set.</p> <p>This bit is required to be RW if the Endpoint or Root Port is capable of initiating DMWr Requests, but otherwise is permitted to be hardwired to 0b.</p> <p>This bit does not serve as a capability bit. This bit is permitted to be RW even if no DMWr Requester capabilities are supported by the Endpoint or Root Port.</p> <p>Default value of this bit is 0b.</p>	RW
1	<p>DMWr Egress Blocking – Applicable and mandatory for Switch Upstream Ports, Switch Downstream Ports, and Root Ports that implement DMWr routing; otherwise must be hardwired to 0b.</p> <p>When this bit is Set, DMWr Requests that target going out this Egress Port must be blocked. See § Section 6.32 .</p> <p>Default value of this bit is 0b.</p>	RW/RO (see description)
2	<p>14-Bit Tag Requester Enable – This bit, in combination with the Extended Tag Field Enable bit and 10-Bit Tag Requester Enable bit, determines how many Tag field bits a Requester is permitted to use. When the 14-Bit Tag Requester Enable bit is Set, the Requester is permitted to use 14-Bit Tags. See § Section 2.2.6.2 for complete details.</p> <p>If software changes the value of this bit while the Function has outstanding Non-Posted Requests, the result is undefined.</p> <p>For VFs, this bit is not supported and is RsvdP. The value in the VF 14-Bit Tag Requester Enable bit in the associated PF's SR-IOV Control Register applies to all its VFs.</p> <p>Non-VF Functions that do not implement 14-Bit Tag Requester capability are permitted to hardwire this bit to 0b.</p> <p>Default value of this bit is 0b.</p>	RW/RO (see description) VF RsvdP
3	<p>L0p Enable – Determines behavior of this Port when sending or responding to Link Management DLLPs of type L0p DLLP.</p> <p>This bit has no effect on Link Management DLLPs where the Link Mgmt Type field is other than L0p DLLP.</p> <p>This bit has no effect if Hardware Autonomous Width Disable is 1b.</p> <p>Default is 1b.</p>	RW

Bit Location	Register Description	Attributes

010b	x4 Link													
011b	x8 Link													
100b	x16 Link													
Others	Reserved													
3	<p>Segment Captured – This bit indicates if the Function has captured a valid Segment value from a Configuration Write Request as described in § Section 2.2.6.2 . When the Destination Segment field is captured from a Configuration Write Request in FM this bit must be set to the value of the DSV bit received with the Request. This bit must be cleared when a Configuration Write Request is received in NFM.</p> <p>Note that this bit will be set when every Link on the path from the Function to the RC is in FM. This bit will be clear if any Link between the Function and the RC is in NFM. Functions should only initiate Route by ID Message Requests targeting Hierarchies other than their own when this bit is Set.</p> <p>This bit is permitted to be hardwired to 0b in devices that don't support FM.</p> <p>FM Requesters and Completers within an RC capture their Segment value in an implementation specific way and must then Set this bit.</p> <p>The value in a Switch Downstream Port must be identical to the value in the associated Switch Upstream Port.</p> <p>Default is Zero in Functions that capture their Segment value.</p>	RO												
4	<p>Remote L0p Supported – This bit indicates that the remote end of the Link supports L0p.</p> <p>Default is zero.</p>	RO												

7.7.10 Lane Margining at the Receiver Extended Capability §

The Lane Margining at the Receiver Extended Capability structure must be implemented in:

- A Function associated with a Downstream Port where the Supported Link Speeds Vector field indicates support for a Link speed of 16.0 GT/s or higher.
- A Function of a single-Function Device associated with an Upstream Port where the Supported Link Speeds Vector field indicates support for a Link speed of 16.0 GT/s or higher.
- Function 0 (and only Function 0) of a Multi-Function Device associated with an Upstream Port where the Supported Link Speeds Vector field indicates support for a Link speed of 16.0 GT/s or higher.

§ Figure 7-125 shows the layout of the Margining Extended Capability. This capability contains a pair of per-Port registers followed by a set of per-Lane registers.

The number of per-Lane entries is determined by the Maximum Link Width (see § Section 7.5.3.6 or § Section 7.9.9.2). Up to 32 entries are permitted regardless of the Maximum Link Width. The value of entries beyond the Maximum Link Width is undefined.

Each per-Lane entry contains the values for that Lane. Lane numbering uses the default Lane number and is thus invariant to Link width and Lane reversal negotiation that occurs during Link training.

Bit Location	Register Description	Attributes
2:0	Receiver Number Status - See § Section 4.2.18.1 for details. The default value is 000b. For Downstream Ports, this field must be reset to the default value if the Port goes to <u>DL_Down</u> status.	RO (see description)
5:3	Margin Type Status - See § Section 4.2.18.1 for details. The default value is 000b. This field must be reset to the default value if the Port goes to <u>DL_Down</u> status.	RO (see description)
6	Usage Model Status - See § Section 4.2.18.1 for details. The default value is 0b. This field must be reset to the default value if the Port goes to <u>DL_Down</u> status.	RO (see description)
15:8	Margin Payload Status - See § Section 4.2.18.1 for details. This field is only meaningful, when the Margin Type is a defined encoding other than 'No Command'. The default value is 00h. This field must be reset to the default value if the Port goes to <u>DL_Down</u> status.	RO (see description)

7.7.11 ACS Extended Capability §

The ACS Extended Capability is an optional capability that provides enhanced access controls (see § Section 6.12). This capability may be implemented by a Root Port, a Switch Downstream Port, or a Multi-Function Device Function. It is never applicable to a PCI Express to PCI Bridge or Root Complex Event Collector. It is not applicable to a Switch Upstream Port unless that Switch Upstream Port is a Function in a Multi-Function Device.

If an SR-IOV Capable Device other than one in a Root Complex implements internal peer-to-peer transactions, ACS is required, and ACS P2P Egress Control must be supported.

Implementation of ACS in RCiEPs is permitted but not required. It is explicitly permitted that within a single Root Complex, some RCiEPs implement ACS and some do not. It is strongly recommended that Root Complex implementations ensure that all accesses originating from RCiEPs (PFs and VFs) without ACS capability are first subjected to processing by a Translation Agent (TA) in the Root Complex before further decoding and processing. The details are outside the scope of this specification.

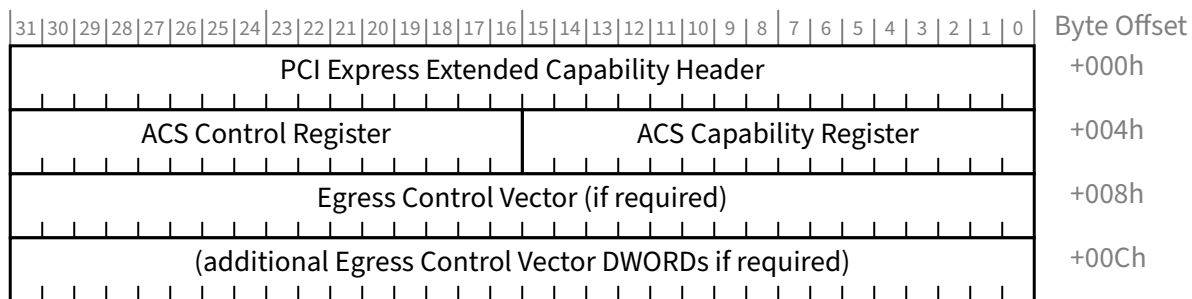

Figure 7-131 ACS Extended Capability §

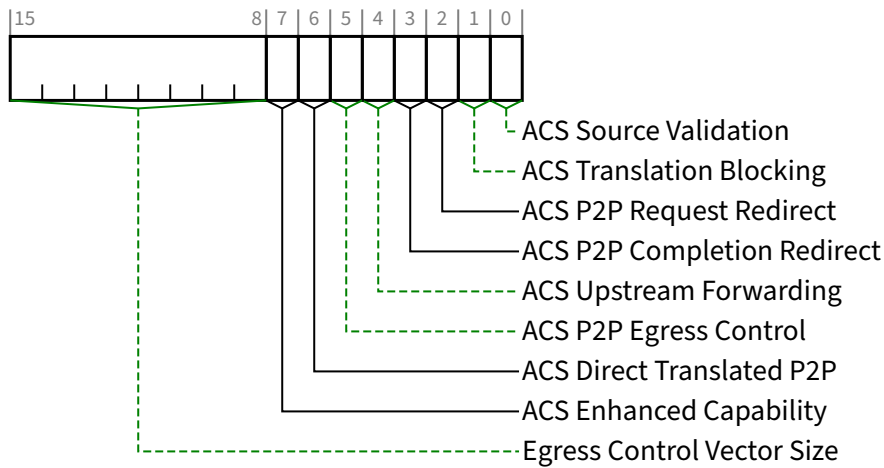

Figure 7-133 ACS Capability Register §

Table 7-117 ACS Capability Register §

Bit Location	Register Description	Attributes
0	ACS Source Validation - Required for Root Ports and Switch Downstream Ports; must be hardwired to 0b otherwise. If 1b, indicates that the component implements <u>ACS Source Validation</u> .	RO
1	ACS Translation Blocking - Required for Root Ports and Switch Downstream Ports; must be hardwired to 0b otherwise. If 1b, indicates that the component implements <u>ACS Translation Blocking</u> .	RO
2	ACS P2P Request Redirect - Required for Root Ports that support peer-to-peer traffic with other Root Ports; required for Switch Downstream Ports; required for Multi-Function Device Functions that support peer-to-peer traffic with other Functions; must be hardwired to 0b otherwise. If 1b, indicates that the component implements <u>ACS P2P Request Redirect</u> .	RO
3	ACS P2P Completion Redirect - Required for all Functions that support <u>ACS P2P Request Redirect</u> ; must be hardwired to 0b otherwise. If 1b, indicates that the component implements <u>ACS P2P Completion Redirect</u> .	RO
4	ACS Upstream Forwarding - Required for Root Ports if the RC supports Redirected Request Validation; required for Switch Downstream Ports; must be hardwired to 0b otherwise. If 1b, indicates that the component implements <u>ACS Upstream Forwarding</u> .	RO
5	ACS P2P Egress Control - Except as stated below, optional for Root Ports, Switch Downstream Ports, and Multi-Function Device Functions; otherwise this bit must be hardwired to Zero. If Set, indicates that the component implements <u>ACS P2P Egress Control</u> . For an SR-IOV Device not in a Root Complex, this bit is required to be Set for Functions if peer-to-peer transactions within the Device are supported.	RO
6	ACS Direct Translated P2P - Required for Root Ports that support Address Translation Services (ATS) and also support peer-to-peer traffic with other Root Ports; required for Switch Downstream Ports; required for Multi-Function Device Functions that support Address Translation Services (ATS) and also support peer-to-peer traffic with other Functions; must be hardwired to 0b otherwise. If 1b, indicates that the component implements <u>ACS Direct Translated P2P</u> .	RO

Bit Location	Register Description	Attributes
7	<p>ACS Enhanced Capability - Required for Root Ports and Switch Downstream Ports that support the ACS Enhanced Capability mechanisms.</p> <p>If Set, indicates that the component supports all of the following mechanisms that are applicable:</p> <ul style="list-style-type: none"> ACS I/O Request Blocking ACS DSP Memory Target Access ACS USP Memory Target Access ACS Unclaimed Request Redirect 	RO
15:8	<p>Egress Control Vector Size - Encodings 01h-FFh directly indicate the number of applicable bits in the Egress Control Vector; the encoding 00h indicates 256 bits.</p> <p>If the ACS P2P Egress Control bit is 0b, the value of the size field is undefined, and the Egress Control Vector Register is not required to be present.</p>	HwInit

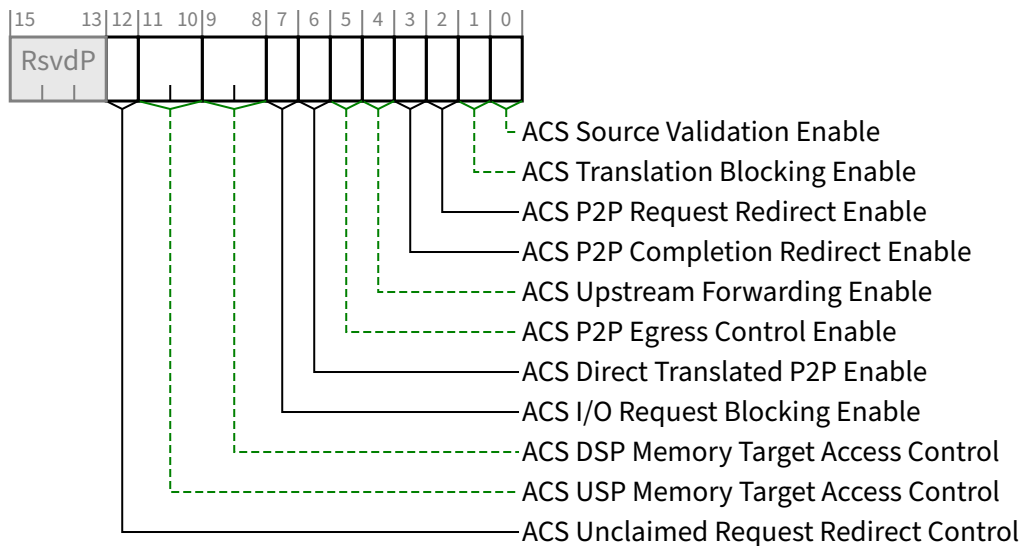

Figure 7-134 ACS Control Register §

Table 7-118 ACS Control Register §

Bit Location	Register Description	Attributes
0	<p>ACS Source Validation Enable - When Set, the component validates the Bus Number from the Requester ID of Upstream Requests against the secondary/subordinate Bus Numbers.</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the ACS Source Validation functionality is not implemented.</p>	RW

Bit Location	Register Description	Attributes
1	<p>ACS Translation Blocking Enable - When Set, the component blocks all Upstream Memory Requests whose <u>Address Type (AT)</u> field is not set to the default value.</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ACS Translation Blocking</u> functionality is not implemented.</p>	<u>RW</u>
2	<p>ACS P2P Request Redirect Enable - In conjunction with <u>ACS P2P Egress Control</u> and <u>ACS Direct Translated P2P</u> mechanisms, determines when the component redirects peer-to-peer Requests Upstream (see § Section 6.12.3). Note that with <u>Downstream Ports</u>, this bit only applies to Upstream Requests arriving at the <u>Downstream Port</u>, and whose normal routing targets a different <u>Downstream Port</u>.</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ACS P2P Request Redirect</u> functionality is not implemented.</p>	<u>RW</u>
3	<p>ACS P2P Completion Redirect Enable - Determines when the component redirects peer-to-peer Completions Upstream; applicable only to Completions¹⁶⁷ whose <u>Relaxed Ordering Attribute</u> is clear.</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ACS P2P Completion Redirect</u> functionality is not implemented.</p>	<u>RW</u>
4	<p>ACS Upstream Forwarding Enable - When Set, the component forwards Upstream any Request or Completion TLPs it receives that were redirected Upstream by a component lower in the hierarchy. Note that this bit only applies to Upstream TLPs arriving at a <u>Downstream Port</u>, and whose normal routing targets the same <u>Downstream Port</u>.</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ACS Upstream Forwarding</u> functionality is not implemented.</p>	<u>RW</u>
5	<p>ACS P2P Egress Control Enable - In conjunction with the <u>Egress Control Vector</u> plus the <u>ACS P2P Request Redirect</u> and <u>ACS Direct Translated P2P</u> mechanisms, determines when to allow, disallow, or redirect peer-to-peer Requests (see § Section 6.12.3).</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ACS P2P Egress Control</u> functionality is not implemented.</p>	<u>RW</u>
6	<p>ACS Direct Translated P2P Enable - When Set, overrides the <u>ACS P2P Request Redirect</u> and <u>ACS P2P Egress Control</u> mechanisms with peer-to-peer Memory Requests whose <u>Address Type (AT)</u> field indicates a <u>Translated address</u> (see § Section 6.12.3).</p> <p>This bit is ignored if <u>ACS Translation Blocking Enable</u> is 1b.</p> <p>Default value of this bit is 0b. Must be hardwired to 0b if the <u>ACS Direct Translated P2P</u> functionality is not implemented.</p>	<u>RW</u>
7	<p>ACS I/O Request Blocking Enable - if Set, Upstream I/O Requests received by the <u>Downstream Port</u> must be handled as <u>ACS Violations</u>.</p> <p>This bit is required for <u>Root Ports</u> and <u>Switch Downstream Ports</u> if the <u>ACS Enhanced Capability</u> bit is Set; otherwise it must be <u>RsvdP</u>. The default value of this bit is 0b.</p>	<u>RW/RsvdP</u>
9:8	<p>ACS DSP Memory Target Access Control - This field controls how a <u>Downstream Port</u> handles Upstream Memory Requests attempting to access any <u>Memory BAR Space</u> on an applicable <u>Root Port</u> or <u>Switch Downstream Port</u> (including the <u>Ingress Port</u>). See § Section 6.12.1.1 .</p> <p>Defined Encodings are:</p> <p>00b Direct Request access enabled</p> <p>01b Request blocking enabled</p> <p>10b Request redirect enabled</p>	<u>RW/RsvdP</u>

167. This includes Read Completions, AtomicOp Completions, and other Completions with or without Data.

Bit Location	Register Description	Attributes
	<p>11b Reserved</p> <p>This field is required for Root Ports and Switch Downstream Ports if the ACS Enhanced Capability bit is Set and there is applicable Memory BAR Space to protect; otherwise it must be RsvdP. The default value of this field is 00b.</p>	
11:10	<p>ACS USP Memory Target Access Control - This field controls how a Switch Downstream Port handles Upstream Memory Requests attempting to access any Memory BAR Space on the Switch Upstream Port. See § Section 6.12.1.1 .</p> <p>Defined Encodings are:</p> <p>00b Direct Request access enabled</p> <p>01b Request blocking enabled</p> <p>10b Request redirect enabled</p> <p>11b Reserved</p> <p>This field is required for Switch Downstream Ports if the ACS Enhanced Capability bit is Set and there is applicable Memory BAR Space to protect; otherwise it must be RsvdP. The default value of this field is 00b.</p>	RW/RsvdP
12	<p>ACS Unclaimed Request Redirect Control - Controls how a Switch Downstream Port handles incoming Requests targeting Memory Space within the Memory aperture of the Switch Upstream Port that is not within a Memory aperture or Memory BAR Space of any Downstream Port within the Switch.</p> <p>When Set, the Switch must forward such Requests Upstream out of the Switch.</p> <p>When Clear, the Switch Downstream Port must handle such Requests as an Unsupported Request (UR).</p> <p>This bit is required for Switch Downstream Ports if the ACS Enhanced Capability bit is Set; otherwise it must be RsvdP. The default value of this bit is 0b.</p>	RW/RsvdP

7.7.11.4 Egress Control Vector Register (Offset 08h) §

The Egress Control Vector is a read-write register that contains a bit-array. The number of bits in the register is specified by the Egress Control Vector Size field, and the register spans multiple DWORDs if required. If the ACS P2P Egress Control bit in the ACS Capability Register is 0b, the Egress Control Vector Size field is undefined and the Egress Control Vector Register is not required to be present.

For the general case of an Egress Control Vector spanning multiple DWORDs, the DWORD offset and bit number within that DWORD for a given arbitrary bit K are specified by the formulas¹⁶⁸:

$$\text{DWORD offset} = 08h + (K \text{ div } 32) \times 4$$

$$\text{DWORD bit\#} = K \text{ mod } 32$$

Equation 7-4 Egress Control Vector Access §

Bits in a DWORD beyond those specified by the Egress Control Vector Size field are RsvdP.

For Root Ports and Switch Downstream Ports, each bit in the bit-array always corresponds to a Port Number. Otherwise, for Functions¹⁶⁹ within a Multi-Function Device, each bit in the bit-array corresponds to one or more Function Numbers,

168. Div is an integer divide with truncation. Mod is the remainder from an integer divide.

169. Including Switch Upstream Ports.

or a Function Group Number. For example, access to Function 2 is controlled by bit number 2 in the bit-array. For both Port Number cases and Function Number cases, the bit corresponding to the Function that implements this Extended Capability structure must be hardwired to 0b.¹⁷⁰

If an ARI Device implements ACS Function Groups (ACS Function Groups Capability is Set), its Egress Control Vector Size is required to be a power-of-2 from 8 to 256, and all of its implemented Egress Control Vector bits must be RW. With ARI Devices, multiple Functions can be associated with a single bit, so for each Function, its associated bit determines how Requests from it targeting other Functions (if any) associated with the same bit are handled.

If ACS Function Groups are enabled in an ARI Device (ACS Function Groups Enable is Set), the first 8 Egress Control Vector bits in each Function are associated with Function Group Numbers instead of Function Numbers. In this case, access control is enforced between Function Groups instead of Functions, and any implemented Egress Control Vector bits beyond the first 8 are unused.

Independent of whether an ARI Device implements ACS Function Groups, its Egress Control Vector Size is not required to cover the entire Function Number range of all Functions implemented by the Device. If ACS Function Groups are not enabled, Function Numbers are mapped to implemented Egress Control Vector bits by taking the modulo of the Egress Control Vector Size, which is constrained to be a power-of-2.

With RCs, some Port Numbers may refer to internal Ports instead of Root Ports. For Root Ports in such RCs, each bit in the bit-array that corresponds to an internal Port must be hardwired to 0b.

Figure 7-135 Egress Control Vector Register §

Table 7-119 Egress Control Vector Register §

Bit Location	Register Description	Attributes
31:0	<p>Egress Control Vector - An N-bit bit-array configured by software, where N is given by the value in the Egress Control Vector Size field. When a given bit is Set, peer-to-peer Requests targeting the associated Port, Function, or Function Group are blocked or redirected (if enabled) (see § Section 6.12.3).</p> <p>§ Figure 7-135 shows a single DWORD register. This register is always an integral number of DWORDs. Default value of each bit is 0b.</p>	RW

The following examples illustrate how the vector might be configured:

- For an 8-Port Switch, each Port will have a separate vector indicating which Downstream Egress Ports it may forward Requests to.
 - Port 1 being not allowed to communicate with any other Downstream Ports would be configured as: 1111 1100b with bit 0 corresponding to the Upstream Port (hardwired to 0b) and bit 1 corresponding to the Ingress Port (hardwired to 0b).
 - Port 2 being allowed to communicate with Ports 3, 5, and 7 would be configured as: 0101 0010b.
- For a 4-Function device, each Function will have a separate vector that indicates which Function it may forward Requests to.

170. For ARI Devices, the bit must be RW. See subsequent description.

Function 0 being not allowed to communicate with any other Functions would be configured as: 1110b with bit 0 corresponding to Function 0 (hardwired to 0b).

Function 1 being allowed to communicate with Functions 2 and 3 would be configured as: 0001b with bit 1 corresponding to Function 1 (hardwired to 0b).

7.8 Common PCI and PCIe Capabilities §

This section, contains a description of common PCI and PCIe capabilities that are individually optional in this but may be required by other PCISIG specifications.

7.8.1 Power Budgeting Extended Capability §

The Power Budgeting Extended Capability allows the system to allocate power to devices that are added to the system at runtime. Through this Capability, a device can report the power it consumes on a variety of power rails, in a variety of device power-management states, in a variety of operating conditions. The system can use this information to ensure that the system is capable of providing the proper power and cooling levels to the device. Failure to indicate proper device power consumption may risk device or system failure.

Implementation of the Power Budgeting Extended Capability is optional for PCI Express devices that are implemented either in a form-factor which does not require Hot-Plug support, or that are integrated on the system board. PCI Express form-factor specifications may require support for power budgeting. Power Budgeting reports device power consumption assuming the device is given appropriate permission (e.g., from Set_Slot_Power_Limit message) and that the external power connections for the device are operating.

The Power Budgeting Extended Capability is permitted to be present in PFs, but VFs must not implement it. If a PF contains the capability, it must report values that cover all associated VFs.

§ Figure 7-136 details allocation of register fields in the Power Budgeting Extended Capability.

Figure 7-136 Power Budgeting Extended Capability §

7.8.1.1 Power Budgeting Extended Capability Header (Offset 00h) §

§ Figure 7-137 details allocation of register fields in the Power Budgeting Extended Capability Header; § Table 7-120 provides the respective bit definitions. Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability header. The Extended Capability ID for the Power Budgeting Extended Capability is 0004h.

Figure 7-137 Power Budgeting Extended Capability Header §

Table 7-120 Power Budgeting Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	<p>PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability.</p> <p>Extended Capability ID for the <u>Power Budgeting Extended Capability</u> is 0004h.</p>	RO
19:16	<p>Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present.</p> <p>Must be 1h for this version of the specification.</p>	RO
31:20	<p>Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities.</p> <p>For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.</p>	RO

7.8.1.2 Power Budgeting Data Select Register (Offset 04h) §

The Power Budgeting Data Select Register is an 8-bit read-write register that indexes the Power Budgeting Data reported through the Power Budgeting Data Register and selects the DWORD of Power Budgeting Data that is to appear in the Power Budgeting Data Register. Values for this register start at zero to select the first DWORD of Power Budgeting Data; subsequent DWORDs of Power Budgeting Data are selected by increasing index values. The default value of this register is undefined.

7.8.1.3 Power Budgeting Control Register (Offset 06h) §

The Power Budgeting Control Register permits system software to enable extended power budgeting and to grant additional power to a Device above that defined by default for the associated form-factor.

§ Figure 7-138 details allocation of register fields in the Aux Power Control register; § Table 7-121 provides the respective bit definitions.

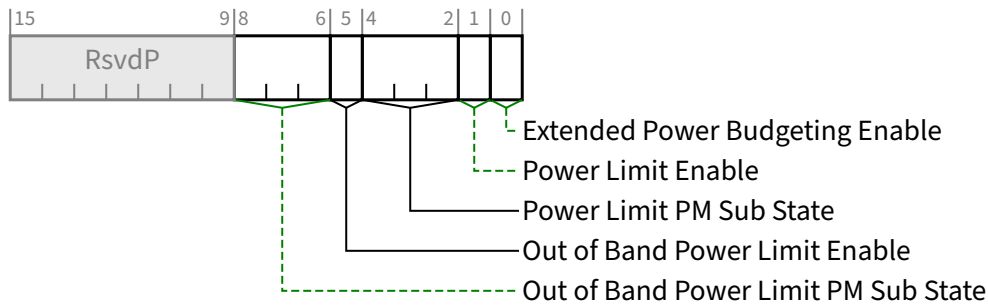

Figure 7-138 Power Budgeting Control Register §

Table 7-121 Power Budgeting Control Register §

Bit Location	Register Description	Attributes
0	<p>Extended Power Budgeting Enable – If Set, Power Budgeting is permitted to return non-zero values in the Power Budgeting Data Register bits 31:21. If Clear, those bits must return all zeros for all values of the Power Budgeting Data Select Register.</p> <p>If Set, the Power Budgeting Sense Detect Register is permitted to return non-zero values. If Clear, that register must return all zeros.</p> <p>This bit is hardwired to 0b when <u>Extended Power Budgeting Supported</u> is Clear.</p> <p>Default is zero.</p>	RW
1	<p>Power Limit Enable – If Set, the <u>Power Limit PM Sub State</u> field is meaningful.</p> <p>The value of this field in the lowest numbered Function with <u>Power Limit Supported Set</u> applies to all Functions of the Device. When present, the value of this bit in all other Functions is ignored by hardware.</p> <p>When <u>Power Limit Supported</u> is Clear, this bit is permitted to be hardwired to zero.</p> <p>It is recommended that system software / firmware configure this field identically in all Functions. Doing so provides a standard mechanism for a device driver to understand its Function's power configuration.</p> <p>Default is zero.</p>	RWS/RsvdP
4:2	<p>Power Limit PM Sub State – If <u>Power Limit Enable</u> is Set, this field, in conjunction with the <u>Out of Band Power Limit Enable</u> and <u>Out of Band Power Limit PM Sub State</u> fields, indicates the PM Sub State used by the Device.</p> <p>The value of this field in the lowest numbered Function with <u>Power Limit Supported Set</u> applies to all Functions of the Device. When present, the value of this field in all other Functions is ignored by hardware.</p> <p>When <u>Power Limit Supported</u> is Clear, this field is permitted to be hardwired to zero.</p> <p>It is recommended that system software / firmware configure this field identically in all Functions. Doing so provides a standard mechanism for a device driver to understand its Function's power configuration.</p> <p>Default is zero.</p>	RWS/RsvdP

Bit Location	Register Description	Attributes
	<p>When this field is present, all Functions of the Device must contain the same value.</p> <p>When <u>Power Limit Supported</u> is Clear, this bit is permitted to be hardwired to zero.</p> <p>It is permitted that this field change after the Function is Configuration Ready. This could happen, for example, if this field is configured via MCTP over PCIe. Mechanisms used to delay access to this field until it is meaningful are outside the scope of this specification (e.g., using the SFI mechanism or using <u>_DSM</u> calls to grant system software access to the fields).</p> <p>Default is zero.</p>	
8:6	<p>Out of Band Power Limit PM Sub State – If <u>Out of Band Power Limit Enable</u> is Set, this field, in conjunction with the <u>Power Limit Enable</u> and <u>Power Limit PM Sub State</u> fields, indicates the PM Sub State used by the Device.</p> <p>When this field is present, all Functions of the Device must contain the same value.</p> <p>When <u>Power Limit Supported</u> is Clear, this bit is permitted to be hardwired to zero.</p> <p>It is permitted that this field change after the Function is Configuration Ready. This could happen, for example, if this field is configured via MCTP over PCIe. Mechanisms used to delay access to this field until it is meaningful are outside the scope of this specification (e.g., using the SFI mechanism or using <u>_DSM</u> calls to grant system software access to the fields).</p> <p>Default is zero.</p>	HwInit/RsvdP

7.8.1.4 Power Budgeting Data Register (Offset 08h) §

This read-only register returns the DWORD of Power Budgeting Data selected by the Power Budgeting Data Select Register. Each DWORD of the Power Budgeting Data describes the power usage of the device in a particular operating condition. Power Budgeting Data for different operating conditions is not required to be returned in any particular order, as long as incrementing the Power Budgeting Data Select Register causes information for a different operating condition to be returned. If the Power Budgeting Data Select Register contains a value greater than or equal to the number of operating conditions for which the device provides power information, this register must return all zeros. The default value of this register is undefined. § Figure 7-139 details allocation of register fields in the Power Budgeting Data Register; § Table 7-122 provides the respective bit definitions.

In earlier versions of this specification, bits 31:21 of this register were RsvdP. In order to ensure that the new uses of these bits do not confuse existing software:

- Extended Power Budgeting entries are hidden when Extended Power Budgeting Enable is Clear (the default). When Extended Power Budgeting Enable is Clear and Power Budgeting Data Select selects an Extended Power Budgeting entry, the Data register must return 0000 0000h.
- Extended Power Budgeting Data entries must be located after non-extended Power Budgeting Data entries (i.e., all entries where bits 31:21 are zero must use a smaller Power Budgeting Data Select value than any entry where bits 31:21 are non-zero).

The Base Power and Data Scale fields describe the power usage of the device; the Power Rail, Type, PM State, and PM Sub State fields describe the conditions under which the device has this power usage.

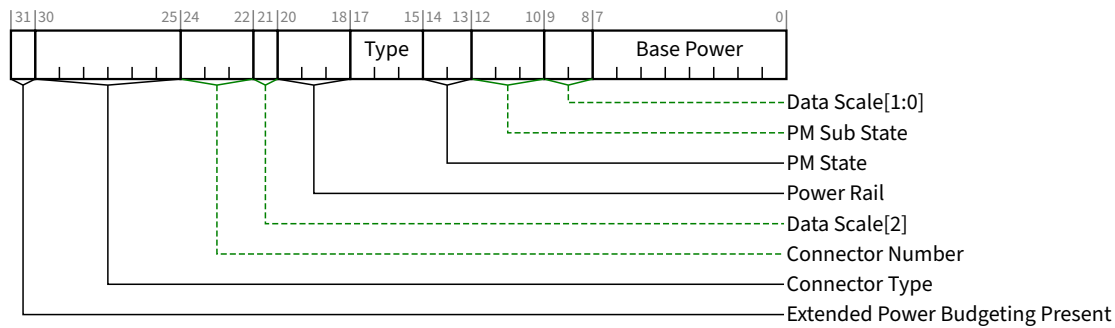

Figure 7-139 Power Budgeting Data Register §

Table 7-122 Power Budgeting Data Register §

Bit Location	Register Description	Attributes																																
7:0	<p>Base Power - Specifies in watts the base power value in the given operating condition. This value must be multiplied by the data scale to produce the actual power consumption value except if <u>Extended Power Budgeting Enable</u> is Clear, the <u>Data Scale[1:0]</u> field equals 00b (1.0x) and <u>Base Power</u> exceeds EFh, the following alternative encodings are used:</p> <table border="0"> <tr><td>F0h</td><td>> 239 W and ≤ 250 W Slot Power Limit</td></tr> <tr><td>F1h</td><td>> 250 W and ≤ 275 W Slot Power Limit</td></tr> <tr><td>F2h</td><td>> 275 W and ≤ 300 W Slot Power Limit</td></tr> <tr><td>F3h</td><td>> 300 W and ≤ 325 W Slot Power Limit</td></tr> <tr><td>F4h</td><td>> 325 W and ≤ 350 W Slot Power Limit</td></tr> <tr><td>F5h</td><td>> 350 W and ≤ 375 W Slot Power Limit</td></tr> <tr><td>F6h</td><td>> 375 W and ≤ 400 W Slot Power Limit</td></tr> <tr><td>F7h</td><td>> 400 W and ≤ 425 W Slot Power Limit</td></tr> <tr><td>F8h</td><td>> 425 W and ≤ 450 W Slot Power Limit</td></tr> <tr><td>F9h</td><td>> 450 W and ≤ 475 W Slot Power Limit</td></tr> <tr><td>FAh</td><td>> 475 W and ≤ 500 W Slot Power Limit</td></tr> <tr><td>FBh</td><td>> 500 W and ≤ 525 W Slot Power Limit</td></tr> <tr><td>FCh</td><td>> 525 W and ≤ 550 W Slot Power Limit</td></tr> <tr><td>FDh</td><td>> 550 W and ≤ 575 W Slot Power Limit</td></tr> <tr><td>FEh</td><td>> 575 W and ≤ 600 W Slot Power Limit</td></tr> <tr><td>FFh</td><td>Reserved for values greater than 600 W</td></tr> </table>	F0h	> 239 W and ≤ 250 W Slot Power Limit	F1h	> 250 W and ≤ 275 W Slot Power Limit	F2h	> 275 W and ≤ 300 W Slot Power Limit	F3h	> 300 W and ≤ 325 W Slot Power Limit	F4h	> 325 W and ≤ 350 W Slot Power Limit	F5h	> 350 W and ≤ 375 W Slot Power Limit	F6h	> 375 W and ≤ 400 W Slot Power Limit	F7h	> 400 W and ≤ 425 W Slot Power Limit	F8h	> 425 W and ≤ 450 W Slot Power Limit	F9h	> 450 W and ≤ 475 W Slot Power Limit	FAh	> 475 W and ≤ 500 W Slot Power Limit	FBh	> 500 W and ≤ 525 W Slot Power Limit	FCh	> 525 W and ≤ 550 W Slot Power Limit	FDh	> 550 W and ≤ 575 W Slot Power Limit	FEh	> 575 W and ≤ 600 W Slot Power Limit	FFh	Reserved for values greater than 600 W	RO

	<p>00 1110b CEM 48VHPWR connector, cable has Sense0 Open and Sense1 Grounded</p> <p>00 1111b CEM 48VHPWR connector, cable has both Sense0 and Sense1 Grounded</p> <p>01 0000b CEM 12V-2x6: 150 W or higher cable present</p> <p>01 0001b CEM 12V-2x6: 300 W or higher cable present</p> <p>01 0010b CEM 12V-2x6: 450 W or higher cable present</p> <p>01 0011b CEM 12V-2x6: 600 W cable present</p> <p>01 0100b to 10 1111b Reserved for PCI-SIG use</p> <p>11 0000b to 11 1111b Vendor Specific Power Connectors</p> <p>Each CEM 2x4 connector must have either one entry with Connector Type 00 0101b or two entries with Connector Types 00 0110b and 00 0111b.</p> <p>Each 12V-2x6 connector must have an entry for the lowest power cable it supports. Each 12V-2x6 connector must have an entry for every cable that has a different power consumption value.</p> <p>This field must be zero if <u>Extended Power Budgeting Enable</u> is Clear.</p> <p>Software must ignore the value in this field if <u>Extended Power Budgeting Present</u> is Clear.</p>	
31	<p>Extended Power Budgeting Present – Indicates that bits 30:22 contain Extended Power Budgeting Data. This bit must be 0b if <u>Extended Power Budgeting Enable</u> is Clear.</p>	RO

Except for Type = 000b and 001b, Power Budgeting data for the same operating condition and PM Sub State values represent simultaneous consumption. Functions must report a complete set of Power Budgeting data for each supported operating condition and PM Sub State combination.

Power Budgeting data with different PM Sub State values represent mutually exclusive consumption. For a given operating condition, a Function is in exactly one PM Sub State. When Power Limit Supported is Clear, implementation specific mechanisms are used to determine the current PM Sub State.

A device that implements the Power Budgeting Extended Capability is required to provide data values for D0 Maximum and D0 Sustained PM State and Type combinations for every power rail from which it consumes power; data for the D0 Maximum and D0 Sustained for Thermal must also be provided if these values are different from the sum of the values for an operating condition reported for D0 Maximum and D0 Sustained on the power rails.

Devices that support auxiliary power or PME from auxiliary power must provide data for the appropriate power Type (Auxiliary or PME Aux) on the appropriate Power Rail(s).

- If the reported PME Aux or Auxiliary value is greater than the default for the associated form-factor, the Function is limited to the form-factor values unless either PME_En or Aux Power PM Enable are Set.
- The PME Aux and Auxiliary entries are mutually exclusive. The values of PME_En and Aux Power PM Enable determine which entries are meaningful.

If the reported PME Aux or Auxiliary value is greater than the Aux_Current, the Function is limited by Aux_Current unless Aux Power PM Enable is Set and one of the following is true:

- Power Limit Enable is Set,
- Out of Band Power Limit Enable is Set, or
- the Request D3_{Cold} Aux Power Limit _DSM call was used to request additional power (for details, see [Firmware]).

If a device implements Emergency Power Reduction State, it must report Power Budgeting values for the following:

- Maximum Emergency Power Reduction State, PM State D0, all power rails used by the device
- Maximum Emergency Power Reduction State, PM State D0, Thermal (if different from the sum of the preceding values)
- Sustained Emergency Power Reduction State, PM State D0, all power rails used by the device
- Sustained Emergency Power Reduction State, PM State: D0, Thermal (if different from the sum of the preceding values)

7.8.1.5 Power Budgeting Capability Register (Offset 0Ch) §

This register indicates the power budgeting capabilities of a device. § Figure 7-140 details allocation of register fields in the Power Budgeting Capability Register; § Table 7-123 provides the respective bit definitions.

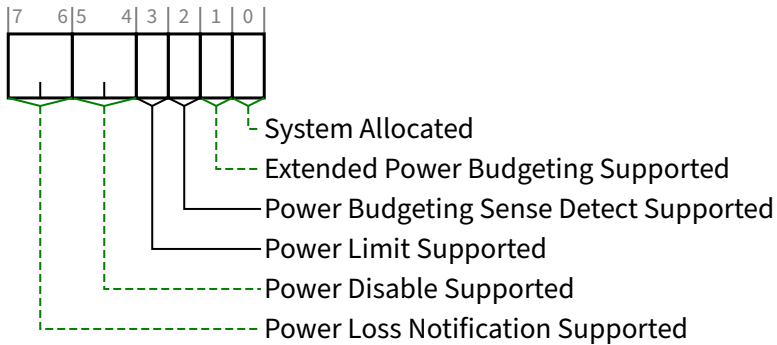

Figure 7-140 Power Budgeting Capability Register §

Table 7-123 Power Budgeting Capability Register §

Bit Location	Register Description	Attributes
0	System Allocated - When Set, this bit indicates that the power budget for the device is included within the system power budget. Reported <u>Power Budgeting Data</u> for this device must be ignored by software for power budgeting decisions if this bit is Set.	<u>HwInit</u>
1	Extended Power Budgeting Supported - If Set, the <u>Extended Power Budgeting Enable</u> bit is meaningful.	<u>HwInit</u>
2	Power Budgeting Sense Detect Supported - If Set, the <u>Power Budgeting Sense Detect Register</u> is meaningful. This bit must be Clear if <u>Extended Power Budgeting Supported</u> is Clear.	<u>HwInit</u>
3	Power Limit Supported - If Set, the <u>Power Limit Enable</u> , <u>Power Limit PM Sub State</u> , <u>Out of Band Power Limit Enable</u> , and <u>Out of Band Power Limit PM Sub State</u> fields are meaningful. This bit must be Clear if <u>Extended Power Budgeting Supported</u> is Clear.	<u>HwInit</u>
5:4	Power Disable Supported - Indicates the supported use model for optional form-factor defined Power Disable functionality. Encodings are: 00b Power Disable support not reported	<u>HwInit</u>

Bit Location	Register Description	Attributes
	<p>01b Power Disable is supported for removal of main power. The timings associated with this mode are optimized to support the use of Power Disable to recover a non-responsive device.</p> <p>10b Power Disable with abbreviated assertion time is supported for removal of main power. The timings associated with this mode are optimized to using Power Disable to request the Device enter or exit D3_{Cold}.</p> <p>11b Reserved</p> <p>For Multi-Function Devices associated with an Upstream Port, all Functions that contain this field must return the same value.</p>	
7:6	<p>Power Loss Notification Supported – This field indicates Device support for the optional Power Loss Notification feature. Power Loss Notification is an optional form-factor feature that permits the platform to inform an add-in card of an upcoming loss of power and optionally for the add-in card to indicate that it is ready for that power loss. In the M.2 form-factor, Power Loss Notification uses the optional PLN# signal and Power Loss Acknowledgment uses the optional PLA_S2# and PLA_S3# signals. Other form-factors may define different mechanisms.</p> <p>Encodings of this field are:</p> <p>00b Power Loss Notification support not reported</p> <p>01b Power Loss Notification supported Power Loss Acknowledgement not supported</p> <p>10b Power Loss Notification supported Power Loss Acknowledgement supported</p> <p>11b Reserved</p> <p>For Multi-Function Devices associated with an Upstream Port, all Functions that contain this field must return the same value.</p>	Hwlnit

7.8.1.6 Power Budgeting Sense Detect Register (Offset 0Dh) §

Whenever the adapter is receiving any power, this register reports, for each implemented power connector, which sense wires are currently detected.

Any adapter that implements a Power Budgeting Extended Capability with Power Budgeting Sense Detect Supported Set, must provide Connector Sense Detect fields for each connector that it supports, and must hardwire the fields for unsupported connectors to all zeros.

This register is RsvdP if Power Budgeting Sense Detect Supported is Clear. This register must return all zeros if Extended Power Budgeting Enable is Clear.

This register is only meaningful in the lowest numbered Function that contains the Power Budgeting Extended Capability. This register is undefined in all other Functions even if the Power Budgeting Sense Detect Supported is Set.

§ Figure 7-141 details allocation of register fields in the Power Budgeting Sense Detect Register; § Table 7-124 provides the respective bit definitions. § Table 7-125 defines the encodings based on Connector Type values.

Figure 7-141 Power Budgeting Sense Detect Register §

Table 7-124 Power Budgeting Sense Detect Register §

11 0000b to 11 1111b	Vendor Specific

7.8.2 Latency Tolerance Reporting (LTR) Extended Capability §

The PCI Express Latency Tolerance Reporting (LTR) Extended Capability is an optional Extended Capability that allows software to provide platform latency information to components with Upstream Ports (Endpoints and Switches), and is required for Switch Upstream Ports and Endpoints if the Function supports the LTR mechanism. It is not applicable to Root Ports, Bridges, or Switch Downstream Ports.

For a Multi-Function Device associated with the Upstream Port of a component that implements the LTR mechanism, this Capability structure must be implemented only in Function 0, and must control the component's Link behavior on behalf of all the Functions of the Device.

RCIEPs implemented as Multi-Function Devices are permitted to implement this Capability structure in more than one Function of the Multi-Function Device.

172. Detecting the 12V-2x6 150 W cable requires additional circuitry. This circuitry is optional when the add-in card always requires more than 150 W from the 12V-2x6 connector.

173. This combination indicates the provided power is less than the connector requirements. The add-in card does not use this cable. This sense data encoding is used to tell software.

174. Detecting the 12V-2x6 150 W cable requires additional circuitry. This circuitry is optional when the add-in card always requires more than 150 W from the 12V-2x6 connector.

175. This combination indicates the provided power is less than the connector requirements. The add-in card does not use this cable. This sense data encoding is used to tell software.

176. This combination indicates the provided power is less than the connector requirements. The add-in card does not use this cable. This sense data encoding is used to tell software.

Figure 7-142 LTR Extended Capability Structure §

7.8.2.1 LTR Extended Capability Header (Offset 00h) §

Figure 7-143 LTR Extended Capability Header §

Table 7-126 LTR Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability for the LTR Extended Capability is 0018h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.	RO

7.8.2.2 Max Snoop Latency Register (Offset 04h) §

Figure 7-144 Max Snoop Latency Register §

Table 7-127 Max Snoop Latency Register §

Bit Location	Register Description	Attributes
9:0	<p>Max Snoop LatencyValue - Along with the <u>Max Snoop LatencyScale</u> field, this register specifies the maximum snoop latency that a device is permitted to request. Software should set this to the platform's maximum supported latency or less. It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms.</p> <p>The default value for this field is 00 0000 0000b.</p>	RW
12:10	<p>Max Snoop LatencyScale - This register provides a scale for the value contained within the <u>Max Snoop LatencyValue</u> field. Encoding is the same as the <u>LatencyScale</u> fields in the LTR Message. See § Section 6.18 . It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms.</p> <p>The default value for this field is 000b.</p> <p>Hardware operation is undefined if software writes a Not Permitted value to this field.</p>	RW

7.8.2.3 Max No-Snoop Latency Register (Offset 06h) §

Figure 7-145 Max No-Snoop Latency Register §

Table 7-128 Max No-Snoop Latency Register §

Bit Location	Register Description	Attributes
9:0	<p>Max No-Snoop LatencyValue - Along with the <u>Max No-Snoop LatencyScale</u> field, this register specifies the maximum no-snoop latency that a device is permitted to request. Software should set this to the platform's maximum supported latency or less. It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms.</p> <p>The default value for this field is 00 0000 0000b.</p>	RW
12:10	<p>Max No-Snoop LatencyScale - This register provides a scale for the value contained within the <u>Max No-Snoop LatencyValue</u> field. Encoding is the same as the <u>LatencyScale</u> fields in the LTR Message. See § Section 6.18 . It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms.</p> <p>The default value for this field is 000b.</p> <p>Hardware operation is undefined if software writes a Not Permitted value to this field.</p>	RW

7.8.3 L1 PM Substates Extended Capability §

The L1 PM Substates Extended Capability is an optional Extended Capability, that is required if L1 PM Substates is implemented at a Port. The L1 PM Substates Extended Capability structure is defined as shown in § Figure 7-146.

For a Multi-Function Device associated with an Upstream Port implementing L1 PM Substates, this Extended Capability Structure must be implemented only in Function 0, and must control the Upstream Port's Link behavior on behalf of all the Functions of the device.

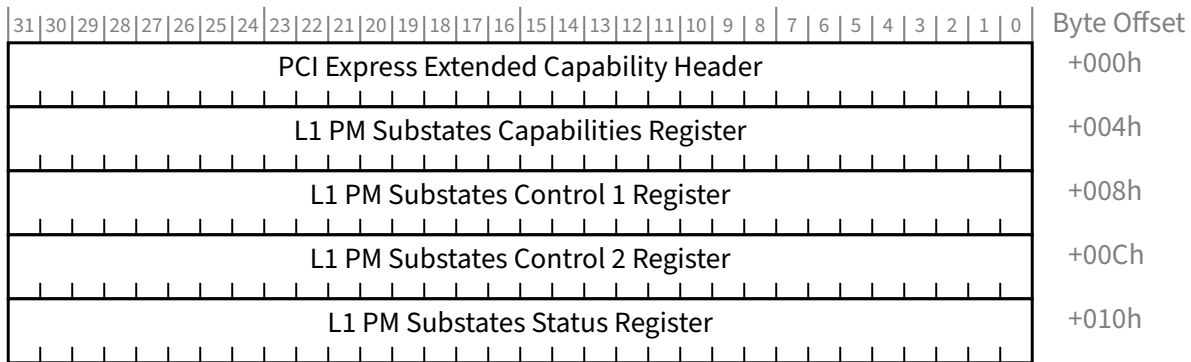

Figure 7-146 L1 PM Substates Extended Capability §

7.8.3.1 L1 PM Substates Extended Capability Header (Offset 00h) §

Figure 7-147 L1 PM Substates Extended Capability Header §

Table 7-129 L1 PM Substates Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for L1 PM Substates is 001Eh.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field must be 2h if the L1 PM Substates Status Register is implemented and must be 1h otherwise.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits.	RO

7.8.3.2 L1 PM Substates Capabilities Register (Offset 04h) §

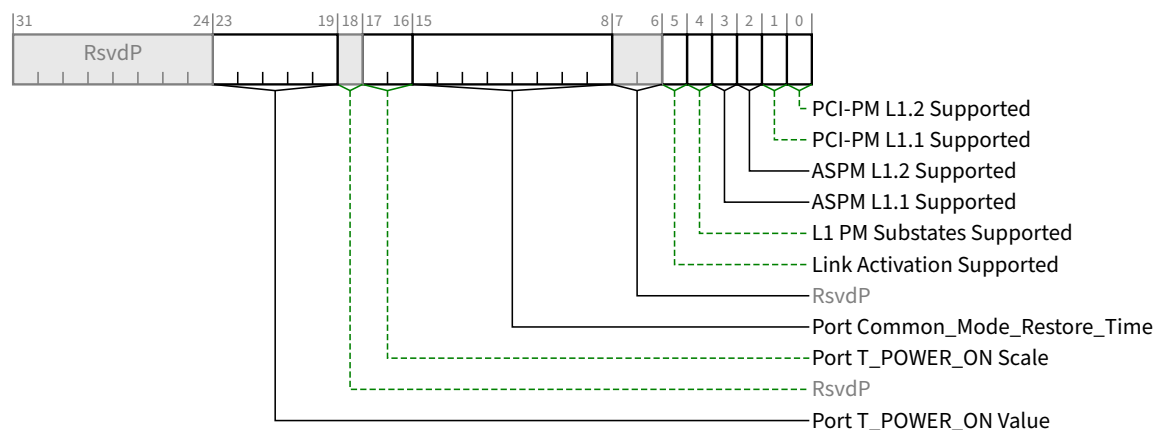

Figure 7-148 L1 PM Substates Capabilities Register §

Table 7-130 L1 PM Substates Capabilities Register §

Bit Location	Register Description	Attributes
0	PCI-PM L1.2 Supported - When Set this bit indicates that PCI-PM <u>L1.2</u> is supported.	<u>HwInit</u>
1	PCI-PM L1.1 Supported - When Set this bit indicates that PCI-PM <u>L1.1</u> is supported, and must be Set by all Ports implementing L1 PM Substates.	<u>HwInit</u>
2	ASPM L1.2 Supported - When Set this bit indicates that ASPM <u>L1.2</u> is supported.	<u>HwInit</u>
3	ASPM L1.1 Supported - When Set this bit indicates that ASPM <u>L1.1</u> is supported.	<u>HwInit</u>
4	L1 PM Substates Supported - When Set this bit indicates that this Port supports <u>L1 PM Substates</u> .	<u>HwInit</u>
5	Link Activation Supported - For Downstream Ports, when Set, this bit indicates that this Port supports <u>Link Activation</u> . See § Section 5.5.6 for details. This bit is of type <u>RsvdP</u> for Upstream Ports.	<u>HwInit/RsvdP</u>
15:8	Port Common_Mode_Restore_Time - Time (in μ s) required for this Port to re-establish common mode as described in § Table 5-11. Required for all Ports for which either the <u>PCI-PM L1.2 Supported</u> bit is Set, <u>ASPM L1.2 Supported</u> bit is Set, or both are Set, otherwise this field is of type <u>RsvdP</u> .	<u>HwInit/RsvdP</u> (See description)
17:16	Port T_POWER_ON Scale - Specifies the scale used for the <u>Port T_POWER_ON Value</u> field in the <u>L1 PM Substates Capabilities Register</u> . Range of Values 00b 2 μ s 01b 10 μ s 10b 100 μ s 11b Reserved	<u>HwInit/RsvdP</u>

Bit Location	Register Description	Attributes
	<p>Required for all Ports for which either the <u>PCI-PM L1.2 Supported</u> bit is Set, <u>ASPM L1.2 Supported</u> bit is Set, or both are Set, otherwise this field is of type <u>RsvdP</u>.</p> <p>Default value is 00b</p>	
23:19	<p>Port T_POWER_ON Value - Along with the Port T_POWER_ON Scale field in the L1 PM Substates Capabilities Register sets the time (in μs) that this Port requires the port on the opposite side of Link to wait in <u>L1.2.Exit</u> after sampling CLKREQ# asserted before actively driving the interface.</p> <p>The value of Port T_POWER_ON is calculated by multiplying the value in this field by the scale value in the <u>Port T_POWER_ON Scale</u> field in the <u>L1 PM Substates Capabilities Register</u>.</p> <p>Default value is 0 0101b</p> <p>Required for all Ports for which either the <u>PCI-PM L1.2 Supported</u> bit is Set, <u>ASPM L1.2 Supported</u> bit is Set, or both are Set, otherwise this field is of type <u>RsvdP</u>.</p>	HwInit/RsvdP

7.8.3.3 L1 PM Substates Control 1 Register (Offset 08h) §

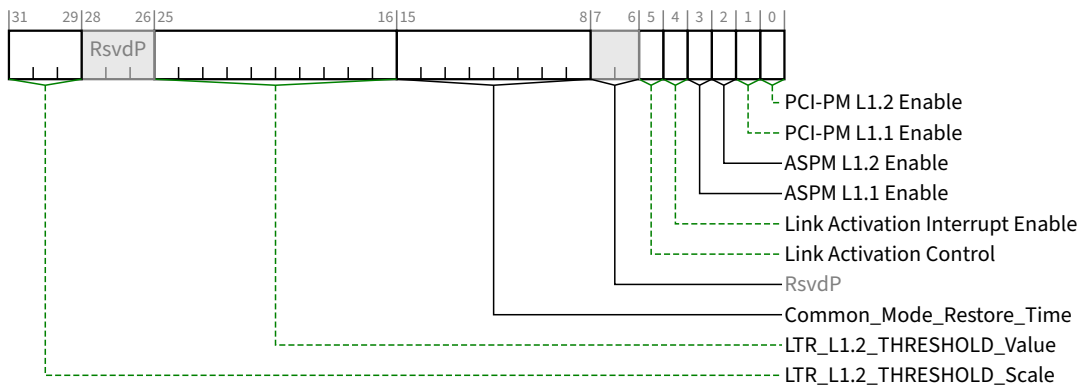

Figure 7-149 L1 PM Substates Control 1 Register §

Table 7-131 L1 PM Substates Control 1 Register §

Bit Location	Register Description	Attributes
0	<p>PCI-PM L1.2 Enable - When Set this bit enables PCI-PM L1.2.</p> <p>Required for both Upstream and Downstream Ports. For Ports for which the <u>PCI-PM L1.2 Supported</u> bit is Clear this bit is permitted to be hardwired to 0.</p> <p>For compatibility with possible future extensions, software must not enable <u>L1 PM Substates</u> unless the <u>L1 PM Substates Supported</u> bit in the <u>L1 PM Substates Capabilities Register</u> is Set.</p> <p>Default value is 0b.</p>	RW
1	<p>PCI-PM L1.1 Enable - When Set this bit enables PCI-PM L1.1.</p> <p>Required for both Upstream and Downstream Ports.</p> <p>For compatibility with possible future extensions, software must not enable <u>L1 PM Substates</u> unless the <u>L1 PM Substates Supported</u> bit in the <u>L1 PM Substates Capabilities Register</u> is Set.</p> <p>Default value is 0b.</p>	RW

Bit Location	Register Description	Attributes
2	<p>ASPM L1.2 Enable - When Set this bit enables ASPM L1.2. Required for both Upstream and Downstream Ports. For Ports for which the ASPM L1.2 Supported bit is Clear this bit is permitted to be hardwired to 0. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported bit in the L1 PM Substates Capabilities Register is Set. Default value is 0b.</p>	<u>RW</u>
3	<p>ASPM L1.1 Enable - When Set this bit enables ASPM L1.1. Required for both Upstream and Downstream Ports. For Ports for which the ASPM L1.1 Supported bit is Clear this bit is permitted to be hardwired to 0. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported bit in the L1 PM Substates Capabilities Register is Set. Default value is 0b.</p>	<u>RW</u>
4	<p>Link Activation Interrupt Enable - When set this bit enables the generation of an interrupt to indicate the completion of the Link Activation process. See § Section 5.5.6 for details. Required for Downstream Ports when the Link Activation Supported bit is Set, otherwise it is permitted to be hardwired to 0b. Must be RsvdP for Upstream Ports. Default value is 0b.</p>	<u>RW/RsvdP</u>
5	<p>Link Activation Control - When this bit is Set, the Port must initiate the Link Activation process. See § Section 5.5.6 for details. Required for Downstream Ports when the Link Activation Supported bit is Set, otherwise it is permitted to be hardwired to 0b. Must be RsvdP for Upstream Ports. Default value is 0b.</p>	<u>RW/RsvdP</u>
15:8	<p>Common_Mode_Restore_Time - Sets value of $T_{COMMONMODE}$ (in μs), which must be used by the Downstream Port for timing the re-establishment of common mode, as described in § Table 5-11. This field must only be modified when the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are both Clear. The Port behavior is undefined if this field is modified when either the ASPM L1.2 Enable and/or PCI-PM L1.2 Enable bit(s) are Set. Required for Downstream Ports for which either the PCI-PM L1.2 Supported bit is Set, ASPM L1.2 Supported bit is Set, or both are Set, otherwise this field is of type RsvdP. This field is of type RsvdP for Upstream Ports. Default value is implementation specific.</p>	<u>RW/RsvdP</u> (See Description)
25:16	<p>LTR_L1.2_THRESHOLD_Value - Along with the LTR_L1.2_THRESHOLD_Scale, this field indicates the LTR threshold used to determine if entry into L1 results in L1.1 (if enabled) or L1.2 (if enabled). The default value for this field is 00 0000 0000b. This field must only be modified when the ASPM L1.2 Enable bit is Clear. The Port behavior is undefined if this field is modified when the ASPM L1.2 Enable bit is Set. Required for all Ports for which the ASPM L1.2 Supported bit is Set, otherwise this field is of type RsvdP.</p>	<u>RW/RsvdP</u> (See Description)
31:29	<p>LTR_L1.2_THRESHOLD_Scale - This field provides a scale for the value contained within the LTR_L1.2_THRESHOLD_Value. Encoding is the same as the LatencyScale fields in the LTR Message (see § Section 6.18).</p>	<u>RW/RsvdP</u> (See description)

Bit Location	Register Description	Attributes
	<p>The default value for this field is 000b.</p> <p>Hardware operation is undefined if software writes a Not-Permitted value to this field.</p> <p>This field must only be modified when the ASPM L1.2 Enable bit is Clear. The Port behavior is undefined if this field is modified when the ASPM L1.2 Enable bit is Set.</p> <p>Required for all Ports Ports for which the ASPM L1.2 Supported bit is Set, otherwise this field is of type RsvdP.</p>

Figure 7-150 L1 PM Substates Control 2 Register §

Table 7-132 L1 PM Substates Control 2 Register §

Bit Location	Register Description	Attributes
1:0	<p>T_POWER_ON Scale - Specifies the scale used for <u>T_POWER_ON Value</u>.</p> <p>Range of Values:</p> <p>00b 2 μs</p> <p>01b 10 μs</p> <p>10b 100 μs</p> <p>11b Reserved</p> <p>Required for all Ports that support L1.2, otherwise this field is of type RsvdP.</p> <p>This field must only be modified when the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are both Clear. The Port behavior is undefined if this field is modified when either the ASPM L1.2 Enable and/or PCI-PM L1.2 Enable bit(s) are Set.</p> <p>Default value is 00b</p>	RW/RsvdP
7:3	<p>T_POWER_ON Value - Along with the <u>T_POWER_ON Scale</u> sets the minimum amount of time (in μs) that the Port must wait in <u>L1.2.Exit</u> after sampling CLKREQ# asserted before actively driving the interface.</p> <p><u>T_POWER_ON</u> is calculated by multiplying the value in this field by the value in the <u>T_POWER_ON Scale</u> field.</p> <p>This field must only be modified when the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are both Clear. The Port behavior is undefined if this field is modified when either the ASPM L1.2 Enable and/or PCI-PM L1.2 Enable bit(s) are Set.</p> <p>Default value is 0 0101b</p> <p>Required for all Ports that support L1.2, otherwise this field is of type RsvdP.</p>	RW/RsvdP

7.8.3.5 L1 PM Substates Status Register (Offset 10h) §

Hardware must implement this register if the Capability Version in the L1 PM Substates Extended Capability Header is 2h or greater. This register is not present if the Capability Version is 1h.

Figure 7-151 L1 PM Substates Status Register §

Table 7-133 L1 PM Substates Status Register §

Bit Location	Register Description	Attributes
0	<p>Link Activation Status - Indicates the status of <u>Link Activation</u>. See § Section 5.5.6 for details.</p> <p>Required for Downstream Ports when the <u>Link Activation Supported</u> bit is Set, otherwise it is hardwired to 0b.</p> <p>Must be <u>RsvdZ</u> for Upstream Ports.</p> <p>Default value is 0b.</p>	RW1C/RsvdZ

7.8.4 Advanced Error Reporting Extended Capability §

The PCI Express Advanced Error Reporting (AER) Capability is an optional Extended Capability that may be implemented by PCI Express device Functions supporting advanced error control and reporting. The Advanced Error Reporting Extended Capability structure definition has additional interpretation for Root Ports and Root Complex Event Collectors; software must interpret the Device/Port Type field in the PCI Express Capabilities register to determine the availability of additional registers for Root Ports and Root Complex Event Collectors.

In an SR-IOV device, if AER is not implemented in a PF, it must not be implemented in its associated VFs. If AER is implemented in the PF, it is optional in its VFs.

In an SR-IOV device, the Header Log space for a PF is independent of any for its associated VFs and must be implemented with dedicated storage space. VFs that implement AER may share Header Log space among VFs associated with a single PF. Shared Header Log space must have storage for at least one header. See § Section 6.2.4.2.1 for further details.

§ Figure 7-152 and § Figure 7-153 show the PCI Express Advanced Error Reporting Extended Capability structure. In § Figure 7-153, the last 6 DW are optional. Implementations are permitted to implement between 0 and 6 additional DW of Header Log (see Header Log Size for details).

Note that if an error reporting bit field is marked as optional in the error registers, the bits must be implemented or not implemented as a group across the Status, Mask and Severity registers. In other words, a Function is required to implement the same error bit fields in corresponding Status, Mask and Severity registers. Bits corresponding to bit fields that are not implemented must be hardwired to 0, unless otherwise specified.

Figure 7-153 Advanced Error Reporting Extended Capability - Functions that support Flit Mode Structure §

7.8.4.1 Advanced Error Reporting Extended Capability Header (Offset 00h) §

§ Figure 7-154 details the allocation of register fields of an Advanced Error Reporting Extended Capability header; § Table 7-134 provides the respective bit definitions.

Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability header. The Extended Capability ID for the Advanced Error Reporting Extended Capability is 0001h.

Figure 7-154 Advanced Error Reporting Extended Capability Header §

Table 7-134 Advanced Error Reporting Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Advanced Error Reporting Extended Capability is 0001h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field must be 3h if Flit Mode Supported is Set. This field must be 2h or 3h if End-End TLP Prefix Supported is Set (see § Section 7.5.3.15). Otherwise this field must be 1h, 2h, or 3h.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.8.4.2 Uncorrectable Error Status Register (Offset 04h) §

The Uncorrectable Error Status Register indicates error detection status of individual errors on a PCI Express device Function. An individual error status bit that is Set indicates that a particular error was detected; software may clear an error status by writing a 1b to the respective bit. Refer to § Section 6.2 for further details. Register bits not implemented by the Function are hardwired to 0b. § Figure 7-155 details the allocation of register fields of the Uncorrectable Error Status Register; § Section 7.8.4.2 provides the respective bit definitions.

For SR-IOV devices, applicable errors categorized as non-Function-specific must be logged in PFs and non-IOV Functions, but not logged in VFs. VFs must log only Function-specific errors, so for VFs the intended attribute for applicable non-Function-specific errors is VF ROZ. This is mandatory for some, but is only strongly recommended for others since earlier versions of this specification required them to be RW1CS. Certain other errors are applicable only for Root Port,

Switch Port, or Function 0 Endpoint Functions, so for VFs their intended attribute is VF ROZ, and they have the same issue with earlier versions of this specification. .

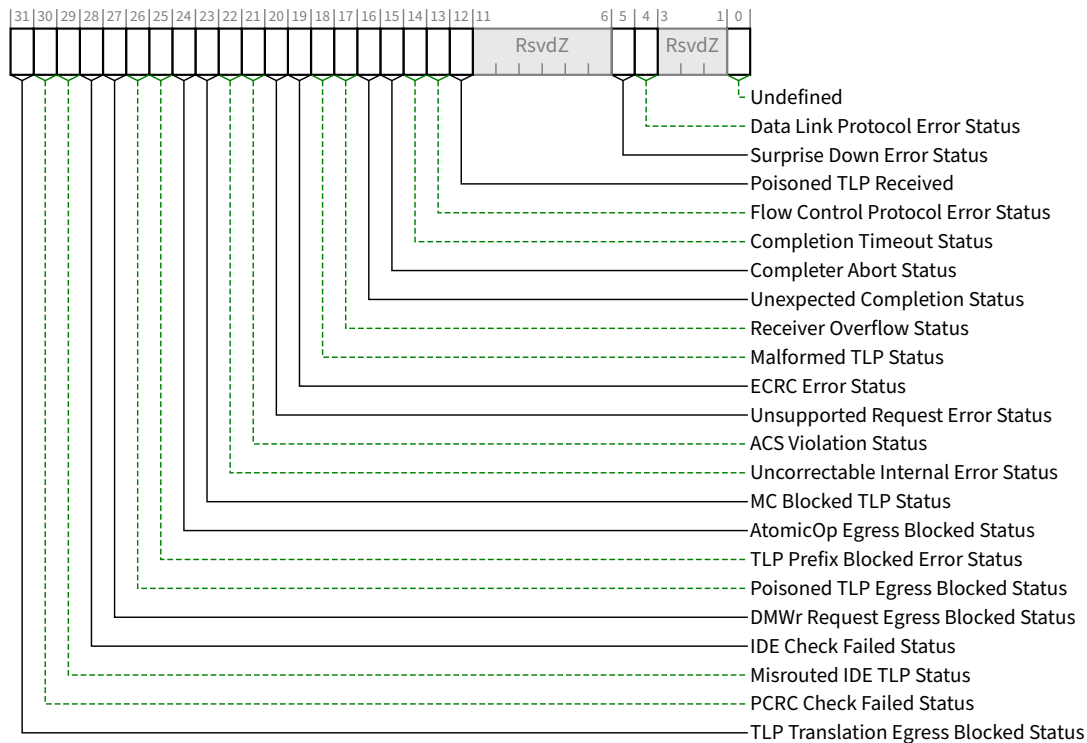

Figure 7-155 Uncorrectable Error Status Register §

Table 7-135 Uncorrectable Error Status Register §

Bit Location	Register Description	Attributes	Default
0	Undefined Undefined - The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate a Link Training Error. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.	Undefined	Undefined
4	Data Link Protocol Error Status	<u>RW1CS</u> <u>VF ROZ</u>	0b
5	Surprise Down Error Status (Optional – Note 1)	<u>RW1CS</u> <u>VF ROZ</u>	0b
12	Poisoned TLP Received Status	<u>RW1CS</u>	0b
13	Flow Control Protocol Error Status (Optional – Note 1)	<u>RW1CS</u> <u>VF ROZ</u>	0b
14	Completion Timeout Status ¹⁷⁷	<u>RW1CS</u>	0b

177. For Switch Ports, required if the Switch Port issues Non-Posted Requests on its own behalf (vs. only forwarding such Requests generated by other devices). If the Switch Port does not issue such Requests, then the Completion Timeout mechanism is not applicable and this bit must be hardwired to 0b.

Bit Location	Register Description	Attributes	Default
15	Completer Abort Status (Optional – Note 1)	RW1CS	0b
16	Unexpected Completion Status	RW1CS	0b
17	Receiver Overflow Status (Optional – Note 1)	RW1CS VF ROZ	0b
18	Malformed TLP Status	RW1CS VF ROZ	0b
19	ECRC Error Status (Optional – Note 1)	RW1CS VF ROZ	0b
20	Unsupported Request Error Status	RW1CS	0b
21	ACS Violation Status (Optional – Note 1)	RW1CS	0b
22	Uncorrectable Internal Error Status (Optional)	RW1CS	0b
23	MC Blocked TLP Status (Optional – Note 1)	RW1CS	0b
24	AtomicOp Egress Blocked Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
25	TLP Prefix Blocked Error Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
26	Poisoned TLP Egress Blocked Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
27	DMWr Request Egress Blocked Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
28	IDE Check Failed Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
29	Misrouted IDE TLP Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
30	PCRC Check Failed Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b
31	TLP Translation Egress Blocked Status (Optional – Note 1)	RW1CS VF ROZ (Note 2)	0b

Notes:

Bit Location	Register Description	Attributes	Default
	<ol style="list-style-type: none"> Must implement if the corresponding Uncorrectable Error Mask bit is implemented. Otherwise, hardwire to 0. VF ROZ is strongly recommended for VF Functions, but for backward compatibility with previous versions of this specification, RW1CS is permitted if the VF implements the corresponding Uncorrectable Error Mask Register bit. 		

7.8.4.3 Uncorrectable Error Mask Register (Offset 08h) §

The Uncorrectable Error Mask Register controls reporting of individual errors by the device Function to the PCI Express Root Complex via a PCI Express error Message. A masked error (respective bit Set in the mask register) is not recorded or reported in the Header Log, TLP Prefix Log, or First Error Pointer, and is not reported to the PCI Express Root Complex by this Function. Refer to § Section 6.2 for further details. There is a mask bit per error bit of the Uncorrectable Error Status register. Register fields for bits not implemented by the Function are hardwired to 0b. § Figure 7-156 details the allocation of register fields of the Uncorrectable Error Mask Register; § Table 7-136 provides the respective bit definitions.

For VF fields marked as VF RsvdP, the associated PF's setting applies to the VF. For VF fields marked as VF ROZ, the error is not applicable to a VF.

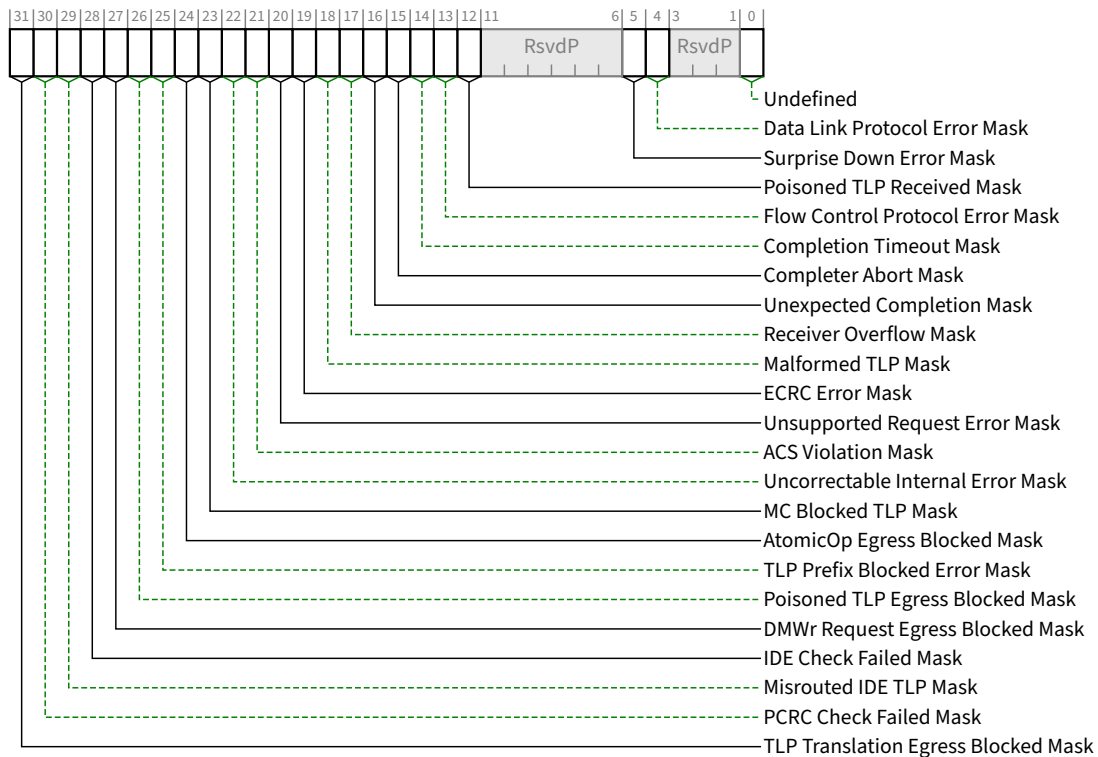

Figure 7-156 Uncorrectable Error Mask Register §

Table 7-136 Uncorrectable Error Mask Register ⁵

Bit Location	Register Description	Attributes	Default
0	Undefined Undefined - The value read from this bit is undefined. In previous versions of this specification, this bit was used to mask a Link Training Error. System software must ignore the value read from this bit. System software must only write a value of 1b to this bit.	Undefined	Undefined
4	Data Link Protocol Error Mask	<u>RWS</u> <u>VF ROZ</u>	0b
5	Surprise Down Error Mask (<u>Surprise Down Error Reporting Capable</u> – Note 1)	<u>RWS</u> <u>VF ROZ</u>	0b
12	Poisoned TLP Received Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
13	Flow Control Protocol Error Mask (Optional)	<u>RWS</u> <u>VF ROZ</u>	0b
14	Completion Timeout Mask ¹⁷⁸	<u>RWS</u> <u>VF RsvdP</u>	0b
15	Completer Abort Mask (Optional)	<u>RWS</u> <u>VF RsvdP</u>	0b
16	Unexpected Completion Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
17	Receiver Overflow Mask (Optional)	<u>RWS</u> <u>VF ROZ</u>	0b
18	Malformed TLP Mask	<u>RWS</u> <u>VF ROZ</u>	0b
19	ECRC Error Mask (<u>ECRC Check Capable</u> – Note 1)	<u>RWS</u> <u>VF ROZ</u>	0b
20	Unsupported Request Error Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
21	ACS Violation Mask (<u>ACS Extended Capability</u> – Note 2)	<u>RWS</u> <u>VF RsvdP</u>	0b
22	Uncorrectable Internal Error Mask (Optional)	<u>RWS</u>	1b
23	MC Blocked TLP Mask (<u>Multicast Extended Capability</u> – Note 2)	<u>RWS</u>	0b
24	AtomicOp Egress Blocked Mask (<u>AtomicOp Egress Blocking</u> – Note 3)	<u>RWS</u> VF ROZ Note 6	0b

178. For Switch Ports, required if the Switch Port issues Non-Posted Requests on its own behalf (vs. only forwarding such Requests generated by other devices). If the Switch Port does not issue such Requests, then the Completion Timeout mechanism is not applicable and this bit must be hardwired to 0b.

Bit Location	Register Description	Attributes	Default
25	TLP Prefix Blocked Error Mask (<u>End-End TLP Prefix Supported – Note 3</u>)	<u>RWS</u> VF ROZ Note 6	0b
26	Poisoned TLP Egress Blocked Mask (<u>Poisoned TLP Egress Blocking Supported – Note 3</u>)	<u>RWS</u> VF ROZ Note 6	1b
27	DMWr Request Egress Blocked Mask (<u>DMWr Egress Blocking – Note 3</u>)	<u>RWS</u> VF ROZ Note 6	0b
28	IDE Check Failed Mask (<u>IDE Extended Capability – Note 4</u>)	<u>RWS</u> VF ROZ Note 6	0b
29	Misrouted IDE TLP Mask (<u>IDE Extended Capability – Note 4</u>)	<u>RWS</u> VF ROZ Note 6	0b
30	PCRC Check Failed Mask (<u>PCRC Supported – Note 5</u>)	<u>RWS</u> VF ROZ Note 6	0b
31	TLP Translation Egress Blocked Mask (Routing elements that translate between FM and NFM in either direction must implement this bit (see <u>§ Section 2.2.1.2</u>))	<u>RWS</u> VF ROZ Note 6	0b

Notes:

1. When Set in a non-VF Function, this AER mask bit must be implemented. Otherwise, for non-VF Functions, it is optional.
2. When a Function implements this Extended Capability (i.e., ACS/Multicast), that Function must implement this AER mask bit.
3. When Set in a non-VF Function, that Function must implement this AER mask bit.
4. When Function 0 implements the IDE Extended Capability, and if Function 0 implements AER, then Function 0 must implement this AER mask bit.
5. When PCRC Supported is Set in Function 0, and if Function 0 implements AER, then Function 0 must implement this AER mask bit.
6. VF ROZ is strongly recommended for VF Functions, but for backward compatibility with previous versions of this specification, RWS is permitted.

7.8.4.4 Uncorrectable Error Severity Register (Offset 0Ch) §

The Uncorrectable Error Severity Register controls whether an individual error is reported as a Non-fatal or Fatal error. An error is reported as fatal when the corresponding error bit in the severity register is Set. If the bit is Clear, the corresponding error is considered non-fatal. Refer to § Section 6.2 for further details. Register fields for bits not implemented by the Function are hardwired to an implementation specific value. § Figure 7-157 details the allocation of register fields of the Uncorrectable Error Severity Register; § Table 7-137 provides the respective bit definitions.

For VF fields marked as VF RsvdP, the associated PF's setting applies to the VF. For VF fields marked as VF ROZ, the error is not applicable to a VF.

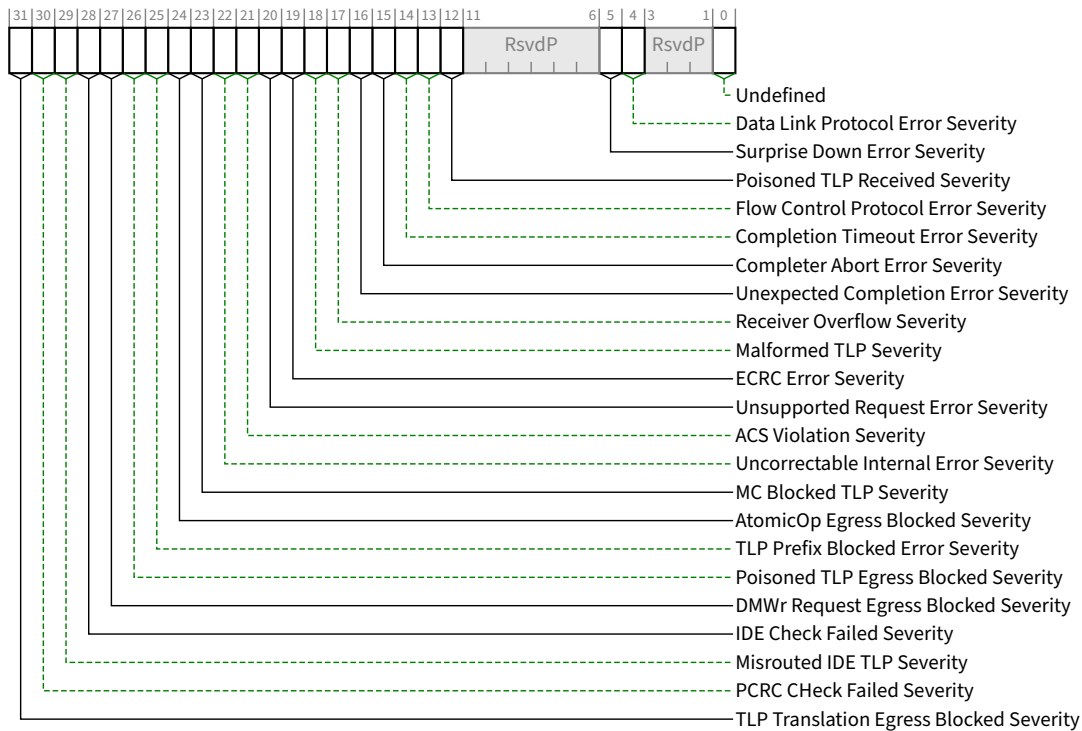

Figure 7-157 Uncorrectable Error Severity Register §

Table 7-137 Uncorrectable Error Severity Register §

Bit Location	Register Description	Attributes	Default
0	Undefined Undefined - The value read from this bit is undefined. In previous versions of this specification, this bit was used to Set the severity of a Link Training Error. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.	Undefined	Undefined
4	Data Link Protocol Error Severity	<u>RWS</u> <u>VF ROZ</u>	1b
5	Surprise Down Error Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u>	1b
12	Poisoned TLP Received Severity	<u>RWS</u> <u>VF RsvdP</u>	0b
13	Flow Control Protocol Error Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u>	1b
14	Completion Timeout Error Severity ¹⁷⁹	<u>RWS</u> <u>VF RsvdP</u>	0b

Bit Location	Register Description	Attributes	Default
15	Completer Abort Error Severity (Optional – Note 1)	<u>RWS</u> <u>VF RsvdP</u>	0b
16	Unexpected Completion Error Severity	<u>RWS</u> <u>VF RsvdP</u>	0b
17	Receiver Overflow Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u>	1b
18	Malformed TLP Severity	<u>RWS</u> <u>VF ROZ</u>	1b
19	ECRC Error Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u>	0b
20	Unsupported Request Error Severity	<u>RWS</u> <u>VF RsvdP</u>	0b
21	ACS Violation Severity (Optional – Note 1)	<u>RWS</u> <u>VF RsvdP</u>	0b
22	Uncorrectable Internal Error Severity (Optional – Note 1)	<u>RWS</u>	1b
23	MC Blocked TLP Severity (Optional – Note 1)	<u>RWS</u>	0b
24	AtomicOp Egress Blocked Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u> Note 2	0b
25	TLP Prefix Blocked Error Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u> Note 2	0b
26	Poisoned TLP Egress Blocked Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u> Note 2	0b
27	DMWr Request Egress Blocked Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u> Note 2	0b
28	IDE Check Failed Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u> Note 2	1b
29	Misrouted IDE TLP Severity (Optional – Note 1)	<u>RWS</u> <u>VF ROZ</u> Note 2	0b
30	PCRC Check Failed Severity (Optional – Note 1)	<u>RWS</u>	0b

179. For Switch Ports, required if the Switch Port issues Non-Posted Requests on its own behalf (vs. only forwarding such Requests generated by other devices). If the Switch Port does not issue such Requests, then the Completion Timeout mechanism is not applicable and this bit must be hardwired to 0b.

Bit Location	Register Description	Attributes	Default
		VF ROZ Note 2	
31	TLP Translation Egress Blocked Severity (Optional – Note 1)	RWS VF ROZ Note 2	0b

Notes:

1. Must implement if the corresponding Uncorrectable Error Mask Register bit is implemented. Otherwise, hardware to 0.
2. VF ROZ is strongly recommended for VF Functions, but for backward compatibility with previous versions of this specification, RWS is permitted if the VF implements the corresponding Uncorrectable Error Mask Register bit.

7.8.4.5 Correctable Error Status Register (Offset 10h) §

The Correctable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. When an individual error status bit is Set, it indicates that a particular error occurred; software may clear an error status by writing a 1b to the respective bit. Refer to § Section 6.2 for further details. Register bits not implemented by the Function are hardwired to 0b. § Figure 7-158 details the allocation of register fields of the Correctable Error Status register; § Table 7-138 provides the respective bit definitions.

For SR-IOV devices, errors categorized as non-Function-specific must be logged in PFs and non-IOV Functions, but not logged in VFs. VFs must log only Function-specific errors.

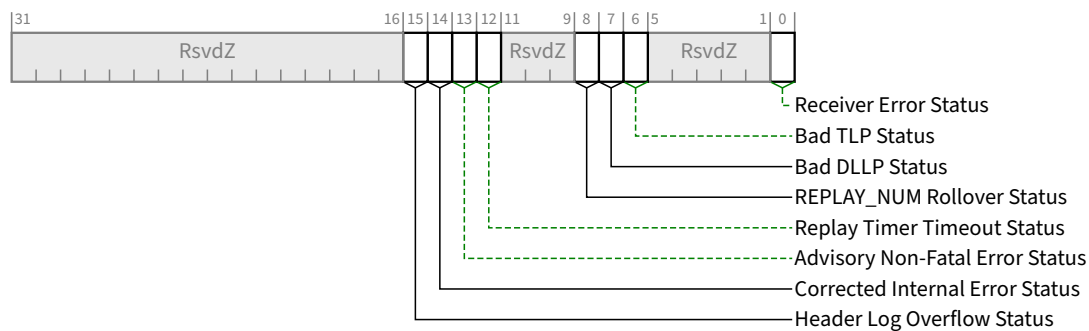

Figure 7-158 Correctable Error Status Register §

Table 7-138 Correctable Error Status Register §

Bit Location	Register Description	Attributes	Default
0	Receiver Error Status ¹⁸⁰	RW1CS VF ROZ	0b

180. For historical reasons, implementation of this bit is optional. If not implemented, this bit must be RsvdZ, and bit 0 of the Correctable Error Mask Register must also not be implemented. Note that some checking for Receiver Errors is required in all cases (see § Section 4.2.1.1.3, § Section 4.2.5.8, and § Section 4.2.7).

Bit Location	Register Description	Attributes	Default
6	Bad TLP Status	RW1CS VF ROZ	0b
7	Bad DLLP Status	RW1CS VF ROZ	0b
8	REPLAY_NUM Rollover Status	RW1CS VF ROZ	0b
12	Replay Timer Timeout Status	RW1CS VF ROZ	0b
13	Advisory Non-Fatal Error Status	RW1CS	0b
14	Corrected Internal Error Status (Optional)	RW1CS	0b
15	Header Log Overflow Status (Optional) If the VF implements Header Log sharing (see § Section 6.2.4.2.1), this bit must be hardwired to Zero.	RW1CS / 0b	0b

7.8.4.6 Correctable Error Mask Register (Offset 14h) §

The Correctable Error Mask Register controls reporting of individual correctable errors by this Function to the PCI Express Root Complex via a PCI Express error Message. A masked error (respective bit Set in the mask register) is not reported to the PCI Express Root Complex by this Function. Refer to § Section 6.2 for further details. There is a mask bit per error bit in the Correctable Error Status register. Register fields for bits not implemented by the Function are hardwired to 0b. § Figure 7-159 details the allocation of register fields of the Correctable Error Mask Register; § Table 7-139 provides the respective bit definitions.

For VF fields marked as VF RsvdP, the associated PF's setting applies to the VF.

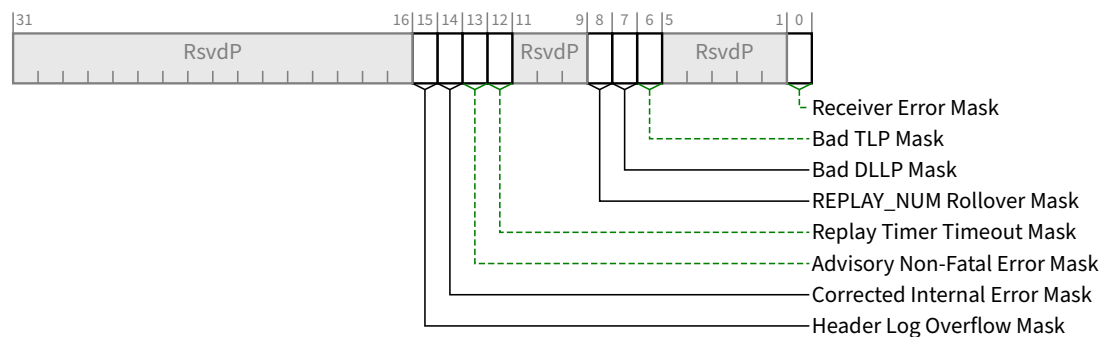

Figure 7-159 Correctable Error Mask Register §

Table 7-139 Correctable Error Mask Register §

Bit Location	Register Description	Attributes	Default
0	Receiver Error Mask ¹⁸¹	<u>RWS</u> <u>VF RsvdP</u>	0b
6	Bad TLP Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
7	Bad DLLP Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
8	REPLAY_NUM Rollover Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
12	Replay Timer Timeout Mask	<u>RWS</u> <u>VF RsvdP</u>	0b
13	Advisory Non-Fatal Error Mask - This bit is Set by default to enable compatibility with software that does not comprehend Role-Based Error Reporting.	<u>RWS</u> <u>VF RsvdP</u>	1b
14	Corrected Internal Error Mask (Optional)	<u>RWS</u>	1b
15	Header Log Overflow Mask (Optional) If the VF implements Header Log sharing (see § Section 6.2.4.2.1), this bit is <u>RsvdP</u> .	<u>RWS / RsvdP</u>	1b

7.8.4.7 Advanced Error Capabilities and Control Register (Offset 18h) §

§ Figure 7-160 details allocation of register fields in the Advanced Error Capabilities and Control register; § Table 7-140 provides the respective bit definitions. Handling of multiple errors is discussed in § Section 6.2.4.2 .

For VF fields marked as VF RsvdP, the associated PF's setting applies to the VF. For VF fields marked as VF ROZ, the error is not applicable to a VF.

181. For historical reasons, implementation of this bit is optional. If not implemented, this bit must be RsvdP, and bit 0 of the Correctable Error Status register must also not be implemented. Note that some checking for Receiver Errors is required in all cases (see Sections 4.2.1.1.3, 4.2.4.7, and 4.2.6).

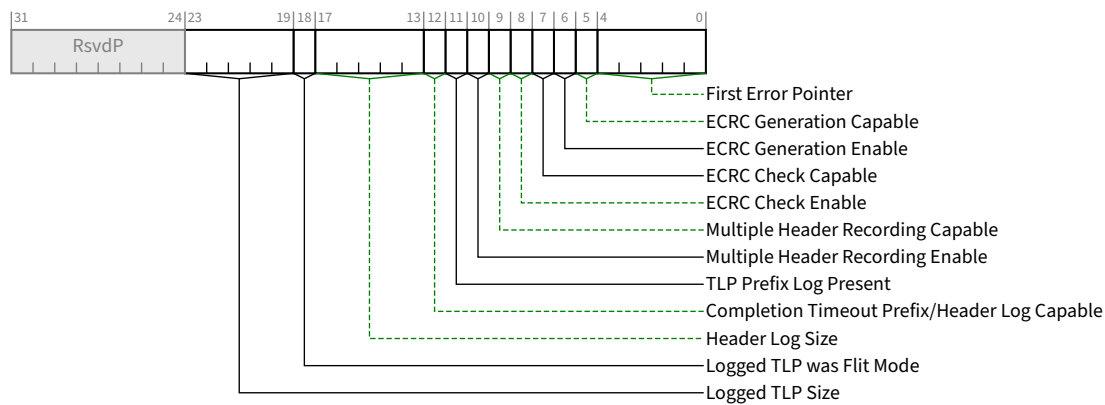

Figure 7-160 Advanced Error Capabilities and Control Register §

Table 7-140 Advanced Error Capabilities and Control Register §

Bit Location	Register Description	Attributes
4:0	First Error Pointer - The First Error Pointer is a field that identifies the bit position of the first error reported in the Uncorrectable Error Status register. Refer to § Section 6.2 for further details.	<u>ROS</u>
5	ECRC Generation Capable - If Set, this bit indicates that the Function is capable of generating ECRC (see § Section 2.7).	<u>RO</u>
6	ECRC Generation Enable - When Set, ECRC generation is enabled (see § Section 2.7). Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Default value of this bit is 0b.	<u>RWS</u> <u>VF RsvdP</u>
7	ECRC Check Capable - If Set, this bit indicates that the Function is capable of checking ECRC (see § Section 2.7).	<u>RO</u>
8	ECRC Check Enable - When Set, ECRC checking is enabled (see § Section 2.7). Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Default value of this bit is 0b.	<u>RWS</u> <u>VF RsvdP</u>
9	Multiple Header Recording Capable - If Set, this bit indicates that the Function is capable of recording more than one error header. Refer to § Section 6.2 for further details. If the VF implements Header Log sharing (see § Section 6.2.4.2.1), this bit must be hardwired to Zero.	<u>RO / 0b</u>
10	Multiple Header Recording Enable - When Set, this bit enables the Function to record more than one error header. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. If the VF implements Header Log sharing (see § Section 6.2.4.2.1), this bit is RsvdP. Default value of this bit is 0b.	<u>RWS / RsvdP</u>
11	TLP Prefix Log Present - If End-End TLP Prefix Supported is Clear, this bit is RsvdP. If Flit Mode Supported is Set, First Error Pointer is valid, and Logged TLP was Flit Mode is Set, this bit must be 0.	<u>ROS / RsvdP</u>

Bit Location	Register Description	Attributes
	<p>If this bit is Set and First Error Pointer is valid, the TLP Prefix Log Register (offset 38h to 44h, also known as <u>Header Log Register DW5-8</u>) contains valid Non-Flit Mode End-End TLP Prefix information.</p> <p>If this bit is Clear or First Error Pointer not valid, the TLP Prefix Log Register does not contain End-End TLP Prefix information (the overlapping field, <u>Header Log Register DW5-8</u>, may contain Flit Mode TLP Header information as specified elsewhere in this section).</p> <p>Default value of this bit is 0.</p> <p>If the VF implements Header Log Sharing (see § Section 6.2.4.2.1), this bit must be Zero when the Header Log contains all 1s due to an overflow condition.</p>	
12	<p>Completion Timeout Prefix/Header Log Capable - If Set, this bit indicates that the Function records the prefix/header of Request TLPs that experience a Completion Timeout error.</p>	<u>HwInit</u>
17:13	<p>Header Log Size - This field indicates the number of DW of Header Log that are implemented.</p> <p>If <u>Flit Mode Supported</u> is Set, see text for requirements.</p> <p>If <u>Flit Mode Supported</u> is Clear and <u>End-End TLP Prefix Supported</u> is Set, this value must either be 0 or must be greater than or equal to 8.</p> <p>If this field is 0 and <u>Flit Mode Supported</u> is Clear, the size of the header log depends on <u>End-End TLP Prefix Supported</u>. If <u>End-End TLP Prefix Supported</u> is Clear, the Header Log is 4 DW, otherwise the Header Log is 8 DW.</p>	<u>HwInit/RsvdP</u>
18	<p>Logged TLP was Flit Mode -- If <u>Flit Mode Supported</u> is Set, <u>First Error Pointer</u> is valid, and this bit is Set, the logged TLP was captured in <u>Flit Mode</u> otherwise the TLP was captured in <u>Non-Flit Mode</u>.</p>	<u>ROS</u>
23:19	<p>Logged TLP Size -- If <u>Flit Mode Supported</u> is Set and <u>First Error Pointer</u> is valid, this field contains the number of DW that were logged in the <u>Header Log Register</u> and, if appropriate, the <u>TLP Prefix Log Register</u>.</p> <p>If <u>Flit Mode Supported</u> is Set, <u>First Error Pointer</u> is valid, the VF implements Header Log Sharing (see § Section 6.2.4.2.1), and a Header Log overflow condition occurred, this field must be 0 (in addition to the Header Log containing all 1s).</p>	<u>ROS</u>

7.8.4.8 Header Log Register (Offset 1Ch) §

The Header Log Register contains the header for the TLP corresponding to a detected error; refer to § Section 6.2 for further details. § Section 6.2 also describes the conditions where the packet header is recorded. This register is 16 bytes and adheres to the format of the headers defined throughout this specification.

The header is captured such that, when read using DW accesses, the fields of the header are laid out in the same way the headers are presented in this document. Therefore, byte 0 of the header is located in byte 3 of the Header Log Register, byte 1 of the header is in byte 2 of the Header Log Register and so forth. For 12-byte headers, only bytes 0 through 11 of the Header Log Register are used and values in bytes 12 through 15 are undefined.

See § Section 6.2.4.2.1 for further requirements when VFs share Header Log space.

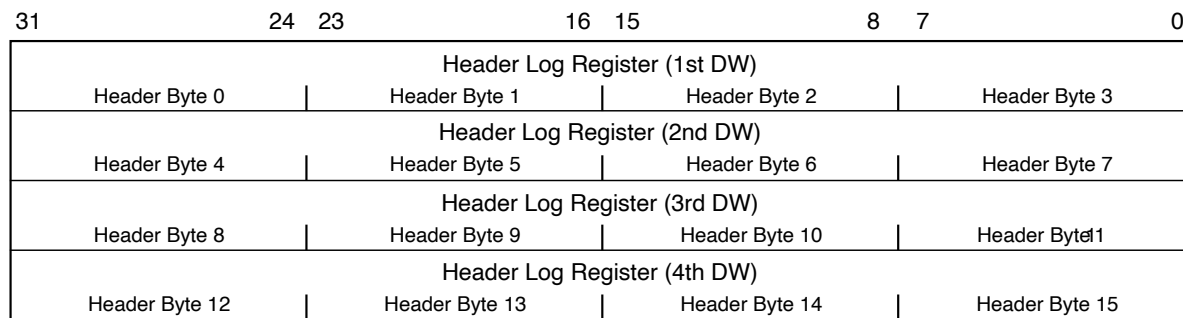

In certain cases where a Malformed TLP is reported, the Header Log Register may contain TLP Prefix information. See § Section 6.2.4.4 for details.

§ Figure 7-161 details allocation of register fields in the Header Log Register; § Table 7-141 provides the respective bit definitions.

When Flit Mode Supported is Set and the link is operating in Flit Mode, the Header Log Register extends into additional DWs as indicated by the Header Log Size field. Software must parse the Type and OHC fields to determine the size and layout of a TLP recorded in the Header Log Register. Hardware is not required to support logging of TLP Headers larger

than the largest size supported by the Port. Hardware is not required to support logging of OHC types not supported by the Port. TLP Trailers are not logged in the Header Log Register. The required minimum size of the Header Log Register is determined by the largest Header Base Size implemented by the Port (up to the maximum defined of 7 DW - See § Table 2-5), plus the largest number of OHC implemented by the Port (up to the maximum defined of 7 DW). Hardware must hardwire to zero the DW of the Header Log Register beyond those required to log the largest supported TLP Header and the overall length of the Advanced Error Reporting Extended Capability is reduced accordingly. As in Non-Flit Mode, Local TLP Prefixes are not logged.

When the link is operating in Non-Flit Mode, End-End TLP Prefixes are logged in the TLP Prefix Log Register.

OM14549A

Figure 7-161 Header Log Register §

Table 7-141 Header Log Register §

Bit Location	Register Description	Attributes	Default
127:0	Header of TLP associated with error	ROS	0

7.8.4.9 Root Error Command Register (Offset 2Ch) §

The Root Error Command Register allows further control of Root Complex response to Correctable, Non-Fatal, and Fatal error Messages than the basic Root Complex capability to generate system errors in response to error Messages (either received or internally generated). Bit fields (see § Figure 7-162) enable or disable generation of interrupts (claimed by the Root Port or Root Complex Event Collector) in addition to system error Messages according to the definitions in § Table 7-142.

For both Root Ports and Root Complex Event Collectors, in order for a received error Message or an internally generated error Message to generate an interrupt enabled by this register, the error Message must be enabled for “transmission” by the Root Port or Root Complex Event Collector (see § Section 6.2.4.1 and § Section 6.2.8.1).

For Functions other than Root Ports and Root Complex Event Collectors: when End-End TLP Prefix Supported is Set, this register is RsvdP and when End-End TLP Prefix Supported is Clear, this register is not required to be implemented.

Figure 7-162 Root Error Command Register §

Table 7-142 Root Error Command Register §

Bit Location	Register Description	Attributes	Default
0	<p>Correctable Error Reporting Enable - When Set, this bit enables the generation of an interrupt when a correctable error is reported by any of the Functions in the <u>Hierarchy Domain</u> associated with this Root Port.</p> <p>Root Complex Event Collectors provide support for the above described functionality for <u>RCIEPs</u>.</p> <p>Refer to § Section 6.2 for further details.</p>	RW	0b
1	<p>Non-Fatal Error Reporting Enable - When Set, this bit enables the generation of an interrupt when a Non-fatal error is reported by any of the Functions in the <u>Hierarchy Domain</u> associated with this Root Port.</p> <p>Root Complex Event Collectors provide support for the above described functionality for <u>RCIEPs</u>.</p> <p>Refer to § Section 6.2 for further details.</p>	RW	0b
2	<p>Fatal Error Reporting Enable - When Set, this bit enables the generation of an interrupt when a Fatal error is reported by any of the Functions in the <u>Hierarchy Domain</u> associated with this Root Port.</p> <p>Root Complex Event Collectors provide support for the above described functionality for <u>RCIEPs</u>.</p> <p>Refer to § Section 6.2 for further details.</p>	RW	0b

System error generation in response to PCI Express error Messages may be turned off by system software using the PCI Express Capability structure described in § Section 7.5.3 when advanced error reporting via interrupts is enabled. Refer to § Section 6.2 for further details.

7.8.4.10 Root Error Status Register (Offset 30h) §

The Root Error Status Register reports status of error Messages (ERR_COR, ERR_NONFATAL, and ERR_FATAL) received by the Root Port, and of errors detected by the Root Port itself (which are treated conceptually as if the Root Port had sent an error Message to itself). In order to update this register, error Messages received by the Root Port and/or internally generated error Messages must be enabled for “transmission” by the primary interface of the Root Port. ERR_NONFATAL and ERR_FATAL Messages are grouped together as uncorrectable. Each correctable and uncorrectable (Non-fatal and Fatal) error source has a first error bit and a next error bit associated with it respectively. When an error is received by a Root Complex, the respective first error bit is Set and the Requester ID is logged in the Error Source Identification Register. A Set individual error status bit indicates that a particular error category occurred; software may clear an error status by writing a 1b to the respective bit. If software does not clear the first reported error before another error Message is received of the same category (correctable or uncorrectable), the corresponding next error status bit will be

set but the Requester ID of the subsequent error Message is discarded. The next error status bits may be cleared by software by writing a 1b to the respective bit as well. Refer to § Section 6.2 for further details. This register is updated regardless of the settings of the Root Control Register and the Root Error Command Register. § Figure 7-163 details allocation of register fields in the Root Error Status Register; § Table 7-143 provides the respective bit definitions. Root Complex Event Collectors provide support for the above-described functionality for RCiEPs (and for the Root Complex Event Collector itself). In order to update this register, error Messages received by the Root Complex Event Collector from its associated RCiEPs and/or internally generated error Messages must be enabled for “transmission” by the Root Complex Event Collector.

For Functions other than Root Ports and Root Complex Event Collectors: when End-End TLP Prefix Supported is Set, this register is RsvdZ and when End-End TLP Prefix Supported is Clear, this register is not required to be implemented.

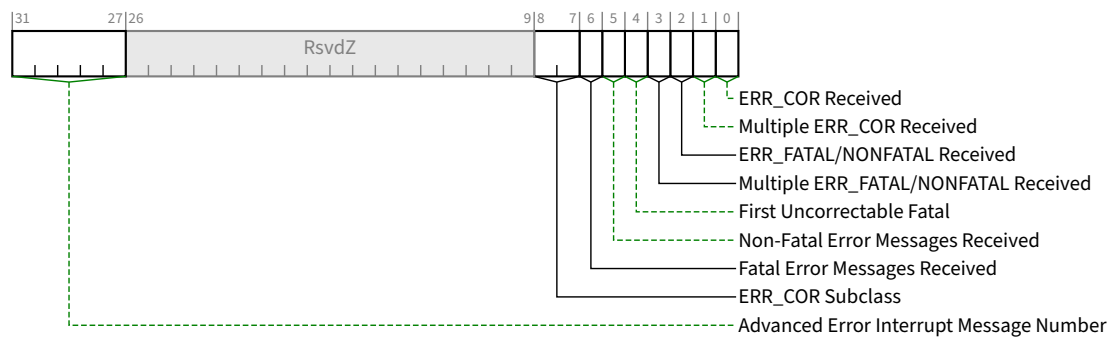

Figure 7-163 Root Error Status Register §

Table 7-143 Root Error Status Register §

Bit Location	Register Description	Attributes
0	ERR_COR Received - Set when a Correctable error Message is received and this bit is not already Set. Default value of this bit is 0b.	<u>RW1CS</u>
1	Multiple ERR_COR Received - Set when a Correctable error Message is received and <u>ERR_COR Received</u> is already Set. Default value of this bit is 0b.	<u>RW1CS</u>
2	ERR_FATAL/NONFATAL Received - Set when either a Fatal or a Non-fatal error Message is received and this bit is not already Set. Default value of this bit is 0b.	<u>RW1CS</u>
3	Multiple ERR_FATAL/NONFATAL Received - Set when either a Fatal or a Non-fatal error is received and <u>ERR_FATAL/NONFATAL Received</u> is already Set. Default value of this bit is 0b.	<u>RW1CS</u>
4	First Uncorrectable Fatal - Set when the first Uncorrectable error Message received is for a Fatal error. Default value of this field is 0b.	<u>RW1CS</u>
5	Non-Fatal Error Messages Received - Set when one or more Non-Fatal Uncorrectable error Messages have been received. Default value of this bit is 0b.	<u>RW1CS</u>

Bit Location	Register Description	Attributes
6	Fatal Error Messages Received - Set when one or more Fatal Uncorrectable error Messages have been received. Default value of this bit is 0b.	RW1CS
8:7	ERR_COR Subclass - If the Function is ERR_COR Subclass capable and the ERR_COR Received bit is not already Set, this field is loaded with the value of the ERR_COR Subclass field in the received ERR_COR Message. See § Section 2.2.8.3 . The value in this field is only valid when the ERR_COR Received bit is Set. If the Function is not ERR_COR Subclass capable, this field is Reserved. If the Function is ERR_COR Subclass capable and a SIG_SFW ERR_COR Message is received, system firmware should be signaled using a system-specific mechanism. Default value of this field is 00b.	ROS/RsvdZ
31:27	Advanced Error Interrupt Message Number - This register indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability. For MSI, the value in this register indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the Message Control Register for MSI. For MSI-X, the value in this register indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this register must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this register must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this register is undefined.	RO

7.8.4.11 Error Source Identification Register (Offset 34h) §

The Error Source Identification Register identifies the source (Requester ID) of first correctable and uncorrectable (Non-fatal/Fatal) errors reported in the Root Error Status Register. Refer to § Section 6.2 for further details. This register is updated regardless of the settings of the Root Control Register and the Root Error Command Register. § Figure 7-164 details allocation of register fields in the Error Source Identification Register; § Table 7-144 provides the respective bit definitions.

For Functions other than Root Ports and Root Complex Event Collectors: when End-End TLP Prefix Supported is Set, this register is RsvdP and when End-End TLP Prefix Supported is Clear, this register is not required to be implemented.

Figure 7-164 Error Source Identification Register §

Table 7-144 Error Source Identification Register §

Bit Location	Register Description	Attributes
15:0	ERR_COR Source Identification - Loaded with the Requester ID indicated in the received ERR_COR Message when the ERR_COR Received bit is not already set. Default value of this field is 0000h.	ROS
31:16	ERR_FATAL/NONFATAL Source Identification - Loaded with the Requester ID indicated in the received ERR_FATAL or ERR_NONFATAL Message when the ERR_FATAL/NONFATAL Received bit is not already set. Default value of this field is 0000h.	ROS

7.8.4.12 TLP Prefix Log Register (Offset 38h) §

The TLP Prefix Log Register captures the End-End TLP Prefix(s) for the TLP corresponding to the detected error; refer to § Section 6.2 for further details. The TLP Prefix Log Register is only meaningful when First Error Pointer is valid and the TLP Prefix Log Present bit is Set (see § Section 7.8.4.7).

The TLP Prefixes are captured such that, when read using DW accesses, the fields of the TLP Prefix are laid out in the same way the fields of the TLP Prefix are described. Therefore, byte 0 of a TLP Prefix is located in byte 3 of the associated TLP Prefix Log Register; byte 1 of a TLP Prefix is located in byte 2; and so forth.

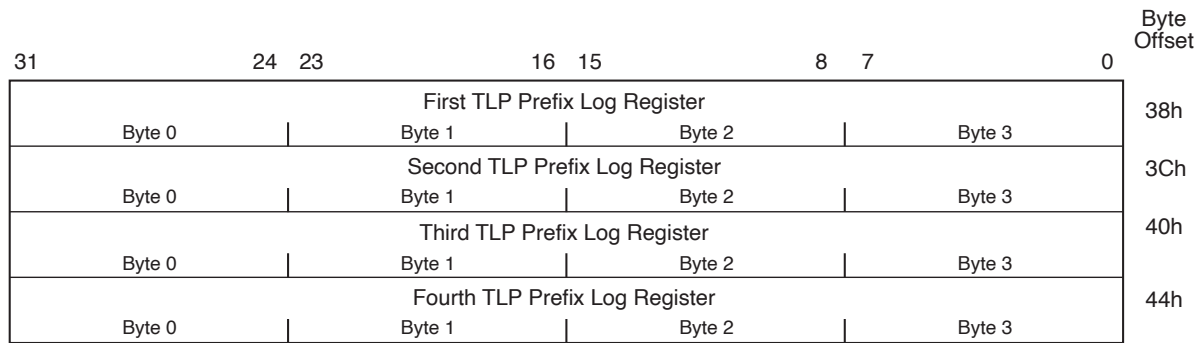

The First TLP Prefix Log Register contains the first End-End TLP Prefix from the TLP (see § Section 6.2.4.4). The Second TLP Prefix Log Register contains the second End-End TLP Prefix and so forth. If the TLP contains fewer than four End-End TLP Prefixes, the remaining TLP Prefix Log Registers contain zero. A TLP that contains more End-End TLP Prefixes than are indicated by the Function's Max End-End TLP Prefixes field must be handled as an error (see § Section 2.2.10.4 for specifics). To allow software to detect this condition, the supported number of End-End TLP Prefixes are logged in this register, the first overflow End-End TLP Prefix is logged in the first DW of the Header Log register and the remaining DWs of the Header Log register are undefined (see § Section 6.2.4.4).

The TLP Prefix Log Registers beyond the number supported by the Function are hardwired to zero. For example, if a Functions, Max End-End TLP Prefixes field contains 10b (indicating 2 DW of buffering) then the third and fourth TLP Prefix Log Registers are hardwired to zero. If the End-End TLP Prefix Supported bit (§ Section 7.5.3.15) is Clear, the TLP Prefix Log Register is not required to be implemented.

For VFs that share Header Log space, this register's contents are undefined when the Header Log contains all 1s due to an overflow condition. See § Section 6.2.4.2.1 for further requirements when VFs share Header Log space.

When Flit Mode Supported is Set and the link is operating in Flit Mode, this register is not present and the Header Log Register extends into this space (see additional DWs as indicated by the Header Log Size field).

When the link is operating in Non-Flit Mode, End-End TLP Prefixes are logged in the TLP Prefix Log Register.

A-0785

Bit Location	Register Description	Attributes	Default
127:0	TLP Prefix Log	ROS	0

7.8.5 Enhanced Allocation Capability Structure (EA) §

Each function that supports the Enhanced Allocation mechanism must implement the Enhanced Allocation capability structure.

Each field is defined in the following sections. Reserved registers must return 0 when read and write operations must have no effect. Read-only registers return valid data when read, and write operations must have no effect.

7.8.5.1 Enhanced Allocation Capability First DW (Offset 00h) §

The first DW of the Enhanced Allocation capability is illustrated in § Figure 7-166, and is documented in § Table 7-146.

Figure 7-166 First DW of Enhanced Allocation Capability §

Table 7-146 First DW of Enhanced Allocation Capability §

Bit Location	Register Description	Attributes
7:0	Capability ID - Must be set to 14h to indicate Enhanced Allocation capability. This field is read only.	<u>HwInit</u>
15:8	Next Capability Pointer - Pointer to the next item in the capabilities list. Must be NULL for the final item in the list. This field is read only.	<u>HwInit</u>

Bit Location	Register Description	Attributes
21:16	Num Entries - Number of entries following the first DW of the capability. Value of 00 0000b is permitted and means there are no entries. This field is read only.	HwInit

7.8.5.2 Enhanced Allocation Capability Second DW (Offset 04h) § [Type 1 Functions Only]

For Type 1 Functions only, there is a second DW in the capability, preceding the first entry. This second DW must be included in the Enhanced Allocation Capability whenever this capability is implemented in a Type 1 Function. The second DW of the Enhanced Allocation capability is illustrated in § Figure 7-167, and is documented in § Table 7-147.

Figure 7-167 Second DW of Enhanced Allocation Capability §

Table 7-147 Second DW of Enhanced Allocation Capability §

Bit Location	Register Description	Attributes
7:0	Fixed Secondary Bus Number - If at least one Function that uses EA is located behind this Function, then this field must be set to indicate the Bus Number for the secondary interface of this Function. If no Function that uses EA is located behind this Function, then this field must be set to 00h.	HwInit
15:8	Fixed Subordinate Bus Number - If at least one Function that uses EA is located behind this Function, then this field must be set to indicate the highest Bus Number below this Function. If no Function that uses-EA is located behind this Function, then this field must be set to 00h.	HwInit

7.8.5.3 Enhanced Allocation Per-Entry Format (Offset 04h or 08h) §

An Enhanced Allocation Entry consists of a First DW followed by between 2 and 4 DW of Base / MaxOffset information.

- For Type 0 Functions, Enhanced Allocation Entries start at offset 04h of this capability.
- For Type 1 Functions, Enhanced Allocation Entries start at offset 08h of this capability.
- Subsequent Enhanced Allocation Entries immediately follow each other.

The first DW of each entry in the Enhanced Allocation capability is illustrated in § Figure 7-168, and is defined in § Table 7-148.

Figure 7-168 First DW of Each Entry for Enhanced Allocation Capability §

Table 7-148 First DW of Each Entry for Enhanced Allocation Capability §

Bit Location	Register Description	Attributes																								
2:0	<p>Entry Size (ES) - Number of DW following the initial DW in this entry.</p> <p>When processing this capability, software is required to use the value in this field to determine the size of this entry, and if this entry is not the final entry, the start of the following entry in the capability. BEI Value	Description																									
0	Entry is equivalent to BAR at location 10h																									
1	Entry is equivalent to BAR at location 14h																									
2	Entry is equivalent to BAR at location 18h																									
3	Entry is equivalent to BAR at location 1Ch																									
4	Entry is equivalent to BAR at location 20h																									
5	Entry is equivalent to BAR at location 24h																									
6	Permitted to be used by a Function with a <u>Type 1 Configuration Space Header</u> only, optionally used to indicate a resource that is located behind the Function																									
7	Equivalent Not Indicated																									
8	Expansion ROM Base Address																									
9-14	Entry relates to <u>VF BARs</u> 0-5 respectively																									
15	Reserved - Software must treat values in this range as “Equivalent Not Indicated”																									
15:8	<p>Primary Properties - Indicates the entry properties as defined in <u>§ Table 7-150</u>.</p>	<u>HwInit</u>																								

Bit Location	Register Description	Attributes
23:16	Secondary Properties - Optionally used to indicate a different but compatible entry property, using properties as defined in § Table 7-150.	<u>HwInit</u>
30	Writable (W) - The value 1b indicates that the Base and MaxOffset fields for this entry are RW and that the Field Size bits for this entry are either RW or HwInit. The value 0b indicates those fields are HwInit. See § Table 7-150 for additional requirements on the value of this field.	<u>HwInit</u>
31	Enable (E) - 1b indicates this entry is enabled, 0b indicates this entry is disabled. If system software disables this entry, the resource indicated must still be associated with this function, and it is not permitted to reallocate this resource to any other entity. This field is permitted to be implemented as HwInit for functions that require the allocation of the associated resource, or as RW for functions that can allow system software to disable this resource, for example if BAR mechanisms are to be used instead of this resource.	<u>RW/HwInit</u>

Rules for use of BEI field:

- A Type 0 Function is permitted to use EA to allocate resources for itself, and such resources must indicate a BEI value of 0-5, 7 or 8.
- A Physical Function (Type 0 Function that supports SR-IOV) is permitted to use EA to allocate resources for its associated Virtual Functions, and such resources must indicate a BEI value of 9-14.
- A Type 1 Function (bridge) is permitted to use EA to allocate resources for itself, and such resources must indicate a BEI value of 0, 1 or 7.
- A Type 1 Function is permitted but not required to indicate resources mapped behind that Function, but if such resources are indicated by the Type 1 Function, the entry must indicate a BEI value of 6.
- For a 64-bit Base Address Register, the BEI indicates the equivalent BAR location for lower DWORD.
- For Memory BARs where the Primary or Secondary Properties is 00h or 01h, it is permitted to assign the same BEI in the range of 0 to 5 once for a range where Base + MaxOffset is below 4 GB, and again for a range where Base + MaxOffset is greater than 4 GB; It is not otherwise permitted to assign the same BEI in the range 0 to 5 for more than one entry.
- For Virtual Function BARs where the Primary or Secondary Properties is 03h or 04h it is permitted to assign the same BEI in the range of 9 to 14 once for a range where Base + MaxOffset is below 4 GB, and again for a range where Base + MaxOffset is greater than 4 GB; It is not otherwise permitted to assign the same BEI in the range 9 to 14 for more than one VF entry.
- For all cases where two entries with the same BEI are permitted, Software must enable use of only one of the two ranges at a time for a given Function.
- It is permitted for an arbitrary number of entries to assign a BEI of 6 or 7.
- At most one entry is permitted with a BEI of 8; if such an entry is present, behavior of the Expansion ROM Base Address Register is changed (see § Section 7.5.1.2.4).
- For Type 1 Functions, BEI values 2 through 5 are reserved.

§ Figure 7-169 illustrates the format of a complete Enhanced Allocation entry for a Type 0 Function. For the Base and MaxOffset fields, bit 1 indicates if the field is a 32b (0) or 64b (1) field.

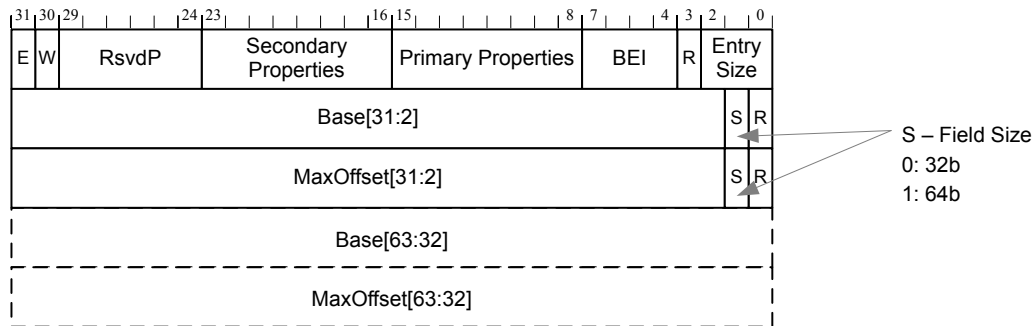

Figure 7-169 Format of Entry for Enhanced Allocation Capability §

The value in the **Base** field ([63:2] or [31:2]) indicates the DW address of the start of the resource range. Bits [1:0] of the address are not included in the **Base** field, and must always be interpreted as 00b.

The value in the **Base** field plus the value in the **MaxOffset** field ([63:2] or [31:2]) indicates the address of the last included DW of the resource range. Bits [1:0] of the **MaxOffset** are not included in the **MaxOffset** field, and must always be interpreted as 11b.

For the **Base** and **MaxOffset** fields, when bits [63:32] are not provided then those bits must be interpreted as all 0's.

Although it is permitted for a **Type 0 Function** to indicate the use of a range that is not naturally aligned and/or not a power of two in size, some system software may fail if this is done. Particularly for ranges that are mapped to legacy BARs by indicating a BEI in the range of 0 to 5, it is strongly recommended that the **Base** and **MaxOffset** fields for a **Type 0 Function** indicate a naturally aligned region.

The Primary Properties[7:0] field must be set by hardware to identify the type of resource indicated by the entry. It is strongly recommended that hardware set the Secondary Properties[7:0] to indicate an alternate resource type which can be used by software when the Primary Properties[7:0] field value is not comprehended by that software, for example when older system software is used with new hardware that implements resources using a value for Primary Properties that was reserved at the time the older system software was implemented. When this is done, hardware must ensure that software operating using the resource according to the value indicated in the Secondary Properties field will operate in a functionally correct way, although it is not required that this operation will result in optimal system performance or behavior.

The Primary Properties[7:0] and Secondary Properties[7:0] fields are defined in § Table 7-150. This table also defines whether or not the entry is permitted to be writeable. The Writeable bit in any entry must be 0b unless both the Primary and Secondary properties of that entry allow otherwise.

Table 7-150 Enhanced Allocation Entry Field Value Definitions for both the Primary Properties and Secondary Properties Fields §

Value (h)	Resource Definition	Writeable permitted
00	Memory Space, Non-Prefetchable.	No
01	Memory Space, Prefetchable.	No
02	I/O Space.	No

Value (h)	Resource Definition	Writeable permitted
03	For use only by <u>Physical Functions</u> to indicate resources for <u>Virtual Function</u> use, Memory Space, Prefetchable.	No
04	For use only by <u>Physical Functions</u> to indicate resources for <u>Virtual Function</u> use, Memory Space, Non-Prefetchable.	No
05	For use only by <u>Type 1 Functions</u> to indicate Memory, Non-Prefetchable, for Allocation Behind that Bridge.	No
06	For use only by <u>Type 1 Functions</u> to indicate Memory, Prefetchable, for Allocation Behind that Bridge.	No
07	For use only by <u>Type 1 Functions</u> to indicate I/O Space for Allocation Behind that Bridge.	No
08-FC	Reserved for future use; System firmware/software must not write to this entry, and must not attempt to interpret this entry or to use this resource. When software reads a Primary Properties value that is within this range, is it strongly recommended that software treat this resource according to the value in the Secondary Properties field, if that field contains a non-reserved value.	Yes
FD	Memory Space Resource Unavailable For Use - System firmware/software must not write to this entry, and must not attempt to use the resource described by this entry for any purpose.	No
FE	I/O Space Resource Unavailable For Use - System firmware/software must not write to this entry, and must not attempt to use the resource described by this entry for any purpose.	No
FF	Entry Unavailable For Use - System firmware/software must not write to this entry, and must not attempt to interpret this entry as indicating any resource. Hardware <i>MUST@FLIT</i> use this value in the Secondary Properties field to indicate that, for proper operation, the hardware requires the use of the resource definition indicated in the Primary Properties field.	No

The following figures illustrate the layout of Enhanced Allocation entries for various cases.

7.8.6 Resizable BAR Extended Capability §

The Resizable BAR Extended Capability is an optional capability that allows hardware to communicate resource sizes, and system software, after determining the optimal size, to communicate this optimal size back to the hardware. Hardware communicates the resource sizes that are acceptable for operation via the Resizable BAR Capability and Control registers. Hardware must support at least one size in the range from 1 MB to 512 GB.

IMPLEMENTATION NOTE: RESIZABLE BAR BACKWARD COMPATIBILITY WITH SOFTWARE §

The Resizable BAR Extended Capability initially supported 20 sizes, ranging from 1 MB to 512 GB, and was later expanded with 16 larger sizes. The hardware requirement to support at least one of the initial sizes ensures backward compatibility with software that comprehends only the initial sizes.

Software determines, through a proprietary mechanism, what the optimal size is for the resource, and programs that size via the BAR Size field of the Resizable BAR Control register. Hardware immediately reflects the size inference in the read-only bits of the appropriate Base Address register. Hardware must Clear any bits that change from RW to read-only, so that subsequent reads return zero. Software must clear the Memory Space Enable bit in the Command register before writing the BAR Size field. After writing the BAR Size field, the contents of the corresponding BAR are undefined. To ensure that it contains a valid address after resizing the BAR, system software must reprogram the BAR, and Set the Memory Space Enable bit (unless the resource is not allocated).

The Resizable BAR Capability and Control registers are permitted to indicate the ability to operate at 4 GB or greater only if the associated BAR is a 64-bit BAR.

This capability is applicable to Functions that have Base Address registers only. The capability is permitted to be present in PFs. Since VFs do not implement standard BARs, the capability must not be present in a VF. The PF's Resizable BAR settings do not affect any settings in the SR-IOV Extended Capability.

It is strongly recommended that a Function not advertise any supported BAR sizes that are larger than the space it would effectively utilize if allocated.

IMPLEMENTATION NOTE: USING THE CAPABILITY DURING RESOURCE ALLOCATION §

System software that allocates resources can use this capability to resize the resources inferred by the Function's BAR's read-only bits. Previous versions of this software determined the resource size by writing FFFF_FFFFh or FFFF_FFFF_FFFF_FFFFh to the BAR, reading back the value, and determining the size by the number of bits that are Set. Following this, the base address is written to the BAR.

System software uses this capability in place of the above mentioned method of determining the resource size, and prior to assigning the base address to the BAR. Potential usable resource sizes are reported by the Function via its Resizable BAR Capability and Control registers. It is intended that the software allocate the largest of the reported sizes that it can, since allocating less address space than the largest reported size can result in lower performance. Software then writes the size to the Resizable BAR Control register for the appropriate BAR for the Function. Following this, the base address is written to the BAR.

For interoperability reasons, it is possible that hardware will set the default size of the BAR to a low size; that is, a size lower than the largest reported in the Resizable BAR Capability and Control registers. Software that does not use this capability to size resources will likely result in sub-optimal resource allocation, where the resources are smaller than desirable, or not allocatable because there is no room for them.

With the Resizable BAR capability, the amount of address space consumed by a device can change. In a resource constrained environment, the allocation of more address space to a device may result in allocation of less of the address space to other memory-mapped hardware, like system RAM. System software responsible for allocating resources in this kind of environment is recommended to distribute the limited address space appropriately.

The Resizable BAR Capability structure defines a PCI Express Extended Capability, which is located in PCI Express Extended Configuration Space, that is, above the first 256 bytes, and is shown below in § Figure 7-174. This structure allows devices with this capability to be identified and controlled. A Capability and a Control register is implemented for each BAR that is resizable. Since a maximum of six BARs may be implemented by any Function, the Resizable BAR Capability structure can range from 12 bytes long (for a single BAR) to 52 bytes long (for all six BARs).

31	Function supports 8 EB BAR - When Set, indicates that the Function supports operating with the BAR sized to 8 EB (2^{63} bytes)	<u>RO</u>

7.8.7 VF Resizable BAR Extended Capability §

The VF Resizable BAR Extended Capability is permitted to be implemented only in PFs that implement at least one VF BAR, and affects the size and base of a PF's VF BARs. Since VFs do not implement the BARs themselves the capability must not be present in a VF. A PF may implement both a VF Resizable BAR Extended Capability and a Resizable BAR capability, as each capability operates independently.

The VF Resizable BAR Extended Capability is an optional capability that permits PFs to be able to have their VF's BARs resized. The VF Resizable BAR Extended Capability permits hardware to communicate the resource sizes that are acceptable for operation via the VF Resizable BAR Extended Capability and Control registers and system software to communicate the optimal size back to the hardware via the VF BAR Size field of the VF Resizable BAR Control register.

Hardware immediately reflects the size inference in the read-only bits of the appropriate VF BAR. The size inferred is the greater of the values decoded from the System Page Size and VF BAR Size fields. Hardware must Clear any bits that change from read-write to read-only, so that subsequent reads return zero. Software must clear the VF MSE bit in the SR-IOV Control Register before writing the VF BAR Size field. After writing the VF BAR Size field, the contents of the corresponding VF BAR are undefined. To ensure that it contains a valid address after resizing the VF BAR, system software must reprogram the VF BAR, and Set the VF MSE bit (unless the resource is not allocated).

The VF Resizable BAR Extended Capability and Control registers are permitted to indicate the ability to operate at 4 GB or greater only if the associated VF BAR is a 64-bit BAR.

It is strongly recommended that a Function not advertise any supported VF BAR size values in this capability that are larger than the space it would effectively utilize if allocated.

IMPLEMENTATION NOTE: USING THE CAPABILITY DURING RESOURCE ALLOCATION §

System software uses this capability in a similar way to the Resizable BAR capability. System software must first configure the System Page Size register (see § Section 9.2.1.1.1). Potential usable memory aperture sizes are reported by the PF, and read, from the VF Resizable BAR Extended Capability and Control registers. It is intended that the software allocate the largest of the reported sizes that it can, since allocating less address space than the largest reported size can result in lower performance. Software then writes the size to the VF Resizable BAR Control register for the appropriate VF BAR for the Function. Following this, the base address is written to the VF BAR.

For interoperability reasons, it is possible that hardware will set the default size of the VF BAR to a low size; a size lower than the largest reported in the VF Resizable BAR Capability Register. Software that does not use this capability to size resources will likely result in sub-optimal resource allocation, where the resources are smaller than desirable, or not allocatable because there is no room for them. It is recommended that system software responsible for allocating resources in a resource constrained environment distribute the limited address space to all memory-mapped hardware, including system RAM, appropriately.

The VF Resizable BAR Extended Capability structure defines a PCI Express Extended Capability which is located in PCI Express Extended Configuration Space, that is, above the first 256 bytes, and is shown below in § Figure 7-178. This structure allows PFs with this capability to be identified and controlled. A Capability register and a Control register are implemented for each VF BAR that is resizable. Since a maximum of 6 VF BARs may be implemented by any PF, the VF Resizable BAR Capability structure can range from 12 bytes long (for a single VF BAR) to 52 bytes long (for all 6 VF BARs).

Table 7-154 VF Resizable BAR Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	<p>PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability.</p> <p>PCI Express Extended Capability ID for the VF Resizable BAR Extended Capability is 0024h.</p>	RO
19:16	<p>Capability Version - This field is a PCI-SIG defined version number that indicates the version of the capability structure present.</p> <p>Must be 1h for this version of the specification.</p>	RO
31:20	<p>Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of capabilities</p>	RO

7.8.7.2 VF Resizable BAR Capability Register (Offset 04h) §

The VF Resizable BAR Capability Register field descriptions are the same as the definitions in the Resizable BAR Capability Register in § Table 7-152. Where those descriptions say ‘BAR’, this register’s description is for ‘VF BAR’. Where those descriptions say ‘Function’, this register’s description is for ‘PF’. Otherwise, the field descriptions, the number of bits, their positions, and their attributes are the same. Consequently § Figure 7-176 similarly allocates the register fields in this register.

7.8.7.3 VF Resizable BAR Control Register (Offset 08h) §

The VF Resizable BAR Control register bits 31:16 follow the same definitions as the Resizable BAR Control register in § Table 7-153.

Figure 7-180 VF Resizable BAR Control Register §

Table 7-155 VF Resizable BAR Control Register §

Bit Location	Register Description	Attributes
2:0	<p>VF BAR Index - This encoded value points to the beginning of this particular VF BAR located in the SR-IOV Extended Capability.</p> <p>0 VF BAR located at offset 24h</p> <p>1 VF BAR located at offset 28h</p> <p>2 VF BAR located at offset 2Ch</p> <p>3 VF BAR located at offset 30h</p> <p>4 VF BAR located at offset 34h</p> <p>5 VF BAR located at offset 38h</p> <p>others All other encodings are reserved.</p> <p>For a 64-bit Base Address register, the <u>VF BAR Index</u> indicates the lower DWORD.</p> <p>This value indicates which VF BAR supports a negotiable size.</p>	RO
7:5	<p>Number of VF Resizable BARs - Indicates the total number of resizable <u>VF BARs</u> in the capability structure for the Function. See § Figure 7-178.</p> <p>The value of this field must be in the range of 01h to 06h. The field is valid in <u>VF Resizable BAR Control register (0)</u> (at offset 08h), and is <u>RsvdP</u> for all others.</p>	RO/RsvdP
13:8	<p>VF BAR Size - This is an encoded value.</p> <p>0 1 MB (2^{20} bytes)</p> <p>1 2 MB (2^{21} bytes)</p> <p>2 4 MB (2^{22} bytes)</p> <p>3 8 MB (2^{23} bytes)</p> <p>...</p> <p>43 8 EB (2^{63} bytes)</p> <p>The default value of this field is equal to the default size of the address space that the VF BAR resource is requesting via the VF BAR's read-only bits.</p> <p>Software must only write values that correspond to those indicated as supported in the VF Resizable BAR Capability and Control registers. Writing an unsupported value will produce undefined results.</p> <p>When this register field is programmed, the value is immediately reflected in the size of the resource, as encoded in the number of read-only bits in the VF BAR.</p>	RW

Bit Location	Register Description	Attributes
31:16	These bits are identical to the Resizable BAR Control Register bits [31:16] defined in § Figure 7-177. Where those descriptions say 'BAR', this register's description is for 'VF BAR'. Where those descriptions say 'Function', this register's description is for 'PF'.	See § Figure 7-177

7.8.8 ARI Extended Capability §

ARI is an optional capability, except as stated below. This capability must be implemented by each Function in an ARI Device. It is not applicable to a Root Port, a Switch Downstream Port, an RCiEP, or a Root Complex Event Collector.

For SR-IOV devices not in a Root Complex, implementing the ARI Extended Capability in each Function is mandatory.

Figure 7-181 ARI Extended Capability §

7.8.8.1 ARI Extended Capability Header (Offset 00h) §

Figure 7-182 ARI Extended Capability Header §

Table 7-156 ARI Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability. PCI Express Extended Capability ID for the <u>ARI Extended Capability</u> is 000Eh.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.	RO

7.8.8.2 ARI Capability Register (Offset 04h) §

Figure 7-183 ARI Capability Register §

Table 7-157 ARI Capability Register §

Bit Location	Register Description	Attributes
0	<p>MFVC Function Groups Capability (M) - Applicable only for Function 0; must be Zero for all other Functions. If Set, indicates that the ARI Device supports <u>Function Group</u> level arbitration via its Multi-Function Virtual Channel (MFVC) Capability structure.</p> <p>Any SR-IOV Device that implements the MFVC Extended Capability with the optional Function Arbitration Table and consumes more than one Bus Number must Set this bit in its Function 0.</p>	RO
1	<p>ACS Function Groups Capability (A) - Applicable only for Function 0; must be Zero for all other Functions. If Set, indicates that the ARI Device supports <u>Function Group</u> level granularity for ACS P2P Egress Control via its ACS Capability structures.</p> <p>Any SR-IOV Device that implements the ACS Capability with the optional Egress Control Vector and consumes more than one Bus Number must Set this bit in its Function 0.</p>	RO
15:8	<p>Next Function Number - With non-VFs, this field indicates the Function Number of the next higher numbered Function in the Device, or 00h if there are no higher numbered Functions. Function 0 starts this linked list of Functions.</p> <p>The presence of Shadow Functions does not affect this field.</p> <p>For VFs, this field is undefined since VFs are located using First VF Offset (see § Section 9.3.3.9) and VF Stride (see § Section 9.3.3.10).</p>	RO

7.8.8.3 ARI Control Register (Offset 06h) §

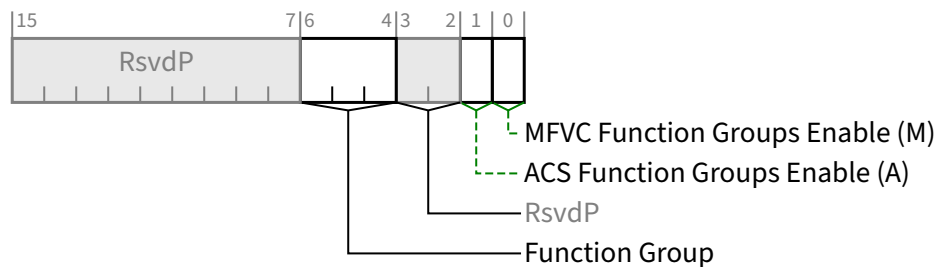

Figure 7-184 ARI Control Register §

Table 7-158 ARI Control Register §

Bit Location	Register Description	Attributes
0	MFVC Function Groups Enable (M) - Applicable only for Function 0; must be hardwired to 0b for all other Functions. When set, the ARI Device must interpret entries in its <u>Function Arbitration Table</u> as <u>Function Group Numbers</u> rather than <u>Function Numbers</u> . Default value of this bit is 0b. Must be hardwired to 0b if the MFVC Function Groups Capability bit is 0b.	RW
1	ACS Function Groups Enable (A) - Applicable only for Function 0; must be hardwired to 0b for all other Functions. When set, each Function in the ARI Device must associate bits within its <u>Egress Control Vector</u> with <u>Function Group Numbers</u> rather than <u>Function Numbers</u> . Default value of this bit is 0b. Must be hardwired to 0b if the ACS Function Groups Capability bit is 0b.	RW
6:4	Function Group - Assigns a <u>Function Group Number</u> to this Function. Default value of this field is 000b. Must be hardwired to 000b if in Function 0, the MFVC Function Groups Capability bit and ACS Function Groups Capability bit are both 0b.	RW

7.8.9 PASID Extended Capability Structure §

The presence of a PASID Extended Capability indicates that one or more Endpoint Functions support sending and receiving TLPs containing a PASID TLP Prefix in NFM or containing OHC with PASID in FM. Separate support and enables are provided for the various optional features.

This capability is only permitted to be implemented in to Endpoints Functions (including RCiEPs). A PF is permitted to implement the PASID capability, but VFs must not implement it. For Root Ports, support and control is outside the scope of this specification.

In earlier revisions of this specification, it was ambiguous whether a single PASID capability or multiple PASID capabilities are supported for an MFD. For backward compatibility, both models are supported. In the PASID Capability and Control register bit definitions, the phrase “applicable Endpoint Function” refers to the following rules:

- If an SFD contains a PASID capability, it must apply to the SFD’s single Endpoint Function.
- If an MFD contains a single PASID capability, it must apply to all Endpoint Functions in the MFD, including all VFs regardless of their PF association.

- If an MFD contains multiple PASID capabilities, each PASID capability that exists must apply only to the Endpoint Function in which it resides, with the exception that if a PF contains a PASID capability, that PASID capability must apply to all VFs associated with that PF.

When a PASID capability applies to multiple Endpoint Functions in a device, the device sends the requesting Function's ID in the Requester ID field of the TLP containing the PASID.

This capability is independent of both the ATS and PRI features defined in § Chapter 10. . Endpoint Functions that contain a PASID Extended Capability need not support ATS or PRI. Endpoint Functions that support ATS or PRI need not support PASID.

§ Figure 7-185 details allocation of the register bits in the PASID Extended Capability structure.

Figure 7-185 PASID Extended Capability Structure §

7.8.9.1 PASID Extended Capability Header (Offset 00h) §

§ Figure 7-186 details allocation of the register fields in the PASID Extended Capability Header; § Table 7-159 provides the respective bit definitions.

Figure 7-186 PASID Extended Capability Header §

Table 7-159 PASID Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PASID Extended Capability ID - Indicates the PASID Extended Capability structure. This field must return a Capability ID of 001Bh indicating that this is a PASID Extended Capability structure.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - The offset to the next PCI Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	RO

7.8.9.2 PASID Capability Register (Offset 04h) §

§ Figure 7-187 details the allocation of register bits of the PASID Capability register; § Table 7-160 provides the respective bit definitions.

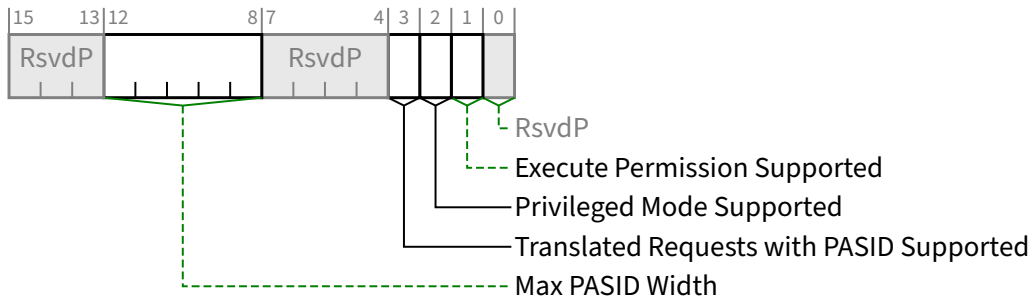

Figure 7-187 PASID Capability Register §

Table 7-160 PASID Capability Register §

Bit Location	Register Description	Attributes
1	Execute Permission Supported - If Set, an applicable Endpoint Function supports sending TLPs that have the <u>Execute Requested</u> bit Set. If Clear, the Endpoint Function will never Set the <u>Execute Requested</u> bit. It is strongly recommended that this bit be hardwired to 0b.	RO
2	Privileged Mode Supported - If Set, an applicable Endpoint Function supports operating in Privileged and Non-Privileged modes, and supports sending requests that have the <u>Privileged Mode Requested</u> bit Set. If Clear, the Endpoint Function will never Set the <u>Privileged Mode Requested</u> bit.	RO
3	Translated Requests with PASID Supported - If Set, indicates that an applicable Endpoint Function supports Translated Requests with PASID (see § Section 10.1.3). This bit is only permitted to be Set if the Endpoint Function supports ATS.	RO
12:8	Max PASID Width - Indicates the width of the PASID field supported by an applicable Endpoint Function. The value n indicates support for PASID values 0 through 2^n-1 (inclusive). The value 0 indicates support for a single PASID (0). The value 20 indicates support for all PASID values (20 bits). This field must be between 0 and 20 (inclusive).	RO

7.8.9.3 PASID Control Register (Offset 06h) §

§ Figure 7-188 details the allocation of register bits of the PASID Control register; § Table 7-161 provides the respective bit definitions.

Figure 7-188 PASID Control Register §

Table 7-161 PASID Control Register §

Bit Location	Register Description	Attributes
0	<p>PASID Enable - If Set, an applicable Endpoint Function is permitted to send and receive TLPs that contain a PASID TLP Prefix. If Clear, the Endpoint Function is not permitted to do so.</p> <p>Behavior is undefined if an applicable Endpoint Function supports ATS and this bit changes value when the Enable (E) bit in that Function's <u>ATS Control Register</u> is Set (see § Section 10.5.1.3).</p> <p>Default is 0b.</p>	RW
1	<p>Execute Permission Enable - If Set, an applicable Endpoint Function is permitted to send Requests that have the <u>Execute Requested</u> bit Set. If Clear, the Endpoint is not permitted to do so.</p> <p>Behavior is undefined if an applicable Endpoint Function supports ATS and this bit changes value when the Enable bit in that Function's <u>ATS Control Register</u> is Set (see § Section 10.5.1.3).</p> <p>If <u>Execute Permission Supported</u> is Clear, this bit is RsvdP.</p> <p>Default is 0b.</p>	RW/RsvdP (see description)
2	<p>Privileged Mode Enable - If Set, an applicable Endpoint Function is permitted to send Requests that have the <u>Privileged Mode Requested</u> bit Set. If Clear, the Endpoint Function is not permitted to do so.</p> <p>Behavior is undefined if an applicable Endpoint Function supports ATS and this bit changes value when the Enable bit in that Function's <u>ATS Control Register</u> is Set (see § Section 10.5.1.3).</p> <p>If <u>Privileged Mode Supported</u> is Clear, this bit is RsvdP.</p> <p>Default is 0b.</p>	RW/RsvdP (see description)
3	<p>Translated Requests with PASID Enable - When Set, the ATC associated with an applicable Endpoint Function is permitted to issue Translated Requests with a PASID TLP Prefix. If the ATC obtained a translation using a Translation Request with PASID, the corresponding Translated Request must carry a PASID that matches the PASID used to obtain the translation. Similarly, if the ATC obtained a translation using a Translation Request without a PASID, the corresponding Translated Request must not carry a PASID.</p> <p>When Clear, the ATC associated with the Endpoint Function is prohibited from issuing Translated Requests with a PASID.</p> <p>Behavior is undefined if an applicable Endpoint Function supports ATS this bit changes value when the Enable (E) bit in that Function's <u>ATS Control Register</u> is Set (see § Section 10.5.1.3).</p> <p>If <u>Translated Requests with PASID Supported</u> bit is Clear, this bit is RsvdP. See (see § Section 10.1.3) for details.</p> <p>Default is 0b.</p>	RW/RsvdP (see description)

7.8.10 FRS Queueing Extended Capability §

The FRS Queueing Extended Capability is required for Root Ports and Root Complex Event Collectors that support the optional normative FRS Queueing capability. See § Section 6.22 . This extended capability is only permitted in Root Ports and Root Complex Event Collectors.

If this capability is present in a Function, that Function must also implement either MSI, MSI-X, or both.

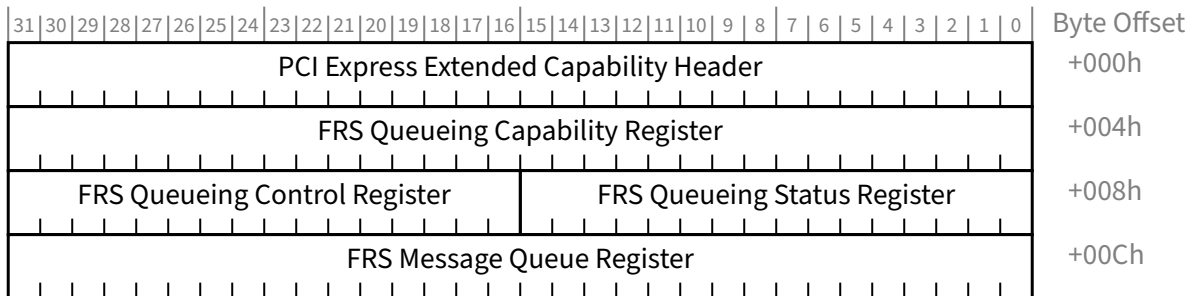

Figure 7-189 FRS Queueing Extended Capability §

7.8.10.1 FRS Queueing Extended Capability Header (Offset 00h) §

Figure 7-190 FRS Queueing Extended Capability Header §

Table 7-162 FRS Queueing Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability. PCI Express Extended Capability ID for the FRS Queueing Extended Capability is 0021h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	RO

7.8.10.2 FRS Queueing Capability Register (Offset 04h) §

Figure 7-191 FRS Queueing Capability Register §

Table 7-163 FRS Queueing Capability Register §

Bit Location	Register Description	Attributes
11:0	<p>FRS Queue Max Depth - Indicates the implemented queue depth, with valid values ranging from 001h (queue depth of 1) to FFFh (queue depth of 4095)</p> <p>The value of <u>FRS Message Queue Depth</u> must not exceed this value.</p> <p>The value 000h is Reserved.</p>	<u>HwInit</u>
20:16	<p>FRS Interrupt Message Number - This register indicates which MSI/MSI-X vector is used for the interrupt message generated in association with <u>FRS Message Received</u> or <u>FRS Message Overflow</u>.</p> <p>For MSI, the value in this register indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the <u>Message Control Register</u> for MSI.</p> <p>For MSI-X, the value in this register indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant.</p> <p>If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this register must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this register must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this register is undefined.</p>	<u>RO</u>

7.8.10.3 FRS Queueing Status Register (Offset 08h) §

Figure 7-192 FRS Queueing Status Register §

Table 7-164 FRS Queueing Status Register §

Bit Location	Register Description	Attributes
0	FRS Message Received - This bit is Set when a new FRS Message is Received or generated by this Root Port or Root Complex Event Collector. Root Ports must Clear this bit when the Link is <u>DL_Down</u> . Default value of this bit is 0b.	<u>RW1C</u>
1	FRS Message Overflow - This bit is Set if the FRS Message queue is full and a new FRS Message is received or generated by this Root Port or Root Complex Event Collector. Root Ports must Clear this bit when the Link is <u>DL_Down</u> . Default value of this bit is 0b.	<u>RW1C</u>

7.8.10.4 FRS Queueing Control Register (Offset 0Ah) §

Figure 7-193 FRS Queueing Control Register §

Table 7-165 FRS Queueing Control Register §

Bit Location	Register Description	Attributes
0	FRS Interrupt Enable - When Set and MSI or MSI-X is enabled, the Port must issue an MSI/MSI-X interrupt to indicate the 0b to 1b transition of either the <u>FRS Message Received</u> or the <u>FRS Message Overflow</u> bits. Default value of this bit is 0b.	<u>RW</u>

7.8.10.5 FRS Message Queue Register (Offset 0Ch) §

The FRS Message Queue Register contains fields from the oldest FRS message in the queue. It also indicates the number of FRS messages in the queue.

A write of any value that includes byte 0 to this register removes the oldest FRS Message from the queue and updates these fields. A write to this register when the queue is empty has no effect.

Figure 7-194 FRS Message Queue Register §

Table 7-166 FRS Message Queue Register §

Bit Location	Register Description	Attributes
15:0	FRS Message Queue Function ID - Recorded from the Requester ID of the oldest <u>FRS Message Received</u> or generated by this Root Port or Root Complex Event Collector and still in the queue. Undefined if <u>FRS Message Queue Depth</u> is 000h.	RO
19:16	FRS Message Queue Reason - Recorded from the FRS Reason of the oldest <u>FRS Message Received</u> or generated by this Root Port or Root Complex Event Collector and still in the queue. Undefined if <u>FRS Message Queue Depth</u> is 000h.	RO
31:20	FRS Message Queue Depth - indicates the current number of <u>FRS Messages</u> in the queue. The value of 000h indicates an empty queue. Default value of this field is 000h.	RO

7.8.11 Flattening Portal Bridge (FPB) Capability §

The Flattening Portal Bridge (FPB) Capability is an optional Capability that is required for any bridge Function that implements FPB. The FPB Capability structure is shown in § Figure 7-195.

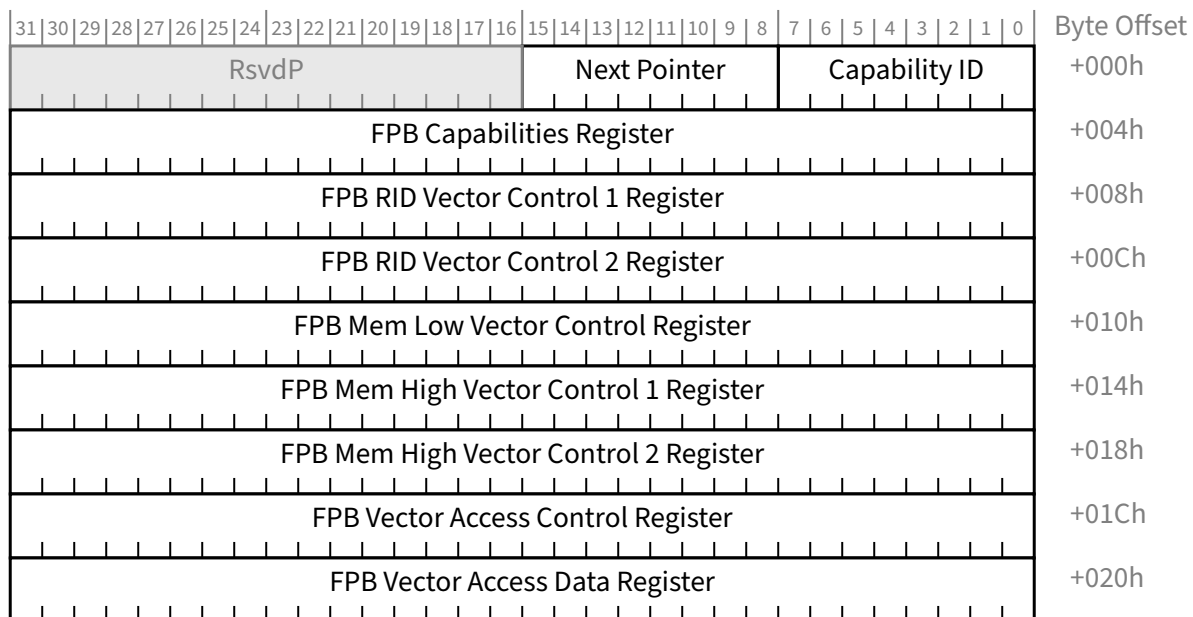

Figure 7-195 FPB Capability Structure §

If a Switch implements FPB then each of its Ports of the Switch must implement an FPB Capability Structure. A Root Complex is permitted to implement the FPB Capability Structure on some or on all of its Root Ports. A Root Complex is permitted to implement the FPB Capability for internal logical busses.

7.8.11.1 FPB Capability Header (Offset 00h) §

Figure 7-196 FPB Capability Header §

Table 7-167 FPB Capability Header §

Bit Location	Register Description	Attributes
7:0	Capability ID - Must be set to 15h	RO
15:8	Next Pointer - Pointer to the next item in the capabilities list. Must be 00h for the final item in the list.	RO

7.8.11.2 FPB Capabilities Register (Offset 04h) §

§ Figure 7-197 details allocation of register fields for FPB Capabilities register and § Table 7-168 describes the requirements for this register.

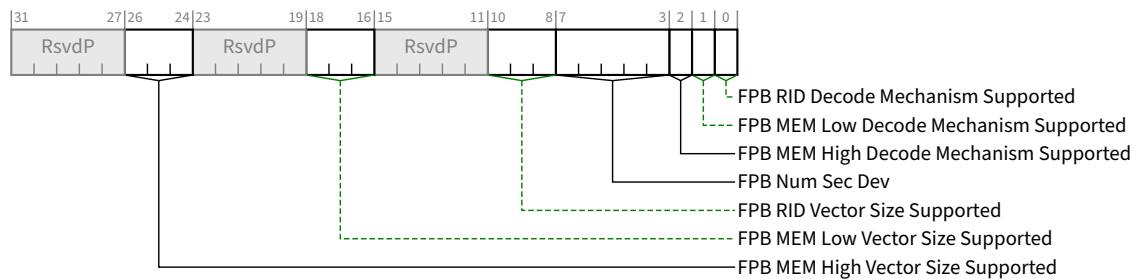

Figure 7-197 FPB Capabilities Register §

Table 7-168 FPB Capabilities Register §

Bit Location	Register Description	Attributes
0	FPB RID Decode Mechanism Supported - If Set, indicates that the FPB RID Vector mechanism is supported.	HwInit
1	FPB MEM Low Decode Mechanism Supported - If Set, indicates that the FPB MEM Low Vector mechanism is supported.	HwInit
2	FPB MEM High Decode Mechanism Supported - If Set, indicates that the FPB Mem High mechanism is supported.	HwInit

Bit Location	Register Description	Attributes																		
7:3	<p>FPB Num Sec Dev - For Upstream Ports of Switches only, this field indicates the quantity of Device Numbers associated with the Secondary Side of the Upstream Port bridge. The quantity is determined by adding one to the numerical value of this field.</p> <p>Although it is recommended that Switch implementations assign Downstream Ports using all 8 allowed Functions per allocated Device Number, such that all Downstream Ports are assigned within a contiguous range of Device and Function Numbers, it is, however, explicitly permitted to assign Downstream Ports to Function Numbers that are not contiguous within the indicated range of Device Numbers, and system software is required to scan for Switch Downstream Ports at every Function Number within the indicated quantity of Device Numbers associated with the Secondary Side of the Upstream Port.</p> <p>This field is Reserved for Downstream Ports.</p>	<u>HwInit/RsvdP</u>																		
10:8	<p>FPB RID Vector Size Supported - Indicates the size of the FPB RID Vector implemented in hardware, and constrains the allowed values software is permitted to write to the <u>FPB RID Vector Granularity</u> field.</p> <p>Defined encodings are:</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Size</th> <th>Allowed Granularities in RID units</th> </tr> </thead> <tbody> <tr> <td>000b</td> <td>256 bits</td> <td>8, 64, 256</td> </tr> <tr> <td>010b</td> <td>1 K bits</td> <td>8, 64</td> </tr> <tr> <td>101b</td> <td>8 K bits</td> <td>8</td> </tr> </tbody> </table> <p>All other encodings are Reserved.</p> <p>If the <u>FPB RID Decode Mechanism Supported</u> bit is Clear, then the value in this field is undefined and must be ignored by software.</p>	Value	Size	Allowed Granularities in RID units	000b	256 bits	8, 64, 256	010b	1 K bits	8, 64	101b	8 K bits	8	<u>HwInit</u>

7.8.11.9 FPB Vector Access Data Register (Offset 20h) §

§ Figure 7-204 details allocation of register fields for FPB Vector Access Data Register and § Table 7-186 describes the requirements for this register.

Figure 7-204 FPB Vector Access Data Register §

Table 7-186 FPB Vector Access Data Register §

Bit Location	Register Description	Attributes
31:0	<p>FPB Vector Access Data - Reads from this register return the DW of data from the FPB Vector at the location determined by the value in the <u>FPB Vector Access Offset Register</u>. Writes to this register replace the</p>	<u>RW</u>

Bit Location	Register Description	Attributes
	DW of data from the FPB Vector at the location determined by the value in the <u>FPB Vector Access Offset Register</u> . Behavior of this field is undefined if software programs unsupported values for FPB Vector Select or FPB Vector Access Offset fields, however hardware is required to complete the access to this register normally. Default value for this field is 0000 0000h	

7.8.12 Flit Performance Measurement Extended Capability §

This capability is optional. This capability is permitted in Downstream Ports, in Function 0 of an Upstream Port, and in RCRBs. This capability is not permitted in other Functions.

This capability is only used in Flit Mode. The capability has no effect in Non-Flit Mode.

The registers LTSSM Performance Measurement Status 1 Register through LTSSM Performance Measurement Status 5 Register are optional. The number implemented is contained in LTSSM Tracking Register Count. Unimplemented registers do not exist (i.e., the capability becomes shorter than shown in § Figure 7-205)

§ Figure 7-205 details allocation of the register bits in the Flit Performance Measurement Extended Capability structure.

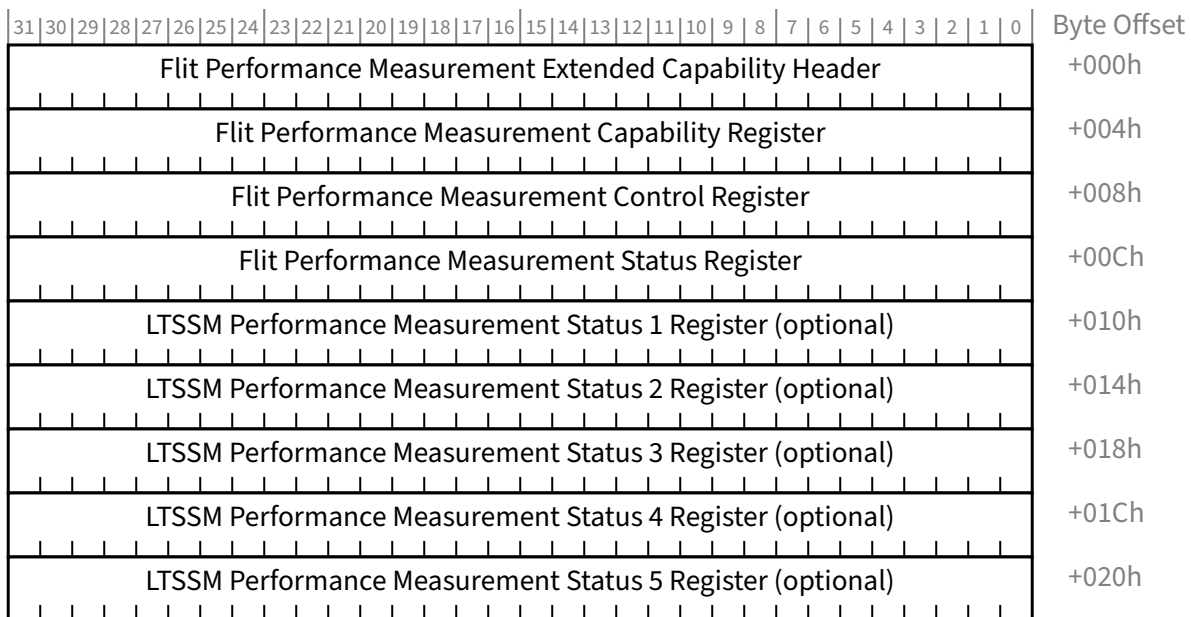

Figure 7-205 Flit Performance Measurement Extended Capability Structure §

7.8.12.1 Flit Performance Measurement Extended Capability Header (Offset 00h) §

§ Figure 7-206 details allocation of the register fields in the Flit Performance Measurement Extended Capability Header; § Table 7-187 provides the respective bit definitions.

Figure 7-206 Flit Performance Measurement Extended Capability Header §

Table 7-187 Flit Performance Measurement Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	Flit Performance Measurement Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Flit Performance Measurement Extended Capability is 0033h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.8.12.2 Flit Performance Measurement Capability Register (Offset 04h) §

Figure 7-207 Flit Performance Measurement Capability Register §

Table 7-188 Flit Performance Measurement Capability Register §

Bit Location	Register Description	Attributes
9:0	Flit Performance Interrupt Vector - contains the MSI or MSI-X Vector number used by this mechanism. If both MSI and MSI-X are implemented, this field is permitted to change value based on which one is enabled. Additionally, when MSI is enabled, this field is permitted to change value based on the value of Multiple Message Enable	RO
12:10	LTSSM Tracking Register Count - Indicates the number of simultaneous LTSSM tracking events that are supported. Value must be between 0 and 5.	HwInit

7.8.12.3 Flit Performance Measurement Control Register (Offset 08h) §

The status register in capability indicates how many events can be simultaneously tracked for the LTSSM state transition tracker. Software must ensure that it does not enable more bits than the Port can enable.

Behavior is undefined if bits 31:1 of this register are changed while Flit Latency Measurement is running (Flit Latency Measurement Enable is 1b and either Flit Response Type is non-zero and Flit Latency Tracking Status is 00b or 01b, or LTSSM State Transition Tracker is non-zero and any of the enabled LTSSM State Transition Tracking Status fields are 00b or 01b).

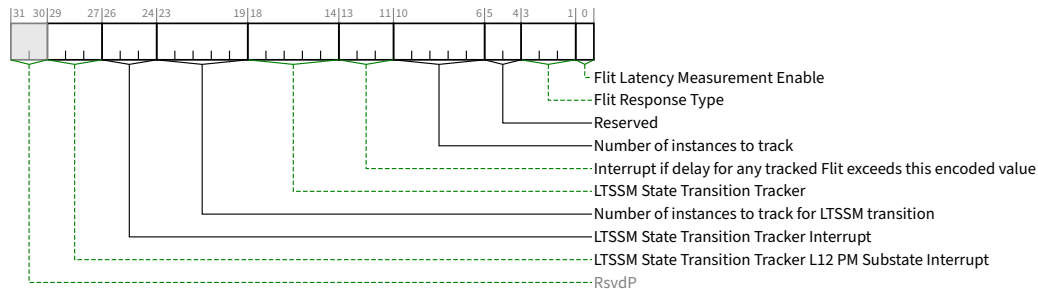

Figure 7-208 Flit Performance Measurement Control Register §

Table 7-189 Flit Performance Measurement Control Register §

Bit Location	Register Description	Attributes
0	<p>Flit Latency Measurement Enable – Setting this bit to 1b enables and starts measuring the Ack/ Nak/ Replay latency of a Flit. Writing a 0b to this bit when a measurement is in progress stops the measurement and sets <u>Flit Latency Tracking Status</u> to 10b. Writing this bit to 1b when it is already 1b has no effect.</p> <p>Unit of measurement is 8 ns.</p> <p>Default is <u>Zero</u>.</p>	RW
3:1	<p>Flit Response Type – Setting the associated bit to 1b enables measuring the Nak to Replay, Flit to Nak, or Flit to Ack latency of a Flit, depending on which bit was written. Behavior is undefined if this field changes value while a measurement is in progress. Behavior is undefined if this field contains a Reserved encoding and Flit Latency Measurement Enable is 1b.</p> <p>001b Flit to Ack Latency – this measures the time period from sending an original Flit to receiving an Ack for precisely that Flit at the same Link Width. It does not include Flits that were replayed or Flits that were implicitly Ack'ed by receiving the Ack for a subsequent Flit.</p> <p>010b Flit to Nak Latency – this measures the time period from sending an original Flit to receiving an Nak for precisely that Flit at the same Link Width. It does not include Flits that were replayed or Flits that were implicitly Nak'ed by receiving a Nak for an earlier Flit.</p> <p>100b Nak to Replay Latency – this measures the time period from sending the first Flit containing a Nak for a given sequence number to receiving the first replay of the requested Flit at the same Link Width</p> <p>Others Reserved</p> <p>Default is <u>Zero</u>.</p>	RW

Bit Location	Register Description	Attributes
5:4	Reserved – This field is permitted to be implemented as either <u>RsvdP</u> or <u>RW</u> with no effects. If implemented as <u>RW</u> , default is <u>Zero</u> .	<u>RsvdP</u> / <u>RW</u>
10:6	<p>Number of instances to track</p> <p>0 0000b track the worst-case delay</p> <p>Others track cumulative delay of the indicated number of Flits</p> <p>Behavior is undefined if this field changes value while a measurement is in progress.</p> <p>When this field is <u>Zero</u>, measurement completes when Flit Latency Measurement Enable is cleared.</p> <p>When this field is <u>non-Zero</u>, measurement completes when the indicated number of Flits have been tracked.</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>
13:11	<p>Interrupt if delay for any tracked Flit exceeds this encoded value</p> <p>000b 000b – do not generate an interrupt</p> <p>001b 100 ns</p> <p>010b 200 ns</p> <p>011b 300 ns</p> <p>Others Reserved</p> <p>Behavior is undefined if this field changes value while a measurement is in progress.</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>
18:14	<p>LTSSM State Transition Tracker – Each bit counts as one independent event:</p> <p>Bit 14 L0 to Recovery due to a Framing Error / software directed while in L0.</p> <p>Bit 15 L0p – Electrical Idle to start of Data Stream on Lane on an upconfig.</p> <p>Bit 16 L1.0 to L0.</p> <p>Bit 17 L1.1 to L0.</p> <p>Bit 18 L1.2 to L0.</p> <p>Behavior is undefined if the number of bits set in this field is greater than <u>LTSSM Tracking Register Count</u>.</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>
23:19	<p>Number of instances to track for LTSSM transition</p> <p>0 0000b track the worst-case delay</p> <p>Others aggregate delay of the number presented here</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>
26:24	<p>LTSSM State Transition Tracker Interrupt - Interrupt if any of the events covered by the low 3 bits of <u>LTSSM State Transition Tracker</u> (bits 16:14 of this register) exceeds this encoded value:</p> <p>000b no interrupt generated</p> <p>001b 6.4 ms</p> <p>010b 12.8 ms</p> <p>011b 19.2 ms</p> <p>Others Reserved</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>

Bit Location	Register Description	Attributes
29:27	<p>LTSSM State Transition Tracker L12 PM Substate Interrupt - Interrupt if any of the events covered by upper 2 bits of LTSSM State Transition Tracker (bits 18:17 of this register) exceeds this value:</p> <p>000b no interrupt generated</p> <p>001b 1 sec</p> <p>010b 2 sec</p> <p>011b 3 sec</p> <p>100b 4 sec</p> <p>101b 5 sec</p> <p>110b 10 sec</p> <p>111b Reserved</p> <p>Default is <u>Zero</u>.</p>	<u>RW</u>

7.8.12.4 Flit Performance Measurement Status Register (Offset 0Ch) §

Figure 7-209 Flit Performance Measurement Status Register §

Table 7-190 Flit Performance Measurement Status Register §

Bit Location	Register Description	Attributes
1:0	<p>Flit Latency Tracking Status</p> <p>00b Not started</p> <p>01b Started</p> <p>10b Completed</p> <p>11b Completed with Error (counter overflow)</p> <p>Default is <u>Zero</u>.</p>	<u>RO</u>
6:2	<p>Flit Latency Tracking – This field indicates the exact number of Flits which have been tracked and recorded in Flit Latency Tracking Counter. This field does not roll over.</p> <p>When <u>Number of instances to track</u> is non-Zero, this field will be less than or equal to <u>Number of instances to track</u>.</p> <p>When <u>Number of instances to track</u> is Zero, this field may contain any value.</p> <p>If <u>Flit Latency Tracking Status</u> is 11b, this field is undefined.</p> <p>Default is <u>Zero</u>.</p>	<u>RO</u>
7	<p>Interrupt generated based on trigger event – this bit is Set to 1b if an interrupt is generated based on the trigger event count due to Flit Latency Tracking. While this bit is Set to 1b, no new interrupts will be generated based on the trigger event.</p>	<u>RW1C</u>

Bit Location	Register Description	Attributes
	Default is <u>Zero</u> .	
23:8	<p>Flit Latency Tracking Counter</p> <p>If Number of instances to track is non-Zero, this field contains the sum of the latency values measures for the tracked Flits. Software can divide this value by the Flit Latency Tracking field to compute the average latency.</p> <p>If Number of instances to track is Zero, this field contains the largest latency measured for the tracked Flits.</p> <p>If Flit Latency Tracking Status is 11b, this field is undefined.</p> <p>The measurement unit is 8 μs.</p> <p>Default is <u>Zero</u>.</p>	<u>RO</u>

IMPLEMENTATION NOTE: FLIT PERFORMANCE MEASUREMENT OPERATION §

Flit Performance Measurement allows software to measure the Link Latency for the selected Flit types. These measurements reflect the timer period from when the tracked Flit is sent to when the tracking complete Flit is received. It is strongly recommended that these two events be consistent with each other (e.g., measure from when the first bit of a

Flit was transmitted to when the first bit of a Flit was received). When performing a measurement, software should disable Link width changes by configuring Target Link Width and Hardware Autonomous Width Disable. Not doing this can result in inaccurate measurement values.

7.8.12.5 LTSSM Performance Measurement Status Register (Offsets 10h to 20h) §

Up to 5 instances of the following register are supported. Each register instance supports measurement of one LTSSM state transition tracking. If multiple entries are supported the order of association is based on the bits being enabled in the control register. Software must not enable additional bits for LTSSM state transition tracking while measurement of some events in that category is in progress.

Figure 7-210 LTSSM Performance Measurement Status Register §

Table 7-191 LTSSM Performance Measurement Status Register §

Bit Location	Register Description	Attributes
1:0	<p>LTSSM State Transition Tracking Status</p> <p>00b Not started</p>	<u>ROS</u>

Bit Location	Register Description	Attributes
	<p>01b Started</p> <p>10b Completed</p> <p>11b Error (including counter overflow)</p> <p>Cleared on 0b to 1b transition of <u>Flit Latency Measurement Enable</u>.</p> <p>Default is <u>Zero</u>.</p>	
6:2	<p>LTSSM State Transition Tracking – number of LTSSM state transitions of the measured type tracked so far.</p> <p>This number does not roll over.</p> <p>Cleared on 0b to 1b transition of <u>Flit Latency Measurement Enable</u>.</p> <p>Default is <u>Zero</u>.</p>	<u>ROS</u>
7	<p>Interrupt generated based on trigger event count due to LTSSM State Transition Tracking – this bit is Set when an interrupt is generated based on the trigger event. While this bit is Set, no new interrupts will be generated based on the trigger event.</p> <p>Default is <u>Zero</u>.</p>	<u>RW1CS</u>
23:8	<p>LTSSM State Transition Tracking Counter</p> <p>The measurement unit is 64 usec.</p> <p>Cleared on 0b to 1b transition of <u>Flit Latency Measurement Enable</u>.</p> <p>Default is <u>Zero</u>.</p>	<u>ROS</u>

7.8.13 Flit Error Injection Extended Capability §

This capability is optional. This capability is permitted in Downstream Ports, in Function 0 of an Upstream Port, and in RCRBs. This capability is not permitted in other Functions.

This capability is only used in Flit Mode. The capability has no effect in Non-Flit Mode.

§ Figure 7-211 details allocation of the register bits in the Flit Error Injection Extended Capability structure.

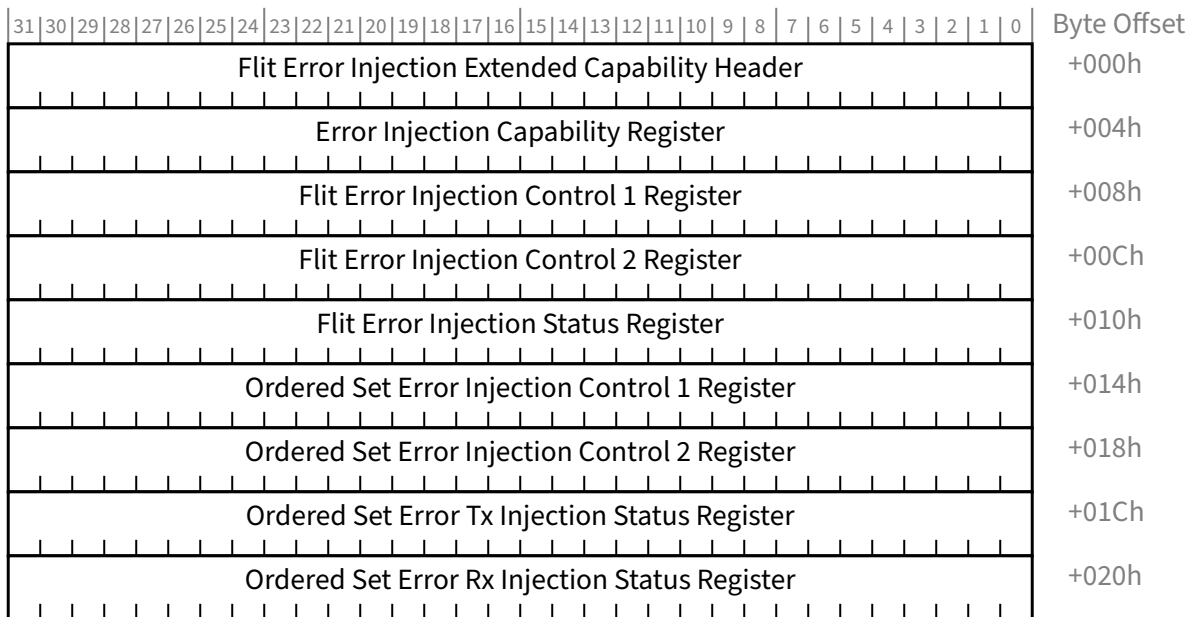

Figure 7-211 Flit Error Injection Extended Capability Structure §

7.8.13.1 Flit Error Injection Extended Capability Header (Offset 00h) §

§ Figure 7-212 details allocation of the register fields in the Flit Error Injection Extended Capability Header; § Table 7-192 provides the respective bit definitions.

Figure 7-212 Flit Error Injection Extended Capability Header §

Table 7-192 Flit Error Injection Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	Flit Error Injection Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Flit Error Injection Extended Capability is 0034h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO

Bit Location	Register Description	Attributes
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.8.13.2 Flit Error Injection Capability Register (Offset 04h) §

Figure 7-213 Flit Error Injection Capability Register §

Table 7-193 Flit Error Injection Capability Register §

Bit Location	Register Description	Attributes
31:0	Reserved	RsvdP

7.8.13.3 Flit Error Injection Control 1 Register (Offset 08h) §

Link level, optional register, both on Tx side as well as Rx side. Behavior is undefined if bits 31:1 of this register change value when error injection is running (Flit Error Injection Enable is 1b and Flit Error Injection Status is 00b or 01b).

Figure 7-214 Flit Error Injection Control 1 Register §

Table 7-194 Flit Error Injection Control 1 Register §

Bit Location	Register Description	Attributes
0	Flit Error Injection Enable – Setting this bit enables and starts the error injection in the Link. Clearing to this bit stops the error injection.	RW

Bit Location	Register Description	Attributes
	Default <u>Zero</u> .	
1	Inject Errors on Transmitted Flits – Setting this bit to 1b enables error injection in the Transmitted Flits. A Port that does not implement this functionality must hardwire this bit to 0b. Default is <u>Zero</u> .	<u>RW</u>
2	Inject Errors on Received Flits – Setting this bit enables error injection in the Received Flits. A Port is permitted to not inject the exact error described but mimic an error injection effect to achieve the desired effect such as logging FEC-correctable errors or causing NAKs after CRC check. A Port that does not implement this functionality must hardwire this bit to 0b. Default is <u>Zero</u> .	<u>RW</u>
15:3	Flit Error Injection Enable Data Rate – These bits enable the Flit error injection for the corresponding data rates when enabled Bit 3 2.5 GT/s Bit 4 5.0 GT/s Bit 5 8.0 GT/s Bit 6 16.0 GT/s Bit 7 32.0 GT/s Bit 8 64.0 GT/s Bits 15:9 RsvdP Default is <u>Zero</u> .	<u>RW / RsvdP</u>
20:16	Number of Errors Injected – This represents the number of errors to be injected on the Transmitted and/or Received Flits independently. A value of 0 indicates that error injection continues till the injection mechanism is disabled. Default is <u>Zero</u> .	<u>RW</u>
28:21	Spacing Between Injected Errors – This represents the next Flit on which error will be injected after the current sequence of Flit error injection completes. A non-0 value indicates the exact number of Flits after which the error is injected; a 0 value will inject the errors after a pseudo-random number of Flits between 1 to 127, chosen with equal probability. This is used on the Transmit and/or Received side independently. Default is <u>Zero</u> .	<u>RW</u>
31:29	Injection on Flit Type – 000b Inject on any Flit Type 001b Inject on any non-IDLE Flit 010b Inject only on Payload Flit 011b Inject only on NOP Flit 100b Inject only on IDLE Flit 101b If Error Type Being Injected is 11b, Inject only on a Payload Flit and then subsequently on the same sequence number for the Consecutive Error Injection times. The entire repeat will be considered as one instance of error injection for the purposes of counting towards the number of errors injected. Reserved encoding if Error Type Being Injected is other than 11b. 110b If Error Type Being Injected is 11b, Inject only on a Payload Flit along with subsequent injection on one selected Payload Flit with the same sequence number for Consecutive Error Injection times. Exactly one sequence number is selected for consecutive error injection	<u>RW</u>

Bit Location	Register Description	Attributes
	<p>among all the outstanding Payload Flits injected with FEC-uncorrectable errors. The entire repeat will be considered as one instance of error injection for the purposes of counting towards the number of errors injected. Reserved encoding if Error Type Being Injected is other than 11b.</p> <p>111b Reserved</p> <p>Default is <u>Zero</u></p>	

7.8.13.4 Flit Error Injection Control 2 Register (Offset 0Ch) §

Link level, optional register, both on Tx side as well as Rx side. Behavior is undefined if this register changes value when error injection is running (Flit Error Injection Enable is 1b and Flit Error Injection Status is 00b or 01b).

Figure 7-215 Flit Error Injection Control 2 Register §

Table 7-195 Flit Error Injection Control 2 Register §

Bit Location	Register Description	Attributes
2:0	<p>Consecutive Error Injection – The number of consecutive Flits that will be injected with the error, irrespective of the type of Flit on which the error is supposed to be initially injected. For the Injection of Flit Type encoding of 101b and 110b, this field has additional meaning, as described above. Even if multiple consecutive Flits will be injected with an error because of this, the entire sequence will count as one towards the number of errors injected.</p> <p>00b No consecutive error injection</p> <p>001b to 110b One to six consecutive error injections</p> <p>111b A pseudo-random number between 7 and 15, each selected with equal probability</p> <p>Default is <u>Zero</u>.</p>	RW
4:3	<p>Error Type Being Injected –</p> <p>00b Random between FEC-correctable or FEC-uncorrectable</p> <p>01b FEC-Correctable error injected only in one FEC group (rotate across the groups in subsequent injections)</p> <p>10b FEC-Correctable error injected in all 3 FEC groups simultaneously</p> <p>11b FEC-Uncorrectable error injected</p> <p>Default is <u>Zero</u>.</p>	RW
11:5	<p>Error Offset within Flit – For FEC-correctable error(s): Byte offset within FEC-group where error will be injected. If this value is greater than the number of bytes in the FEC group, an error must be injected on any byte in the FEC-group with equal probability using a pseudo-random number generator.</p>	RW

Bit Location	Register Description	Attributes
	For uncorrectable error(s): Distance between subsequent injected error bytes with the initial starting position at byte 0. If at least 8 bytes have not been injected with an error, the Port must inject errors in some of the FEC bytes to get to 8 bytes in error. Default is <u>Zero</u> .	
19:12	Error Magnitude – magnitude of error injected in each byte where error has been injected 00h any pseudo-random non-0 value with equal probability Others exact error magnitude Default is <u>Zero</u> .	<u>RW</u>

7.8.13.5 Flit Error Injection Status Register (Offset 10h) §

Figure 7-216 Flit Error Injection Status Register §

Table 7-196 Flit Error Injection Status Register §

Bit Location	Register Description	Attributes
1:0	Flit Error Tx Injection Status 00b Not injected any error yet 01b At least one error is injected, but not completed 10b Error injection completed 11b Error case – error injection aborted, either <u>Flit Error Injection Enable</u> was cleared while injection was incomplete or optionally <u>Flit Error Injection Control 1 [31:1]</u> or <u>Flit Error Injection Control 2</u> was changed while Injection was enabled and not complete. This field is cleared on the 0b to 1b transition of <u>Flit Error Injection Enable</u> . Default is <u>Zero</u> .	<u>RO</u>
3:2	Flit Error Rx Injection Status 00b Not injected any error yet 01b At least one error is injected, but not completed 10b Error injection completed 11b Error case – error injection aborted, either <u>Flit Error Injection Enable</u> was cleared while injection was incomplete or optionally <u>Flit Error Injection Control 1 [31:1]</u> or <u>Flit Error Injection Control 2</u> was changed while Injection was enabled and not complete. This field is cleared on the 0b to 1b transition of <u>Flit Error Injection Enable</u> . Default is <u>Zero</u> .	<u>RO</u>

7.8.13.6 Ordered Set Error Injection Control 1 Register (Offset 14h) §

Link level, optional register, both on Tx side as well as Rx side. A Port that does not implement the functionality must hardwire these bits to 0b. Behavior is undefined if bits 63:1 of this register change value when Ordered Set Injection Enable is Set and Ordered Set Error Injection Status is 00b or 01b.

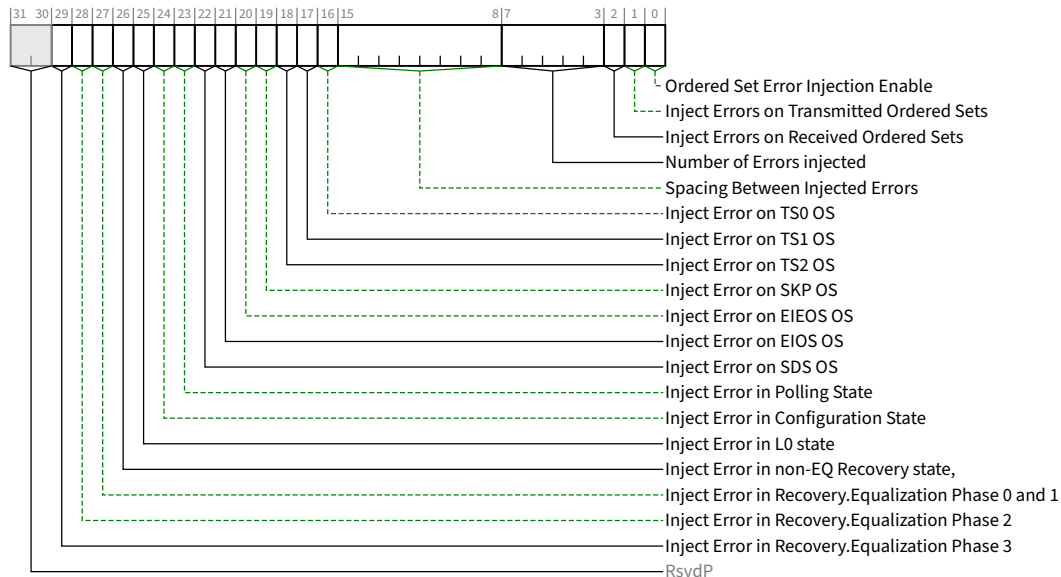

Figure 7-217 Ordered Set Error Injection Control 1 Register §

Table 7-197 Ordered Set Error Injection Control 1 Register §

Bit Location	Register Description	Attributes
0	<p>Ordered Set Error Injection Enable – Setting this bit enables and starts Error Injection on the Link. Clearing this bit stops the error injection.</p> <p>Behavior is undefined if <u>Ordered Set Error Injection Enable</u> is Set and <u>Inject Errors on Transmitted Ordered Sets</u> and <u>Inject Errors on Received Ordered Sets</u> are both Clear.</p> <p>Default is <u>Zero</u>.</p>	RWS
1	<p>Inject Errors on Transmitted Ordered Sets – Setting this bit to 1b enables error injection in the Transmitted Ordered Sets. A Port that does not implement this functionality must hardwire this bit to 0b.</p> <p>Behavior is undefined if <u>Ordered Set Error Injection Enable</u>, <u>Inject Errors on Transmitted Ordered Sets</u>, and <u>Inject Errors on Received Ordered Sets</u> are all Set.</p> <p>Default is <u>Zero</u>.</p>	RWS
2	<p>Inject Errors on Received Ordered Sets – Setting this bit enables error injection in the Received Ordered Sets. A Port is permitted to not inject the exact error described but treat the Ordered Set as invalid. A Port that does not implement this functionality must hardwire this bit to 0b.</p> <p>Behavior is undefined if <u>Ordered Set Error Injection Enable</u>, <u>Inject Errors on Transmitted Ordered Sets</u>, and <u>Inject Errors on Received Ordered Sets</u> are all Set.</p> <p>Default is <u>Zero</u>.</p>	RWS

Bit Location	Register Description	Attributes
7:3	Number of Errors injected – This represents the number of errors to be injected. A value of 0 indicates that error injection continues till the injection mechanism is disabled. Default is <u>Zero</u> .	<u>RWS</u>
15:8	Spacing Between Injected Errors – This represents the next OS on which error will be injected after the current OS error injection completes. A non-0 value indicates the exact number of OSs after which the error is injected; a 0 value will inject the errors after a pseudo-random number of OSs between 1 to 127, chosen with equal probability. This is used on the Transmit and/or Received side independently. Default is <u>Zero</u> .	<u>RWS</u>
16	Inject Error on TS0 OS – When Set, injects errors on <u>TS0 OS</u> .	<u>RWS</u>
17	Inject Error on TS1 OS – When Set, injects errors on <u>TS1 OS</u> .	<u>RWS</u>
18	Inject Error on TS2 OS – When Set, injects errors on <u>TS2 OS</u> .	<u>RWS</u>
19	Inject Error on SKP OS – When Set, injects errors on <u>SKP OS</u> .	<u>RWS</u>
20	Inject Error on EIEOS OS – When Set, injects errors on <u>EIEOS OS</u> .	<u>RWS</u>
21	Inject Error on EIOS OS – When Set, injects errors on <u>EIOS OS</u> .	<u>RWS</u>
22	Inject Error on SDS OS – When Set, injects errors on <u>SDS OS</u> .	<u>RWS</u>
23	Inject Error in Polling State – When Set, injects errors in the <u>Polling LTSSM state</u> .	<u>RWS</u>
24	Inject Error in Configuration State – When Set, injects errors in the <u>Configuration LTSSM state</u> .	<u>RWS</u>
25	Inject Error in L0 state – When Set, injects errors in the <u>L0 LTSSM state</u> .	<u>RWS</u>
26	Inject Error in non-EQ Recovery state , – When Set, injects errors in the <u>Recovery LTSSM states</u> except for the <u>Recovery.Equalization substate</u> .	<u>RWS</u>
27	Inject Error in Recovery.Equalization Phase 0 and 1 – When Set, injects errors <u>Recovery.Equalization Phase 0 and Phase 1</u> .	<u>RWS</u>
28	Inject Error in Recovery.Equalization Phase 2 – When Set, injects errors <u>Recovery.Equalization Phase 2</u> .	<u>RWS</u>
29	Inject Error in Recovery.Equalization Phase 3 – When Set, injects errors <u>Recovery.Equalization Phase 3</u> .	<u>RWS</u>

7.8.13.7 Ordered Set Error Injection Control 2 Register (Offset 18h) §

Figure 7-218 Ordered Set Error Injection Control 2 Register §

Table 7-198 Ordered Set Error Injection Control 2 Register §

Bit Location	Register Description	Attributes
15:0	Error Injection Bytes – Individual bytes where errors (any magnitude) will be injected; all 0s indicates a byte will be chosen based on a pseudo-random generator between 1 and 16. For SKP OS, each bit covers 2.5 Bytes instead of one byte	RWS
31:16	Lane Number for Error Injection – A value of 1b in one or more bit positions indicates that the corresponding Lane number will participate in error injection when enabled. Bit 0 of this field corresponds to Lane 0.	RWS

7.8.13.8 Ordered Set Error Tx Injection Status Register (Offset 1Ch) §

This register contains a set of fields for Tx Ordered Set Error Injection. The description for Tx Injection Status TS0 applies to all fields in this register.

7.9 Additional PCI and PCIe Capabilities §

This section, contains a description of additional PCI and PCIe capabilities that are individually optional in this but may be required by other PCISIG specifications.

7.9.1 Virtual Channel Extended Capability §

The Virtual Channel Extended Capability (***VC Extended Capability***) is an optional Extended Capability required for devices that have Ports (or for individual Functions) that support functionality beyond the default Traffic Class (TC0) over the default Virtual Channel (VC0). This may apply to devices with only one VC that support TC filtering or to devices that support multiple VCs. Note that a PCI Express device that supports only TC0 over VC0 does not require VC Extended Capability and associated registers. § Figure 7-221 provides a high level view of the Virtual Channel Extended Capability structure. This structure controls Virtual Channel assignment for PCI Express Links and may be present in any device (or RCRB) that contains (controls) a Port, or any device that has a Multi-Function Virtual Channel (MFVC) Capability structure. Some registers/fields in the Virtual Channel Extended Capability structure may have different interpretation

for Endpoints, Switch Ports, Root Ports and RCRB. Software must interpret the Device/Port Type field in the PCI Express Capabilities register to determine the availability and meaning of these registers/fields.

The number of (extended) Virtual Channels is indicated by the Extended VC Count field in the Port VC Capability Register 1. Software must interpret this field to determine the availability of extended VC Resource registers.

The VC Extended Capability structure is permitted in the Extended Configuration Space of all single-Function devices or in RCRBs.

Each VF uses the Virtual Channel of its associated PF. VFs themselves must not contain any Virtual Channel Capabilities.

A Multi-Function Device at an Upstream Port is permitted to contain a Multi-Function Virtual Channel (MFVC) Capability structure (see § Section 7.9.2). If a Multi-Function Device contains an MFVC Capability structure, any or all of its Functions with the exception of VFs are permitted to contain a VC Extended Capability structure. Per-Function VC Extended Capability structures are also permitted for devices inside a Switch that contain only Switch Downstream Port Functions, or for RCiEPs. Otherwise, only Function 0 is permitted to contain a VC Extended Capability structure.

To preserve software backward compatibility, two Extended Capability IDs are permitted for VC Extended Capability structures: 0002h and 0009h. Any VC Extended Capability structure in a device that also contains an MFVC Capability structure must use the Extended Capability ID 0009h. A VC Extended Capability structure in a device that does not contain an MFVC Capability structure must use the Extended Capability ID 0002h.

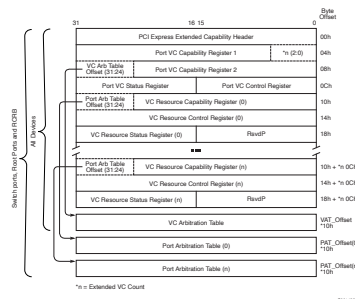

Figure 7-221 Virtual Channel Extended Capability Structure §

The following sections describe the registers/fields of the Virtual Channel Extended Capability structure.

7.9.1.1 Virtual Channel Extended Capability Header (Offset 00h) §

Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability header. A Virtual Channel Extended Capability must use one of two Extended Capability IDs: 0002h or 0009h. Refer to § Section 7.9.1 for rules governing when each should be used. § Figure 7-222 details allocation of register fields in the Virtual Channel Extended Capability Header; § Table 7-201 provides the respective bit definitions.

Figure 7-222 Virtual Channel Extended Capability Header §

Table 7-201 Virtual Channel Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the <u>Virtual Channel Extended Capability</u> is either 0002h or 0009h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.1.2 Port VC Capability Register 1 (Offset 04h) §

The Port VC Capability Register 1 describes the configuration of the Virtual Channels associated with a PCI Express Port. § Figure 7-223 details allocation of register fields in the Port VC Capability Register 1; § Table 7-202 provides the respective bit definitions.

Figure 7-223 Port VC Capability Register 1 §

Table 7-202 Port VC Capability Register 1 §

Bit Location	Register Description	Attributes
2:0	Extended VC Count - Indicates the number of (extended) Virtual Channels in addition to the default VC supported by the device. This field is valid for all Functions. This value indicates the number of (extended) VC Resource Capability, Control, and Status registers that are present in Configuration Space in addition to the required VC Resource registers for the default VC. The minimum value of this field is 0 (for devices that only support the default VC and only have 1 set of VC Resource Registers for that VC). The maximum value is 7.	RO
6:4	Low Priority Extended VC Count - Indicates the number of (extended) Virtual Channels in addition to the default VC belonging to the low-priority VC (LPVC) group that has the lowest priority with respect to other VC resources in a strict-priority VC Arbitration. This field is valid for all Functions. The minimum value of this field is 000b and the maximum value is Extended VC Count.	RO

Bit Location	Register Description	Attributes
9:8	<p>Reference Clock - Indicates the reference clock for Virtual Channels that support time-based WRR Port Arbitration. This field is valid for RCRBs, Switch Ports, and Root Ports that support peer-to-peer traffic. It is not valid for Root Ports that do not support peer-to-peer traffic, Endpoints, and Switches or Root Complexes not implementing WRR, and must be hardwired to 00b.</p> <p>Defined encodings are:</p> <p>00b 100 ns reference clock</p> <p>01b - 11b Reserved</p>	RO
11:10	<p>Port Arbitration Table Entry Size - Indicates the size (in bits) of Port Arbitration table entry in the Function. This field is valid only for RCRBs, Switch Ports, and Root Ports that support peer-to-peer traffic. It is not valid and must be hardwired to 00b for Root Ports that do not support peer-to-peer traffic and Endpoints.</p> <p>Defined encodings are:</p> <p>00b The size of Port Arbitration table entry is 1 bit.</p> <p>01b The size of Port Arbitration table entry is 2 bits.</p> <p>10b The size of Port Arbitration table entry is 4 bits.</p> <p>11b The size of Port Arbitration table entry is 8 bits.</p>	RO

7.9.1.3 Port VC Capability Register 2 (Offset 08h) §

The Port VC Capability Register 2 provides further information about the configuration of the Virtual Channels associated with a PCI Express Port. § Figure 7-224 details allocation of register fields in the Port VC Capability Register 2; § Table 7-203 provides the respective bit definitions.

Figure 7-224 Port VC Capability Register 2 §

Table 7-203 Port VC Capability Register 2 §

Bit Location	Register Description	Attributes
7:0	<p>VC Arbitration Capability - Indicates the types of VC Arbitration supported by the Function for the LPVC group. This field is valid for all Functions that report a Low Priority Extended VC Count field greater than 0. For all other Functions, this field must be hardwired to 00h.</p> <p>Each Bit Location within this field corresponds to a VC Arbitration Capability defined below. When more than 1 bit in this field is Set, it indicates that the Port can be configured to provide different VC arbitration services.</p> <p>Defined bit positions are:</p> <p>Bit 0 Hardware fixed arbitration scheme, e.g., Round Robin</p>	RO

Bit Location	Register Description	Attributes
	<p>Bit 1 Weighted Round Robin (WRR) arbitration with 32 phases</p> <p>Bit 2 WRR arbitration with 64 phases</p> <p>Bit 3 WRR arbitration with 128 phases</p> <p>Bits 4-7 Reserved</p>	
31:24	<p>VC Arbitration Table Offset - Indicates the location of the VC Arbitration Table. This field is valid for all Functions.</p> <p>This field contains the zero-based offset of the table in DQWORDS (16 bytes) from the base address of the <u>Virtual Channel Extended Capability</u> structure. A value of 0 indicates that the table is not present.</p>	<u>RO</u>

7.9.1.4 Port VC Control Register (Offset 0Ch) §

§ Figure 7-225 details allocation of register fields in the Port VC Control Register; § Table 7-204 provides the respective bit definitions.

Figure 7-225 Port VC Control Register §

Table 7-204 Port VC Control Register §

Bit Location	Register Description	Attributes
0	<p>Load VC Arbitration Table - Used by software to update the VC Arbitration Table. This bit is valid for all Functions when the selected VC Arbitration uses the VC Arbitration Table.</p> <p>Software sets this bit to request hardware to apply new values programmed into VC Arbitration Table; clearing this bit has no effect. Software checks the VC Arbitration Table Status bit to confirm that new values stored in the VC Arbitration Table are latched by the VC arbitration logic.</p> <p>This bit always returns 0b when read.</p>	<u>RW</u>
3:1	<p>VC Arbitration Select - Used by software to configure the VC arbitration by selecting one of the supported VC Arbitration schemes indicated by the VC Arbitration Capability field in the <u>Port VC Capability Register 2</u>. This field is valid for all Functions.</p> <p>The permissible values of this field are numbers corresponding to one of the asserted bits in the VC Arbitration Capability field.</p> <p>This field cannot be modified when more than one VC in the LPVC group is enabled.</p>	<u>RW</u>
4	<p>All VCs Enabled - Setting this bit indicates that all VCs that will be used by the Port have been enabled. Setting this bit allows hardware to allocate assigned buffer resources across the enabled VCs.</p>	<u>RW</u>

Bit Location	Register Description	Attributes
	Setting this bit is optional. If this bit remains Clear and some VC Resources are never enabled, performance may be affected but the Link and all enabled VCs must operate correctly. Behavior is undefined if this bit is Set and any VC Enable bit in this capability changes value. Default value of this bit is 0b.	

7.9.1.5 Port VC Status Register (Offset 0Eh) §

The Port VC Status Register provides status of the configuration of Virtual Channels associated with a Port. § Figure 7-226 details allocation of register fields in the Port VC Status Register; § Table 7-205 provides the respective bit definitions.

Figure 7-226 Port VC Status Register §

Table 7-205 Port VC Status Register §

Bit Location	Register Description	Attributes
0	VC Arbitration Table Status - Indicates the coherency status of the VC Arbitration Table. This bit is valid for all Functions when the selected VC uses the VC Arbitration Table. This bit is Set by hardware when any entry of the VC Arbitration Table is written by software. This bit is Cleared by hardware when hardware finishes loading values stored in the VC Arbitration Table after software sets the Load VC Arbitration Table bit in the <u>Port VC Control Register</u> . Default value of this bit is 0b.	RO

7.9.1.6 VC Resource Capability Register §

The VC Resource Capability Register describes the capabilities and configuration of a particular Virtual Channel resource. § Figure 7-227 details allocation of register fields in the VC Resource Capability Register; § Table 7-206 provides the respective bit definitions.

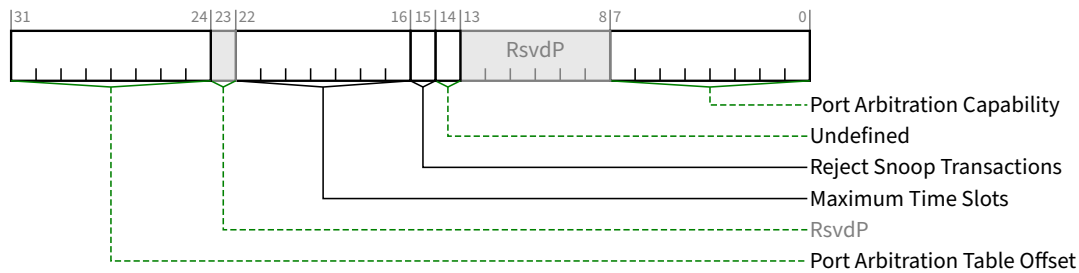

Figure 7-227 VC Resource Capability Register §

Table 7-206 VC Resource Capability Register §

Bit Location	Register Description	Attributes
7:0	<p>Port Arbitration Capability - Indicates types of Port Arbitration supported by the VC resource. This field is valid for all Switch Ports, Root Ports that support peer-to-peer traffic, and RCRBs, but not for Endpoints or Root Ports that do not support peer-to-peer traffic.</p> <p>Each Bit Location within this field corresponds to a Port Arbitration Capability defined below. When more than 1 bit in this field is Set, it indicates that the VC resource can be configured to provide different arbitration services.</p> <p>Software selects among these capabilities by writing to the <u>Port Arbitration Select</u> field (see § Section 7.9.1.7).</p> <p>Defined bit positions are:</p> <ul style="list-style-type: none"> Bit 0 Non-configurable hardware-fixed arbitration scheme, e.g., Round Robin (RR) Bit 1 Weighted Round Robin (WRR) arbitration with 32 phases Bit 2 WRR arbitration with 64 phases Bit 3 WRR arbitration with 128 phases Bit 4 Time-based WRR with 128 phases Bit 5 WRR arbitration with 256 phases Bits 6-7 Reserved 	RO
14	<p>Undefined Undefined - The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate Advanced Packet Switching. System software must ignore the value read from this bit.</p>	RO
15	<p>Reject Snoop Transactions - When Clear, transactions with or without the No Snoop bit Set within the TLP header are allowed on this VC. When Set, any transaction for which the No Snoop attribute is applicable but is not Set within the TLP header is permitted to be rejected as an Unsupported Request. Refer to § Section 2.2.6.5 for information on where the No Snoop attribute is applicable. This bit is valid for Root Ports and RCRB; it is not valid for Endpoints or Switch Ports.</p>	HwInit
22:16	<p>Maximum Time Slots - Indicates the maximum number of time slots (minus one) that the VC resource is capable of supporting when it is configured for time-based WRR Port Arbitration. For example, a value 000 0000b in this field indicates the supported maximum number of time slots is 1 and a value of 111 1111b indicates the supported maximum number of time slots is 128. This field is valid for all Switch Ports, Root Ports that support peer-to-peer traffic, and RCRBs, but is not valid for Endpoints or Root Ports that do not support peer-to-peer traffic. In addition, this field is valid only when the <u>Port Arbitration Capability</u> field indicates that the VC resource supports time-based WRR Port Arbitration.</p>	HwInit

Bit Location	Register Description	Attributes
31:24	<p>Port Arbitration Table Offset - Indicates the location of the Port Arbitration Table associated with the VC resource. This field is valid for all Switch Ports, Root Ports that support peer-to-peer traffic, and RCRBs, but is not valid for Endpoints or Root Ports that do not support peer-to-peer traffic.</p> <p>This field contains the zero-based offset of the table in DQWORDS (16 bytes) from the base address of the Virtual Channel Extended Capability structure. A value of 00h indicates that the table is not present.</p>	RO

7.9.1.7 VC Resource Control Register §

§ Figure 7-228 details allocation of register fields in the VC Resource Control Register; § Table 7-207 provides the respective bit definitions.

Figure 7-228 VC Resource Control Register §

Table 7-207 VC Resource Control Register §

Bit Location	Register Description	Attributes
7:0	<p>TC/VC Map - This field indicates the TCs that are mapped to the VC resource. This field is valid for all Functions.</p> <p>Bit locations within this field correspond to TC values. For example, when bit 7 is Set in this field, TC7 is mapped to this VC resource. When more than 1 bit in this field is Set, it indicates that multiple TCs are mapped to the VC resource.</p> <p>In order to remove one or more TCs from the TC/VC Map of an enabled VC, software must ensure that no new or outstanding transactions with the TC labels are targeted at the given Link.</p> <p>Default value of this field is FFh for the first VC resource and is 00h for other VC resources.</p> <p>Note: Bit 0 of this field is read-only. It must be Set for the default VC0 and Clear for all other enabled VCs.</p>	RW (see the note for exceptions)
16	<p>Load Port Arbitration Table - When Set, this bit updates the Port Arbitration logic from the Port Arbitration Table for the VC resource. This bit is valid for all Switch Ports, Root Ports that support peer-to-peer traffic, and RCRBs, but is not valid for Endpoints or Root Ports that do not support peer-to-peer traffic. In addition, this bit is only valid when the Port Arbitration Table is used by the selected Port Arbitration scheme (that is indicated by a Set bit in the Port Arbitration Capability field selected by Port Arbitration Select).</p> <p>Software sets this bit to signal hardware to update Port Arbitration logic with new values stored in Port Arbitration Table; clearing this bit has no effect. Software uses the Port Arbitration Table Status bit to confirm whether the new values of Port Arbitration Table are completely latched by the arbitration logic.</p> <p>This bit always returns 0b when read.</p>	RW

Bit Location	Register Description	Attributes																
	Default value of this bit is 0b.																	
19:17	<p>Port Arbitration Select - This field configures the VC resource to provide a particular Port Arbitration service. This field is valid for RCRBs, Root Ports that support peer-to-peer traffic, and Switch Ports, but is not valid for Endpoints or Root Ports that do not support peer-to-peer traffic.</p> <p>The permissible value of this field is a number corresponding to one of the asserted bits in the <u>Port Arbitration Capability</u> field of the VC resource.</p>	<u>RW</u>																
26:24	<p>VC ID - This field assigns a VC ID to the VC resource (see note for exceptions). This field is valid for all Functions.</p> <p>This field cannot be modified when the VC is already enabled.</p> <p>Note:</p> <p>For the first VC resource (default VC), this field is read-only and must be hardwired to 000b.</p>	<u>RW</u>																
29:27	<p>Shared Flow Control Usage Limit - this field controls what percentage of the available Shared Flow Control a given FC/VC is permitted to consume.</p> <p>This limit is applied independently for each Flow Control credit type. For example, if this field contains 101b and Shared Flow Control Usage Limit Enable is Set, a Posted TLP may not pass the Tx Gate if doing so would cause that VC to consume more than 62.5% of the available Shared Posted Header credits or if doing so would cause that VC to consume more than 62.5% of the available Shared Data credits.</p> <p>If Shared Flow Control Usage Limit Enable is Clear, this field is ignored and this VC is permitted to consume all of the shared credits.</p> <p>When Shared Flow Control Usage Limit Enable is Set, and this field contains 000b, this VC is not permitted to consume any shared credits.</p> <p>Behavior is undefined when all VCs have Shared Flow Control Usage Limit Enable Set and the sum of the Shared Flow Control Limit values for all VCs is less than 100%.</p> <p>Encodings are:</p> <table border="0"> <tr><td>000b</td><td>0%</td></tr> <tr><td>001b</td><td>12.5%</td></tr> <tr><td>010b</td><td>25%</td></tr> <tr><td>011b</td><td>37.5%</td></tr> <tr><td>100b</td><td>50%</td></tr> <tr><td>101b</td><td>62.5%</td></tr> <tr><td>110b</td><td>75%</td></tr> <tr><td>111b</td><td>87.5%</td></tr> </table> <p>Behavior is undefined if this field changes value while VC Enable and Shared Flow Control Usage Limit Enable are both Set.</p> <p>This field is <u>RsvdP</u> when <u>Flit Mode Supported</u> is Clear.</p> <p>When <u>Extended VC Count</u> is 0, this field is permitted to be hardwired to any value.</p> <p>When this field is <u>RW</u>, the default value is implementation specific.</p>	000b	0%	001b	12.5%	010b	25%	011b	37.5%	100b	50%	101b	62.5%	110b	75%	111b	87.5%	<u>RW / RO / RsvdP</u>
000b	0%																	
001b	12.5%																	
010b	25%																	
011b	37.5%																	
100b	50%																	
101b	62.5%																	
110b	75%																	
111b	87.5%																	
30	<p>Shared Flow Control Usage Limit Enable - When Set, this bit enables use of the Shared Flow Control Usage Limit value above at the transmitter for this Virtual Channel.</p> <p>Behavior is undefined if the value of this bit changes while VC Enable is Set.</p> <p>This bit is <u>RsvdP</u> when <u>Flit Mode Supported</u> is Clear.</p>	<u>RW / RO / RsvdP</u>																

Bit Location	Register Description	Attributes
	<p>When <u>Extended VC Count</u> is 0, this bit is permitted to be hardwired to 0b.</p> <p>When this bit is <u>RW</u>, the default value is implementation specific.</p>	
31	<p>VC Enable - This bit, when Set, enables a Virtual Channel. The Virtual Channel is disabled when this bit is cleared. This bit is valid for all Functions.</p> <p>Software must use the VC Negotiation Pending bit to check whether the VC negotiation is complete.</p> <p>For VC0, the attribute is <u>RO</u>. If no <u>SVC</u> capability is implemented in this Port, this bit's value must be 1b; otherwise, this bit's value must always be the same value as the <u>Use VC/MFVC</u> bit in the <u>SVC Port Status Register</u>. See § Section 6.3.5.</p> <p>For other VCs, if no <u>SVC</u> capability is implemented in this Port or if the <u>Use VC/MFVC</u> bit is Set, the default value of this bit is 0b and the attribute is <u>RW</u>; otherwise, this bit must be <u>RO</u> with a value of 0b.</p> <p>To enable a Virtual Channel in a Port using VC mechanisms, the VC Enable bit for that Virtual Channel must be Set. The corresponding Virtual Channel in the Link partner Port must be enabled as well, and that Virtual Channel may be in <u>SVC</u>, <u>VC</u>, or <u>MFVC</u> capabilities. To disable a Virtual Channel, Virtual Channel must be disabled in both components on the Link. Software must ensure that no traffic is using a Virtual Channel at the time it is disabled. Software must fully disable a Virtual Channel in both components on a Link before re-enabling the Virtual Channel.</p> <p>When this bit is forced to be <u>RO</u> with a value of 0b due to the <u>Use VC/MFVC</u> bit being Clear, its associated VC is disabled, rendering most of its control registers to be ineffective.</p>	<u>RW/HwInit</u>

7.9.1.8 VC Resource Status Register §

§ Figure 7-229 details allocation of register fields in the VC Resource Status Register; § Table 7-208 provides the respective bit definitions.

Figure 7-229 VC Resource Status Register §

Table 7-208 VC Resource Status Register §

Bit Location	Register Description	Attributes
0	<p>Port Arbitration Table Status - This bit indicates the coherency status of the Port Arbitration Table associated with the VC resource. This bit is valid for <u>RCRBs</u>, Root Ports that support peer-to-peer traffic, and Switch Ports, but is not valid for Endpoints or <u>Root Ports</u> that do not support peer-to-peer traffic. In addition, this bit is valid only when the <u>Port Arbitration Table</u> is used by the selected Port Arbitration for the VC resource.</p> <p>This bit is Set by hardware when any entry of the Port Arbitration Table is written to by software. This bit is Cleared by hardware when hardware finishes loading values stored in the <u>Port Arbitration Table</u> after software sets the <u>Load Port Arbitration Table</u> bit.</p>	<u>RO</u>

Bit Location	Register Description	Attributes
	Default value of this bit is 0b.	
1	<p>VC Negotiation Pending - This bit indicates whether the Virtual Channel negotiation (initialization or disabling) is in pending state. This bit is valid for all Functions.</p> <p>The value of this bit is defined only when the Link is in the <u>DL_Active</u> state and the Virtual Channel is enabled (its VC Enable bit is Set).</p> <p>When this bit is Set by hardware, it indicates that the VC resource has not completed the process of negotiation. This bit is Cleared by hardware after the VC negotiation is complete (on exit from the <u>FC_INIT2</u> state). For VC0, this bit is permitted to be hardwired to 0b.</p> <p>Before using a Virtual Channel, software must check whether the VC Negotiation Pending bits for that Virtual Channel are Clear in both components on the Link.</p>	<u>RO</u>

7.9.1.9 VC Arbitration Table §

The VC Arbitration Table is a read-write register array that is used to store the arbitration table for VC Arbitration. This register array is valid for all Functions when the selected VC Arbitration uses a WRR table. Functions that do not support WRR VC arbitration are not required to implement a VC Arbitration Table. If it exists, the VC Arbitration Table is located by the VC Arbitration Table Offset field.

The VC Arbitration Table is a register array with fixed-size entries of 4 bits. § Figure 7-230 depicts the table structure of an example VC Arbitration Table with 32 phases. Each 4-bit table entry corresponds to a phase within a WRR arbitration period. The definition of table entry is depicted in § Table 7-209. The lower 3 bits (bits 0-2) contain the VC ID value, indicating that the corresponding phase within the WRR arbitration period is assigned to the Virtual Channel indicated by the VC ID (must be a valid VC ID that corresponds to an enabled VC).

The highest bit (bit 3) of the table entry is Reserved. The length of the table depends on the selected VC Arbitration as shown in § Table 7-210.

When the VC Arbitration Table is used by the default VC Arbitration method, the default values of the table entries must be all zero to ensure forward progress for the default VC (with VC ID of 0).

Figure 7-230 Example VC Arbitration Table with 32 Phases §

Table 7-209 Definition of the 4-bit Entries in the VC Arbitration Table §

Bit Location	Description	Attributes
2:0	VC ID	<u>RW</u>
3	<u>RsvdP</u>	<u>RW</u>

Table 7-210 Length of the VC Arbitration Table §

VC Arbitration Select	VC Arbitration Table Length
001b	32 entries
010b	64 entries
011b	128 entries

7.9.1.10 Port Arbitration Table §

The Port Arbitration Table register is a read-write register array that is used to store the WRR or time-based WRR arbitration table for Port Arbitration for the VC resource. This register array is valid for all Switch Ports, Root Ports that support peer-to-peer traffic, and RCRBs, but is not valid for Endpoints or Root Ports that do not support peer-to-peer traffic. It is only present when one or more asserted bits in the Port Arbitration Capability field indicate that the component supports a Port Arbitration scheme that uses a programmable arbitration table. Furthermore, it is only valid when one of the above-mentioned bits in the Port Arbitration Capability field is selected by the Port Arbitration Select field.

The Port Arbitration Table represents one Port arbitration period. § Figure 7-231 shows the structure of an example Port Arbitration Table with 128 phases and 2-bit table entries. Each table entry containing a Port Number corresponds to a phase within a Port arbitration period. For example, a table with 2-bit entries can be used by a Switch component with up to four Ports. A Port Number written to a table entry indicates that the phase within the Port Arbitration period is assigned to the selected PCI Express Port (the Port Number must be a valid one).

- When the WRR Port Arbitration is used for a VC of any Egress Port, at each arbitration phase, the Port Arbiter serves one transaction from the Ingress Port indicated by the Port Number of the current phase. When finished, it immediately advances to the next phase. A phase is skipped, i.e., the Port Arbiter simply moves to the next phase immediately if the Ingress Port indicated by the phase does not contain any transaction for the VC (note that a phase cannot contain the Egress Port's Port Number).
- When the Time-based WRR Port Arbitration is used for a VC of any given Port, at each arbitration phase aligning to a virtual timeslot, the Port Arbiter serves one transaction from the Ingress Port indicated by the Port Number of the current phase. It advances to the next phase at the next virtual timeslot. A phase indicates an “idle” timeslot, i.e., the Port Arbiter does not serve any transaction during the phase, if:
 - the phase contains the Egress Port's Port Number, or
 - the Ingress Port indicated by the phase does not contain any transaction for the VC.
 - The Port Arbitration Table Entry Size field in the Port VC Capability Register 1 determines the table entry size. The length of the table is determined by the Port Arbitration Select field as shown in § Table 7-211.
 - When the Port Arbitration Table is used by the default Port Arbitration for the default VC, the default values for the table entries must contain at least one entry for each of the other PCI Express Ports of the component to ensure forward progress for the default VC for each Port. The table may contain RR or RR-like fair Port Arbitration for the default VC.

Figure 7-231 Example Port Arbitration Table with 128 Phases and 2-bit Table Entries §

Table 7-211 Length of Port Arbitration Table §

Port Arbitration Select	Port Arbitration Table Length
001b	32 entries
010b	64 entries
011b	128 entries
100b	128 entries
101b	256 entries

7.9.2 Multi-Function Virtual Channel Extended Capability §

The Multi-Function Virtual Channel Extended Capability (**MFVC Capability**) is an optional Extended Capability that permits enhanced QoS management in a Multi-Function Device, including TC/VC mapping, optional VC arbitration, and optional Function arbitration for Upstream Requests. When implemented, the MFVC Extended Capability structure must be present in the Extended Configuration Space of Function 0 of the Multi-Function Device's Upstream Port. § Figure 7-232 provides a high level view of the MFVC Extended Capability structure. This MFVC Extended Capability structure controls Virtual Channel assignment at the PCI Express Upstream Port of the Multi-Function Device, while a VC Extended Capability structure, if present in a Function, controls the Virtual Channel assignment for that individual Function.

The number of (extended) Virtual Channels is indicated by the MFVC Extended VC Count field in the Port VC Capability Register 1. Software must interpret this field to determine the availability of extended MFVC VC Resource registers.

A Multi-Function Device is permitted to have an MFVC Extended Capability structure even if none of its Functions have a VC Extended Capability structure. However, an MFVC Extended Capability structure is permitted only in Function 0 in the Upstream Port of a Multi-Function Device.

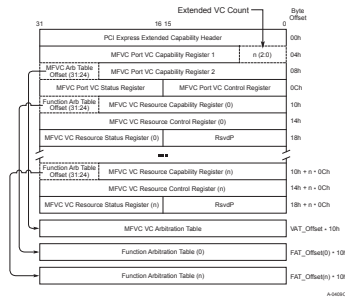

Figure 7-232 MFVC Capability Structure §

The following sections describe the registers/fields of the MFVC Extended Capability structure.

7.9.2.1 MFVC Extended Capability Header (Offset 00h) §

Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability header. The Extended Capability ID for the MFVC Extended Capability is 0008h. § Figure 7-233 details allocation of register fields in the MFVC Extended Capability header; § Table 7-212 provides the respective bit definitions.

Figure 7-233 MFVC Extended Capability Header §

Table 7-212 MFVC Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the MFVC Extended Capability is 0008h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.2.2 MFVC Port VC Capability Register 1 (Offset 04h) §

The MFVC Port VC Capability Register 1 describes the configuration of the Virtual Channels associated with a PCI Express Port of the Multi-Function Device. § Figure 7-234 details allocation of register fields in the MFVC Port VC Capability Register 1; § Table 7-213 provides the respective bit definitions.

Figure 7-234 MFVC Port VC Capability Register 1 §

Table 7-213 MFVC Port VC Capability Register 1 §

Bit Location	Register Description	Attributes
2:0	<p>Extended VC Count - Indicates the number of (extended) Virtual Channels in addition to the default VC supported by the device.</p> <p>This value indicates the number of (extended) MFVC VC Resource Capability, Control, and Status registers that are present in Configuration Space in addition to the required MFVC VC Resource registers for the default VC.</p> <p>The minimum value of this field is 0 (for devices that only support the default VC and only have 1 set of MFVC VC Resource registers for that VC). The maximum value is 7.</p>	RO
6:4	<p>Low Priority Extended VC Count - Indicates the number of (extended) Virtual Channels in addition to the default VC belonging to the low-priority VC (LPVC) group that has the lowest priority with respect to other VC resources in a strict-priority VC Arbitration.</p> <p>The minimum value of this field is 000b and the maximum value is Extended VC Count.</p>	RO
9:8	<p>Reference Clock - Indicates the reference clock for Virtual Channels that support time-based WRR Function Arbitration.</p> <p>Defined encodings are:</p> <p>00b 100 ns reference clock</p> <p>01b - 11b Reserved</p>	RO
11:10	<p>Function Arbitration Table Entry Size - Indicates the size (in bits) of Function Arbitration table entry in the device.</p> <p>Defined encodings are:</p> <p>00b Size of Function Arbitration table entry is 1 bit</p> <p>01b Size of Function Arbitration table entry is 2 bits</p> <p>10b Size of Function Arbitration table entry is 4 bits</p> <p>11b Size of Function Arbitration table entry is 8 bits</p>	RO

7.9.2.3 MFVC Port VC Capability Register 2 (Offset 08h) §

The MFVC Port VC Capability Register 2 provides further information about the configuration of the Virtual Channels associated with a PCI Express Port of the Multi-Function Device. § Figure 7-235 details allocation of register fields in the MFVC Port VC Capability Register 2; § Table 7-214 provides the respective bit definitions.

Figure 7-235 MFVC Port VC Capability Register 2 §

Table 7-214 MFVC Port VC Capability Register 2 §

Bit Location	Register Description	Attributes
7:0	<p>VC Arbitration Capability - Indicates the types of VC Arbitration supported by the device for the LPVC group. This field is valid for all devices that report a Low Priority Extended VC Count greater than 0.</p> <p>Each Bit Location within this field corresponds to a VC Arbitration Capability defined below. When more than 1 bit in this field is Set, it indicates that the device can be configured to provide different VC arbitration services.</p> <p>Defined bit positions are:</p> <ul style="list-style-type: none"> Bit 0 Hardware fixed arbitration scheme, e.g., Round Robin Bit 1 Weighted Round Robin (WRR) arbitration with 32 phases Bit 2 WRR arbitration with 64 phases Bit 3 WRR arbitration with 128 phases Bits 4-7 Reserved 	RO
31:24	<p>VC Arbitration Table Offset - Indicates the location of the MFVC VC Arbitration Table.</p> <p>This field contains the zero-based offset of the table in DQWORDS (16 bytes) from the base address of the MFVC Extended Capability structure. A value of 00h indicates that the table is not present.</p>	RO

7.9.2.4 MFVC Port VC Control Register (Offset 0Ch) §

§ Figure 7-236 details allocation of register fields in the Port VC Control register; § Table 7-215 provides the respective bit definitions.

Figure 7-236 MFVC Port VC Control Register §

Table 7-215 MFVC Port VC Control Register §

Bit Location	Register Description	Attributes
0	<p>Load VC Arbitration Table - Used by software to update the MFVC VC Arbitration Table. This bit is valid when the selected VC Arbitration uses the MFVC VC Arbitration Table.</p> <p>Software Sets this bit to request hardware to apply new values programmed into MFVC VC Arbitration Table; Clearing this bit has no effect. Software checks the VC Arbitration Table Status bit in the MFVC Port VC Status register to confirm that new values stored in the MFVC VC Arbitration Table are latched by the VC arbitration logic.</p> <p>This bit always returns 0b when read.</p>	RW
3:1	<p>VC Arbitration Select - Used by software to configure the VC arbitration by selecting one of the supported VC Arbitration schemes indicated by the VC Arbitration Capability field in the MFVC Port VC Capability Register 2.</p> <p>The permissible values of this field are numbers corresponding to one of the asserted bits in the VC Arbitration Capability field.</p> <p>This field cannot be modified when more than one VC in the LPVC group is enabled.</p>	RW
4	<p>All VCs Enabled - Setting this bit indicates that all VCs that will be used by the Port have been enabled. Setting this bit allows hardware to allocate assigned buffer resources across the enabled VCs.</p> <p>Setting this bit is optional. If this bit remains Clear and some VC Resources are never enabled, performance may be affected but the Link and all enabled VCs must operate correctly.</p> <p>Behavior is undefined if this bit is Set and any VC Enable bit in this capability changes value.</p> <p>Default value of this bit is 0b.</p>	RW

7.9.2.5 MFVC Port VC Status Register (Offset 0Eh) §

The MFVC Port VC Status Register provides status of the configuration of Virtual Channels associated with a Port of the Multi-Function Device. § Figure 7-237 details allocation of register fields in the MFVC Port VC Status Register; § Table 7-216 provides the respective bit definitions.

Figure 7-237 MFVC Port VC Status Register §

Table 7-216 MFVC Port VC Status Register §

Bit Location	Register Description	Attributes
0	<p>VC Arbitration Table Status - Indicates the coherency status of the MFVC VC Arbitration Table. This bit is valid when the selected VC uses the MFVC VC Arbitration Table.</p> <p>This bit is Set by hardware when any entry of the MFVC VC Arbitration Table is written by software. This bit is Cleared by hardware when hardware finishes loading values stored in the MFVC VC Arbitration Table after software sets the Load VC Arbitration Table bit in the MFVC Port VC Control Register.</p> <p>Default value of this bit is 0b.</p>	RO

7.9.2.6 MFVC VC Resource Capability Register §

The MFVC VC Resource Capability Register describes the capabilities and configuration of a particular Virtual Channel resource. § Figure 7-238 details allocation of register fields in the MFVC VC Resource Capability Register; § Table 7-217 provides the respective bit definitions.

Figure 7-238 MFVC VC Resource Capability Register §

Table 7-217 MFVC VC Resource Capability Register §

Bit Location	Register Description	Attributes
7:0	<p>Function Arbitration Capability - Indicates types of Function Arbitration supported by the VC resource.</p> <p>Each Bit Location within this field corresponds to a Function Arbitration Capability defined below. When more than 1 bit in this field is Set, it indicates that the VC resource can be configured to provide different arbitration services.</p> <p>Software selects among these capabilities by writing to the Function Arbitration Select field (see § Section 7.9.2.7).</p> <p>Defined bit positions are:</p>	RO

Bit Location	Register Description	Attributes
	<p>Bit 0 Non-configurable hardware-fixed arbitration scheme, e.g., Round Robin (RR)</p> <p>Bit 1 Weighted Round Robin (WRR) arbitration with 32 phases</p> <p>Bit 2 WRR arbitration with 64 phases</p> <p>Bit 3 WRR arbitration with 128 phases</p> <p>Bit 4 Time-based WRR with 128 phases</p> <p>Bit 5 WRR arbitration with 256 phases</p> <p>Bits 6-7 Reserved</p>	
22:16	<p>Maximum Time Slots - Indicates the maximum number of time slots (minus 1) that the VC resource is capable of supporting when it is configured for time-based WRR Function Arbitration. For example, a value of 000 0000b in this field indicates the supported maximum number of time slots is 1 and a value of 111 1111b indicates the supported maximum number of time slots is 128.</p> <p>This field is valid only when the <u>Function Arbitration Capability</u> indicates that the VC resource supports time-based WRR Function Arbitration.</p>	<u>HwInit</u>
31:24	<p>Function Arbitration Table Offset - Indicates the location of the Function Arbitration Table associated with the VC resource.</p> <p>This field contains the zero-based offset of the table in DQWORDS (16 bytes) from the base address of the MFVC Extended Capability structure. A value of 00h indicates that the table is not present.</p>	<u>RO</u>

7.9.2.7 MFVC VC Resource Control Register §

§ Figure 7-239 details allocation of register fields in the MFVC VC Resource Control Register; § Table 7-218 provides the respective bit definitions.

Figure 7-239 MFVC VC Resource Control Register §

Table 7-218 MFVC VC Resource Control Register §

Bit Location	Register Description	Attributes
7:0	<p>TC/VC Map - This field indicates the TCs that are mapped to the VC resource.</p> <p>Bit Locations within this field correspond to TC values. For example, when bit 7 is Set in this field, TC7 is mapped to this VC resource. When more than 1 bit in this field is Set, it indicates that multiple TCs are mapped to the VC resource.</p> <p>In order to remove one or more TCs from the TC/VC Map of an enabled VC, software must ensure that no new or outstanding transactions with the TC labels are targeted at the given Link.</p>	RW (see the note for exceptions)

Bit Location	Register Description	Attributes														
	<p>Default value of this field is FFh for the first VC resource and is 00h for other VC resources.</p> <p>Note:</p> <p>Bit 0 of this field is read-only. It must be hardwired to 1b for the default VC0 and hardwired to 0b for all other enabled VCs.</p>															
16	<p>Load Function Arbitration Table - When Set, this bit updates the Function Arbitration logic from the Function Arbitration Table for the VC resource. This bit is only valid when the Function Arbitration Table is used by the selected Function Arbitration scheme (that is indicated by a Set bit in the <u>Function Arbitration Capability</u> field selected by <u>Function Arbitration Select</u>).</p> <p>Software sets this bit to signal hardware to update Function Arbitration logic with new values stored in the Function Arbitration Table; clearing this bit has no effect. Software uses the Function Arbitration Table Status bit to confirm whether the new values of Function Arbitration Table are completely latched by the arbitration logic.</p> <p>This bit always returns 0b when read.</p> <p>Default value of this bit is 0b.</p>	<u>RW</u>														
19:17	<p>Function Arbitration Select - This field configures the VC resource to provide a particular Function Arbitration service.</p> <p>The permissible value of this field is a number corresponding to one of the asserted bits in the <u>Function Arbitration Capability</u> field of the VC resource.</p>	<u>RW</u>														
26:24	<p>VC ID - This field assigns a VC ID to the VC resource (see note for exceptions).</p> <p>This field cannot be modified when the VC is already enabled.</p> <p>Note:</p> <p>For the first VC resource (default VC), this field is a read-only field that must be hardwired to 000b.</p>	<u>RW</u>														
29:27	<p>Shared Flow Control Usage Limit - this field controls what percentage of the available Shared Flow Control a given FC/VC is permitted to consume.</p> <p>This limit is applied independently for each Flow Control credit type. For example, if this field contains 101b and Shared Flow Control Usage Limit Enable is Set, a Posted TLP may not pass the Tx Gate if doing so would cause that VC to consume more than 62.5% of the available Shared Posted Header credits or if doing so would cause that VC to consume more than 62.5% of the available Shared Data credits.</p> <p>If Shared Flow Control Usage Limit Enable is Clear, this field is ignored and this VC is permitted to consume all of the shared credits.</p> <p>When Shared Flow Control Usage Limit Enable is Set, and this field contains 000b, this VC is not permitted to consume any shared credits.</p> <p>Behavior is undefined when all VCs have Shared Flow Control Usage Limit Enable Set and the sum of the Shared Flow Control Limit values for all VCs is less than 100%.</p> <p>Encodings are:</p> <table data-bbox="289 1598 479 1879"> <tr><td>000b</td><td>0%</td></tr> <tr><td>001b</td><td>12.5%</td></tr> <tr><td>010b</td><td>25%</td></tr> <tr><td>011b</td><td>37.5%</td></tr> <tr><td>100b</td><td>50%</td></tr> <tr><td>101b</td><td>62.5%</td></tr> <tr><td>110b</td><td>75%</td></tr> </table>	000b	0%	001b	12.5%	010b	25%	011b	37.5%	100b	50%	101b	62.5%	110b	75%	<u>RW / RO / RsvdP</u>
000b	0%															
001b	12.5%															
010b	25%															
011b	37.5%															
100b	50%															
101b	62.5%															
110b	75%															

Bit Location	Register Description	Attributes
	<p>111b 87.5%</p> <p>Behavior is undefined if this field changes value while VC Enable and Shared Flow Control Usage Limit Enable are both Set.</p> <p>This field is RsvdP when Flit Mode Supported is Clear.</p> <p>When Extended VC Count is 0, this field is permitted to be hardwired to 000b.</p> <p>When this field is RW, the default value is implementation specific.</p>	
30	<p>Shared Flow Control Usage Limit Enable - When Set, this bit enables use of the Shared Flow Control Usage Limit value above at the transmitter for this Virtual Channel.</p> <p>Behavior is undefined of the value of this bit changes while VC Enable is Set.</p> <p>This bit is RsvdP when Flit Mode Supported is Clear.</p> <p>When Extended VC Count is 0, this bit is permitted to be hardwired to 0b.</p> <p>When this bit is RW, the default value is implementation specific.</p>	RW / RO / RsvdP
31	<p>VC Enable - When Set, this bit enables a Virtual Channel. The Virtual Channel is disabled when this bit is cleared.</p> <p>Software must use the VC Negotiation Pending bit to check whether the VC negotiation is complete.</p> <p>For VC0, the attribute is RO. If no SVC capability is implemented in this Port, this bit's value must be 1b; otherwise, this bit's value must always be the same value as the Use VC/MFVC bit in the SVC Port Status Register. See § Section 6.3.5 .</p> <p>For other VCs, if no SVC capability is implemented in this Port or if the Use VC/MFVC bit is Set, the default value of this bit is 0b and the attribute is RW; otherwise, this bit must be RO with a value of 0b.</p> <p>To enable a Virtual Channel, in a Port using MFVC mechanisms, the VC Enable bit for that Virtual Channel must be Set. The corresponding Virtual Channel in the Link partner Port must be enabled as well, and that Virtual Channel may be in SVC, VC, or MFVC capabilities. To disable a Virtual Channel, the Virtual Channel must be disabled in both components on the Link. Software must ensure that no traffic is using a Virtual Channel at the time it is disabled. Software must fully disable a Virtual Channel in both components on a Link before re-enabling the Virtual Channel.</p> <p>When this bit is forced to be RO with a value of 0b due to the Use VC/MFVC bit being Clear, its associated VC is disabled, rendering most of its control registers to be ineffective.</p>	RW/HwInit

7.9.2.8 MFVC VC Resource Status Register §

§ Figure 7-240 details allocation of register fields in the MFVC VC Resource Status Register; § Table 7-219 provides the respective bit definitions.

Figure 7-240 MFVC VC Resource Status Register §

Table 7-219 MFVC VC Resource Status Register §

Bit Location	Register Description	Attributes
0	<p>Function Arbitration Table Status - This bit indicates the coherency status of the Function Arbitration Table associated with the VC resource. This bit is valid only when the Function Arbitration Table is used by the selected Function Arbitration for the VC resource.</p> <p>This bit is Set by hardware when any entry of the Function Arbitration Table is written to by software. This bit is Cleared by hardware when hardware finishes loading values stored in the Function Arbitration Table after software sets the <u>Load Function Arbitration Table</u> bit.</p> <p>Default value of this bit is 0b.</p>	RO
1	<p>VC Negotiation Pending - This bit indicates whether the Virtual Channel negotiation (initialization or disabling) is in pending state.</p> <p>When this bit is Set by hardware, it indicates that the VC resource is still in the process of negotiation. This bit is Cleared by hardware after the VC negotiation is complete. For a non-default Virtual Channel, software may use this bit when enabling or disabling the VC. For the default VC, this bit indicates the status of the process of Flow Control initialization.</p> <p>Before using a Virtual Channel, software must check whether the VC Negotiation Pending bits for that Virtual Channel are Clear in both components on a Link.</p>	RO

7.9.2.9 MFVC VC Arbitration Table §

The definition of the MFVC VC Arbitration Table in the MFVC Extended Capability structure is identical to that in the VC Extended Capability structure (see § Section 7.9.1.9).

7.9.2.10 Function Arbitration Table §

The Function Arbitration Table register in the MFVC Extended Capability structure takes the same form as the Port Arbitration Table register in the VC Extended Capability structure (see § Section 7.9.1.10).

The Function Arbitration Table register is a read-write register array that is used to store the WRR or time-based WRR arbitration table for Function Arbitration for the VC resource. It is only present when one or more asserted bits in the Function Arbitration Capability field indicate that the Multi-Function Device supports a Function Arbitration scheme that uses a programmable arbitration table. Furthermore, it is only valid when one of the above-mentioned bits in the Function Arbitration Capability field is selected by the Function Arbitration Select field.

The Function Arbitration Table represents one Function arbitration period. Each table entry containing a Function Number or Function Group¹⁸² Number corresponds to a phase within a Function Arbitration period. The table entry size requirements are as follows:

- The table entry size for non-ARI devices must support enough values to specify all implemented Functions plus at least one value that does not correspond to an implemented Function. For example, a table with 2-bit entries can be used by a Multi-Function Device with up to three Functions.
- The table entry size for ARI Devices must be either 4 bits or 8 bits.
 - If MFVC Function Groups are enabled, each entry maps to a single Function Group. Arbitration between multiple Functions within a Function Group is implementation specific, but must guarantee forward progress.

182. If an ARI Device supports MFVC Function Groups capability and ARI-aware software enables it, arbitration is based on Function Groups instead of Functions. See § Section 7.8.8.

- If MFVC Function Groups are not enabled and 4-bit entries are implemented, a given entry maps to all Functions whose Function Number modulo 8 matches its value. Similarly, if 8-bit entries are implemented, a given entry maps to all Functions whose Function Number modulo 128 matches its value. If a given entry maps to multiple Functions, arbitration between those Functions is implementation specific, but must guarantee forward progress.

A Function Number or Function Group Number written to a table entry indicates that the phase within the Function Arbitration period is assigned to the selected Function or Function Group (the Function Number or Function Group Number must be a valid one).

- When the WRR Function Arbitration is used for a VC of the Egress Port of the Multi-Function Device, at each arbitration phase the Function Arbiter serves one transaction from the Function or Function Group indicated by the Function Number or Function Group Number of the current phase. When finished, it immediately advances to the next phase. A phase is skipped, i.e., the Function Arbiter simply moves to the next phase immediately if the Function or Function Group indicated by the phase does not contain any transaction for the VC.
- When the Time-based WRR Function Arbitration is used for a VC of the Egress Port of the Multi-Function Device, at each arbitration phase aligning to a virtual timeslot, the Function Arbiter serves one transaction from the Function or Function Group indicated by the Function Number or Function Group Number of the current phase. It advances to the next phase at the next virtual timeslot. A phase indicates an “idle” timeslot, i.e., the Function Arbiter does not serve any transaction during the phase, if:
 - the phase contains the Number of a Function or a Function Group that does not exist, or
 - the Function or Function Group indicated by the phase does not contain any transaction for the VC.

The Function Arbitration Table Entry Size field in the MFVC Port VC Capability Register 1 determines the table entry size. The length of the table is determined by the Function Arbitration Select field as shown in § Table 7-220.

When the Function Arbitration Table is used by the default Function Arbitration for the default VC, the default values for the table entries must contain at least one entry for each of the active Functions or Function Groups in the Multi-Function Device to ensure forward progress for the default VC for the Multi-Function Device’s Upstream Port. The table may contain RR or RR-like fair Function Arbitration for the default VC.

Table 7-220 Length of Function Arbitration Table §

Function Arbitration Select	Function Arbitration Table Length
001b	32 entries
010b	64 entries
011b	128 entries
100b	128 entries
101b	256 entries

7.9.3 Device Serial Number Extended Capability §

The Device Serial Number Extended Capability is an optional Extended Capability that may be implemented by any PCI Express device Function. The Device Serial Number is a read-only 64-bit value that is unique for a given PCI Express device. § Figure 7-241 details allocation of register fields in the Device Serial Number Extended Capability structure.

It is permitted but not recommended for RCiEPs to implement this Capability.

RCiEPs that implement this Capability are permitted but not required to return the same Device Serial Number value as that reported by other RCiEPs of the same Root Complex.

All Multi-Function Devices other than RCiEPs that implement this Capability must implement it for Function 0; other Functions that implement this Capability must return the same Device Serial Number value as that reported by Function 0.

RCiEPs are permitted to implement or not implement this Capability on an individual basis, independent of whether they are part of a Multi-Function Device.

A PCI Express component other than a Root Complex containing multiple Devices such as a PCI Express Switch that implements this Capability must return the same Device Serial Number for each device.

The Device Serial Number Extended Capability is permitted to be present in PFs. If a PF contains the capability, its value applies to all associated VFs. VFs are permitted but not recommended to implement this capability. VFs that implement this capability must return the same Device Serial Number value as that reported by their associated PF.

Figure 7-241 Device Serial Number Extended Capability Structure §

7.9.3.1 Device Serial Number Extended Capability Header (Offset 00h) §

§ Figure 7-242 details allocation of register fields in the Device Serial Number Extended Capability Header; § Table 7-221 provides the respective bit definitions. Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability header. The Extended Capability ID for the Device Serial Number Extended Capability is 0003h.

Figure 7-242 Device Serial Number Extended Capability Header §

Table 7-221 Device Serial Number Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Device Serial Number Extended Capability is 0003h.	RO

Bit Location	Register Description	Attributes
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.3.2 Serial Number Register (Offset 04h) §

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit extended unique identifier [EUI-64].
§ Figure 7-243 details allocation of register fields in the Serial Number register; § Table 7-222 provides the respective bit definitions.

Figure 7-243 Serial Number Register §

Table 7-222 Serial Number Register §

Bit Location	Register Description	Attributes
63:0	PCI Express Device Serial Number - This field contains the IEEE defined 64-bit Extended Unique Identifier [EUI-64]. This identifier includes a 24-bit company id value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. PCI Express Device Serial Number[07:00] = EUI[63:56] PCI Express Device Serial Number[15:08] = EUI[55:48] PCI Express Device Serial Number[23:16] = EUI[47:40] PCI Express Device Serial Number[31:24] = EUI[39:32] PCI Express Device Serial Number[39:32] = EUI[31:24] PCI Express Device Serial Number[47:40] = EUI[23:16] PCI Express Device Serial Number[55:48] = EUI[15:08] PCI Express Device Serial Number[63:56] = EUI[07:00]	RO

7.9.4 Vendor-Specific Capability §

The Vendor-Specific Capability is a capability structure in PCI-compatible Configuration Space (first 256 bytes) as shown in § Figure 7-244.

The Vendor-Specific Capability allows device vendors to use the Capability mechanism for vendor-specific information. The layout of the information is vendor-specific, except for the first three bytes, as explained below.

A single PCI Express Function is permitted to contain multiple VSEC structures.

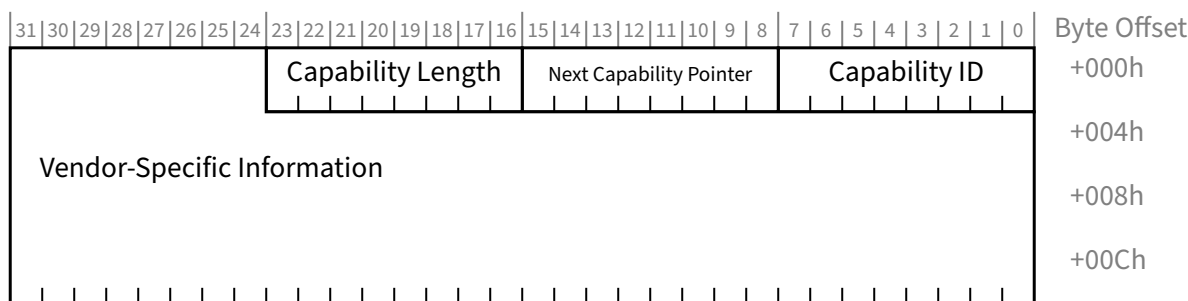

Figure 7-244 Vendor-Specific Capability §

Table 7-223 Vendor-Specific Capability §

Bit Location	Register Description	Attributes
7:0	Capability ID - Indicates the PCI Express Capability structure. This field must return a Capability ID of 09h indicating that this is a Vendor-Specific Capability structure.	RO
15:8	Next Capability Pointer - This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities.	RO
23:16	Capability Length - This field provides the number of bytes in the Capability structure (including the three bytes consumed by the Capability ID, Next Capability Pointer, and Capability Length field).	RO
31:24	Vendor Specific Information	Vendor Specific

7.9.5 Vendor-Specific Extended Capability §

The Vendor-Specific Extended Capability (**VSEC Capability**) is an optional Extended Capability that is permitted to be implemented by any PCI Express Function or RCRB. This allows PCI Express component vendors to use the Extended Capability mechanism to expose vendor-specific registers.

A single PCI Express Function or RCRB is permitted to contain multiple VSEC structures.

An example usage is a set of vendor-specific features that are intended to go into an on-going series of components from that vendor. A VSEC structure can tell vendor-specific software which features a particular component supports, including components developed after the software was released.

§ Figure 7-245 details allocation of register fields in the VSEC structure. The structure of the Vendor-Specific Extended Capability Header and the Vendor-Specific Header is architected by this specification.

With a PCI Express Function, the structure and definition of the vendor-specific Registers area is determined by the vendor indicated by the Vendor ID field located at byte offset 00h in PCI-compatible Configuration Space. With an RCRB, a VSEC is permitted only if the RCRB also contains an RCRB Header Extended Capability structure, which contains a Vendor ID field indicating the vendor.

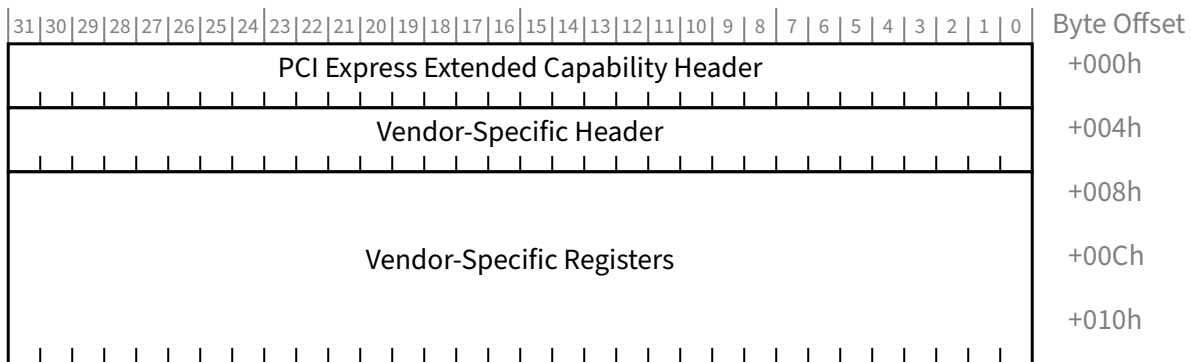

Figure 7-245 VSEC Capability Structure §

7.9.5.1 Vendor-Specific Extended Capability Header (Offset 00h) §

§ Figure 7-246 details allocation of register fields in the Vendor-Specific Extended Capability Header; § Table 7-224 provides the respective bit definitions. Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability Header. The Extended Capability ID for the Vendor-Specific Extended Capability is 000Bh.

Figure 7-246 Vendor-Specific Extended Capability Header §

Table 7-224 Vendor-Specific Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Vendor-Specific Extended Capability is 000Bh.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.5.2 Vendor-Specific Header (Offset 04h) §

§ Figure 7-247 details allocation of register fields in the Vendor-Specific Header; § Table 7-225 provides the respective bit definitions.

Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

Figure 7-247 Vendor-Specific Header §

Table 7-225 Vendor-Specific Header §

Bit Location	Register Description	Attributes
15:0	VSEC ID - This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field.	RO
19:16	VSEC Rev - This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field.	RO
31:20	VSEC Length - This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers.	RO

7.9.6 Designated Vendor-Specific Extended Capability (DVSEC) §

The Designated Vendor-Specific Extended Capability (**DVSEC Capability**) is an optional Extended Capability that is permitted to be implemented by any PCI Express Function or RCRB. This allows PCI Express component vendors to use the Extended Capability mechanism to expose vendor-specific registers that can be present in components by a variety of vendors.

A single PCI Express Function or RCRB is permitted to contain multiple DVSEC Capability structures.

An example usage is a set of vendor-specific features that are intended to go into an on-going series of components from a collection of vendors. A DVSEC Capability structure can tell vendor-specific software which features a particular component supports, including components developed after the software was released.

§ Figure 7-248 details allocation of register fields in the DVSEC Capability structure. The structure of the PCI Express Extended Capability Header and the Designated Vendor-Specific header is architected by this specification.

The DVSEC Vendor-Specific Register area begins at offset 0Ah.

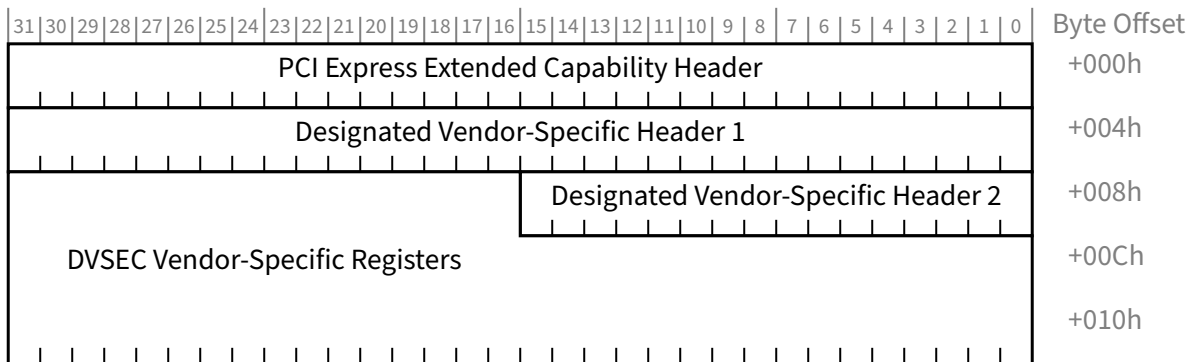

Figure 7-248 Designated Vendor-Specific Extended Capability §

7.9.6.1 Designated Vendor-Specific Extended Capability Header (Offset 00h) §

§ Figure 7-249 details allocation of register fields in the Designated Vendor-Specific Extended Capability Header; § Table 7-226 provides the respective bit definitions. Refer to § Section 7.9.3 for a description of the PCI Express Extended Capability Header. The Extended Capability ID for the Designated Vendor-Specific Extended Capability is 0023h.

Figure 7-249 Designated Vendor-Specific Extended Capability Header §

Table 7-226 Designated Vendor-Specific Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Designated Vendor-Specific Extended Capability is 0023h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.6.2 Designated Vendor-Specific Header 1 (Offset 04h) §

§ Figure 7-250 details allocation of register fields in the Designated Vendor-Specific Header 1; § Table 7-227 provides the respective bit definitions.

Vendor-specific software must qualify the DVSEC Vendor ID before attempting to interpret the DVSEC Revision field.

Figure 7-250 Designated Vendor-Specific Header 1 §

Table 7-227 Designated Vendor-Specific Header 1 §

Bit Location	Register Description	Attributes
15:0	DVSEC Vendor ID - This field is the Vendor ID associated with the vendor that defined the contents of this capability.	RO
19:16	DVSEC Revision - This field is a vendor-defined version number that indicates the version of the DVSEC structure. Software must qualify the <u>DVSEC Vendor ID</u> and <u>DVSEC ID</u> before interpreting this field.	RO
31:20	DVSEC Length - This field indicates the number of bytes in the entire DVSEC structure, including the <u>PCI Express Extended Capability Header</u> , the <u>DVSEC Header 1</u> , <u>DVSEC Header 2</u> , and <u>DVSEC vendor-specific registers</u> .	RO

7.9.6.3 Designated Vendor-Specific Header 2 (Offset 08h) §

§ Figure 7-251 details allocation of register fields in the Designated Vendor-Specific Header 2; § Table 7-228 provides the respective bit definitions.

Vendor-specific software must qualify the DVSEC Vendor ID before attempting to interpret the DVSEC ID field.

Figure 7-251 Designated Vendor-Specific Header 2 §

Table 7-228 Designated Vendor-Specific Header 2 §

Bit Location	Register Description	Attributes
15:0	DVSEC ID - This field is a vendor-defined ID that indicates the nature and format of the DVSEC structure. Software must qualify the <u>DVSEC Vendor ID</u> before interpreting this field.	RO

7.9.7 RCRB Header Extended Capability §

The PCI Express RCRB Header Extended Capability is an optional Extended Capability that may be implemented in an RCRB to provide a Vendor ID and Device ID for the RCRB and to permit the management of parameters that affect the behavior of Root Complex functionality associated with the RCRB.

Figure 7-252 RCRB Header Extended Capability Structure §

7.9.7.1 RCRB Header Extended Capability Header (Offset 00h) §

§ Figure 7-253 details allocation of register fields in the RCRB Header Extended Capability Header. § Table 7-229 provides the respective bit definitions. Refer to § Section 7.6.3 for a description of the PCI Express Enhanced Capabilities header. The Extended Capability ID for the RCRB Header Extended Capability is 000Ah.

Figure 7-253 RCRB Header Extended Capability Header §

Table 7-229 RCRB Header Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the <u>RCRB Header Extended Capability</u> is 000Ah.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.7.2 RCRB Vendor ID and Device ID register (Offset 04h) §

§ Figure 7-254 details allocation of register fields in the RCRB Vendor ID and Device ID register; § Table 7-230 provides the respective bit definitions.

Table 7-230 RCRB Vendor ID and Device ID register §

Bit Location	Register Description	Attributes
15:0	Vendor ID - PCI-SIG assigned. Analogous to the equivalent field in PCI-compatible Configuration Space. This field provides a means to associate an <u>RCRB</u> with a particular vendor.	RO
31:16	Device ID - Vendor assigned. Analogous to the equivalent field in PCI-compatible Configuration Space. This field provides a means for a vendor to classify a particular <u>RCRB</u> .	RO

7.9.7.3 RCRB Capabilities register (Offset 08h) §

§ Figure 7-255 details allocation of register fields in the RCRB Capabilities register; § Table 7-231 provides the respective bit definitions.

Figure 7-255 RCRB Capabilities register §

Table 7-231 RCRB Capabilities register §

Bit Location	Register Description	Attributes
0	Configuration RRS Software Visibility - When Set, this bit indicates that the Root Complex is capable of returning Request Retry Status (RRS) Completion Status in response to a Configuration Request for all Root Ports and integrated devices associated with this RCRB (see § Section 2.3.1).	RO

7.9.7.4 RCRB Control register (Offset 0Ch) §

§ Figure 7-256 details allocation of register fields in the RCRB Control register; § Table 7-232 provides the respective bit definitions.

Figure 7-256 RCRB Control register §

Table 7-232 RCRB Control register §

Bit Location	Register Description	Attributes
0	Configuration RRS Software Visibility Enable - When Set, this bit enables the Root Complex to return Request Retry Status (RRS) Completion Status in response to a Configuration Request for all Root Ports and integrated devices associated with this RCRB (see § Section 2.3.1). RCRBs that do not implement this capability must hardwire this bit to 0b. Default value of this bit is 0b.	RW

7.9.8 Root Complex Link Declaration Extended Capability §

The Root Complex Link Declaration Extended Capability is an optional Capability that is permitted to be implemented by Root Ports, RCIEPs, or RCRBs to declare a Root Complex's internal topology.

A Root Complex consists of one or more following elements:

- PCI Express Root Port
- A default system Egress Port or an internal sink unit such as memory (represented by an RCRB)
- Internal Data Paths/Links (represented by an RCRB on either side of an internal Link)

- Integrated devices
- Functions

A Root Complex Component is a logical aggregation of the above described Root Complex elements. No single element can be part of more than one Root Complex Component. Each Root Complex Component must have a unique Component ID.

A Root Complex is represented either as an opaque Root Complex or as a collection of one or more Root Complex Components.

The Root Complex Link Declaration Extended Capability is permitted to be present in a Root Complex element's Configuration Space or RCRB. It declares Links from the respective element to other elements of the same Root Complex Component or to an element in another Root Complex Component. The Links are required to be declared bidirectional such that each valid data path from one element to another has corresponding Link Entries in the Configuration Space (or RCRB) of both elements.

The Root Complex Link Declaration Extended Capability is permitted to also declare an association between a Configuration Space element (Root Port or RCiEP) and an RCRB Header Extended Capability (see § Section 7.9.7) contained in an RCRB that affects the behavior of the Configuration Space element. Note that an RCRB Header association is not declared bidirectional; the association is only declared by the Configuration Space element and not by the target RCRB.

IMPLEMENTATION NOTE: TOPOLOGIES TO AVOID §

Topologies that create more than one data path between any two Root Complex elements (either directly or through other Root Complex elements) may not be able to support bandwidth allocation in a standard manner. The description of how traffic is routed through such a topology is implementation specific, meaning that general purpose-operating systems may not have enough information about such a topology to correctly support bandwidth allocation. In order to circumvent this problem, these operating systems may require that a single RCRB element (of type Internal Link) not declare more than one Link to a Root Complex Component other than the one containing the RCRB element itself.

The Root Complex Link Declaration Extended Capability, as shown in § Figure 7-257, consists of the PCI Express Extended Capability header and Root Complex Element Self Description followed by one or more Root Complex Link Entries.

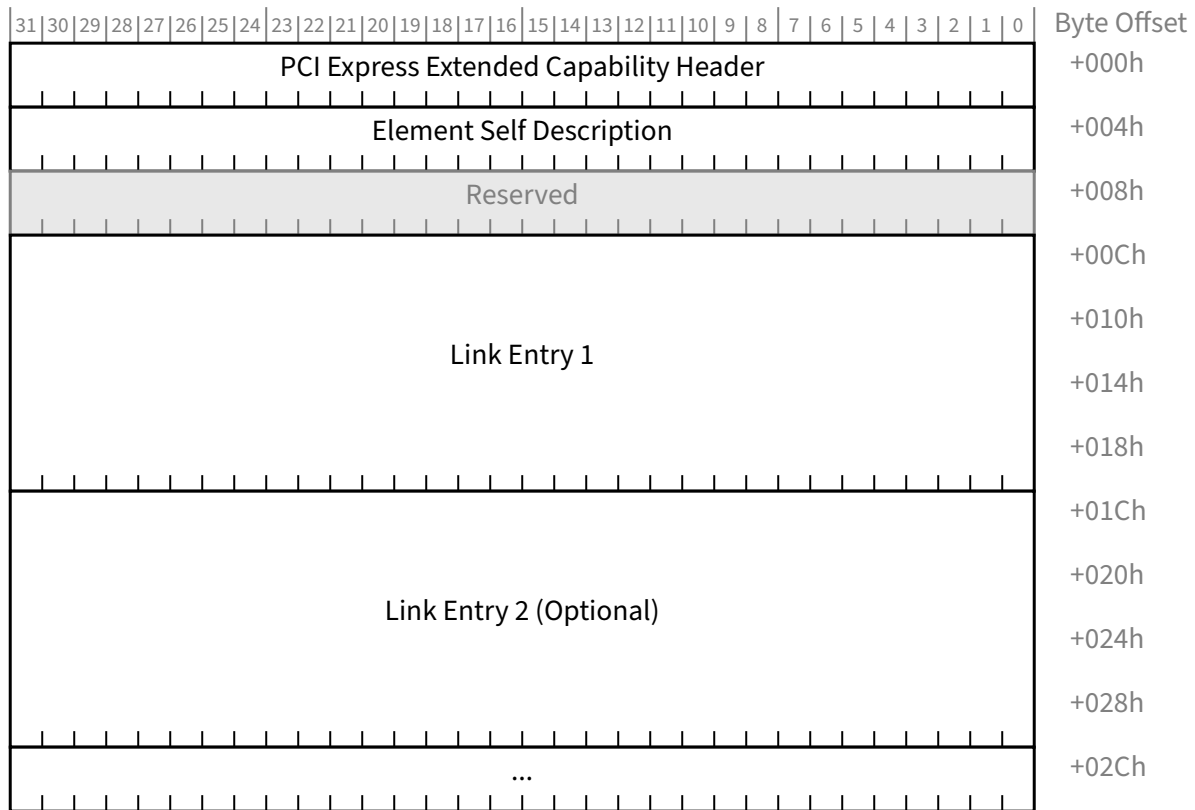

Figure 7-257 Root Complex Link Declaration Extended Capability §

7.9.8.1 Root Complex Link Declaration Extended Capability Header (Offset 00h) §

The Extended Capability ID for the Root Complex Link Declaration Extended Capability is 0005h.

Figure 7-258 Root Complex Link Declaration Extended Capability Header §

Table 7-233 Root Complex Link Declaration Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the <u>Root Complex Link Declaration Extended Capability</u> is 0005h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits.	RO

7.9.8.2 Element Self Description Register (Offset 04h) §

The Element Self Description Register provides information about the Root Complex element containing the Root Complex Link Declaration Extended Capability.

Figure 7-259 Element Self Description Register §

Table 7-234 Element Self Description Register §

Bit Location	Register Description	Attributes
3:0	Element Type - This field indicates the type of the Root Complex Element. Defined encodings are: 0h Configuration Space Element 1h System Egress Port or internal sink (memory) 2h Internal Root Complex Link 3h-Fh Reserved	RO
15:8	Number of Link Entries - This field indicates the number of <u>Link Entries</u> following the Element Self Description. This field must report a value of 01h or higher.	HwInit
23:16	Component ID - This field identifies the Root Complex Component that contains this Root Complex Element. Component IDs must start at 01h, as a value of 00h is Reserved.	HwInit

Bit Location	Register Description	Attributes
31:24	Port Number - This field specifies the Port Number associated with this element with respect to the Root Complex Component that contains this element. An element with a Port Number of 00h indicates the default Egress Port to configuration software.	Hwlnit

7.9.8.3 Link Entries §

Link Entries start at offset 10h of the Root Complex Link Declaration Extended Capability structure. Each Link Entry consists of a Link description followed by a 64-bit Link Address at offset 08h from the start of Link Entry identifying the target element for the declared Link. A Link Entry declares an internal Link to another Root Complex Element.

Figure 7-260 Link Entry §

7.9.8.3.1 Link Description Register §

The Link Description Register is located at offset 00h from the start of a Link Entry and is defined as follows:

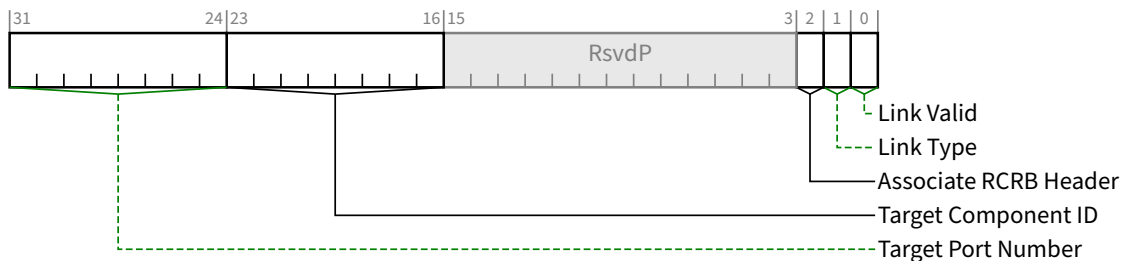

Figure 7-261 Link Description Register §

Table 7-235 Link Description Register §

Bit Location	Register Description	Attributes
0	Link Valid - When Set, this bit indicates that the Link Entry specifies a valid Link. Link Entries that do not have either this bit Set or the <u>Associate RCRB Header</u> bit Set (or both) are ignored by software.	Hwlnit
1	Link Type - This bit indicates the target type of the Link and defines the format of the <u>Link Address</u> field. Defined <u>Link Type</u> values are:	Hwlnit

Bit Location	Register Description	Attributes
	<p>0b Link points to memory-mapped space¹⁸³ (for RCRB). The <u>Link Address</u> specifies the 64-bit base address of the target RCRB.</p> <p>1b Link points to Configuration Space (for a Root Port or RCiEP). The <u>Link Address</u> specifies the configuration address (PCI Segment Group, Bus, Device, Function) of the target element.</p>	
2	<p>Associate RCRB Header - When Set, this bit indicates that the Link Entry associates the declaring element with an RCRB Header Extended Capability in the target RCRB. Link Entries that do not have either this bit Set or the <u>Link Valid</u> bit Set (or both) are ignored by software.</p> <p>The <u>Link Type</u> bit must be Clear when this bit is Set.</p>	HwInit
23:16	<p>Target Component ID - This field identifies the Root Complex Component that is targeted by this <u>Link Entry</u>. Components IDs must start at 01h, as a value of 00h is Reserved</p>	HwInit
31:24	<p>Target Port Number - This field specifies the Port Number associated with the element targeted by this <u>Link Entry</u>; the Target Port Number is with respect to the Root Complex Component (identified by the <u>Target Component ID</u>) that contains the target element.</p>	HwInit

7.9.8.3.2 Link Address §

The Link Address is a HwInit field located at offset 08h from the start of a Link Entry that identifies the target element for the Link Entry. For a Link of Link Type 0 in its Link Description, the Link Address specifies the memory-mapped base address of RCRB. For a Link of Link Type 1 in its Link Description, the Link Address specifies the Configuration Space address of a PCI Express Root Port or an RCiEP.

7.9.8.3.2.1 Link Address for Link Type 0 §

For a Link pointing to a memory-mapped RCRB (Link Type bit = 0), the first DWORD specifies the lower 32 bits of the RCRB base address of the target element as shown below; bits 11:0 are hardwired to 000h and Reserved for future use. The second DWORD specifies the high order 32 bits (63:32) of the RCRB base address of the target element.

Figure 7-262 Link Address for Link Type 0 §

7.9.8.3.2.2 Link Address for Link Type 1 §

For a Link pointing to the Configuration Space of a Root Complex element (Link Type bit = 1), bits in the first DWORD specify the Bus, Device, and Function Number of the target element. As shown in § Figure 7-263, bits 2:0 (N) encode the number of bits n associated with the Bus Number, with N = 000b specifying n = 8 and all other encodings specifying

183. The memory-mapped space for accessing an RCRB is not the same as Memory Space, and must not overlap with Memory Space.

$n = \langle \text{value of } N \rangle$. Bits 11:3 are Reserved and hardwired to 0. Bits 14:12 specify the Function Number, and bits 19:15 specify the Device Number. Bits $(19 + n):20$ specify the Bus Number, with $1 \leq n \leq 8$.

Bits 31: $(20 + n)$ of the first DWORD together with the second DWORD optionally identify the target element's hierarchy for systems implementing the PCI Express Enhanced Configuration Access Mechanism by specifying bits 63: $(20 + n)$ of the memory-mapped Configuration Space base address of the PCI Express hierarchy associated with the targeted element; single hierarchy systems that do not implement more than one memory mapped Configuration Space are allowed to report a value of zero to indicate default Configuration Space.

A Configuration Space base address [63: $(20 + n)$] equal to zero indicates that the Configuration Space address defined by bits $(19 + n):12$ (Bus Number, Device Number, and Function Number) exists in the default PCI Segment Group; any non-zero value indicates a separate Configuration Space base address.

Software must not use n outside the context of evaluating the Bus Number and memory-mapped Configuration Space base address for this specific target element. In particular, n does not necessarily indicate the maximum Bus Number supported by the associated PCI Segment Group.

Figure 7-263 Link Address for Link Type 1 §

Table 7-236 Link Address for Link Type 1 §

Bit Location	Register Description	Attributes
2:0	N - Encoded number of Bus Number bits	<u>HwInit</u>
14:12	Function Number	<u>HwInit</u>
19:15	Device Number	<u>HwInit</u>
$(19 + n):20$	Bus Number	<u>HwInit</u>
63: $(20 + n)$	PCI Express Configuration Space Base Address ($1 \leq n \leq 8$) Note: A Root Complex that does not implement multiple Configuration Spaces is allowed to report this field as 0.	<u>HwInit</u>

7.9.9 Root Complex Internal Link Control Extended Capability §

The Root Complex Internal Link Control Extended Capability is an optional Capability that controls an internal Root Complex Link between two distinct Root Complex Components. This Capability is valid for RCRBs that declare an Element Type field as Internal Root Complex Link in the Element Self-Description register of the Root Complex Link Declaration Capability structure.

The Root Complex Internal Link Control Extended Capability structure is defined as shown in § Figure 7-264.

Figure 7-264 Root Complex Internal Link Control Extended Capability §

7.9.9.1 Root Complex Internal Link Control Extended Capability Header (Offset 00h) §

The Extended Capability ID for the Root Complex Internal Link Control Extended Capability is 0006h.

Figure 7-265 Root Complex Internal Link Control Extended Capability Header §

Table 7-237 Root Complex Internal Link Control Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	<p>PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability.</p> <p>The Extended Capability ID for the Root Complex Internal Link Control Extended Capability is 0006h.</p>	RO
19:16	<p>Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present.</p> <p>Must be 1h for this version of the specification.</p>	RO
31:20	<p>Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities.</p> <p>For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.</p> <p>The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits.</p>	RO

7.9.9.2 Root Complex Link Capabilities Register (Offset 04h) §

The Root Complex Link Capabilities Register identifies capabilities for this Link.

Figure 7-266 Root Complex Link Capabilities Register §

Table 7-238 Root Complex Link Capabilities Register §

Bit Location	Register Description	Attributes
3:0	<p>Max Link Speed - This field indicates the maximum Link speed of the associated Link.</p> <p>The encoded value specifies a bit location in the Supported Link Speeds Vector (in the <u>Root Complex Link Capabilities Register</u>) that corresponds to the maximum Link speed.</p> <p>Defined encodings are:</p> <p>0001b Supported Link Speeds Vector field bit 0</p> <p>0010b Supported Link Speeds Vector field bit 1</p> <p>0011b Supported Link Speeds Vector field bit 2</p> <p>0100b Supported Link Speeds Vector field bit 3</p> <p>0101b Supported Link Speeds Vector field bit 4</p> <p>0110b Supported Link Speeds Vector field bit 5</p> <p>0111b Supported Link Speeds Vector field bit 6</p> <p>Others All other encodings are reserved.</p> <p>A Root Complex that does not support this feature must report 0000b in this field.</p>	RO
9:4	<p>Maximum Link Width - This field indicates the maximum width of the given Link.</p> <p>Defined encodings are:</p> <p>00 0001b x1</p> <p>00 0010b x2</p> <p>00 0100b x4</p> <p>00 1000b x8</p> <p>01 0000b x16</p> <p>All other encodings are Reserved. A Root Complex that does not support this feature must report 00 0000b in this field.</p>	RO
11:10	<p>Active State Power Management (ASPM) Support - This field indicates the level of ASPM supported on the given Link.</p> <p>Defined encodings are:</p> <p>00b No ASPM Support</p> <p>01b L0s Supported</p> <p>10b L1 Supported</p> <p>11b L0s and L1 Supported</p>	RO

Bit Location	Register Description	Attributes
14:12	<p>L0s Exit Latency - This field indicates the L0s exit latency for the given Link. The value reported indicates the length of time this Port requires to complete transition from L0s to L0. If L0s is not supported, the value is undefined.</p> <p>Defined encodings are:</p> <p>000b Less than 64 ns</p> <p>001b 64 ns to less than 128 ns</p> <p>010b 128 ns to less than 256 ns</p> <p>011b 256 ns to less than 512 ns</p> <p>100b 512 ns to less than 1 μs</p> <p>101b 1 μs to less than 2 μs</p> <p>110b 2 μs to 4 μs</p> <p>111b More than 4 μs</p>	RO
17:15	<p>L1 Exit Latency - This field indicates the L1 exit latency for the given Link. The value reported indicates the length of time this Port requires to complete transition from ASPM L1 to L0. If ASPM L1 is not supported, the value is undefined.</p> <p>Defined encodings are:</p> <p>000b Less than 1 μs</p> <p>001b 1 μs to less than 2 μs</p> <p>010b 2 μs to less than 4 μs</p> <p>011b 4 μs to less than 8 μs</p> <p>100b 8 μs to less than 16 μs</p> <p>101b 16 μs to less than 32 μs</p> <p>110b 32 μs to 64 μs</p> <p>111b More than 64 μs</p>	RO
24:18	<p>Supported Link Speeds Vector - This field indicates the supported Link speed(s) of the associated Link. For each bit, a value of 1b indicates that the corresponding Link speed is supported; otherwise, the Link speed is not supported. See § Section 8.2.1 for further requirements.</p> <p>Bit definitions within this field are:</p> <p>Bit 0 2.5 GT/s</p> <p>Bit 1 5.0 GT/s</p> <p>Bit 2 8.0 GT/s</p> <p>Bit 3 16.0 GT/s</p> <p>Bit 4 32.0 GT/s</p> <p>Bit 5 64.0 GT/s</p> <p>Bit 6 RsvdP</p>	RO

IMPLEMENTATION NOTE: SUPPORTED LINK SPEEDS WITH EARLIER HARDWARE §

Hardware components compliant to versions prior to the [PCIe-3.0] did not implement the Supported Link Speeds Vector field and instead returned 0000 000b in bits 24:18.

For software to determine the supported Link speeds for components where this field is contains 0000 000b, software can read bits 3:0 of the Root Complex Link Capabilities Register (now defined to be the Max Link Speed field), and interpret the value as follows:

0001b

2.5 GT/s Link speed supported

0010b

5.0 GT/s and 2.5 GT/s Link speeds supported

For such components, the same encoding is also used for the values for the Current Link Speed field (in the Root Complex Link Status Register).

IMPLEMENTATION NOTE: SOFTWARE MANAGEMENT OF LINK SPEEDS WITH FUTURE HARDWARE §

It is strongly encouraged that software primarily utilize the Supported Link Speeds Vector instead of the Max Link Speed field, so that software can determine the exact set of supported speeds on current and future hardware. This can avoid software being confused if a future specification defines Links that do not require support for all slower speeds.

7.9.9.3 Root Complex Link Control Register (Offset 08h) §

The Root Complex Link Control Register controls parameters for this internal Link.

Figure 7-267 Root Complex Link Control Register §

Table 7-239 Root Complex Link Control Register §

Bit Location	Register Description	Attributes
1:0	<p>Active State Power Management (ASPM) Control - This field controls the level of ASPM enabled on the given Link.</p> <p>Defined encodings are:</p> <p>00b Disabled</p> <p>01b L0s Entry Enabled</p> <p>10b L1 Entry Enabled</p> <p>11b L0s and L1 Entry Enabled</p> <p>Note: “L0s Entry Enabled” enables the Transmitter to enter L0s. If L0s is supported, the Receiver must be capable of entering L0s even when the Transmitter is disabled from entering L0s (00b or 10b).</p> <p>In Flit Mode, L0s is not supported, bit 0 of this field is ignored and has no effect (i.e., encodings 01b and 00b are equivalent as are encodings 11b and 10b).</p> <p>Default value of this field is implementation specific.</p> <p>Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s, as indicated by their ASPM Support field values. Otherwise, the result is undefined.</p> <p>ASPM L1 must be enabled by software in the Upstream component on a Link prior to enabling ASPM L1 in the Downstream component on that Link. When disabling ASPM L1, software must disable ASPM L1 in the Downstream component on a Link prior to disabling ASPM L1 in the Upstream component on that Link. ASPM L1 must only be enabled on the Downstream component if both components on a Link support ASPM L1.</p> <p>A Root Complex that does not support this feature for the given internal Link must hardwire this field to 00b.</p>	RW
7	<p>Extended Synch - This bit when Set forces the transmission of additional Ordered Sets when exiting the L0s state (see § Section 4.2.5.6) and when in the Recovery state (see § Section 4.2.7.4.1). This mode provides external devices (e.g., logic analyzers) monitoring the Link time to achieve bit and Symbol lock before the Link enters the L0 state and resumes communication.</p> <p>A Root Complex that does not support this feature for the given internal Link must hardwire this bit to 0b.</p> <p>In Flit Mode, this bit is ignored and has no effect since L0s is not supported.</p> <p>Default value for this bit is 0b.</p>	RW

7.9.9.4 Root Complex Link Status Register (Offset 0Ah) §

The Root Complex Link Status Register provides information about Link specific parameters.

7.9.10 Root Complex Event Collector Endpoint Association Extended Capability §

The Root Complex Event Collector Endpoint Association Extended Capability is implemented by Root Complex Event Collectors. It declares the RCIEPs supported by the Root Complex Event Collector. A Root Complex Event Collector must

implement the Root Complex Event Collector Endpoint Association Extended Capability; no other PCI Express Device Function is permitted to implement this Capability.

The Root Complex Event Collector Endpoint Association Extended Capability, as shown in § Figure 7-269, consists of the PCI Express Extended Capability header followed by a DWORD bitmap enumerating RCiEPs on the same Bus, and optionally an additional range of Bus Numbers that may contain RCiEPs associated with the Root Complex Event Collector. Functions other than RCiEPs (e.g., Root Ports) contained in the range described by this Capability are not associated with this Root Complex Event Collector.

Figure 7-269 Root Complex Event Collector Endpoint Association Extended Capability §

7.9.10.1 Root Complex Event Collector Endpoint Association Extended Capability Header (Offset 00h) §

The Extended Capability ID for the Root Complex Event Collector Endpoint Association Extended Capability is 0007h. § Figure 7-270 details allocation of fields in the Root Complex Event Collector Endpoint Association Extended Capability Header; § Table 7-241 provides the respective bit definitions.

Figure 7-270 Root Complex Event Collector Endpoint Association Extended Capability Header §

Table 7-241 Root Complex Event Collector Endpoint Association Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	<p>PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability.</p> <p>The Extended Capability ID for the Root Complex Event Collector Endpoint Association Extended Capability is 0007h.</p>	RO
19:16	<p>Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present.</p> <p>Must be 2h if the Extended Capability contains the RCEC Associated Bus Numbers Register (see § Section 7.9.10.3). Must be 1h otherwise.</p>	RO

Bit Location	Register Description	Attributes
31:20	<p>Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities.</p> <p>For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.</p> <p>The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits.</p>	RO

7.9.10.2 Association Bitmap for RCiEPs (Offset 04h) §

The Association Bitmap for RCiEPs is a read-only register that sets the bits corresponding to the Device Numbers of RCiEPs associated with the Root Complex Event Collector on the same Bus Number as the Event Collector itself. The bit corresponding to the Device Number of the Root Complex Event Collector must always be Set.

7.9.10.3 RCEC Associated Bus Numbers Register (Offset 08h) §

The RCEC Associated Bus Numbers Register is a read-only register that indicates an additional range of Bus Numbers containing RCiEPs associated with this Root Complex Event Collector. It is permitted for Functions other than RCiEPs, including Root Ports, to appear within the Association Bus Range. Only RCiEPs in the range are associated with this Root Complex Event Collector. This register is present if the Capability Version is 2h or greater.

This register does not indicate association between an Event Collector and any Virtual Functions within the Association Bus Range (see § Section 9.2.1.2). This register does not indicate association between an Event Collector and any Function on the same Bus Number as the Event Collector itself, however it is permitted for the Association Bus Range to include the Bus Number of the Root Complex Event Collector.

Figure 7-271 RCEC Associated Bus Numbers Register §

Table 7-242 RCEC Associated Bus Numbers Register §

Bit Location	Register Description	Attributes
15:8	<p>RCEC Next Bus - This field contains the lowest additional bus number containing RCiEPs associated with this Root Complex Event Collector. If all of the Devices associated with this Root Complex Event Collector are on the same bus as the Event Collector, then this field must be set to FFh.</p>	HwInit
23:16	<p>RCEC Last Bus - This field contains the highest additional bus number containing RCiEPs associated with this Root Complex Event Collector.</p> <p>If all of the Devices associated with this Root Complex Event Collector are on the same bus as the Event Collector, then this field must be set to 00h.</p>	HwInit

IMPLEMENTATION NOTE: RCEC ASSOCIATED BUS NUMBER COMPATIBILITY WITH LEGACY SOFTWARE §

Legacy software may not support the use of the RCEC Associated Bus Numbers Register as a mechanism to associate Devices with a RCEC. Such software may see events in the RCEC from Devices on different bus numbers that it does not consider to be associated with the Root Complex Event Collector. System Software is strongly encouraged to report all events seen on the Root Complex Event Collector, regardless of whether or not it can determine association.

7.9.11 Multicast Extended Capability §

Multicast is an optional normative functionality that is controlled by the Multicast Extended Capability structure. The Multicast Extended Capability is applicable to Root Ports, RCRBs, Switch Ports, Endpoint Functions, and RCiEPs. It is not applicable to PCI Express to PCI/PCI-X Bridges.

Multicast support is optional in SR-IOV devices. If a VF implements a Multicast capability, its associated PF must implement a Multicast capability.

In the cases of a Switch or Root Complex or a component that contains multiple Functions, multiple copies of this Capability structure are required - one for each Endpoint Function, Switch Port, or Root Port that supports Multicast. To provide implementation efficiencies, certain fields within each of the Multicast Extended Capability structures within a component must be programmed the same and results are indeterminate if this is not the case. The fields and registers that must be configured with the same values include MC_Enable, MC_Num_Group, MC_Base_Address and MC_Index_Position. These same fields in an Endpoint's Multicast Extended Capability structure must match those configured into a Multicast Extended Capability structure of the Switch or Root Complex above the Endpoint or in which the RCiEP is integrated.

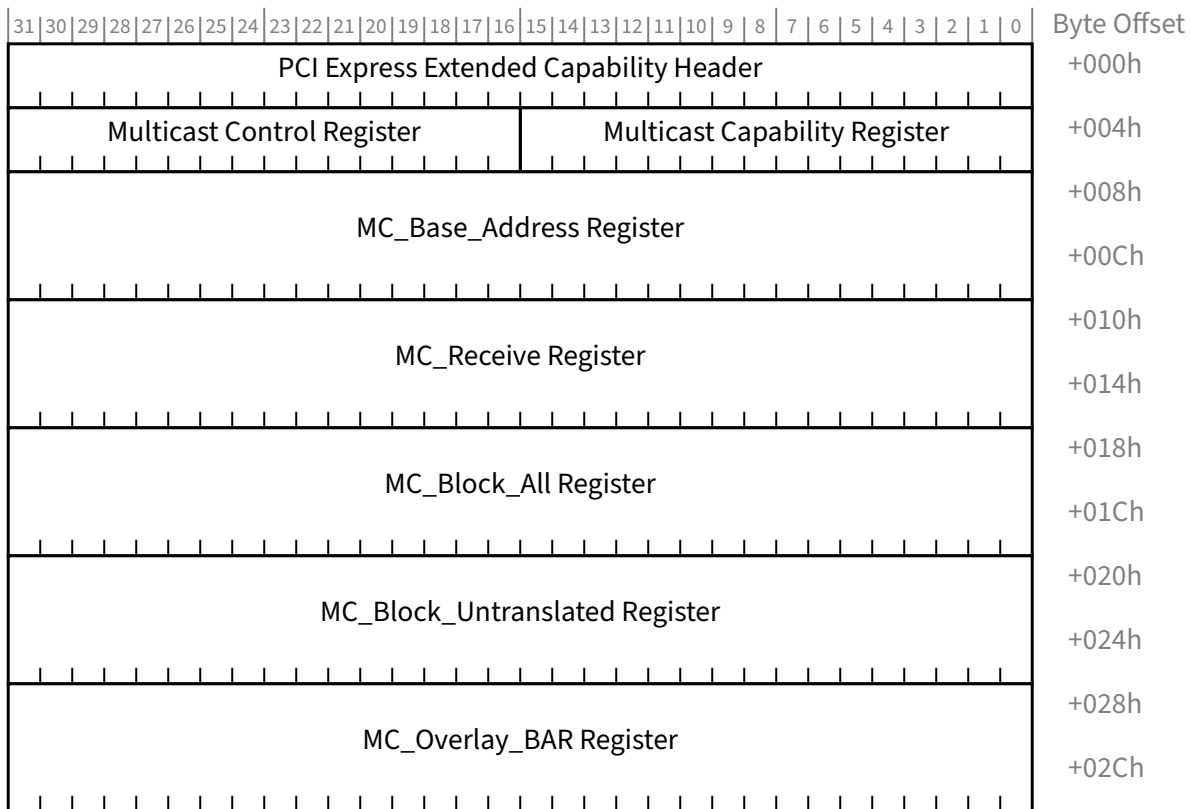

Figure 7-272 Multicast Extended Capability Structure §

7.9.11.1 Multicast Extended Capability Header (Offset 00h) §

§ Figure 7-273 details allocation of the fields in the Multicast Extended Capability Header and § Table 7-243 provides the respective bit definitions.

Figure 7-273 Multicast Extended Capability Header §

Table 7-244 Multicast Capability Register §

Bit Location	Register Description	Attributes
5:0	MC_Max_Group - Value indicates the maximum number of Multicast Groups that the component supports, encoded as M-1. A value of 00h indicates that one Multicast Group is supported. For VFs, this field is <u>RsvdP</u> . The value from the associated PF applies.	<u>RO</u> <u>VF RsvdP</u>
13:8	MC_Window_Size_Requested - In Endpoints, the log ₂ of the Multicast Window size requested. <u>RsvdP</u> in Switch and Root Ports. For VFs, this field is <u>RsvdP</u> . The value from the associated PF applies.	<u>RO</u> <u>VF RsvdP</u>
15	MC_ECRC_Regeneration_Supported - If Set, indicates that ECRC regeneration is supported. This bit must not be Set unless the Function supports Advanced Error Reporting, and the ECRC Check Capable bit in the <u>Advanced Error Capabilities and Control Register</u> is also Set. However, if ECRC regeneration is supported, its operation is not contingent upon the setting of the ECRC Check Enable bit in the <u>Advanced Error Capabilities and Control Register</u> . This bit is applicable to <u>Switch and Root Ports</u> and is <u>RsvdP</u> in all other Functions.	<u>RO/RsvdP</u>

7.9.11.3 Multicast Control Register (Offset 06h) §

§ Table 7-245 details allocation of the fields in the Multicast Control Register and § Table 7-245 provides the respective bit definitions.

Figure 7-275 Multicast Control Register §

Table 7-245 Multicast Control Register §

Bit Location	Register Description	Attributes
5:0	MC_Num_Group - Value indicates the number of Multicast Groups configured for use, encoded as N-1. The default value of 00 0000b indicates that one Multicast Group is configured for use. Behavior is undefined if value exceeds MC_Max_Group. This parameter indirectly defines the upper limit of the Multicast address range. This field is ignored if MC_Enable is Clear. Default value is 00 0000b. For VFs, this field is RsvdP. The value from the associated PF applies.	RW VF RsvdP
15	MC_Enable - When Set, the Multicast mechanism is enabled for the component. Default value is 0b.	RW

7.9.11.4 MC_Base_Address Register (Offset 08h) §

The MC_Base_Address Register contains the MC_Base_Address and the MC_Index_Position. § Figure 7-276 details allocation of the fields in the MC_Base_Address Register and § Table 7-246 provides the respective bit definitions.

Figure 7-276 MC_Base_Address Register §

Table 7-246 MC_Base_Address Register §

Bit Location	Register Description	Attributes
5:0	MC_Index_Position - The location of the LSB of the Multicast Group number within the address. Behavior is undefined if this value is less than 12 and MC_Enable is Set. Default is 0. For VFs, this field is RsvdP. The value from the associated PF applies.	RW VF RsvdP

Bit Location	Register Description	Attributes
63:12	MC_Base_Address - The base address of the Multicast address range. The behavior is undefined if MC_Enable is Set and bits in this field corresponding to address bits that contain the Multicast Group number or address bits less than MC_Index_Position are non-zero. Default is 0. For VFs, this field is RsvdP. The value from the associated PF applies.	RW VF RsvdP

7.9.11.5 MC_Receive Register (Offset 10h) §

The MC_Receive Register provides a bit vector denoting which Multicast groups the Function should accept, or in the case of Switch and Root Complex Ports, forward Multicast TLPs. This register is required in all Functions that implement the MC Capability structure.

§ Figure 7-277 details allocation of the fields in the MC_Receive Register and § Table 7-247 provides the respective bit definitions.

Figure 7-277 MC_Receive Register §

Table 7-247 MC_Receive Register §

Bit Location	Register Description	Attributes
MC_Max_Group:0	MC_Receive - For each bit that's Set, this Function gets a copy of any Multicast TLPs for the associated Multicast Group. Bits above MC_Num_Group are ignored by hardware. Default value of each bit is 0b.	RW
All other bits	Reserved	RsvdP

7.9.11.6 MC_Block_All Register (Offset 18h) §

The MC_Block_All Register provides a bit vector denoting which Multicast groups the Function should block. This register is required in all Functions that implement the MC Capability structure.

§ Figure 7-278 details allocation of the fields in the MC_Block_All Register and § Table 7-248 provides the respective bit definitions.

Figure 7-278 MC_Block_All Register §

Table 7-248 MC_Block_All Register §

Bit Location	Register Description	Attributes
MC_Max_Group:0	MC_Block_All - For each bit that is Set, this Function is blocked from sending TLPs to the associated Multicast Group. Bits above MC_Num_Group are ignored by hardware. Default value of each bit is 0b.	RW
All other bits	Reserved	RsvdP

7.9.11.7 MC_Block_Untranslated Register (Offset 20h) §

The MC_Block_Untranslated Register is used to determine whether or not a TLP that includes an Untranslated Address should be blocked. This register is required in all Functions that implement the MC Capability structure. However, an Endpoint Function that does not implement the ATS capability may implement this register as RsvdP.

§ Figure 7-279 details allocation of the fields in the MC_Block_Untranslated Register and § Table 7-249 provides the respective bit definitions.

Figure 7-279 MC_Block_Untranslated Register §

Table 7-249 MC_Block_Untranslated Register §

Bit Location	Register Description	Attributes
MC_Max_Group:0	MC_Block_Untranslated - For each bit that is Set, this Function is blocked from sending TLPs containing Untranslated Addresses to the associated MCG. Bits above MC_Num_Group are ignored by hardware. Default value of each bit is 0b.	RW
All other bits	Reserved	RsvdP

7.9.11.8 MC_Overlay_BAR Register (Offset 28h) §

The MC_Overlay_BAR Register is required in Switch and Root Complex Ports that support the Multicast Extended Capability and not implemented in Endpoints. Software must interpret the Device/Port Type field in the PCI Express Capabilities Register to determine if the MC_Overlay_BAR Register is present in a Function.

The MC_Overlay_BAR specifies the base address of a window in unicast space onto which Multicast TLPs going out an Egress Port are overlaid by a process of address replacement. This allows a single BAR in an Endpoint attached to the Switch or Root Port to be used for both unicast and Multicast traffic. At a Switch Upstream Port, it allows the Multicast address range, or a portion of it, to be overlaid onto host memory.

§ Figure 7-280 details allocation of the fields in the MC_Overlay_BAR Register and § Table 7-250 provides the respective bit definitions.

Figure 7-280 MC_Overlay_BAR Register §

Table 7-250 MC_Overlay_BAR Register §

Bit Location	Register Description	Attributes
5:0	MC_Overlay_Size - If 6 or greater, specifies the size in bytes of the overlay aperture as a power of 2. If less than 6, disables the overlay mechanism. Default value is 00 0000b.	RW
63:6	MC_Overlay_BAR - Specifies the base address of the window onto which MC TLPs passing through this Function will be overlaid. Default value is 0.	RW

7.9.12 Dynamic Power Allocation Extended Capability (DPA Capability) §

The DPA Capability structure is shown in § Figure 7-281.

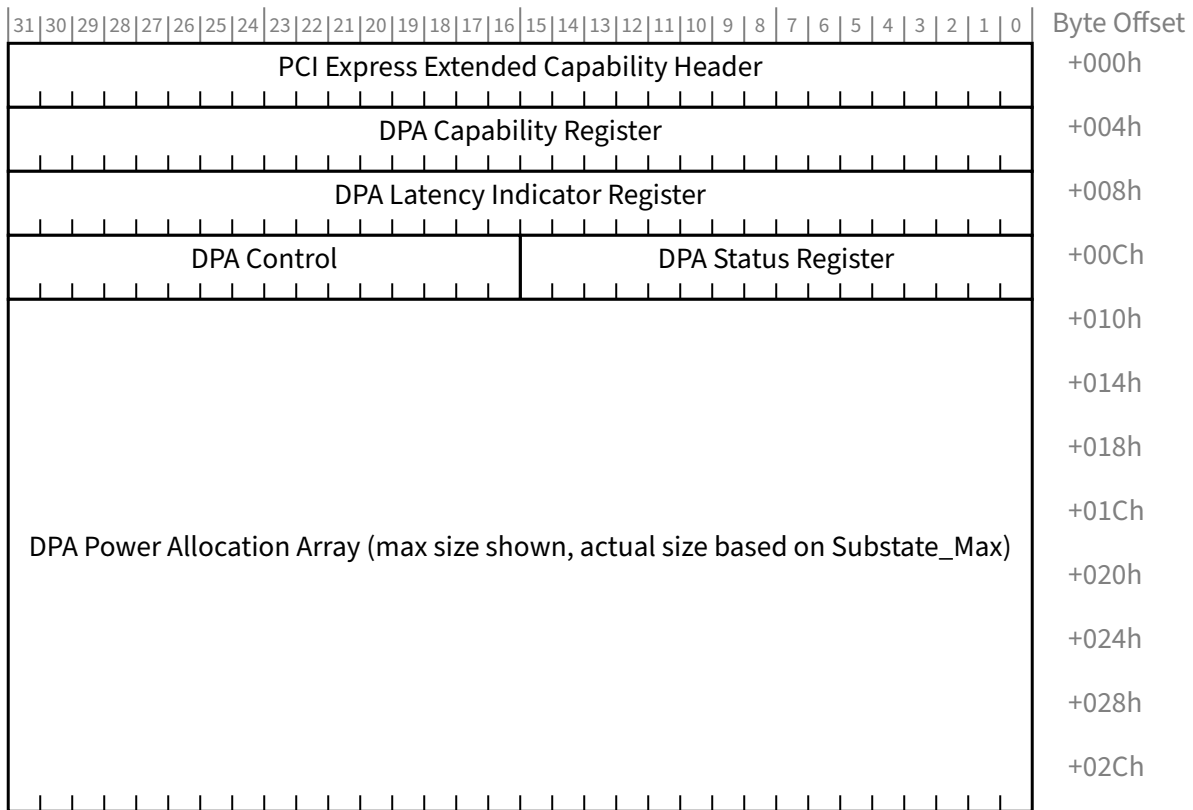

Figure 7-281 Dynamic Power Allocation Extended Capability Structure §

7.9.12.1 DPA Extended Capability Header (Offset 00h) §

Figure 7-282 DPA Extended Capability Header §

Table 7-251 DPA Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the DPA Extended Capability is 0016h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.	RO

7.9.12.2 DPA Capability Register (Offset 04h) §

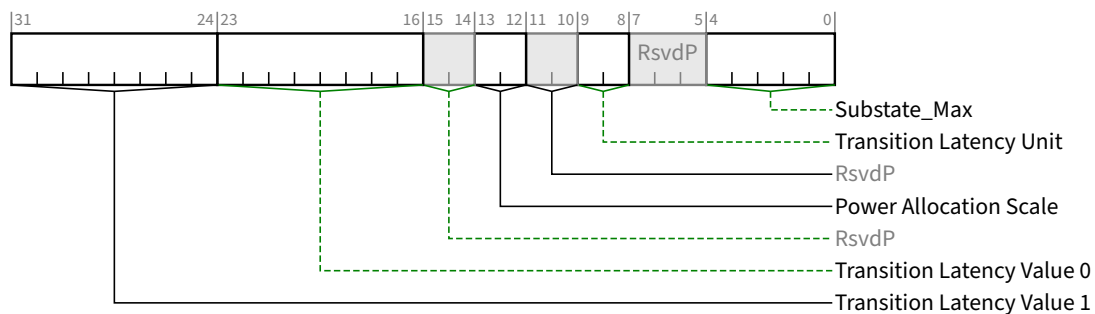

Figure 7-283 DPA Capability Register §

Table 7-252 DPA Capability Register §

Bit Location	Register Description	Attributes
4:0	Substate_Max - Value indicates the maximum substate number, which is the total number of supported substates minus one. A value of 0 0000b indicates support for one substate.	RO

Bit Location	Register Description	Attributes
9:8	<p>Transition Latency Unit (Tlunit) - A substate's Transition Latency Value is multiplied by the <u>Transition Latency Unit</u> to determine the maximum Transition Latency for the substate.</p> <p>Defined encodings are</p> <p>00b 1 ms</p> <p>01b 10 ms</p> <p>10b 100 ms</p> <p>11b Reserved</p>	RO
13:12	<p>Power Allocation Scale (PAS) - The encodings provide the scale to determine power allocation per substate in Watts. The value corresponding to the substate in the <u>Substate Power Allocation</u> field is multiplied by this field to determine the power allocation for the substate.</p> <p>Defined encodings are</p> <p>00b 10.0x</p> <p>01b 1.0x</p> <p>10b 0.1x</p> <p>11b 0.01x</p>	RO
23:16	<p>Transition Latency Value 0 (Xlcy0) - This value is multiplied by the <u>Transition Latency Unit</u> to determine the maximum Transition Latency for the substate</p>	RO
31:24	<p>Transition Latency Value 1 (Xlcy1) - This value is multiplied by the <u>Transition Latency Unit</u> to determine the maximum Transition Latency for the substate.</p>	RO

7.9.12.3 DPA Latency Indicator Register (Offset 08h) §

Figure 7-284 DPA Latency Indicator Register §

Table 7-253 DPA Latency Indicator Register §

Bit Location	Register Description	Attributes
31:0	<p>Transition Latency Indicator Bits - Each bit indicates which Transition Latency Value is associated with the corresponding substate. A value of 0b indicates <u>Transition Latency Value 0</u>; a value of 1b indicates <u>Transition Latency Value 1</u>.</p> <p>Only bits [Substate_Max:0] are defined. Bits above <u>Substate_Max</u> are <u>RsvdP</u>.</p>	RO

7.9.12.4 DPA Status Register (Offset 0Ch) §

Figure 7-285 DPA Status Register §

Table 7-254 DPA Status Register §

Bit Location	Register Description	Attributes
4:0	Substate Status - Indicates current substate for this Function. Default is 0 0000b.	RO
8	Substate Control Enabled - Used by software to disable the Substate Control field in the DPA Control Register. Hardware sets this bit following a Conventional Reset or FLR. Software clears this bit by writing a 1b to it. Software is unable to set this bit directly. When this bit is Set, the Substate Control field determines the current substate. When this bit is Clear, the Substate Control field has no effect on the current substate. Default value is 1b.	RW1C

7.9.12.5 DPA Control Register (Offset 0Eh) §

Figure 7-286 DPA Control Register §

Table 7-255 DPA Control Register §

Bit Location	Register Description	Attributes
4:0	Substate Control - Used by software to configure the Function substate. Software writes the substate value in this field to initiate a substate transition. When the Substate Control Enabled bit in the DPA Status Register is Set, this field determines the Function substate. When the Substate Control Enabled bit in the DPA Status Register is Clear, this field has no effect on the Function substate.	RW

Bit Location	Register Description	Attributes
	Default value is 0 0000b.	

7.9.12.6 DPA Power Allocation Array §

Figure 7-287 DPA Power Allocation Array §

Each Substate Power Allocation register indicates the power allocation value for its associated substate. The number of Substate Power Allocation registers implemented must be equal to the number of substates supported by Function, which is Substate_Max plus one.

Figure 7-288 Substate Power Allocation Register (0 to Substate_Max) §

Table 7-256 Substate Power Allocation Register (0 to Substate_Max) §

Bit Location	Register Description	Attributes
7:0	Substate Power Allocation - The value in this field is multiplied by the <u>Power Allocation Scale</u> to determine power allocation in Watts for the associated substate.	RO

7.9.13 TPH Requester Extended Capability §

The TPH Requester Extended Capability structure is required for all Functions that are capable of generating Request TLPs with TPH. For a Multi-Function Device, this capability must be present in each Function that is capable of generating Request TLPs with TPH.

The capability is optional for PFs and VFs. However, if a VF associated with a given PF contains the capability, all VFs associated with that PF must contain the capability.

For fields in the TPH Requester Capability Register (offset 04h), all VFs associated with a given PF must have the same values in all fields, but the PF's fields may have values different from those in its VFs.

Figure 7-289 TPH Extended Capability Structure §

7.9.13.1 TPH Requester Extended Capability Header (Offset 00h) §

Figure 7-290 TPH Requester Extended Capability Header §

Table 7-257 TPH Requester Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the TPH Requester Extended Capability is 0017h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.	RO

7.9.13.2 TPH Requester Capability Register (Offset 04h) §

Figure 7-291 TPH Requester Capability Register §

Table 7-258 TPH Requester Capability Register §

Bit Location	Register Description	Attributes
0	No ST Mode Supported - If set indicates that the Function supports the <u>No ST Mode</u> of operation. This mode is required to be supported by all Functions that implement this Capability structure. This bit must have a value of 1b.	RO
1	Interrupt Vector Mode Supported - If set indicates that the Function supports the Interrupt Vector Mode of operation.	RO
2	Device Specific Mode Supported - If set indicates that the Function supports the Device Specific Mode of operation.	RO
8	Extended TPH Requester Supported - If Set indicates that the Function is capable of generating Requests with additional TPH information using the <u>TPH TLP Prefix</u> . See § Section 2.2.7.1.1 for additional details.	RO
10:9	ST Table Location - Value indicates if and where the ST Table is located. Defined Encodings are: 00b ST Table is not present 01b ST Table is located in the TPH Requester Extended Capability structure 10b ST Table is located in the MSI-X Table (see § Section 7.7.2.) 11b Reserved A Function that only supports the <u>No ST Mode</u> of operation must have a value of 00b in this field. A Function may report a value of 10b only if it implements an MSI-X Capability.	RO
26:16	ST Table Size - Value indicates the maximum number of ST Table entries the Function may use. Software reads this field to determine the ST Table Size N, which is encoded as N-1. For example, a returned value of 000 0000 0011b indicates a table size of four entries. There is an upper limit of 64 entries when the ST Table is located in the <u>TPH Requester Extended Capability</u> structure. When the ST Table is located in the MSI-X Table, this value is limited by the size of the MSI-X Table. This field is only applicable for Functions that implement an ST Table as indicated by the <u>ST Table Location</u> field. Otherwise, the value in this field is undefined.	RO

7.9.13.3 TPH Requester Control Register (Offset 08h) §

Figure 7-292 TPH Requester Control Register §

Table 7-259 TPH Requester Control Register §

Bit Location	Register Description	Attributes
2:0	<p>ST Mode Select - selects the ST Mode of operation.</p> <p>Defined encodings are:</p> <p>000b No ST Mode</p> <p>001b Interrupt Vector Mode</p> <p>010b Device Specific Mode</p> <p>others reserved for future use</p> <p>Functions that support only the <u>No ST Mode</u> of operation must hardwire this field to 000b.</p> <p>Function operation is undefined if software enables a mode of operation that does not correspond to a mode supported by the Function.</p> <p>The default value of this field is 000b.</p> <p>See § Section 6.17.3 for details on ST modes of operation.</p>	<u>RW</u>
9:8	<p>TPH Requester Enable - Controls the ability to issue Request TLPs using either TPH or Extended TPH.</p> <p>Defined encodings are:</p> <p>00b Function operating as a Requester is not permitted to issue Requests with TPH or Extended TPH</p> <p>01b Function operating as a Requester is permitted to issue Requests with TPH and is not permitted to issue Requests with Extended TPH</p> <p>10b Reserved</p> <p>11b Function operating as a Requester is permitted to issue Requests with TPH and Extended TPH</p> <p>Functions that advertise that they do not support Extended TPH are permitted to hardwire bit 9 of this field to 0b.</p> <p>The default value of this field is 00b.</p>	<u>RW</u>

7.9.13.4 TPH ST Table (Starting from Offset 0Ch) §

Figure 7-293 TPH ST Table §

The TPH ST Table must be implemented in the TPH Requester Extended Capability structure if the value of the ST Table Location field is 01b. For all other values, the ST Entry registers must not be implemented. Each implemented ST Entry is 16 bits. The number of ST Entry registers implemented must be equal to the number of ST Table entries supported by the Function, which is the value of the ST Table Size field plus one.

Figure 7-294 TPH ST Table Entry §

Table 7-260 TPH ST Table Entry §

Bit Location	Register Description	Attributes
7:0	ST Lower - This field contains the lower 8 bits of a Steering Tag. Default value of this field is 00h.	<u>RW</u>
15:8	ST Upper - If the Function's <u>Extended TPH Requester Supported</u> bit is Set, then this field contains the upper 8 bits of a Steering Tag. Otherwise, this field is <u>RsvdP</u> . Default value of this field is 00h.	<u>RW</u>

7.9.14 DPC Extended Capability §

The Downstream Port Containment (DPC) Extended Capability is an optional normative capability that provides a mechanism for Downstream Ports to contain uncorrectable errors and enable software to recover from them. See § Section 6.2.11 . This capability may be implemented by a Root Port or a Switch Downstream Port. It is not applicable to any other Device/Port type.

If a Downstream Port implements the DPC Extended Capability, that Port must also be capable of reporting the DL_Active state, and indicate so by Setting the Data Link Layer Link Active Reporting Capable bit in the Link Capabilities Register. See § Section 7.5.3.6 .

If a Downstream Port implements the DPC Extended Capability, it is strongly recommended for that Port to support ERR_COR Subclass capability, and indicate so by Setting the ERR_COR Subclass Capable bit in the Device Capabilities Register. See § Section 7.5.3.3 .

The various RP PIO registers must be implemented only by Root Ports that support RP Extensions for DPC, as indicated by the RP Extensions for DPC bit in the DPC Capability Register.

7.9.14.1 DPC Extended Capability Header (Offset 00h) §

Figure 7-297 DPC Extended Capability Header §

Table 7-261 DPC Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability. PCI Express Extended Capability ID for the DPC Extended Capability is 001Dh.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	RO

7.9.14.2 DPC Capability Register (Offset 04h) §

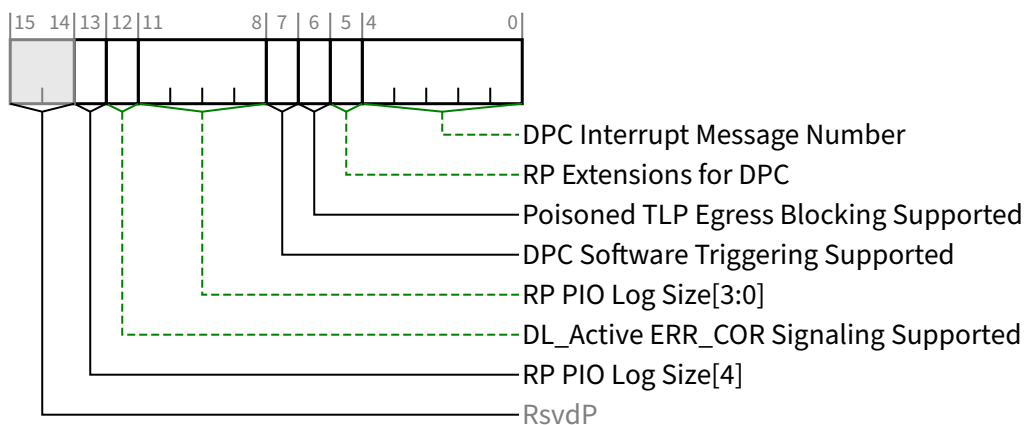

Figure 7-298 DPC Capability Register §

Table 7-262 DPC Capability Register §

Bit Location	Register Description	Attributes
4:0	<p>DPC Interrupt Message Number - This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with the DPC Capability structure.</p> <p>For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the <u>Multiple Message Enable</u> field in the <u>Message Control Register</u> for MSI.</p> <p>For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant.</p> <p>If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined.</p>	RO
5	<p>RP Extensions for DPC - If Set, this bit indicates that a Root Port supports a defined set of DPC Extensions that are specific to Root Ports. Switch Downstream Ports must not Set this bit.</p>	RO
6	<p>Poisoned TLP Egress Blocking Supported - If Set, this bit indicates that the Root Port or Switch Downstream Port supports the ability to block the transmission of a poisoned TLP from its Egress Port. Root Ports that support <u>RP Extensions for DPC</u> must Set this bit.</p>	RO
7	<p>DPC Software Triggering Supported - If Set, this bit indicates that a Root Port or Switch Downstream Port supports the ability for software to trigger DPC. Root Ports that support <u>RP Extensions for DPC</u> must Set this bit.</p>	RO
11:8	<p>RP PIO Log Size[3:0] - This field indicates how many DWORDs are allocated for the RP PIO log registers, comprised by the RP PIO Header Log, the RP PIO ImpSpec Log, and RP PIO TLP Prefix Log.</p> <ul style="list-style-type: none"> • If the Root Port does not support <u>RP Extensions for DPC</u>, the value of this field must be <u>Zero</u>. • If the Root Port supports <u>RP Extensions for DPC</u> but does not support Flit Mode, the value of this field must be 4 or greater. • If the Root Port supports both <u>RP Extensions for DPC</u> and Flit Mode, see § <u>Section 6.2.11.3</u> for requirements. <p>See § <u>Section 7.9.14.11</u> , § <u>Section 7.9.14.12</u> , and § <u>Section 7.9.14.13</u> .</p>	RO
12	<p>DL_Active ERR_COR Signaling Supported - If Set, this bit indicates that the Root Port or Switch Downstream Port supports the ability to signal with ERR_COR when the Link transitions to the DL_Active state. Root Ports that support <u>RP Extensions for DPC</u> must Set this bit.</p>	RO
13	<p>RP PIO Log Size[4] - This bit is an extension of <u>RP PIO Log Size[3:0]</u> for use in Flit Mode. If Flit Mode is not supported, this bit is <u>RsvdP</u>.</p>	RO/RsvdP

7.9.14.3 DPC Control Register (Offset 06h) §

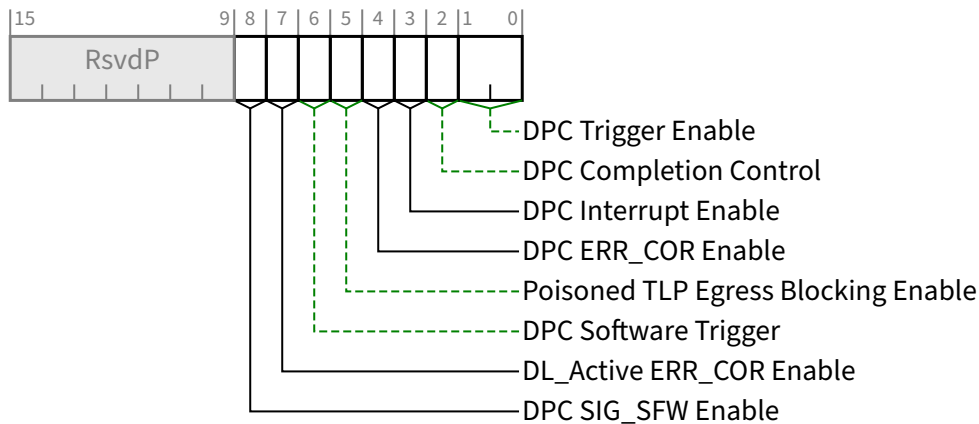

Figure 7-299 DPC Control Register §

Table 7-263 DPC Control Register §

Bit Location	Register Description	Attributes
1:0	<p>DPC Trigger Enable - This field enables DPC and controls the conditions that cause DPC to be triggered.</p> <p>Defined encodings are:</p> <p>00b DPC is disabled</p> <p>01b DPC is enabled and is triggered when the Downstream Port detects an unmasked uncorrectable error or when the Downstream Port receives an ERR_FATAL Message</p> <p>10b DPC is enabled and is triggered when the Downstream Port detects an unmasked uncorrectable error or when the Downstream Port receives an ERR_NONFATAL or ERR_FATAL Message</p> <p>11b Reserved</p> <p>Default value of this field is 00b.</p>	RW
2	<p>DPC Completion Control - This bit controls the Completion Status for Completions formed during DPC. See § Section 2.9.3 .</p> <p>Defined encodings are:</p> <p>0b Completer Abort (CA) Completion Status</p> <p>1b Unsupported Request (UR) Completion Status</p> <p>Default value of this bit is 0b.</p>	RW
3	<p>DPC Interrupt Enable - When Set, this bit enables the generation of an interrupt to indicate that DPC has been triggered. See § Section 6.2.11.1 .</p> <p>Default value of this bit is 0b.</p>	RW
4	<p>DPC ERR_COR Enable - When Set, this bit enables the sending of an ERR_COR Message to indicate that DPC has been triggered. See § Section 6.2.11.2 .</p> <p>Default value of this bit is 0b.</p>	RW

Bit Location	Register Description	Attributes
5	<p>Poisoned TLP Egress Blocking Enable - This bit must be RW if the <u>Poisoned TLP Egress Blocking Supported</u> bit is Set; otherwise, it is permitted to be hardwired to 0b. Software must not Set this bit unless the <u>Poisoned TLP Egress Blocking Supported</u> bit is Set.</p> <p>When Set, this bit enables the associated Egress Port to block the transmission of poisoned TLPs. See § Section 2.7.2.1 .</p> <p>Default value of this bit is 0b.</p>	RW/RO
6	<p>DPC Software Trigger - This bit must be RW if the <u>DPC Software Triggering Supported</u> bit is Set; otherwise, it is permitted to be hardwired to 0b.</p> <p>If DPC is enabled and the <u>DPC Trigger Status</u> bit is Clear, when software writes 1b to this bit, DPC is triggered. Otherwise, software writing a 1b to this bit has no effect.</p> <p>It is permitted to write 1b to this bit while simultaneously writing updated values to other fields in this register, notably the <u>DPC Trigger Enable</u> field. For this case, the <u>DPC Software Trigger</u> semantics are based on the updated value of the <u>DPC Trigger Enable</u> field.</p> <p>This bit always returns 0b when read.</p>	RW/RO
7	<p>DL_Active ERR_COR Enable - This bit must be RW if the <u>DL_Active ERR_COR Signaling Supported</u> bit is Set; otherwise, it is permitted to be hardwired to 0b. Software must not Set this bit unless the <u>DL_Active ERR_COR Signaling Supported</u> bit is Set.</p> <p>When Set, this bit enables the associated Downstream Port to signal with <u>ERR_COR</u> when the Link transitions to the <u>DL_Active</u> state. See § Section 6.2.11.5 .</p> <p>Default value of this bit is 0b.</p>	RW/RO
8	<p>DPC SIG_SFW Enable - This bit must be implemented if the <u>ERR_COR Subclass Capable</u> bit in the Device Capabilities Register is Set; otherwise, it is permitted to be hardwired to 0b. If the <u>ERR_COR Subclass Capable</u> bit is Clear and software Sets this bit, the behavior is undefined.</p> <p>When Set, this bit enables sending an <u>ERR_COR</u> Message to indicate a DPC event that's been enabled for <u>ERR_COR</u> signaling. See § Section 6.2.11.2 and § Section 6.2.11.5 . This is an additional and alternative way to enable overall DPC <u>ERR_COR</u> signaling beyond the <u>Correctable Error Reporting Enable</u> bit in the Device Control Register. This bit does not affect a Function's ability to send <u>ERR_COR</u> Messages other than the <u>ECS SIG_SFW</u> subclass.</p> <p>Default value of this bit is 0b.</p>	RW/RO

7.9.14.4 DPC Status Register (Offset 08h) §

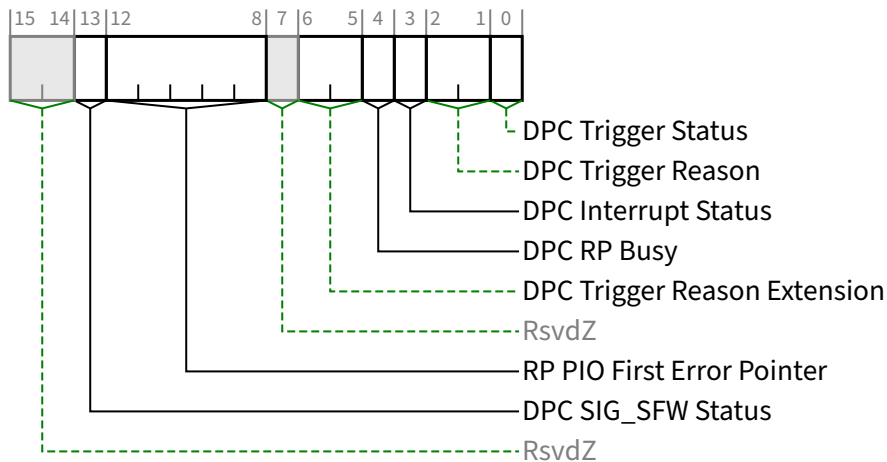

Figure 7-300 DPC Status Register §

Table 7-264 DPC Status Register §

Bit Location	Register Description	Attributes
0	<p>DPC Trigger Status - When Set, this bit indicates that DPC has been triggered, and by definition the Port is “in DPC”. DPC is event triggered.</p> <p>While this bit is Set, hardware must direct the LTSSM to the Disabled State. This bit must be cleared before the LTSSM can be released from the Disabled State, after which the Port is no longer in DPC, and the LTSSM must transition to the Detect State. See § Section 6.2.11 for requirements on how long software must leave the Downstream Port in DPC. Once these requirements are met, software is permitted to clear this bit regardless of the state of other status bits associated with the triggering event.</p> <p>After clearing this bit, software must honor timing requirements defined in § Section 6.6.1 with respect to the first Configuration Read following a Conventional Reset.</p> <p>Default value of this bit is 0b.</p>	<u>RW1CS</u>
2:1	<p>DPC Trigger Reason - This field indicates why DPC has been triggered. Defined encodings are:</p> <ul style="list-style-type: none"> 00b DPC was triggered due to an unmasked uncorrectable error 01b DPC was triggered due to receiving an ERR_NONFATAL 10b DPC was triggered due to receiving an ERR_FATAL 11b DPC was triggered due to a reason that is indicated by the <u>DPC Trigger Reason Extension</u> field. <p>This field is valid only when the <u>DPC Trigger Status</u> bit is Set; otherwise the value of this field is undefined.</p>	<u>ROS</u>
3	<p>DPC Interrupt Status - This bit is Set if DPC is triggered while the <u>DPC Interrupt Enable</u> bit is Set. This may cause the generation of an interrupt. See § Section 6.2.11.1 .</p> <p>Default value of this bit is 0b.</p>	<u>RW1CS</u>

Bit Location	Register Description	Attributes
4	<p>DPC RP Busy - When the <u>DPC Trigger Status</u> bit is Set and this bit is Set, the Root Port is busy with internal activity that must complete before software is permitted to Clear the <u>DPC Trigger Status</u> bit. If software Clears the <u>DPC Trigger Status</u> bit while this bit is Set, the behavior is undefined.</p> <p>This field is valid only when the <u>DPC Trigger Status</u> bit is Set; otherwise the value of this field is undefined.</p> <p>This bit is applicable only for Root Ports that support <u>RP Extensions for DPC</u>, and is Reserved for Switch Downstream Ports.</p> <p>Default value of this bit is undefined.</p>	<u>RO/RsvdZ</u>
6:5	<p>DPC Trigger Reason Extension - This field serves as an extension to the <u>DPC Trigger Reason</u> field. When that field is valid and has a value of 11b, this field indicates why DPC has been triggered. Defined encodings are:</p> <p>00b DPC was triggered due to an RP PIO error</p> <p>01b DPC was triggered due to the DPC Software Trigger bit</p> <p>10b Reserved</p> <p>11b Reserved</p> <p>This field is valid only when the <u>DPC Trigger Status</u> bit is Set and the value of the <u>DPC Trigger Reason</u> field is 11b; otherwise the value of this field is undefined.</p>	<u>ROS</u>
12:8	<p>RP PIO First Error Pointer - The value of this field identifies a bit position in the <u>RP PIO Status Register</u>, and this field is considered valid when that bit is Set. When this field is valid, and software writes a 1b to the indicated RP PIO Status bit (thus clearing it), this field must revert to its default value.</p> <p>This field is applicable only for Root Ports that support <u>RP Extensions for DPC</u>, and otherwise is Reserved.</p> <p>If this field is not Reserved, its default value is 1 1111b, indicating a permanently Reserved RP PIO Status bit, thus guaranteeing that this field is not considered valid.</p>	<u>ROS/RsvdZ</u>
13	<p>DPC SIG_SFW Status - If the Function supports <u>ERR_COR</u> Subclass capability, this bit must be implemented; otherwise, it must be hardwired to 0b. If implemented, this bit is Set when a <u>SIG_SFW ERR_COR</u> Message is sent to signal a DPC event. See § Section 6.2.11.2 and § Section 6.2.11.5 .</p> <p>Default value of this bit is 0b</p>	<u>RW1CS/RsvdZ</u>

7.9.14.11 RP PIO Header Log Register (Offset 20h) §

This register is implemented only in Root Ports that support RP Extensions for DPC. The RP PIO Header Log Register contains the header from the Request TLP associated with a recorded RP PIO error. Refer to § Section 6.2.11.3 for further details. In Non-Flit Mode, this register is 16 bytes. In Flit Mode, this register is between 52 and 76 bytes and is split into two portions at Offset 20h and Offset 34h. In both Flit Mode and Non-Flit Mode, this register is formatted identically to the Header Log register in AER. See § Section 7.8.4.8.

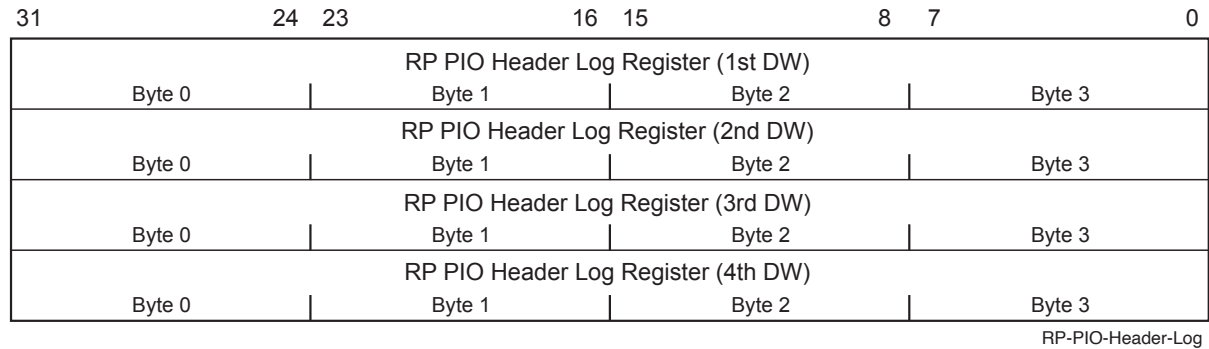

Figure 7-307 RP PIO Header Log Register §

Table 7-271 RP PIO Header Log Register §

Bit Location	Register Description	Attributes	Default
127:0	TLP Header - of the TLP associated with the error	<u>ROS</u>	0

7.9.14.12 RP PIO ImpSpec Log Register (Offset 30h) §

This register is permitted to be implemented only in Root Ports that support RP Extensions for DPC. The RP PIO ImpSpec Log Register, if implemented, contains implementation specific information associated with the recorded error, e.g., indicating the source of the Request TLP. Space is allocated for this register if the value of the RP PIO Log Size field is 5 or greater. If space is allocated for the register, but the register is not implemented, the bits must be hardwired to 0b.

Figure 7-308 RP PIO ImpSpec Log Register §

Table 7-272 RP PIO ImpSpec Log Register §

Bit Location	Register Description	Attributes	Default
31:0	RP PIO ImpSpec Log	<u>ROS</u>	0

7.9.14.13 RP PIO TLP Prefix Log Register (Offset 34h) §

This register is permitted to be implemented only in Root Ports that support RP Extensions for DPC.

In Non-Flit Mode, the RP PIO TLP Prefix Log Register contains any End-End TLP Prefixes from the TLP corresponding to a recorded RP PIO error. Refer to § Section 6.2.11.3 for further details.

In Flit Mode, the RP PIO TLP Prefix Log Register does not exist and this configuration space is a continuation of the RP PIO TLP Header Log Register.

If the Root Port supports tracking Non-Posted Requests that contain End-End TLP Prefixes, this register must be implemented, and must be of sufficient size to record the maximum number of End-End TLP Prefixes for any tracked Request. See § Section 2.9.3 . The allocated size in DWORDs of the RP PIO TLP Prefix Log Register is the RP PIO Log Size minus 5 if the RP PIO Log Size is 9 or less, or 4 if the RP PIO Log Size is greater than 9. The implemented size of the TLP Prefix Log must be less than or equal to the Root Port's Max End-End TLP Prefixes field value. For the case where the Root Port never transmits Non-Posted Requests containing End-End TLP Prefixes, the allocated and implemented size of the TLP Prefix Log is permitted to be 0. Any DWORDs allocated but not implemented must be hardwired to zero.

This register is formatted identically to the TLP Prefix Log register in AER, although this register's allocated size is variable, whereas the register in AER is always 4 DWORDs. See § Section 7.8.4.12 . The First TLP Prefix Log register contains the first End-End TLP Prefix from the TLP, the Second TLP Prefix Log register contains the second End-End TLP Prefix, and so forth. If the TLP contains fewer TLP Prefixes than this register accommodates, any remaining TLP Prefix Log registers must contain zero.

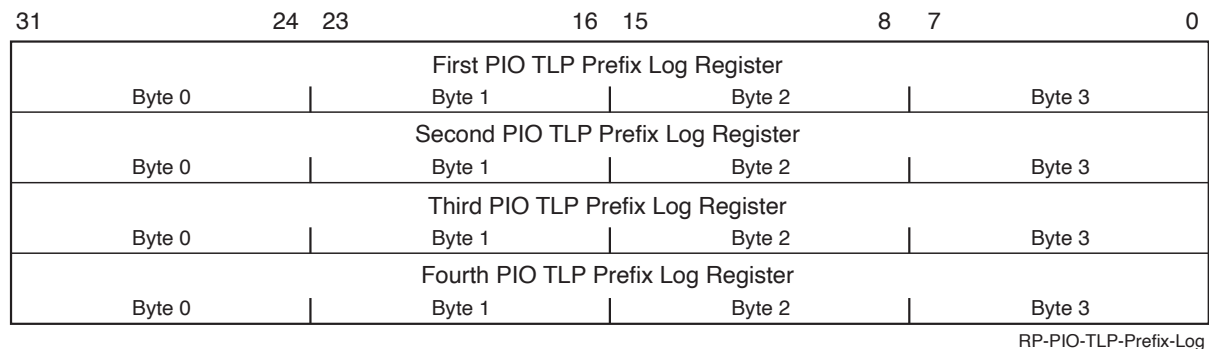

Figure 7-309 RP PIO TLP Prefix Log Register §

Bit Location	Register Description	Attributes	Default
127:0	RP PIO TLP Prefix Log	ROS	0

7.9.15 Precision Time Measurement Extended Capability (PTM Extended Capability) §

The Precision Time Measurement Extended Capability is an optional Extended Capability for discovering and controlling the distribution of a PTM Hierarchy. For Root Complexes, this Capability is required in any Root Port, RCiEP, or RCRB that supports PTM. For Functions associated with an Upstream Port that support PTM, this Capability is required in exactly one Function of that Upstream Port and that Capability controls the PTM behavior of all PTM capable Functions associated with that Upstream Port. For Switch Downstream Ports, PTM behavior is controlled by the same PTM Capability that controls the associated Switch Upstream Port. The PTM Capability is not permitted in Bridges, Switch Downstream Ports, and Root Complex Event Collectors.

For Switches, a single instance of this Capability controls behavior for the entire Switch. If the Upstream Port of the Switch is associated with an MFD, it is not required that the controlling Function be the Function corresponding to the Switch Upstream Port. For a given Switch, if this Capability is present, all Downstream Ports of the Switch must implement the requirements defined in § Section 6.21.3.2 .

Figure 7-310 PTM Extended Capability Structure §

7.9.15.1 PTM Extended Capability Header (Offset 00h) §

Figure 7-311 PTM Extended Capability Header §

Table 7-274 PTM Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Precision Time Measurement Capability is 001Fh.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.	RO

7.9.15.2 PTM Capability Register (Offset 04h) §

This register describes a Function's support for Precision Time Measurement. Not all fields within this register apply to all Functions capable of implementing PTM.

Figure 7-312 PTM Capability Register §

Table 7-275 PTM Capability Register §

Bit Location	Register Description	Attributes
0	<p>PTM Requester Capable - Indicates the Function implements the PTM Requester role (see § Section 6.21.3.1).</p> <p>Endpoints and RCIEPs are permitted to Set this bit to indicate that they implement the PTM Requester role.</p> <p>Switch Upstream Ports must Set this bit if the Switch contains one or more of the following:</p> <ul style="list-style-type: none"> • A Downstream Port that implements the PTM Responder role. • An additional Function that implements the PTM Requester role. 	HwInit
1	<p>PTM Responder Capable - Root Ports and RCRBs are permitted to, and Switches supporting PTM must, Set this bit to indicate they implement the PTM Responder role (see § Section 6.21.3.2).</p> <p>If <u>PTM Root Capable</u> is Set, then this bit must be Set.</p>	HwInit
2	<p>PTM Root Capable - Root Ports, RCRBs, and Switches are permitted to Set this bit if they are capable of being a source of PTM Master Time (see § Section 6.21.1).</p> <p>All other Functions must hardwire this bit to 0b.</p>	HwInit
3	<p>ePTM Capable - If Set, indicates that this device supports Enhanced Precision Time Measurement (ePTM). This bit <i>MUST@FLIT</i> be Set in all PTM Devices.</p>	HwInit
4	<p>PTM Propagation Delay Adaptation Capable - When Set, this field indicates the Port supports the PTM Propagation Delay Adaptation Capability, controlled via the PTM Propagation Delay Adaptation Interpretation B bit in the Link Control Register. For a Switch, when Set in the Upstream Port of the Switch, indicates that the Upstream Port and all Downstream Ports of the Switch support the PTM Propagation Delay Adaptation Capability, controlled per Port via the <u>PTM Propagation Delay Adaptation Interpretation B</u> bit in the <u>Link Control Register</u> of each Port.</p>	HwInit
15:8	<p>Local Clock Granularity - Encodings are:</p> <p>0000 0000b Time Source does not implement a local clock. It simply propagates timing information obtained from further Upstream in the PTM Hierarchy when responding to PTM Request messages.</p> <p>0000 0001b to 1111 1110b Indicates the period of this Time Source's local clock in ns.</p> <p>1111 1111b Indicates the period of this Time Source's local clock is greater than 254 ns.</p>	HwInit/RsvdP

Bit Location	Register Description	Attributes
	<p>If the PTM Root Select bit is Set, this local clock is used to provide PTM Master Time. Otherwise, the Time Source uses this local clock to locally track PTM Master Time received from further Upstream within a PTM Hierarchy.</p> <p>This field is <u>RsvdP</u> if the PTM Root Capable bit is 0b.</p>	

7.9.15.3 PTM Control Register (Offset 08h) §

This register controls a Function's participation in the Precision Time Measurement mechanism. Not all fields within this register apply to all Functions capable of implementing PTM.

Figure 7-313 PTM Control Register §

Table 7-276 PTM Control Register §

Bit Location	Register Description	Attributes
0	<p>PTM Enable - When Set, this Function is permitted to participate in the PTM mechanism according to its selected role(s) (see § Section 6.21.2).</p> <p>Default value is 0b.</p>	<u>RW</u>
1	<p>Root Select - When Set, if the PTM Enable bit is also Set, this Time Source is the PTM Root.</p> <p>Within each PTM Hierarchy, it is recommended that system software select only the furthest Upstream Time Source to be the PTM Root.</p> <p>Default value is 0b. If the value of the <u>PTM Root Capable</u> bit is 0b, this bit is permitted to be hardwired to 0b.</p>	<u>RW/RO</u>
15:8	<p>Effective Granularity - For Functions implementing the PTM Requester Role, this field provides information relating to the expected accuracy of the PTM clock, but does not otherwise affect the PTM mechanism.</p> <p>For Endpoints, system software must program this field to the value representing the maximum <u>Local Clock Granularity</u> reported by the PTM Root and all intervening PTM Time Sources.</p> <p>For RCiEPs, system software must set this field to the value reported in the <u>Local Clock Granularity</u> field by the associated PTM Time Source.</p> <p>Permitted values:</p> <p>0000 0000b Unknown PTM granularity - one or more Switches between this Function and the PTM Root reported a <u>Local Clock Granularity</u> value of 0000 0000b.</p> <p>0000 0001b to 1111 1110b Indicates the effective PTM granularity in ns.</p>	<u>RW/RO</u>

Bit Location	Register Description	Attributes
	<p>1111 1111b Indicates the effective PTM granularity is greater than 254 ns.</p> <p>Default value is 0000 0000b. If <u>PTM Requester Capable</u> is Clear, this field is permitted to be hardwired to 0000 0000b.</p>	

7.9.16 Readiness Time Reporting Extended Capability §

The Readiness Time Reporting Extended Capability provides an optional mechanism for describing the time required for a Device or Function to become Configuration-Ready. In the indicated situations, software is permitted to issue Requests to the Device or Function after waiting for the time advertised in this capability and need not wait for the (longer) times required elsewhere.

Software is permitted to issue requests upon the earliest of:

- Receiving a Readiness Notifications message (see § Section 6.22).
- Waiting the appropriate time as specified in this document or in applicable specifications including the [PCI] and the [PCI-PM].
- Waiting the time indicated in the associated field of this capability.
- Waiting the time defined by system software or firmware ¹⁸⁴.

Software is permitted to cache values from this capability and to use those cached values as long as the same device operating in the same manner has not changed.

This capability is permitted to be implemented in all Functions.

The capability is optional for PFs and VFs. However, if a VF associated with a given PF contains the capability, all VFs associated with that PF must contain the capability and report the same time values.

For VFs, see § Section 5.10.1). Other Functions must be Configuration-Ready if:

- The Immediate Readiness bit is Clear and at least Reset Time has elapsed after the completion of Conventional Reset
 - If the Immediate Readiness bit is Set, Reset Time does not apply, and is Reserved
- The Function is associated with an Upstream Port and at least DL_Up Time has elapsed after the Downstream Port above that Function reported Data Link Layer Link Active (see § Section 7.5.3.8).
- The Function supports Function Level Reset and at least FLR Time has elapsed after that Function was issued a Function Level Reset.
- Immediate_Readiness_on_Return_to_D0 is Clear and at least D3_{Hot} to D0 Time has elapsed after that Function was directed to the D0 state from D3_{Hot}.
 - If the Immediate_Readiness_on_Return_to_D0 bit is Set, D3_{Hot} to D0 Time does not apply, and is Reserved

When Immediate_Readiness_on_Return_to_D0 is Clear, a Function must be Configuration-Ready when at least D3_{Hot} to D0 Time has elapsed after the Function was directed to the D0 state from D3_{Hot}. In addition, the Function must be in either the D0_{uninitialized} or D0_{active} state, depending on the value of the No_Soft_Reset bit.

184. For example, using ACPI tables to provide the equivalent of this capability.

If the above conditions do not apply, Function behavior is not determined by the Readiness Time Reporting Extended Capability, and the Function must respond as defined elsewhere (including, for example, no response or a response with Configuration Retry Status).

The time values reported are determined by implementation specific mechanisms. A Valid bit is defined in this capability to permit a device to defer reporting time values, for example to allow hardware initialization through driver-based mechanisms. If the Valid bit remains Clear and 1 minute has elapsed after device driver(s) have started, software is permitted to assume that no values will be reported.

Registers and fields in the Readiness Time Reporting Extended Capability are shown in § Figure 7-314. Time values are encoded in floating point as shown in § Figure 7-315. The actual time value is $Value \times Multiplier[Scale]$. For example, the value A1Eh represents about 1 second (actually 1.006 sec) and the value 80Ah represents about 10 ms (actually 10.240 ms).

Figure 7-314 Readiness Time Reporting Extended Capability §

Scale	Multiplier
0	1 ns
1	32 ns
2	1,024 ns
3	32,768 ns
4	1,048,576 ns
5	33,554,432 ns
6	Reserved
7	Reserved

Multiplier = 32^{Scale}

23:12	<p>D3_{Hot} to D0 Time - If <u>Immediate_Readiness_on_Return_to_D0</u> is Clear, <u>D3_{Hot} to D0 Time</u> is the time that a non-VF Function requires after it is directed from <u>D3_{Hot} to D0</u> before it is <u>Configuration-Ready</u> and has returned to either <u>D0_{uninitialized}</u> or <u>D0_{active}</u> state. For VF semantics, see § Section 5.10.1.</p> <p>This field is <u>RsvdP</u> if the <u>Immediate_Readiness_on_Return_to_D0</u> bit is Set.</p> <p>For a VF that does not implement the <u>PCI Power Management Capability</u>, this field is undefined.</p> <p>This field is undefined when the <u>Valid</u> bit is Clear.</p> <p>This field must be less than or equal to the encoded value 80Ah.</p>	<u>HwInit/RsvdP</u>

7.9.17 Hierarchy ID Extended Capability §

The Hierarchy ID Extended Capability provides an optional mechanism for passing a unique identifier to Functions within a Hierarchy. At most one instance of this capability is permitted in a Function. This capability is not applicable to Bridges, Root Complex Event Collectors, and RCRBs.

This capability takes three forms:

In Upstream Ports:

- This capability is permitted any Function associated with an Upstream Port.
- This capability is optional in Switch Upstream Ports. Support in Switch Upstream and Downstream Ports is independently optional.
- This capability is mandatory in Functions that use the Hierarchy ID Message. This includes use by the Function's driver.
- Functions, other than VFs, that have Hierarchy ID Writeable Clear, must report the Message Requester ID, Hierarchy ID, System GUID Authority ID, and System GUID fields from the most recently received Hierarchy ID Message.
- All VFs that have Hierarchy ID Writeable Clear, must report the same Hierarchy ID Valid, Message Requester ID, Hierarchy ID, System GUID Authority ID, and System GUID values as their associated PF.
- PFs must implement this capability if any of their VFs implement this capability.
- Functions that have Hierarchy ID Writeable Set must report the Hierarchy ID Valid, Message Requester ID, Hierarchy ID, System GUID Authority ID, and System GUID values programmed by software.

In Downstream Ports:

- This capability is permitted in any Downstream Port. It is recommended that it be implemented in Root Ports.
- When present in a Switch Downstream Port, this capability must be implemented in all Downstream Ports of the Switch. Support in Switch Upstream and Downstream Ports is independently optional.
- In Downstream Ports, the Hierarchy ID, System GUID Authority ID, and System GUID fields are Read / Write and contain the values to send in the Hierarchy ID Message.
- A Hierarchy ID capability is not affected by Hierarchy ID Messages forwarded through the associated Downstream Port.

In RCiEPs:

- VFs that have Hierarchy ID Writeable Clear must report the same Message Requester ID, Hierarchy ID, System GUID Authority ID, and System GUID values as their associated PF.
- PFs must implement this capability if any of their VFs implement this capability.
- Functions, other than VFs, that have Hierarchy ID Writeable Clear, must report the same Hierarchy ID Valid, Message Requester ID, Hierarchy ID, System GUID Authority ID, and System GUID values. The source of this information is outside the scope of this specification.
- Functions that have Hierarchy ID Writeable Set must report the Hierarchy ID Valid, Message Requester ID, Hierarchy ID, System GUID Authority ID, and System GUID values programmed by software.

§ Figure 7-319 details the layout of the Hierarchy ID Extended Capability.

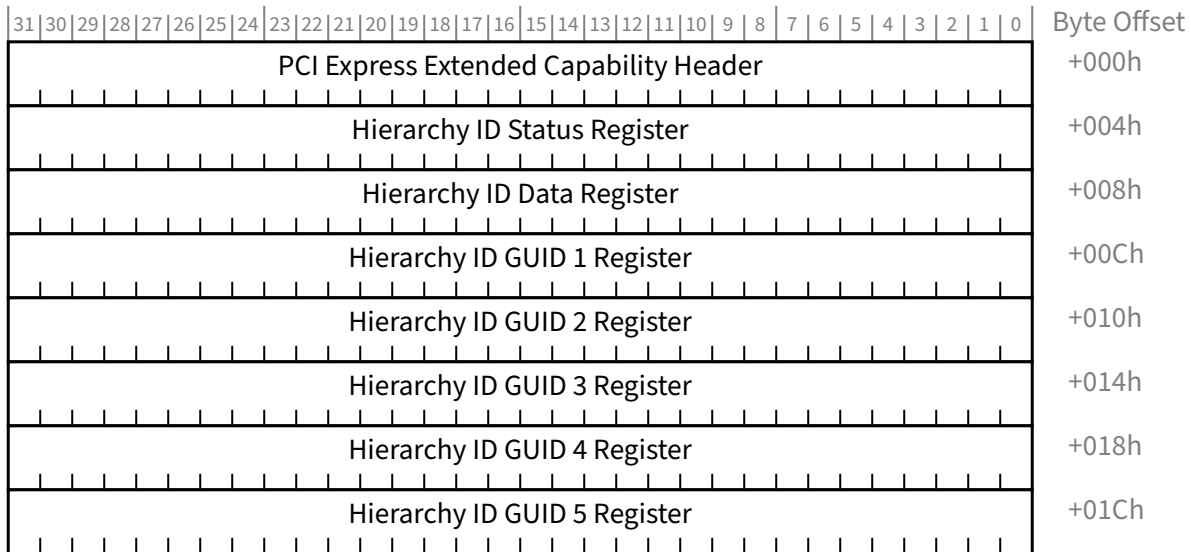

Figure 7-319 Hierarchy ID Extended Capability §

7.9.17.1 Hierarchy ID Extended Capability Header (Offset 00h) §

§ Figure 7-320 and § Table 7-281 detail allocation of fields in the Hierarchy ID Extended Capability Header.

Figure 7-320 Hierarchy ID Extended Capability Header §

Table 7-281 Hierarchy ID Extended Capability Header §

Bit Location	Description	Attributes
15:0	Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Hierarchy ID Extended Capability is 0028h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities in configuration space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating the list of Capabilities) or greater than 0FFh.	RO

7.9.17.2 Hierarchy ID Status Register (Offset 04h) §

§ Figure 7-321 and § Table 7-282 detail allocation of fields in the Hierarchy ID Status Register.

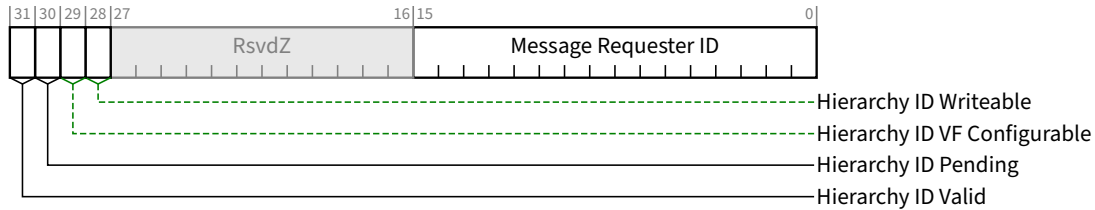

Figure 7-321 Hierarchy ID Status Register §

Table 7-282 Hierarchy ID Status Register §

Bit Location	Description	Attributes
15:0	<p>Message Requester ID - In an Upstream Port, this field contains the Requester ID from the most recently received Hierarchy ID Message. This field is meaningful only if Hierarchy ID Valid is 1b. This value identifies the Downstream Port (within this Hierarchy) that sent the Hierarchy ID Message. This information is not considered part of the Hierarchy ID as it can vary within the Hierarchy (e.g., different Root Ports of one Root Complex), but helps in debug situations to identify the provenance of the Hierarchy ID information.</p> <p>In a Downstream Port, this field is <u>RsvdZ</u>.</p> <p>For <u>RCiEPs</u>, this field is <u>RsvdZ</u>.</p> <p>This field defaults to 0000h.</p>	<u>RO/RsvdZ</u>
28	<p>Hierarchy ID Writeable - This bit is Set to indicate that the Hierarchy ID Data and GUID registers are read/write. This bit is Clear to indicate that the Hierarchy ID and GUID registers are read only.</p> <p>In Downstream Ports this bit is hardwired to 1b.</p> <p>In Upstream Ports, Functions that are not VFs must hardwire this bit to 0b.</p> <p><u>RCiEPs</u> that are not VFs, must hardwire this bit to either 0b or 1b.</p> <p>VFs in an Upstream Port and Root Complex Integrated VFs are permitted to either:</p> <ul style="list-style-type: none"> • hardwire this bit to 0b or • implement this bit as read / write with a default value of 0b. 	<u>RW/RO</u>
29	<p>Hierarchy ID VF Configurable - This bit indicates that Hierarchy ID Writeable can be configured.</p> <p>If Hierarchy ID Writeable is implemented as read / write, this bit is 1b. Otherwise this bit is 0b.</p>	<u>RO</u>
30	<p>Hierarchy ID Pending - In Downstream Ports this requests the transmission of a Hierarchy ID Message. Setting it requests transmission of a message based on the Hierarchy Data and GUID registers in this capability. This bit is cleared when either the transmit request is satisfied or the Link enters DL_Down. Behavior is undefined if the Hierarchy Data or GUID registers in this capability are written while this bit is Set.</p> <p>In Downstream Ports, this bit is Read / Write defaulting to 0b.</p> <p>In all other Functions, this bit is <u>RsvdZ</u>.</p>	<u>RW/RsvdZ</u>

Bit Location	Description	Attributes
31	<p>Hierarchy ID Valid - This bit indicates that the remaining fields in this capability are meaningful.</p> <p>In Downstream Ports, this bit is hardwired to 1b.</p> <p>In all other Functions, the following rules apply:</p> <ul style="list-style-type: none"> • If <u>Hierarchy ID Writeable</u> is Set, this bit is read/write, default 0b. • If <u>Hierarchy ID Writeable</u> is Clear, this bit is read only, default 0b. <ul style="list-style-type: none"> ◦ In VFs, this bit contains the same value as the associated PF. ◦ In Functions other than VFs that are associated with an Upstream Port, this bit is Set when a <u>Hierarchy ID Message</u> is received, and Cleared when the Link is DL_Down. ◦ In RCiEPs other than VFs, this bit contains a system provided value. The mechanism for determining this value is outside the scope of this specification. 	RW/RO

7.9.18 Vital Product Data Capability (VPD Capability) §

Support of VPD is optional. All Functions are permitted to contain the capability. This includes all Functions of a Multi-Function Device associated with an Upstream Port as well as RCiEPs. This also includes PFs and VFs.

Vital Product Data (VPD) is information that uniquely identifies hardware and, potentially, software elements of a system. The VPD can provide the system with information on various Field Replaceable Units such as part number, serial number, and other detailed information. The objective from a system point of view is to make this information available to the system owner and service personnel. VPD typically resides in a storage device (for example, a serial EEPROM) associated with the Function.

VFs and PFs that implement the VPD Capability must ensure that there can be no “data leakage” between VFs and/or PFs via the VPD Capability.

Details of the VPD Data is defined in § Section 6.27 .

Access to the VPD is provided using the Capabilities List in Configuration Space. The VPD Capability structure is shown in § Figure 7-328.

Figure 7-328 VPD Capability Structure §

The following protocols are used transfer data between the VPD Data field and the VPD storage component.

- To read VPD information:
 1. Issue single write to the VPD Address Register writing the flag bit (F) to 0b and VPD Address with the address to read.
 2. The hardware device will set F to 1b when 4 bytes of data from the storage component have been transferred to VPD Data.
 3. Software can monitor F and, after it becomes 1b, read the VPD information from VPD Data.

Behavior is undefined if either the VPD Address or VPD Data is written, prior to the flag bit becoming 1b.

- To write VPD information to the read/write portion of the VPD space:
 1. Write the data to VPD Data
 2. Then issue a single write to the VPD Address Register with F set to 1b and VPD Address set to the address where the VPD Data is to be stored.
 3. The software then monitors F and when it is set to 0b (by device hardware), the VPD Data (all 4 bytes) has been transferred from VPD Data to the storage component.

If either the VPD Address or VPD Data is written, prior to F being becoming 0b, the results of the write operation to the storage component are unpredictable.

Behavior is undefined if a read or write of the storage component is requested and VPD Address is outside the range of the storage component.

The VPD (both the read only items and the read/write fields) is stored information and will have no direct control of any device operations.

7.9.18.1 VPD Address Register §

The VPD Address Register is used to request a read or write of the VPD storage component.

Figure 7-329 VPD Address Register §

Table 7-289 VPD Address Register §

Bit Location	Description	Attributes
14:0	VPD Address - DWORD-aligned byte address of the VPD to be accessed. Behavior is undefined if the lowest 2 bits of this field are non-zero. The lowest two bits of the field must be either <u>RW</u> , or <u>RO</u> with a value of 00b. The remaining bits of the field must be <u>RW</u> . Default is implementation specific.	<u>RW/RO</u> (see description)
15	F - The F bit is always written along with VPD Address. The value of F indicates the direction of transfer being requested (0b = read, 1b = write). When the transfer is complete, the F bit value changes to indicate completion (1b = read complete, 0b = write complete). Default is implementation specific.	<u>RW</u>

7.9.18.2 VPD Data Register §

Figure 7-330 VPD Data Register §

Table 7-290 VPD Data Register §

Bit Location	Description	Attributes
31:0	VPD Data - VPD Data can be read through this register. The least significant byte of this register (at offset 04h in this capability structure) corresponds to the byte of VPD at the address specified by VPD Address. Behavior is undefined for any read or write of this register with Byte Enables other than 1111b. Default is implementation specific.	<u>RW</u>

7.9.19 Native PCIe Enclosure Management Extended Capability (NPEM Extended Capability) §

The Native PCIe Enclosure Management Extended (NPEM) Capability is an optional extended capability that is permitted to be implemented by Root Ports, Switch Downstream Ports, and Endpoints.

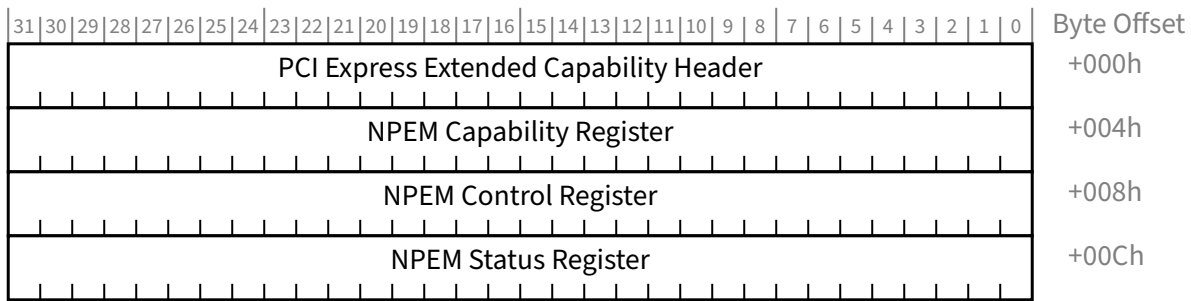

Figure 7-331 NPEM Extended Capability §

7.9.19.1 NPEM Extended Capability Header (Offset 00h) §

Figure 7-332 NPEM Extended Capability Header §

Table 7-291 NPEM Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the extended capability. PCI Express Extended Capability ID for the <u>NPEM Extended Capability</u> is 0029h.	<u>RO</u>
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the capability structure present. Must be 1h for this version of the specification.	<u>RO</u>
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	<u>RO</u>

7.9.19.2 NPEM Capability Register (Offset 04h) §

The NPEM Capability Register contains an overall NPEM Capable bit and a bit map of states supported in the implementation. Implementations are required to support OK, Locate, Fail, and Rebuild states if NPEM Capable bit is Set. All other states are optional.

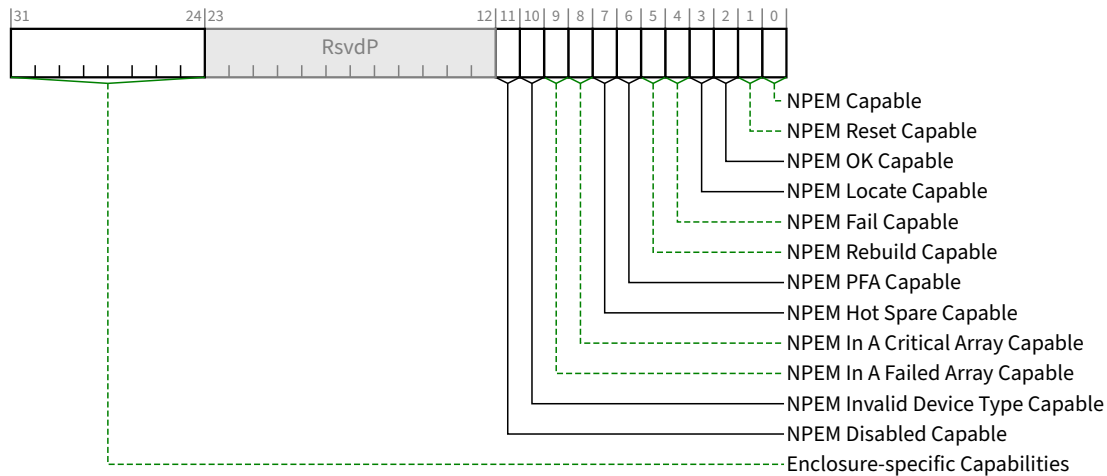

Figure 7-333 NPEM Capability Register §

Table 7-292 NPEM Capability Register §

Bit Location	Register Description	Attributes
0	NPEM Capable - When Set, this bit indicates that the enclosure has NPEM functionality.	<u>HwInit</u>
1	NPEM Reset Capable - A value of 1b indicates support for the optional NPEM Reset mechanism described in § Section 6.28 . This capability is independently optional.	<u>HwInit</u>
2	NPEM OK Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM OK state. This bit must be Set if <u>NPEM Capable</u> is also Set.	<u>HwInit</u>
3	NPEM Locate Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM Locate state. This bit must be Set if <u>NPEM Capable</u> is also Set.	<u>HwInit</u>
4	NPEM Fail Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM Fail state. This bit must be Set if <u>NPEM Capable</u> is also Set.	<u>HwInit</u>
5	NPEM Rebuild Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM Rebuild state. This bit must be Set if <u>NPEM Capable</u> is also Set.	<u>HwInit</u>
6	NPEM PFA Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM PFA state. This capability is independently optional.	<u>HwInit</u>
7	NPEM Hot Spare Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM Hot Spare state. This capability is independently optional.	<u>HwInit</u>
8	NPEM In A Critical Array Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM In A Critical Array state. This capability is independently optional.	<u>HwInit</u>
9	NPEM In A Failed Array Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM In A Failed Array state. This capability is independently optional.	<u>HwInit</u>
10	NPEM Invalid Device Type Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM_Invalid_ Device_Type state. This capability is independently optional.	<u>HwInit</u>

Bit Location	Register Description	Attributes
11	NPEM Disabled Capable - When Set, this bit indicates that enclosure has the ability to indicate the NPEM_Disabled state. This capability is independently optional.	<u>HwInit</u>
31:24	Enclosure-specific Capabilities - The definition of enclosure-specific bits is outside the scope of this specification.	<u>HwInit</u>

7.9.19.3 NPEM Control Register (Offset 08h) §

The NPEM Control Register contains an overall NPEM Enable bit and a bit map of states that software controls.

Use of Enclosure-specific bits is outside the scope of this specification.

All writes to this register, including writes that do not change the register value, are NPEM commands and should eventually result in a command completion indication in the NPEM Status Register.

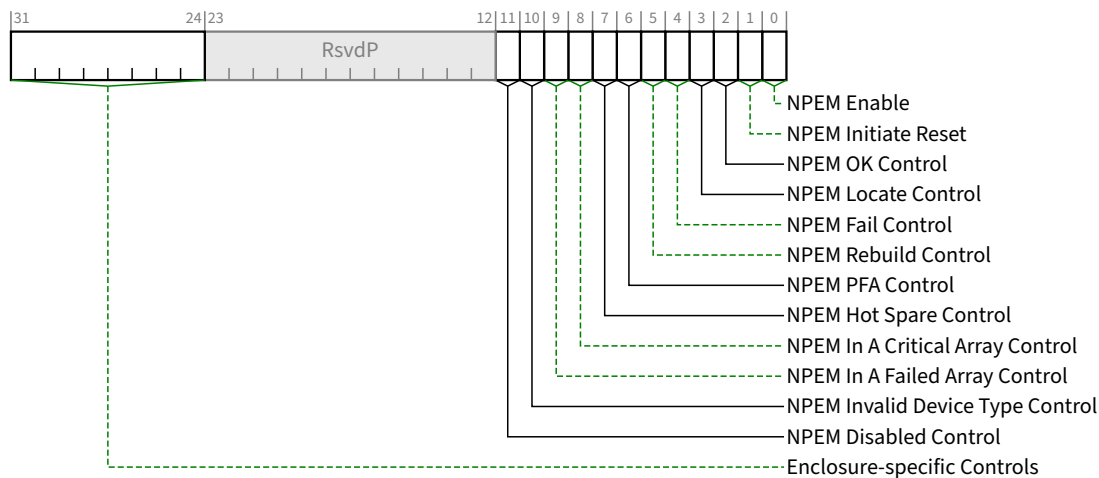

Figure 7-334 NPEM Control Register §

Table 7-293 NPEM Control Register §

Bit Location	Register Description	Attributes
0	NPEM Enable - When Set, this bit enables the NPEM capability. When Clear, this bit disables the NPEM capability. Default value of this bit is 0b. When enabled, this capability operates as defined in this specification. When disabled, the other bits in this capability have no effect and any associated indications are outside the scope of this specification.	<u>RW</u>
1	NPEM Initiate Reset - If <u>NPEM Reset Capable</u> bit is 1b, then a write of 1b to this bit initiates NPEM Reset. If <u>NPEM Reset Capable</u> bit is 0b, then this bit is permitted to be read-only with a value of 0b. The value read by software from this bit must always be 0b.	<u>RW/RO</u>
2	NPEM OK Control - When Set, this bit specifies that the NPEM OK indication be turned ON. When Clear, this bit specifies that the NPEM OK indication be turned OFF.	<u>RW/RO</u>

Bit Location	Register Description	Attributes
	<p>If <u>NPEM OK Capable bit</u> in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	
3	<p>NPEM Locate Control - When Set, this bit specifies that the NPEM Locate indication be turned ON. When Clear, this bit specifies that the NPEM Locate indication be turned OFF.</p> <p>If <u>NPEM Locate Capable bit</u> in the <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
4	<p>NPEM Fail Control - When Set, this bit specifies that the NPEM Fail indication be turned ON. When Clear, this bit specifies that the NPEM Fail indication be turned OFF.</p> <p>If <u>NPEM Fail Capable bit</u> in the <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
5	<p>NPEM Rebuild Control - When Set, this bit specifies that the NPEM Rebuild indication be turned ON. When Clear, this bit specifies that the NPEM Rebuild indication be turned OFF.</p> <p>If <u>NPEM Rebuild Capable bit</u> in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
6	<p>NPEM PFA Control - When Set, this bit specifies that the NPEM PFA indication be turned ON. When Clear, this bit specifies that the NPEM PFA indication be turned OFF.</p> <p>If <u>NPEM PFA Capable bit</u> in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
7	<p>NPEM Hot Spare Control - When Set, this bit specifies that the NPEM Hot Spare indication be turned ON. When Clear, this bit specifies that the NPEM Hot Spare indication be turned OFF.</p> <p>If <u>NPEM Hot Spare Capable bit</u> in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
8	<p>NPEM In A Critical Array Control - When Set, this bit specifies that the NPEM In A Critical Array indication be turned ON. When Clear, this bit specifies that the NPEM In A Critical Array indication be turned OFF.</p> <p>If <u>NPEM In A Critical Array Capable bit</u> in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
9	<p>NPEM In A Failed Array Control - When Set, this bit specifies that the NPEM In A Failed Array indication be turned ON. When Clear, this bit specifies that the NPEM In A Failed Array indication be turned OFF.</p> <p>If <u>NPEM In A Failed Array Capable bit</u> in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b.</p> <p>Default value of this bit is 0b</p>	<u>RW/RO</u>
10	<p>NPEM Invalid Device Type Control - When Set, this bit specifies that the NPEM Invalid Device Type indication be turned ON. When Clear, this bit specifies that the NPEM Invalid Device Type indication be turned OFF.</p>	<u>RW/RO</u>

Bit Location	Register Description	Attributes
	If <u>NPEM Invalid Device Type Capable</u> bit in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b. Default value of this bit is 0b	
11	NPEM Disabled Control - When Set, this bit specifies that the NPEM Disabled indication be turned ON. When Clear, this bit specifies that the NPEM Disabled indication be turned OFF. If <u>NPEM Disabled Capable</u> bit in <u>NPEM Capability Register</u> is 0b, this bit is permitted to be read-only with a value of 0b. Default value of this bit is 0b	<u>RW/RO</u>
31:24	Enclosure-specific Controls - The definition of enclosure-specific bits is outside the scope of this specification. Enclosure-specific software is permitted to change the value of this field. Other software must preserve the existing value when writing this register. Default value of this field is 00h	<u>RW/RO</u>

7.9.19.4 NPEM Status Register (Offset 0Ch) §

Figure 7-335 NPEM Status Register §

Table 7-294 NPEM Status Register §

Bit Location	Register Description	Attributes
0	NPEM Command Completed - This bit is Set when an NPEM command has completed, and the NPEM controller is ready to accept a subsequent command. This bit is permitted to be hardwired to 1b if the enclosure is able to accept writes that update any portion of the NPEM Control register without any delay between successive writes. Default value of this bit is 0b. Software must wait for an NPEM command to complete before issuing the next NPEM command. However, if this bit is not set within 1 second limit on command execution, software is permitted to repeat the NPEM command or issue the next NPEM command. If software issues a write before the Port has completed processing of the previous command and before the 1 second time limit has expired, the Port is permitted to either accept or discard the write. Such a write is considered a programming error, and could result in a discrepancy between the NPEM Control Register and the enclosure element state. To recover from such a programming error and return the enclosure to a consistent state, software must issue a write to the <u>NPEM Control Register</u> which conforms to the NPEM command completion rules.	<u>RW1C / RO</u>
31:24	Enclosure-specific Status - The definition of enclosure specific bits is outside the scope of this specification. Enclosure specific software is permitted to write non-zero values to this field. Other software must write 00h to this field.	<u>RsvdZ/RO/RW1C</u>

Bit Location	Register Description	Attributes
	The default value of this field is enclosure-specific. This field is permitted to be hardwired to 00h.	

7.9.20 Alternate Protocol Extended Capability §

The Alternate Protocol Extended Capability structure is optional in components that implement Alternate Protocol Negotiation. It is only permitted in:

- A Function associated with a Downstream Port.
- Function 0 (and only Function 0) of a Device associated with an Upstream Port.

§ Figure 7-336 details allocation of register fields in the Alternate Protocol Extended Capability structure.

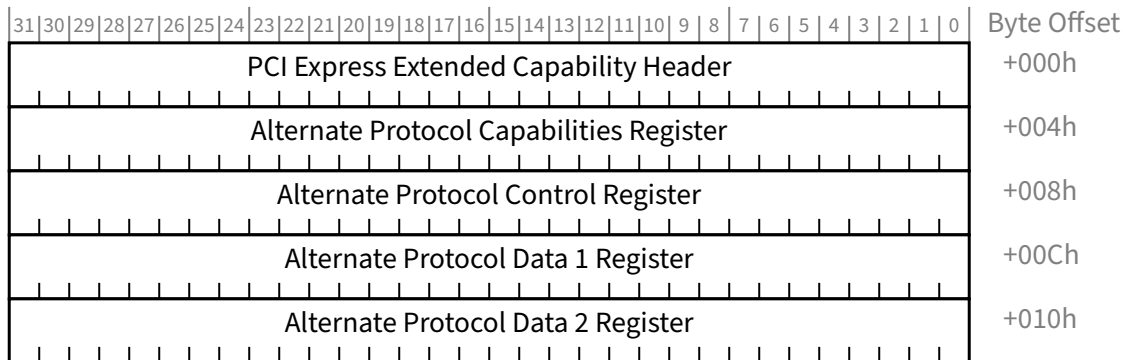

Figure 7-336 Alternate Protocol Extended Capability §

Figure 7-337 Alternate Protocol Extended Capability Header §

Table 7-295 Alternate Protocol Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability.	<u>RO</u>

Bit Location	Register Description	Attributes
	The Extended Capability ID for the Alternate Protocol Capability is 002Bh.	
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.20.2 Alternate Protocol Capabilities Register (Offset 04h) §

Figure 7-338 Alternate Protocol Capabilities Register §

Table 7-296 Alternate Protocol Capabilities Register §

Bit Location	Register Description	Attributes
7:0	Alternate Protocol Count - Indicates the number of Alternate Protocols or protocols that support Training Set Messages on one or more Lanes of this Link. The value of this field must be greater than or equal to 0.	HwInit
8	Alternate Protocol Selective Enable Supported - If Set, the Alternate Protocol Selective Enable Mask Register is present. If Clear, the Alternate Protocol Selective Enable Mask Register is not present and Alternate Protocol Negotiation is controlled solely by the Alternate Protocol Negotiation Global Enable bit. In Upstream Ports, this bit is hardwired to 0b. In Downstream Ports, this bit is HwInit with an implementation specific default value.	RO/HwInit

7.9.20.3 Alternate Protocol Control Register (Offset 08h) §

Figure 7-339 Alternate Protocol Control Register §

Table 7-297 Alternate Protocol Control Register §

Bit Location	Register Description	Attributes
7:0	<p>Alternate Protocol Index Select - This field determines which Lane and which Alternate Protocol of that Lane is visible in Alternate Protocol Data 1 Register and Alternate Protocol Data 2 Register.</p> <p>The default value of this field is 00h. Unused bits in this field are permitted to be hardwired to 0b.</p> <p>If Alternate Protocol Count is 01h, this field is permitted to be hardwired to 00h.</p> <p>Behavior is undefined if this field is greater than Alternate Protocol Count.</p> <p>Specific Alternate Protocol Index Select values are permitted to be disabled without renumbering other protocol index values. Disabled entries return an Alternate Protocol Vendor ID of FFFFh.</p>	RW
8	<p>Alternate Protocol Negotiation Global Enable - When this bit is Set, Alternate Protocol Negotiation is enabled for this Link. When this bit is Clear, Alternate Protocol Negotiation is disabled for this Link.</p> <p>This bit is RW for Downstream Ports. It is HwInit for Upstream Ports.</p> <p>Default is 0b.</p>	RW/HwInit (see description)

7.9.20.4 Alternate Protocol Data 1 Register (Offset 0Ch) §

Figure 7-340 Alternate Protocol Data 1 Register §

Table 7-298 Alternate Protocol Data 1 Register §

Bit Location	Register Description	Attributes
2:0	<p>Alternate Protocol Usage Information - This field contains the Modified TS Usage associated alternate protocol associated with the Alternate Protocol Index Select value.</p> <p>If Alternate Protocol Vendor ID is FFFFh, the value of this field is undefined.</p>	RO
15:5	<p>Alternate Protocol Details - This field contains the Alternate Protocol Details associated alternate protocol associated with the Alternate Protocol Index Select value.</p> <p>If Alternate Protocol Vendor ID is FFFFh, the value of this field is undefined.</p>	RO
31:16	<p>Alternate Protocol Vendor ID - This field contains the Vendor ID associated alternate protocol associated with the Alternate Protocol Index Select value.</p> <p>Bits 7:0 of this field contain bits 7:0 of Vendor ID (Symbol 10).</p> <p>Bits 15:8 of this field contain bits 15:8 of Vendor ID (Symbol 11).</p> <p>If Alternate Protocol Index Select is greater than or equal to Alternate Protocol Count, this field contains FFFFh.</p> <p>If Alternate Protocol Index Select is associated with a disabled alternate protocol, this field contains FFFFh.</p>	RO

7.9.20.5 Alternate Protocol Data 2 Register (Offset 10h) §

Figure 7-341 Alternate Protocol Data 2 Register §

Table 7-299 Alternate Protocol Data 2 Register §

Bit Location	Register Description	Attributes
23:0	<p>Modified TS Information 2 - This field contains the value for symbols 12 through 14 for the alternate protocol associated with the <u>Alternate Protocol Index Select</u> value.</p> <p>If <u>Alternate Protocol Vendor ID</u> is FFFFh, the value of this field is undefined.</p> <p>Bits 7:0 contain the value of Symbol 12.</p> <p>Bits 16:8 contain the value of Symbol 13.</p> <p>Bits 23:16 contain the value of Symbol 14.</p>	RO

7.9.20.6 Alternate Protocol Selective Enable Mask Register (Offset 14h) §

This register is present if Alternate Protocol Selective Enable Supported is Set.

This register consists of a bit mask of size Alternate Protocol Count bits. Each bit corresponds to a valid value of Alternate Protocol Index Select. This register is an integral number of DWORDs in size.

When Alternate Protocol Negotiation Global Enable is Set, a particular bit in this register is Set, and the corresponding Alternate Protocol is not disabled (see Alternate Protocol Index Select), the next Alternate Protocol negotiation is permitted to consider using that Alternate Protocol. When a particular bit in this register is Clear, the next Alternate Protocol negotiation is not permitted to consider using the corresponding Alternate Protocol.

Changes to this field will affect the next Alternate Protocol negotiation and have no effect on current operation of the Link (regardless of current protocol).

Figure 7-342 Alternate Protocol Selective Enable Mask Register §

Table 7-300 Alternate Protocol Selective Enable Mask Register §

Bit Location	Register Description	Attributes
0	<p>Alternate Protocol Selective Enable Mask - PCI Express - The PCI Express Protocol is always index 00h. The default value of this bit is 1b (i.e., PCI Express is always enabled by default).</p>	RWS

Bit Location	Register Description	Attributes
	This bit is permitted to be hardwired to 1b.	
31:1	<p>Alternate Protocol Selective Enable Mask - Others - Other bits in this register represent protocols other than PCI Express. The default values of these “other” bits is implementation specific.</p> <p>The width of this field is shown here as 32 bits. The actual width depends on <u>Alternate Protocol Count</u>.</p> <p>Bits in this field corresponding to disabled Alternate Protocol Index values are permitted to be hardwired to 0b.</p> <p>Bits in this field corresponding to <u>Alternate Protocol Index Select</u> values above <u>Alternate Protocol Count</u> are permitted to be hardwired to 0b.</p>	<u>RWS</u>

7.9.21 Conventional PCI Advanced Features Capability (AF) §

This capability is optional. It is permitted only in Conventional PCI Functions that are integrated into a Root Complex. A Function may contain at most one instance of this capability.

§ Figure 7-343 shows the layout of this capability.

Note: Due to document production limitations, this figure shows an 8 byte capability while the actual capability is only 6 bytes long. Bytes 6 and 7 in the figure are not part of the capability.

Figure 7-343 Conventional PCI Advanced Features Capability (AF) §

7.9.21.1 Advanced Features Capability Header (Offset 00h) §

Figure 7-344 Advanced Features Capability Header §

Table 7-301 Advanced Features Capability Header §

Bit Location	Register Description	Attributes
7:0	CAP_ID - The value of 13h in this field identifies the Function as being AF capable.	<u>RO</u>

Bit Location	Register Description	Attributes
15:8	NXT_PTR - Pointer to the next item in the capabilities list. Must be 00h for the final item in the list.	RO
23:16	LENGTH - AF Structure Length (Bytes). Shall return a value of 06h.	RO

7.9.21.2 AF Capabilities Register (Offset 03h) §

Figure 7-345 AF Capabilities Register §

Table 7-302 AF Capabilities Register §

Bit Location	Register Description	Attributes
0	TP_CAP - Set to indicate support for the <u>Transactions Pending (TP)</u> bit. TP_CAP must be Set if FLR_CAP is Set.	HwInit
1	FLR_CAP - Set to indicate support for <u>Function Level Reset (INITIATE_FLR)</u> .	HwInit
7:2	Reserved Reserved - Shall be implemented as read only returning a value of 000 0000b.	RO

7.9.21.3 Conventional PCI Advanced Features Control Register (Offset 04h) §

Figure 7-346 Conventional PCI Advanced Features Control Register §

Table 7-303 Conventional PCI Advanced Features Control Register §

Bit Location	Register Description	Attributes
0	Function Level Reset (INITIATE_FLR) - A write of 1b initiates a <u>Function Level Reset (FLR)</u> . Registers and state information that do not apply to Conventional PCI are exempt from the <u>FLR</u> requirements in this specification (see § Section 6.6.2). The value read by software from this bit shall always be 0b.	RW

Bit Location	Register Description	Attributes
7:1	Reserved Reserved - Shall be implemented as read only returning a value of 000 0000b.	<u>RO</u>

7.9.21.4 AF Status Register (Offset 05h) §

Figure 7-347 AF Status Register §

Table 7-304 AF Status Register §

Bit Location	Register Description	Attributes
0	Transactions Pending (TP) - A value of 1b indicates that the Function has issued one or more non-posted transactions which have not been completed, including non-posted transactions that a target has terminated with Retry. A value 0b indicates that all non-posted transactions have been completed.	<u>RO</u>
7:1	Reserved Reserved - Shall be implemented as read only returning a value of 000 0000b.	<u>RO</u>

7.9.22 SFI Extended Capability §

The SFI (System Firmware Intermediary) Extended Capability is an optional capability that provides system firmware with enhanced control over primarily hot-plug mechanisms, and enables system firmware to operate as an intermediary between certain events and the operating system (see § Section 6.7.4). This capability may be implemented by a Root Port or a Switch Downstream Port. It is not applicable to any other Device/Port type.

If a Downstream Port implements the SFI Extended Capability, that Port must support ERR_COR Subclass capability, and indicate so by Setting the ERR_COR Subclass Capable bit in the Device Capabilities Register. See see § Section 7.5.3.3 .

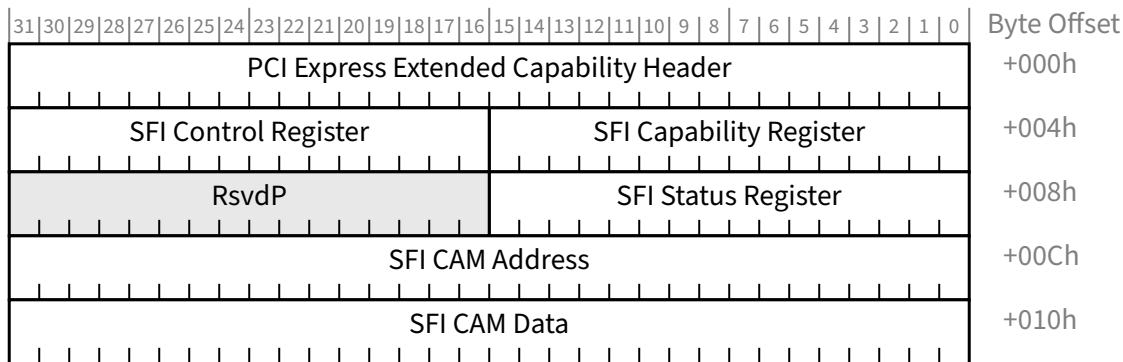

Figure 7-348 SFI Extended Capability §

7.9.22.1 SFI Extended Capability Header (Offset 00h) §

§ Figure 7-349 and § Table 7-305 detail allocation of fields in the Extended Capability header.

Figure 7-349 SFI Extended Capability Header §

Table 7-305 SFI Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the SFI Extended Capability is 002Ch.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.22.2 SFI Capability Register (Offset 04h) §

Figure 7-350 SFI Capability Register §

Table 7-306 SFI Capability Register §

Bit Location	Register Description	Attributes
0	SFI OOB PD Supported - When Set, this bit indicates that this slot supports reporting the out-of-band presence detect state. If this Downstream Port has no implemented slot (as indicated by the Slot Implemented bit in the PCI Express Capabilities Register), then the value of this bit must be 0b.	HwInit

7.9.22.3 SFI Control Register (Offset 06h) §

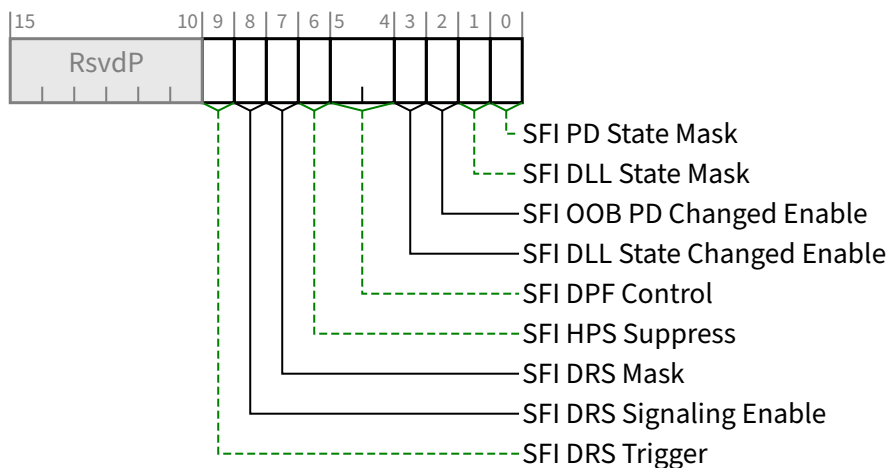

Figure 7-351 SFI Control Register §

Table 7-307 SFI Control Register §

Bit Location	Register Description	Attributes
0	SFI PD State Mask - When Set, this bit masks the Presence Detect State bit in the Slot Status Register, making its value 0b, regardless of the actual presence detect state. Otherwise, its value indicates the actual state.	RW

Bit Location	Register Description	Attributes								
	<p>If the value of the <u>Presence Detect State</u> bit changes when the <u>SFI PD State Mask</u> bit value changes, this must cause a <u>Presence Detect Changed</u> event (see § Section 6.7.3).</p> <p>Default value of this bit is 0b.</p>									
1	<p>SFI DLL State Mask - When Set, this bit masks the <u>Data Link Layer Link Active</u> bit in the <u>Link Status Register</u>, making its value 0b, regardless of the actual <u>Data Link Layer</u> state. Otherwise, its value indicates the actual state.</p> <p>If the value of the <u>Data Link Layer Link Active State</u> bit changes when the <u>SFI DLL State Mask</u> bit value changes, this must cause a <u>Data Link Layer State Changed</u> event (see § Section 6.7.3).</p> <p>Default value of this bit is 0b.</p>	RW								
2	<p>SFI OOB PD Changed Enable - When Set, this bit enables sending an <u>ERR_COR</u> Message for the <u>SFI OOB PD Changed</u> event. See § Section 6.7.4.1 for other necessary conditions.</p> <p>This bit must be RW if the <u>SFI OOB PD Supported</u> bit is Set; otherwise, it is permitted to be hardwired to 0b. If the <u>SFI OOB PD Supported</u> bit is Clear and software Sets this bit, the behavior is undefined.</p> <p>Default value of this bit is 0b.</p>	RW/RO								
3	<p>SFI DLL State Changed Enable - When Set, this bit enables sending an <u>ERR_COR</u> Message for the <u>SFI DLL State Changed</u> event. See § Section 6.7.4.1 for other necessary conditions.</p> <p>Default value of this bit is 0b.</p>	RW								
5:4	<p>SFI DPF Control - This field controls the level of <u>Downstream Port Filtering (DPF)</u> enabled on the <u>Downstream Port</u>, governing which <u>Request TLPs</u> targeting <u>Downstream Components</u> get filtered; that is, handled as if the Link is in <u>DL_Down</u>. See § Section 6.7.4.2.</p> <p>Defined encodings are:</p> <table> <tr> <td>00b</td> <td>Disabled</td> </tr> <tr> <td>01b</td> <td>Filter all Request TLPs</td> </tr> <tr> <td>10b</td> <td>Filter only Configuration Request TLPs</td> </tr> <tr> <td>11b</td> <td>Reserved</td> </tr> </table> <p>Default value of this field is 00b.</p>	00b	Disabled	01b	Filter all Request TLPs	10b	Filter only Configuration Request TLPs	11b	Reserved	RW
00b	Disabled									
01b	Filter all Request TLPs									
10b	Filter only Configuration Request TLPs									
11b	Reserved									
6	<p>SFI HPS Suppress - When Set, this bit forces the <u>Hot-Plug Surprise (HPS)</u> bit in the <u>Slot Capabilities Register</u> to be Clear and disables associated <u>Hot-Plug Surprise</u> functionality. See § Section 6.7.4.4.</p> <p>Default value of this bit is 0b.</p>	RW								
7	<p>SFI DRS Mask - When Set, this bit masks the <u>DRS Message Received</u> bit in the <u>Link Status 2 Register</u>, making its value 0b, regardless of the actual <u>DRS Message Received</u> state. Otherwise, its value indicates the actual state.</p> <p>If the value of the <u>DRS Message Received</u> bit changes from Clear to Set when the <u>SFI DRS Mask</u> bit is Cleared, this must trigger any notification enabled by the <u>DRS Signaling Control</u> field in the <u>Link Control Register</u> (see § Section 7.5.3.7).</p> <p>Default value of this bit is 0b.</p>	RW								
8	<p>SFI DRS Signaling Enable - When Set, this bit enables sending an <u>ERR_COR</u> Message for the <u>SFI DRS Received</u> event. See § Section 6.7.4.1 for other necessary conditions.</p> <p>Default value of this bit is 0b.</p>	RW								
9	<p>SFI DRS Trigger - If the <u>SFI DRS Mask</u> bit is Clear, when software writes a 1b to this bit, the <u>Downstream Port</u> must behave as if a <u>DRS Message</u> was received. Otherwise, software writing a 1b to this bit has no effect.</p>	RW								

Bit Location	Register Description	Attributes
	<p>It is permitted to write 1b to this bit while simultaneously writing updated values to other fields in this register, notably the SFI DRS Mask bit. For this case, the SFI DRS Trigger semantics are based on the updated value of the SFI DRS Mask bit.</p> <p>This bit always returns 0b when read.</p>	

7.9.22.4 SFI Status Register (Offset 08h) §

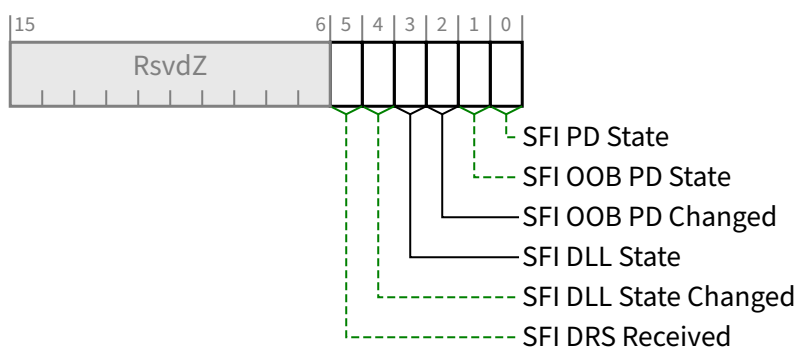

Figure 7-352 SFI Status Register §

Table 7-308 SFI Status Register §

Bit Location	Register Description	Attributes
0	<p>SFI PD State - This bit always indicates the actual presence detect state associated with the Presence Detect State bit in the Slot Status Register, even when the value of that bit is being masked by the SFI PD State Mask bit.</p>	RO
1	<p>SFI OOB PD State - This bit indicates the out-of-band presence detect state, independent of the in-band presence detect state.</p> <p>This bit must be implemented if the SFI OOB PD Supported bit is Set; otherwise, it is permitted to be hardwired to 0b.</p>	RO
2	<p>SFI OOB PD Changed - This bit is Set when the value reported in the SFI OOB PD State bit is changed.</p>	RW1C
3	<p>SFI DLL State - This bit always indicates the actual link state associated with the Data Link Layer Link Active bit in the Link Status Register, even when the value of that bit is being masked by the SFI DLL State Mask bit.</p>	RO
4	<p>SFI DLL State Changed - This bit is Set when the value reported in the SFI DLL State bit is changed.</p>	RW1C
5	<p>SFI DRS Received - This bit always indicates the actual state associated with the DRS Message Received bit in the Link Status 2 Register, even when the value of that bit is being masked by the SFI PD State Mask bit.</p> <p>Clearing the SFI DRS Received bit (by writing a 1b to it) must also cause the actual state associated with the DRS Message Received bit to be Cleared.</p>	RW1C

7.9.22.5 SFI CAM Address Register (Offset 0Ch) §

Figure 7-353 SFI CAM Address Register §

Table 7-309 SFI CAM Address Register §

Bit Location	Register Description	Attributes
27:0	SFI CAM Address - This field specifies the target Bus, Device, and Function Numbers, along with the Extended Register Number and Register Number, in the format specified by § Table 7-1.	RW

7.9.22.6 SFI CAM Data Register (Offset 10h) §

Figure 7-354 SFI CAM Data Register §

Table 7-310 SFI CAM Data Register §

Bit Location	Register Description	Attributes
31:0	SFI CAM Data - When this field is read, the SFI CAM generates and transmits a Configuration Read Request on the Link below this Port. When this field is written, the SFI CAM generates and transmits a Configuration Write Request on the Link below this Port. In both cases, the target of the Configuration Request is determined by the value of the SFI CAM Address Register. See § Section 6.7.4.3.	RW

7.9.23 Subsystem ID and Subsystem Vendor ID Capability §

The Subsystem ID and Subsystem Vendor ID Capability is an optional capability used to uniquely identify the add-in card or subsystem where the PCI device resides. It provides a mechanism for add-in card vendors to distinguish their add-in cards from one another even though the add-in cards may have the same PCI bridge on them (and, therefore, the same Vendor ID and Device ID). The format of the capability is shown in § Figure 7-355. The fields are described in § Table 7-311 and § Table 7-312.

This capability is only permitted in Functions with Type 1 Configuration Space Headers.

Figure 7-355 Subsystem ID and Subsystem Vendor ID Capability §

7.9.23.1 Subsystem ID and Subsystem Vendor ID Capability Header (Offset 00h) §

Figure 7-356 Subsystem ID and Subsystem Vendor ID Capability Header §

Table 7-311 Subsystem ID and Subsystem Vendor ID Capability Header §

Bit Location	Register Description	Attributes
7:0	Capability ID - Indicates the PCI Express Capability structure. This field must return a Capability ID of 0Dh indicating that this is a Subsystem ID and Subsystem Vendor ID Capability structure.	RO
15:8	Next Capability Pointer - This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities.	RO

7.9.23.2 Subsystem ID and Subsystem Vendor ID Capability Data (Offset 04h) §

Figure 7-357 Subsystem ID and Subsystem Vendor ID Capability Data §

Table 7-312 Subsystem ID and Subsystem Vendor ID Capability Data §

Bit Location	Register Description	Attributes
15:0	SSVID - The SSVID identifies the manufacturer of the add-in card or subsystem. The SSVID is assigned by PCI-SIG to insure uniqueness (the Vendor ID is used as the SSVID also). This field is read-only.	HwInit

Bit Location	Register Description	Attributes
31:16	SSID - The SSID identifies the particular add-in card or subsystem and is assigned by the vendor. This field is read-only.	<u>Hwlnit</u>

7.9.24 Data Object Exchange Extended Capability §

The Data Object Exchange (DOE) Extended Capability is an optional Extended Capability for discovering and controlling a mechanism for the exchange of data objects (see § Section 6.30). It is permitted for a Function to implement more than one instance of this Extended Capability.

§ Figure 7-358 illustrates the Data Object Exchange Extended Capability structure.

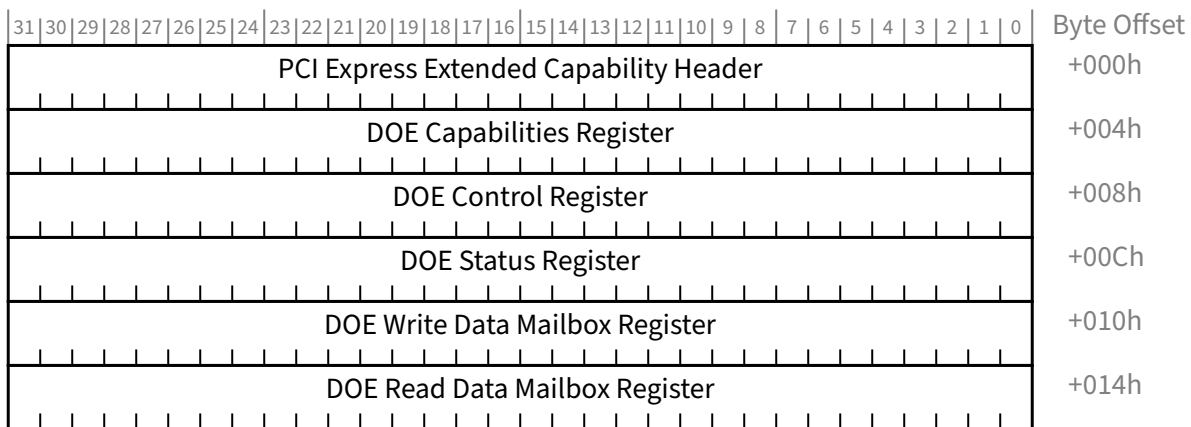

Figure 7-358 Data Object Exchange Extended Capability §

7.9.24.1 DOE Extended Capability Header (Offset 00h) §

Figure 7-359 DOE Extended Capability Header §

Table 7-313 DOE Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID – This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Data Object Exchange Extended Capability is 002Eh.	<u>RO</u>

Bit Location	Register Description	Attributes
19:16	<p>Capability Version – This field is a PCI-SIG defined version number that indicates the version of the Capability structure present.</p> <p>Must be 2h for this version of the specification.</p> <p>New implementations compliant to the older version of this specification must indicate Capability Version 1h.</p>	RO
31:20	<p>Next Capability Offset – This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.</p>	RO

7.9.24.2 DOE Capabilities Register (Offset 04h) §

Figure 7-360 DOE Capabilities Register §

Table 7-314 DOE Capabilities Register §

Bit Location	Register Description	Attributes
0	<p>DOE Interrupt Support – When Set, this bit indicates DOE support of software notification of DOE events using MSI/MSI-X.</p>	HwInit
11:1	<p>DOE Interrupt Message Number - When the DOE Interrupt Support bit is Set, this field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with DOE.</p> <p>For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the Message Control Register for MSI.</p> <p>For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. For a given MSI-X implementation, the entry must remain constant.</p> <p>If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined.</p> <p>When the <u>DOE Interrupt Support</u> bit is Clear the value in this field is undefined.</p>	RO
12	<p>DOE Attention Mechanism Support – This bit, when Set, indicates the DOE instance supports the optional DOE Attention mechanism.</p>	HwInit
13	<p>DOE Async Message Support – This bit, when Set, indicates the DOE instance supports the optional DOE Async Message mechanism.</p>	HwInit

7.9.24.3 DOE Control Register (Offset 08h) §

Figure 7-361 DOE Control Register §

Table 7-315 DOE Control Register §

Bit Location	Register Description	Attributes
0	<p>DOE Abort – A write of 1b to this bit must cause all data object transfer operations associated with this DOE instance to be aborted.</p> <p>Reads from this bit must always return 0b.</p>	RW (see description)
1	<p>DOE Interrupt Enable – When this bit is Set, the <u>DOE Interrupt Support</u> bit is Set, and MSI/MSI-X is enabled, the DOE instance must issue an MSI/MSI-X interrupt as defined in § Section 6.30.3.</p> <p>When <u>DOE Interrupt Support</u> is Clear, this bit is permitted to be Reserved.</p> <p>Default value of this bit is 0b.</p>	RW/RsvdP
2	<p>DOE Attention Not Needed – When <u>DOE Attention Mechanism Support</u> is Set, this bit when Set enables the DOE instance to enter and stay in a state where it is not immediately available for use. When this bit is Clear the DOE instance must remain in a responsive state.</p> <p>When <u>DOE Attention Mechanism Support</u> is Clear, this bit is permitted to be Reserved.</p> <p>Default value of this bit is 0b.</p>	RW/RsvdP
3	<p>DOE Async Message Enable – If <u>DOE Async Message Support</u> is Set, this bit, when Set, enables the use of the DOE Async Message mechanism.</p> <p>When <u>DOE Async Message Support</u> is Clear, this bit is permitted to be Reserved.</p> <p>Default value of this bit is 0b.</p>	RW/RsvdP
31	<p>DOE Go – A write of 1b to this bit indicates to the DOE instance that it can start consuming the data object transferred through the <u>DOE Write Data Mailbox Register</u>.</p> <p>Behavior is undefined if the <u>DOE Go</u> bit is Set before the entire data object has been written to the <u>DOE Write Data Mailbox Register</u>.</p> <p>Behavior is undefined if the <u>DOE Go</u> bit is written with 1b when the <u>DOE Busy</u> bit is Set.</p> <p>Reads from this bit must always return 0b.</p>	RW (see description)

7.9.24.4 DOE Status Register (Offset 0Ch) §

Figure 7-362 DOE Status Register §

Table 7-316 DOE Status Register §

Bit Location	Register Description	Attributes
0	<p>DOE Busy — When Set, this bit indicates the DOE instance is temporarily unable to receive a new data object through the <u>DOE Write Data Mailbox Register</u>.</p> <p>The DOE instance must Set this bit when processing a received data object, and Clear this bit when it is able to receive a new data object.</p> <p>The DOE instance must Set this bit following an abort or reset if, as a result of the abort/reset, it is temporarily unable to receive a data object, and then must Clear this bit when it is able to receive a new data object.</p>	<u>RO</u>
1	<p>DOE Interrupt Status – If <u>DOE Interrupt Support</u> is Set, then this bit must be Set when an interrupt-triggering event occurs.</p> <p>If <u>DOE Interrupt Support</u> is Clear, this bit is Reserved.</p> <p>Default value of this bit is 0b.</p>	<u>RW1C/RsvdZ</u>
2	<p>DOE Error – This bit, when Set, indicates that there has been an internal error associated with a data object received, or that a data object has been received for which the DOE instance is unable to provide a response.</p> <p>The DOE instance must Clear this bit, if it is not already Clear, when 1b is written to the DOE Abort bit in the <u>DOE Control Register</u>. Writing 1b to the <u>DOE Abort</u> bit is the only mechanism for software to Clear this bit.</p> <p>The transition of this bit from Clear to Set is an interrupt triggering event.</p> <p>Default value of this bit is 0b.</p>	<u>RO</u>
3	<p>DOE Async Message Status – If <u>DOE Async Message Support</u> is Set, this bit, when Set, indicates the DOE instance has one or more asynchronous messages to transfer.</p> <p>The transition of this bit from Clear to Set is an interrupt triggering event.</p> <p>If <u>DOE Async Message Support</u> is Clear, this bit is Reserved.</p> <p>Default value of this bit is 0b.</p>	<u>RO/RsvdZ</u>
4	<p>DOE At Attention – When <u>DOE Attention Mechanism Support</u> is Set, this bit, when Set, indicates the DOE interface is presently in a state of readiness.</p> <p>The transition of this bit from Clear to Set is an interrupt triggering event.</p>	<u>RO</u>

Bit Location	Register Description	Attributes
	When <u>DOE Attention Mechanism Support</u> is Clear, this bit is Reserved.	
31	<p>Data Object Ready – When Set, this bit indicates the DOE instance has a data object available to be read by system firmware/software.</p> <p>If there is no additional data object ready for transfer, the DOE instance must clear this bit after the entire data object has been transferred, as indicated by software writing to the <u>DOE Read Data Mailbox Register</u> after reading the final DW of the data object.</p> <p>The DOE instance must clear this bit, if not already clear, upon a write of 1b to the <u>DOE Abort</u> bit in the <u>DOE Control Register</u>.</p> <p>The transition of this bit from Clear to Set is an interrupt triggering event.</p> <p>Default value of this bit is 0b.</p>	<u>RO</u>

A successfully completed write to this register adds one DW to the incoming data object.</p> <p>Setting the DOE Go bit in the <u>DOE Control Register</u> indicates to the DOE Instance that the final DW of the data object has been written to this register.</p> <p>Reads of this register must return all 0's.</p>	RW (see description)

7.9.24.6 DOE Read Data Mailbox Register (Offset 14h) §

Figure 7-364 DOE Read Data Mailbox Register §

Table 7-318 DOE Read Data Mailbox Register §

Bit Location	Register Description	Attributes
31:0	<p>DOE Read Data Mailbox – If the <u>Data Object Ready</u> bit is Set, a read of this register returns the current DW of the data object.</p> <p>A write of any value to this register indicates a successful transfer of the current data object DW, and the DOE instance must return the next DW in the data object upon the next read of this register as long as the <u>Data Object Ready</u> bit remains Set.</p> <p>It is permitted for multiple data objects to be read from this register back-to-back. When this scenario occurs, the <u>Data Object Ready</u> bit will remain Set until this register is written after the final DW is read.</p> <p>A write of any value to this register when the <u>Data Object Ready</u> bit is Clear must have no effect.</p> <p>The value read from this register when the <u>Data Object Ready</u> bit is Clear must be 0000 0000h.</p>	RW (see description)

7.9.25 Shadow Functions Extended Capability §

Unimplemented Functions possess Transaction ID resources by virtue of their Bus/Device/Function Number space, and therefore associated Requester ID space, and associated Tags, even though there is no Function implemented there to use them. The Shadow Functions Extended Capability is an optional capability that permits a Requester to use the Transaction ID resources of another otherwise unimplemented Function to generate more outstanding Requests than it would otherwise be able to using only the Transaction ID resources of the Function it is associated with. The Requester generates some of its Requests via the Function it is associated with and generates other Requests via the Shadow Function. If the Requester exceeds the Transaction ID resources of a single Function, it is permitted to implement this capability and split its Transaction ID space across that Function and additional Shadow Functions defined by this capability.

A Requester implementing a Shadow Function uses the characteristics and attributes of the Function containing this capability. Requests made via the associated Function will use the associated Function's BDF to populate the Requester ID. Requests made via the Shadow Function will use the BDF calculated from the value in the Shadow Function Number field of the corresponding Shadow Function Instance register entry to populate the Requester ID. Other characteristics and attributes of the Shadow Function are taken from the associated Function's Configuration Space.

The Shadow Function Number field in the Shadow Function Instance register entry for each Shadow Function is used to calculate the value of the Bus/Device/Function number (Bus/Function number for ARI devices) (BDF) for that Shadow Function. That BDF space assigned to the Shadow Function must be available, that is it corresponds to an otherwise unimplemented Function.

Additional requirements for implementing Shadow Functions are:

- Any access to the Configuration Space region of the BDF associated with the Shadow Function, without errors that would have different behavior, must be responded to with a Completion with UR status.
- For non-ARI Devices, the Shadow Function must reside in the same Device as the Function it is shadowing. ARI must be supported if the Shadow Function Number is greater than 7.
- A Function is permitted to have more than one Shadow Function.
- A Function is permitted to have at most one instance of this capability.
- This capability is permitted to be implemented in any Function capable of operating as a Requester.
- For VFs, the Shadow Functions must be assigned in a manner that accommodates the VF Discovery algorithm (see § Section 9.2.1.2).
- Requesters are permitted to generate Posted Requests that are not Message Signaled Interrupt (MSI/MSI-X) Requests using the Transaction ID space of a Shadow Function.

- Requesters are not permitted to generate Message Signaled Interrupt (MSI/MSI-X) Requests using the Transaction ID space of a Shadow Function.
- Functions utilizing Shadow Functions must be aware that accesses utilizing the Shadow Function's Transaction ID resources appear to the rest of the system with the same semantics as if the access was from any independent Function and deal with those implications.
- The software for the Translation Agent is responsible for maintaining the integrity of address translation resources. Behavior is undefined if address translation resources are not updated before the Shadow Function's Requester makes a Request.
- Translation Requests issued by a Shadow Function are cached in the ATC associated with the main Function. When enabled, Functions are permitted to use translations across the "main" and Shadow Functions regardless of which Function issued the associated Translation Request. See § Section 10.2 .
- The software for handling Page Request Messages is responsible for coordinating usage across Shadow Functions. See § Section 10.4.1 and § Section 10.5.2.5 .
- Behavior is undefined if software enabling FPB configures a Shadow Function to use the same Requester ID as another Function.
- For a Multi-Function Device that supports ACS P2P Egress Control, any enabled Shadow Functions must be taken into account when configuring the Egress Control Vector to allow P2P traffic between the Requester and its Shadow Functions, and other Functions in the Device.

IMPLEMENTATION NOTE:

SHADOW FUNCTION NUMBER PROGRAMMING §

The value programmed into the Shadow Function Number field should place the Shadow Function on the same Bus Number as the Function declaring it. Otherwise, ACS Source Validation might not operate appropriately, Completions targeting the Shadow Function might not be routed correctly, or other misbehaviors might occur.

Multiple Shadow Functions for a Function are permitted to be assigned by this Capability. The Number of Shadow Functions field in the Shadow Functions Capability register defines the number of Shadow Functions assigned and the number of Shadow Function Instance register entries in the Capability and therefore the length of the Capability structure.

§ Figure 7-365 shows the Shadow Functions Extended Capability structure.

N = the value of the Number of Shadow Functions field.

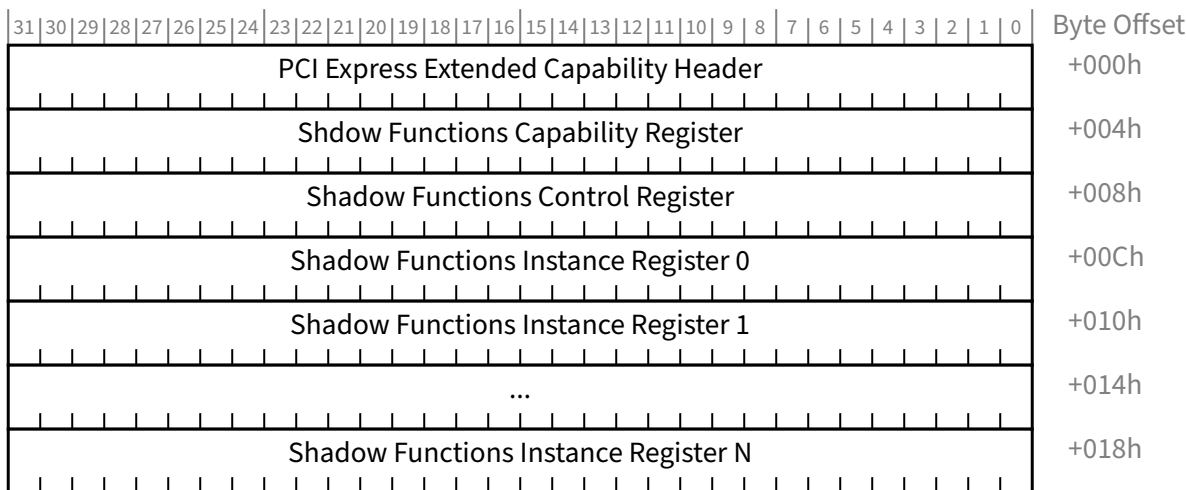

Figure 7-365 Shadow Functions Extended Capability Structure §

7.9.25.1 Shadow Functions Extended Capability Header (Offset 00h) §

§ Figure 7-366 details allocation of the register fields in the Shadow Functions Extended Capability Header; § Table 7-319 provides the respective bit definitions.

Figure 7-366 Shadow Functions Extended Capability Header §

Table 7-319 Shadow Functions Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	Shadow Functions Extended Capability ID - Indicates the Shadow Functions Extended Capability structure. This field must return a Capability ID of 002Dh indicating that this is a <u>Shadow Functions Extended Capability</u> structure.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - The offset to the next PCI Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	RO

7.9.25.2 Shadow Functions Capability Register (Offset 04h) §

§ Figure 7-367 details the allocation of register bits of the Shadow Functions Capability register; § Table 7-320 provides the respective bit definitions.

Figure 7-367 Shadow Functions Capability Register §

Table 7-320 Shadow Functions Capability Register §

Bit Location	Register Description	Attributes
7:0	<p>Number of Shadow Functions – This is one less than the number of Shadow Functions implemented by this Function. This defines the number of Shadow Function Instance register entries that are in the Capability, and therefore the length of the Capability structure.</p> <p>The default value for this field is 00h.</p>	HwInit

7.9.25.3 Shadow Functions Control Register (Offset 08h) §

§ Figure 7-368 details the allocation of register bits of the Shadow Functions Control register; § Table 7-321 provides the respective bit definitions.

Figure 7-368 Shadow Functions Control Register §

Table 7-321 Shadow Functions Control Register §

Bit Location	Register Description	Attributes
0	<p>Shadow Functions Enable - When Set, permits the Requester to generate Requests using the Transaction ID resources of all of the Shadow Functions defined by this Capability. See § Section 7.9.25 for limitations on the type of Requests permitted.</p> <p>When Clear, the Requester is not permitted to generate Requests using the Transaction ID resources of any of the Shadow Functions defined by this Capability.</p> <p>Behavior is undefined when this bit is Set in Functions with the Phantom Functions Enabled bit Set.</p>	RW

Bit Location	Register Description	Attributes
	Behavior is undefined if the value of this bit is changed while the Function has outstanding Non-Posted Requests. Default is 0b.	

7.9.25.4 Shadow Functions Instance Register Entry §

§ Figure 7-369 details the allocation of register bits of the Shadow Functions Control register; § Table 7-322 provides the respective bit definitions.

Figure 7-369 Shadow Functions Instance Register Entry §

Table 7-322 Shadow Functions Instance Register Entry §

Bit Location	Register Description	Attributes
15:0	Shadow Function Number - This is the Bus/Device/Function offset (Bus/Function offset for ARI Devices) of the Shadow Function. Add this value to BDF of the Function with this capability using unsigned, 16-bit arithmetic, ignoring any carry.	HwInit

7.9.26 IDE Extended Capability §

All Ports that implement IDE must implement the IDE Extended Capability. The IDE Extended Capability must consist of the IDE Extended Capability Header, the IDE Capability Register, and the IDE Control Register, followed by zero to 8 Link IDE register blocks, followed by zero to 255 Selective IDE register blocks (see § Figure 7-370). All Ports that implement IDE must implement the IDE Extended Capability. The IDE Extended Capability must consist of the IDE Extended Capability Header, the IDE Capability Register, and the IDE Control Register, followed by zero to 8 Link IDE register blocks, followed by zero to 255 Selective IDE register blocks (see § Figure 7-370).

It is permitted to implement this extended capability in Functions associated with Downstream Ports, and in Function 0 associated with an Upstream Port. Multi-Function Devices associated with Upstream Ports, including cases where one or more Functions represent the Upstream Port of a Switch, must be implemented such that Function 0 implements this extended capability representing the Multi-Function Device as a whole.

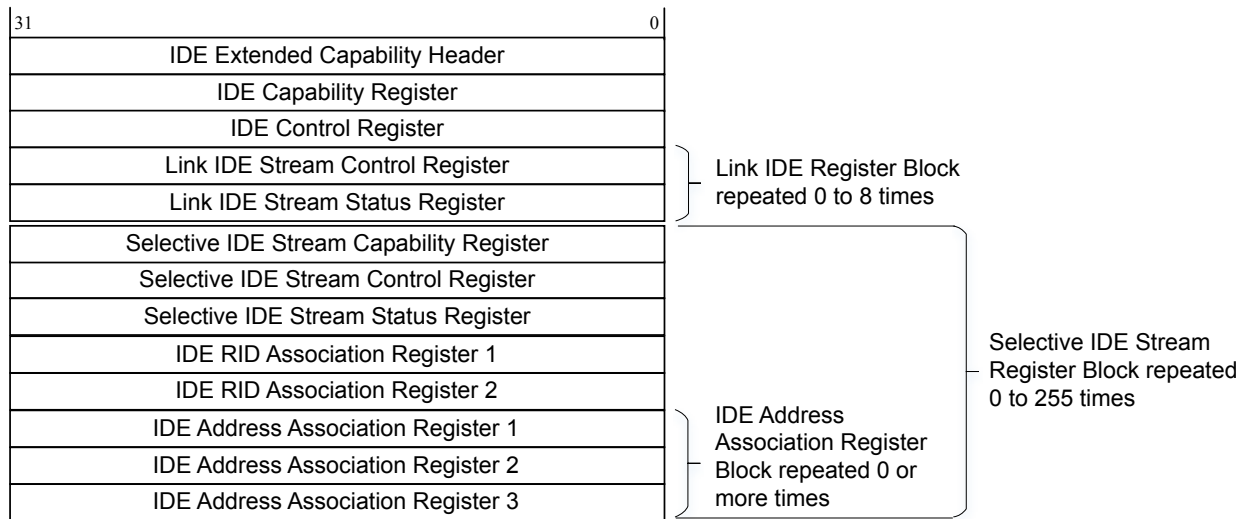

Figure 7-370 IDE Extended Capability Structure §

7.9.26.1 IDE Extended Capability Header (Offset 00h) §

Figure 7-371 IDE Extended Capability Header §

Table 7-323 IDE Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID – This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Integrity and Data Encryption (IDE) Exchange Extended Capability is 0030h.	<u>HwInit</u>
19:16	Capability Version – This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	<u>HwInit</u>
31:20	Next Capability Offset – This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities.	<u>HwInit</u>

7.9.26.2 IDE Capability Register (Offset 04h) §

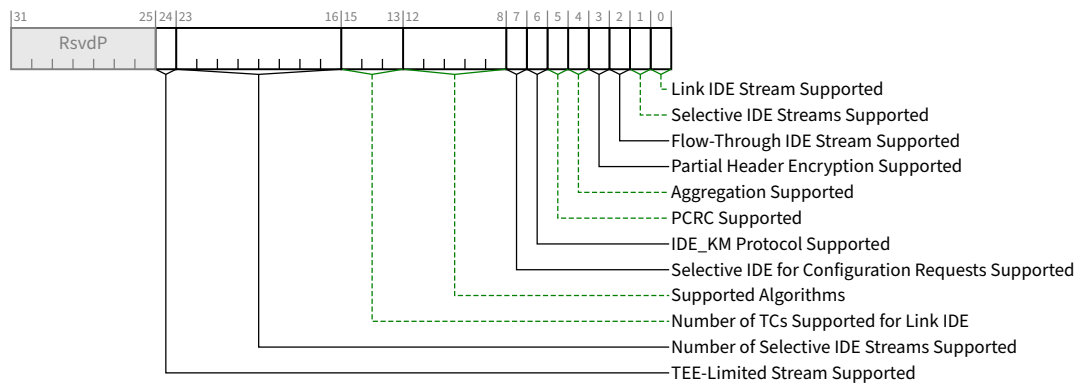

Figure 7-372 IDE Capability Register §

Table 7-324 IDE Capability Register §

Bit Location	Register Description	Attributes
0	Link IDE Stream Supported – When Set, indicates that the Port supports Link IDE Streams, and that one or more Link IDE Stream Register block(s) immediately follow the IDE Control Register, per the value in the <u>Number of TCs Supported for Link IDE</u> field. When Clear, there must be no Link IDE Stream Register blocks present.	HwInit / RsvdP
1	Selective IDE Streams Supported – When Set, indicates that the Port support Selective IDE Streams, and that one or more Selective IDE Stream Register block(s) are implemented, per the value in the <u>Number of Selective IDE Streams Supported</u> field. When Clear, there must be no Selective IDE Stream Register blocks present.	HwInit / RsvdP
2	Flow-Through IDE Stream Supported – For a Switch or Root Port, when Set indicates support for passing Selective IDE Streams to all other Switch or Root Ports. If this bit is Set and both <u>Link IDE Stream Supported</u> and <u>Selective IDE Streams Supported</u> are Clear, then no Link IDE register blocks or Selective IDE register blocks are required. Reserved for Endpoints.	HwInit / RsvdP
3	Partial Header Encryption Supported – If <u>Link IDE Stream Supported</u> or <u>Selective IDE Streams Supported</u> are Set, then this bit, when Set, indicates the Port supports partial header encryption. Undefined if <u>Link IDE Stream Supported</u> and <u>Selective IDE Streams Supported</u> are both Clear.	HwInit
4	Aggregation Supported – If <u>Link IDE Stream Supported</u> or <u>Selective IDE Streams Supported</u> are Set, then this bit, when Set, indicates the Port supports aggregation. Undefined if <u>Link IDE Stream Supported</u> and <u>Selective IDE Streams Supported</u> are both Clear.	HwInit
5	PCRC Supported – When Set, indicates that the Port supports the generation and checking of PCRC.	HwInit
6	IDE_KM Protocol Supported – When Set, indicates that the Port supports the IDE_KM protocol in the responder role as defined in § Section 6.33.3	HwInit

Bit Location	Register Description	Attributes
7	<p>Selective IDE for Configuration Requests Supported – For a Root Port, Switch Upstream Port, or Endpoint Upstream Port, if <u>Selective IDE Streams Supported</u> is Set, then this bit, if Set, indicates that the Port supports the association of Configuration Requests with Selective IDE Streams.</p> <p>For a Switch Upstream Port, when Set, this bit indicates the Switch supports Selective IDE for Configuration Requests targeting all Functions of the Switch.</p> <p>This bit is Reserved for Switch Downstream Ports.</p> <p>If <u>Selective IDE Streams Supported</u> is Clear, this bit is Reserved.</p>	HwInit / RsvdP
12:8	<p>Supported Algorithms – Indicates the supported algorithms for securing IDE TLPs, encoded as:</p> <p>0 0000b AES-GCM 256 key size, 96b MAC</p> <p>Others Reserved</p>	HwInit
15:13	<p>Number of TCs Supported for Link IDE – If <u>Link IDE Stream Supported</u> is Set, indicates the number of TCs supported for Link IDE Streams encoded as:</p> <p>000b One TC supported</p> <p>001b 2 TCs supported</p> <p>010b 3 TCs supported</p> <p>011b 4 TCs supported</p> <p>100b 5 TCs supported</p> <p>101b 6 TCs supported</p> <p>110b 7 TCs supported</p> <p>111b 8 TCs supported</p> <p>If <u>Link IDE Stream Supported</u> is Clear, this field is undefined.</p>	HwInit
23:16	<p>Number of Selective IDE Streams Supported – If <u>Selective IDE Streams Supported</u> is Set then this field indicates number of Selective IDE Streams Supported such that 0=1 Stream.</p> <p>A corresponding number of <u>Selective IDE Stream Register Block(s)</u> must be implemented. If <u>Link IDE Stream Supported</u> is Clear, then these blocks must immediately follow the IDE Control Register. If <u>Link IDE Stream Supported</u> is Set, then these blocks must immediately follow the Link IDE Stream Control and Status Registers.</p> <p>If <u>Selective IDE Streams Supported</u> is Clear, this field is undefined.</p>	HwInit / RsvdP
24	<p>TEE-Limited Stream Supported – When Set, indicates that the TEE-Limited Stream control mechanism is supported.</p> <p>If <u>Selective IDE Streams Supported</u> is Clear, this bit is Reserved.</p>	HwInit / RsvdP

7.9.26.3 IDE Control Register (Offset 08h) §

Figure 7-373 IDE Control Register §

Table 7-325 IDE Control Register §

Bit Location	Register Description	Attributes
2	Flow-Through IDE Stream Enabled – For Switch Ports and Root Ports, Enables the Port for flow-through operation of TLPs associated with Selective IDE Streams. Reserved for Upstream Ports associated with Endpoints.	RW / RsvdP

7.9.26.4 Link IDE Register Block §

A Link IDE register block must consist of one Link IDE Stream Control Register followed by one Link IDE Stream Status Register. If the Link IDE Stream Supported bit in the IDE Capability Register is Set, then this register block must be instantiated once for each Traffic Class (TC) supported as indicated in the Number of TCs Supported for Link IDE field.

7.9.26.4.1 Link IDE Stream Control Register §

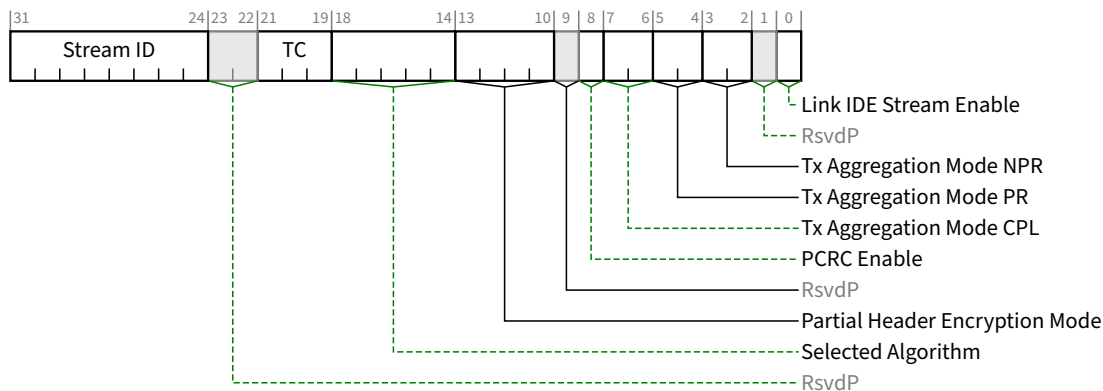

Figure 7-374 Link IDE Stream Control Register §

Table 7-326 Link IDE Stream Control Register §

Bit Location	Register Description	Attributes
0	<p>Link IDE Stream Enable – When Set, enables Link IDE Stream such that IDE operation will start when triggered by means of the IDE_KM protocol (see § Section 6.33.3). When Cleared, must immediately transition the Stream to Insecure.</p> <p>Software must not modify the PCRC Enable bit while this bit is Set; otherwise, the result is undefined.</p> <p>It is permitted for the default value to be 1b if and only if implementation specific means can ensure that the Link IDE Stream will default into a state where operation in the Secure state is possible, otherwise the default value must be 0b.</p>	<u>RW</u>
3:2	<p>Tx Aggregation Mode NPR – If Aggregation Supported is Set then this field selects the level of aggregation for Transmitted Non-Posted Requests for this Stream, encoded as:</p> <p>00b No aggregation</p> <p>01b Up to 2 Non-Posted Requests</p> <p>10b Up to 4 Non-Posted Requests</p> <p>11b Up to 8 Non-Posted Requests</p> <p>Reserved If <u>Aggregation Supported</u> is Clear.</p> <p>Default value is 00b</p>	<u>RW / RsvdP</u>
5:4	<p>Tx Aggregation Mode PR – If Aggregation Supported is Set then this field selects the level of aggregation for Transmitted Posted Requests for this Stream, encoded as:</p> <p>00b No aggregation</p> <p>01b Up to 2 Posted Requests</p> <p>10b Up to 4 Posted Requests</p> <p>11b Up to 8 Posted Requests</p> <p>Reserved If <u>Aggregation Supported</u> is Clear.</p> <p>Default value is 00b</p>	<u>RW / RsvdP</u>
7:6	<p>Tx Aggregation Mode CPL – If Aggregation Supported is Set then this field selects the level of aggregation for Trasmitted Completions for this Stream, encoded as:</p> <p>00b No aggregation</p> <p>01b Up to 2 Completions</p> <p>10b Up to 4 Completions</p> <p>11b Up to 8 Completions</p> <p>Reserved If <u>Aggregation Supported</u> is Clear.</p> <p>Default value is 00b</p>	<u>RW / RsvdP</u>
8	<p>PCRC Enable – When Set, Transmitted IDE TLPs associated with this Stream that include P content must include PCRC, and Received TLPs must be checked for PCRC failure.</p> <p>Reserved if <u>PCRC Supported</u> is Clear.</p> <p>Default value is 0b.</p>	<u>RW / RsvdP</u>
13:10	<p>Partial Header Encryption Mode – Selects the mode to be used for partial header encryption of IDE TLPs for this IDE Stream. Must be programmed to the same value in both the Partner Ports. Must be configured while <u>Link IDE Stream Enable</u> is Clear. When <u>Link IDE Stream Enable</u> is Set, the setting is sampled, and this field becomes <u>RO</u> with reads returning the sampled value.</p> <p>0000b No partial header encryption</p>	<u>RW / RO / RsvdP</u>

Bit Location	Register Description	Attributes
	<p>0001b Address[17:2] Encrypted, and, if present, the First DW BE and Last DW BE fields</p> <p>0010b Address[25:2] Encrypted, and, if present, the First DW BE and Last DW BE fields</p> <p>0011b Address[33:2] Encrypted, and, if present, the First DW BE and Last DW BE fields</p> <p>0100b Address[41:2] Encrypted, and, if present, the First DW BE and Last DW BE fields</p> <p>Others Reserved</p> <p>If <u>Partial Header Encryption Supported</u> is Clear, this field is Reserved.</p>	
18:14	<p>Selected Algorithm – Selects the algorithm to be used for securing IDE TLPs for this IDE Stream. Must be programmed to the same value in both the Upstream and Downstream Ports. Must be configured while <u>Link IDE Stream Enable</u> is Clear. When <u>Link IDE Stream Enable</u> is Set, the setting is sampled, and this field becomes RO with reads returning the sampled value.</p> <p>0 0000b AES-GCM 256 key size, 96b MAC</p> <p>Others Reserved</p>	RW / RO
21:19	<p>TC – System firmware/software must program this field to indicate the TC associated with this Link IDE Register block.</p> <p>Default value is 000b</p>	RW / RsvdP
31:24	<p>Stream ID – Indicates the Stream ID associated with this Link IDE Stream. Software must program the same Stream ID into both Ports associated with a given Link IDE Stream. Default value is 00h.</p>	RW

7.9.26.4.2 Link IDE Stream Status Register §

Figure 7-375 Link IDE Stream Status Register §

Table 7-327 Link IDE Stream Status Register §

Bit Location	Register Description	Attributes
3:0	<p>Link IDE Stream State – When <u>Link IDE Stream Enable</u> is Set, this field indicates the state of the Port. Encodings:</p> <p>0000b Insecure</p> <p>0010b Secure</p> <p>Others Reserved – Software must handle reserved values as indicating unknown state</p> <p>When <u>Link IDE Stream Enable</u> is Clear, the value of this field must be 0000b.</p>	RO
31	<p>Received IDE Fail Message – When Set, indicates that one or more IDE Fail Message(s) have been Received for this Stream.</p>	RW1C

7.9.26.5 Selective IDE Stream Register Block §

A Selective IDE Stream register block must consist of one Selective IDE Stream Capability Register, followed by one Selective IDE Stream Control Register, followed by one Selective IDE Stream Status Register, followed by one Selective IDE RID Association register Block, followed by zero or more Selective IDE Address Association Register Block(s). If the Selective IDE Streams Supported bit in the IDE Capability Register is Set, then this register block must be instantiated once for each Selective IDE Stream supported as indicated in the Number of Selective IDE Streams Supported field.

7.9.26.5.1 Selective IDE Stream Capability Register §

Figure 7-376 Selective IDE Stream Capability Register §

Table 7-328 Selective IDE Stream Capability Register §

Bit Location	Register Description	Attributes
3:0	<p>Number of Address Association Register Blocks – Indicates the number of Selective IDE Address Association register blocks for this Selective IDE Stream.</p> <p>The number of Selective IDE Address Association register blocks for a given IDE Stream is hardware implementation specific, and is permitted to be any number between 0 and 15.</p>	RO

7.9.26.5.2 Selective IDE Stream Control Register §

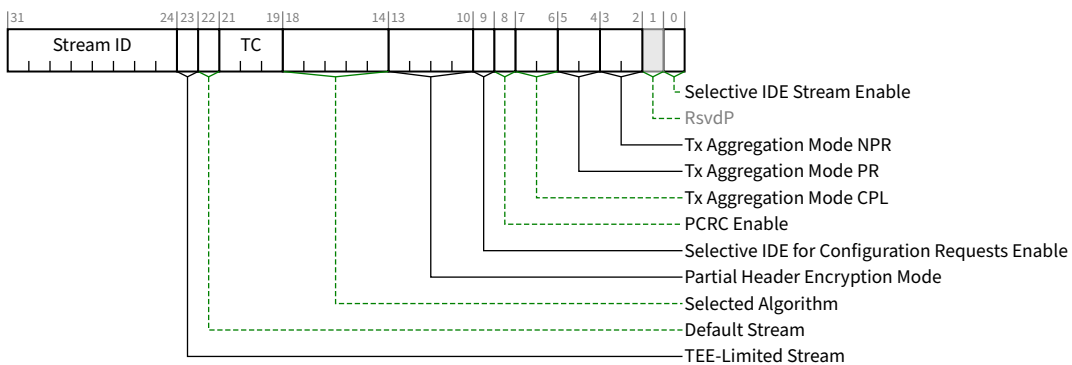

Figure 7-377 Selective IDE Stream Control Register §

Table 7-329 Selective IDE Stream Control Register §

Bit Location	Register Description	Attributes
0	<p>Selective IDE Stream Enable – When Set, enables this IDE Stream such that IDE operation will start when triggered by means of the IDE_KM protocol (see § Section 6.33.3). When Cleared, must immediately transition the Stream to Insecure. Software must configure the following before Setting this bit, and must not modify them while this bit is Set; otherwise, the result is undefined:</p> <ul style="list-style-type: none"> • Selected Algorithm (below) • PCRC Enable • Requester ID Limit in IDE RID Association Register 1 • Requester ID Base, and Segment Base if applicable, in IDE RID Association Register 2 • V bit in IDE RID Association Register 2 <p>If this bit is Set when the V bit is Clear, the IDE Stream must transition to Insecure.</p> <p>When Cleared, must immediately transition the Stream to Insecure.</p> <p>It is strongly recommended that the IDE Address Association Registers, and the Default Stream bit (if applicable), also be programmed prior to Setting this bit.</p> <p>Default value is 0b.</p>	<u>RW</u>
3:2	<p>Tx Aggregation Mode NPR – If Aggregation Supported is Set then this field selects the level of aggregation for Transmitted Non-Posted Requests for this Stream, encoded as:</p> <p>00b No aggregation</p> <p>01b Up to 2 Non-Posted Requests</p> <p>10b Up to 4 Non-Posted Requests</p> <p>11b Up to 8 Non-Posted Requests</p> <p>Reserved If <u>Aggregation Supported</u> is Clear.</p> <p>Default value is 00b</p>	<u>RW / RsvdP</u>
5:4	<p>Tx Aggregation Mode PR – If Aggregation Supported is Set then this field selects the level of aggregation for Transmitted Posted Requests for this Stream, encoded as:</p> <p>00b No aggregation</p> <p>01b Up to 2 Posted Requests</p> <p>10b Up to 4 Posted Requests</p> <p>11b Up to 8 Posted Requests</p> <p>Reserved If <u>Aggregation Supported</u> is Clear.</p> <p>Default value is 00b</p>	<u>RW / RsvdP</u>

Bit Location	Register Description	Attributes
31:0	Memory Base Upper – Corresponds to Address bits [63:32]	RW

7.9.27 Null Capability §

The Null Capability is a capability structure in PCI-compatible Configuration Space (first 256 bytes) as shown in § Figure 7-384.

The Null Capability contains no registers. This capability is present in the linked list (Next Capability Pointer), but should otherwise be ignored by software. The layout of the information is shown in § Figure 7-384.

A single PCI Express Function is permitted to contain multiple Null Capability structures.

Figure 7-384 Null Capability §

Table 7-336 Null Capability §

Bit Location	Register Description	Attributes
7:0	Capability ID - Indicates the PCI Express Capability structure. This field must return a Capability ID of 00h indicating that this is a <u>Null Capability</u> structure.	RO
15:8	Next Capability Pointer - This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities.	RO

7.9.28 Null Extended Capability §

The Null Extended Capability is an optional Extended Capability that is permitted to be implemented by any PCI Express Function or RCRB. This capability contains no registers. This capability is present in the linked list (Next Capability Offset) but should otherwise be ignored by software.

A single PCI Express Function or RCRB is permitted to contain multiple Null Extended Capability structures.

§ Figure 7-385 details allocation of register fields in the Null Extended Capability; § Table 7-337 provides the respective bit definitions. The Extended Capability ID for the Null Extended Capability is 0000h.

Figure 7-385 Null Extended Capability §

Table 7-337 Null Extended Capability §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Null Extended Capability is 0000h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field is permitted to contain any value.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

7.9.29 Streamlined Virtual Channel Extended Capability (SVC) §

The Streamlined Virtual Channel (SVC) Extended Capability is an optional Extended Capability required for Ports that support capabilities associated with this structure, including UIO. It is permitted, but not required, for Functions in a Port to implement the SVC Extended Capability as well as the MFVC Extended Capability and/or VC Capabilities. See § Section 6.3.5.

UIO requires the use of the SVC capability and is not supported by the VC or MFVC capabilities. UIO is supported only in Flit Mode, but in Non-Flit Mode the SVC capability can be used by non-UIO traffic.

For an Upstream Port, the SVC Extended Capability structure is permitted to be implemented only in Function 0, and that instance applies to all Functions associated with that Port. The SVC Extended Capability structure is permitted to be implemented in any Downstream Port, or in an RCRB. If the SVC Extended Capability structure is implemented in a USP

containing one or more Switch USP Functions, it must be implemented in all associated Switch DSP Functions. A Root Complex is permitted to implement the Extended Capability structure in some Root Ports and not others.

The number of (extended) Virtual Channels is indicated by the SVC Extended VC Count field in the SVC Port VC Capability Register 1. Software must interpret this field to determine the availability of extended SVC Resource registers.

1	<p>SVC VC Negotiation Pending – This bit indicates whether the Virtual Channel negotiation (initialization or disabling) is in pending state. This bit is valid for all Functions.</p> <p>The value of this bit is defined only when the Link is in the DL_Active state and the corresponding <u>SVC VC Enable</u> bit is Set.</p> <p>This bit is Set by hardware to indicate that the VC resource has not completed the process of negotiation. This bit is Cleared by hardware after the VC negotiation is complete (on exit from the FC_INIT2 state). For VC0, this bit is permitted to be hardwired to 0b.</p> <p>Before using a Virtual Channel, software must check whether the <u>SVC VC Negotiation Pending</u> bits for that Virtual Channel are Clear in both components on the Link.</p>	RO

7.9.30 MMIO Register Block Locator Extended Capability (MRBL) §

The MMIO Register Block Locator Extended Capability (MRBL) is an optional Extended Capability for discovering register blocks in Memory Space that can be used to exchange various types of data structures between system software and a Function (See § Section 6.35 § Section 6.35).

It is permitted to implement the MRBL Extended Capability in any type of Function. A single PCI Express Function is permitted to contain at most one instance of this capability.

The number of register blocks included the MRBL structure is described in the MRBL Capabilities Register (§ Section 7.9.30.2 § Section 7.9.30.2). A Function that implements the MRBL Extended Capability shall support at least one MRBL Locator Register (§ Section 7.9.30.3).

Each register block is described by a MRBL Locator Register (§ Section 7.9.30.3) to specify the location and type of the registers within Memory Space. Each register block must be contained within the address range covered by the associated BAR. § Figure 7-394 illustrates the MRBL Extended Capability structure.

Figure 7-394 MRBL Extended Capability §

7.9.30.1 MRBL Extended Capability Header (Offset 00h) §

§ Figure 7-395 details allocation of register fields in the MRBL Extended Capability Header; § Table 7-345 provides the respective bit definitions. Refer to § Section 7.6.3 for a description of the PCI Express Extended Capability Header. The Extended Capability ID for the MRBL Extended Capability is 0036h.

8. Electrical Sub-Block §

8.1 Electrical Specification Introduction §

Key attributes of the Electrical Specification Include:

- Support for NRZ signaling at 2.5, 5.0, 8.0, 16.0, 32.0 GT/s, and PAM4 signaling at 64.0 GT/s data rates
- Support for common and separate independent reference clock architectures
- Support for Spread Spectrum clocking
- Reduced swing mode for lower power Link operation
- In-band receiver detection and electrical idle detection
- Channel compliance methodology
- Adaptive transmitter equalization and reference receiver equalization allowing closed eye channel support at 8.0, 16.0, and 32.0 GT/s, and 64.0 GT/s
- Lane margining
- AC coupled channel

Please note that throughout this specification, the term GT/s is used to refer to the number of encoded bits transferred in a second on a direction of a lane. In PAM4 signaling, two bits are encoded in one UI with four voltage levels § Section 4.2.3.1.1 . Consequently, the Nyquist frequency is 16 GHz for both 32.0 GT/s NRZ and 64.0 GT/s PAM4.

Because of four voltage levels and reduced amplitude for each voltage level, 64.0 GT/s PAM4 signaling is sensitive to noise and burst errors. The Bit Error Rate (BER), also referred as First Bit Error Rate (FBER) in § Chapter 4. for 64.0 GT/s is 10^{-6} . FBER refers to Bit Error Rate without accounting for any burst error. For 2.5, 5.0, 8.0, 16.0, and 32.0 GT/s data rates, BER of 10^{-12} implicitly assumes FBER of 10^{-12} and do not account for any types of burst error.

The 6.0 version of the PCI Express Electrical Specification is organized into separate sections for the Transmitter, Receiver, the Channel, and the Refclk. In this version most parameters have been regularized such that a common set of parameters is used to define compliance at all data rates.

8.2 Interoperability Criteria §

8.2.1 Data Rates §

A device must support 2.5 GT/s and is not permitted to skip support for any data rates between 2.5 GT/s and the highest supported rate.

8.2.2 Refclk Architectures §

PCIe supports two Refclk data architectures: Common Refclk, and Independent Refclk. These are described in detail in § Section 8.6 . A PCIe device may support one or more of these architectures.

8.3 Transmitter Specification §

8.3.1 Measurement Setup for Characterizing Transmitters §

The PCI Express electrical specification references all measurements to the device's pin. However, the pin of a device under test (DUT) is not generally accessible, and the closest accessible point is usually a pair of microwave-type coaxial connectors separated from the DUT pins by several inches of PCB trace, called the breakout channel on a silicon test board. On a test board with many Lanes the minimum breakout channel length is constrained by the need to route to many coaxial connectors. Typically, this limitation holds true for both the Tx and the Rx pins. § Figure 8-1 illustrates a typical test connection to a DUT, showing a single Tx Lane breakout.

A low jitter Refclk source is used when the silicon supports using an external reference clock in order that the jitter measurements for the DUT include only contributions from the Transmitter.

When testing a Transmitter it is desirable to have as many other PCI Express Lanes sending or receiving the compliance pattern as is feasible. Similarly, if the device supports other I/O it should also be sending or receiving on these interfaces. The goal is to have the Tx test environment replicate that found in a real system as closely as possible.

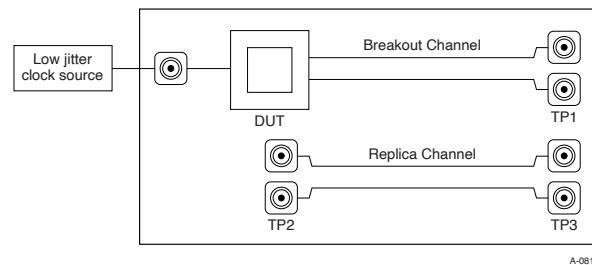

Figure 8-1 Tx Test Board for Non-Embedded Refclk §

The 6.0 version of the Tx specification also includes explicit support for Transmitters utilizing embedded Refclks. In this case the Tx under test is not driven with a low jitter clock source, and both the Tx data and Tx Refclk out must be sampled simultaneously by means of a 2-port measurement as shown in § Figure 8-2. For more details consult § Section 8.3.5.3 . When an implementation is tested that is configured for the independent reference clock architecture only the data is sampled for both the Non-Embedded and Embedded reference clock cases.

Figure 8-2 Tx Test board for Embedded Refclk §

8.3.1.1 Breakout and Replica Channels §

In order to specify a Transmitter with a uniform set of Tx parameters it is necessary to establish a one-to-one correspondence between what is measurable at TP1 and the corresponding Tx voltage or jitter at the pin. This may be achieved by means of a breakout channel and a replica channel. The replica channel reproduces the electrical characteristics of the breakout channel as closely as possible, matching its length, layer transitions, etc., making it possible to de-embed Tx measurements to the pin of the DUT. All voltage parameters are de-embedded to the pins unless otherwise specified. While the specification does not define precise electrical characteristics for the replica and breakout channels, it is advisable to adhere to the following guidelines:

- Breakout channels should be the same length for each Lane and routed on as few layers as possible, thereby reducing the number of replica channels that need to be built and measured.
- Each routing layer on a test board should have a separate breakout channel where the via and pad structures of the breakout and replica channels on respective layers match as closely as possible.
- Breakout and replica channels should be designed to have an insertion loss of less than 2 dB at the Nyquist frequency for the signaling rate (4 dB at Nyquist if the maximum signaling rate is 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s) and a return loss of greater than 15 dB to Nyquist when measured from either TP2 or TP3, which may require use of low loss dielectric, wide signal traces and back-drilling of break-out vias or use of micro-via technology.
- The impedance targets for the breakout channel are 100 Ω differential and 50 Ω single-ended. For best accuracy the actual breakout channel impedance should be within $\pm 5\%$ of these values. For larger deviations a more complex de-embedding technique may be required.

8.3.2 Voltage Level Definitions §

A differential voltage is defined by taking the voltage difference between two conductors. In this specification, a differential signal or differential pair is comprised of a voltage on a positive conductor, V_{D+} , and a negative conductor, V_{D-} . The differential voltage (V_{DIFF}) is defined as the difference of the positive conductor voltage and the negative conductor voltage ($V_{DIFF} = V_{D+} - V_{D-}$). The Common Mode Voltage (V_{CM}) is defined as the average or mean voltage present on the same differential pair ($V_{CM} = (V_{D+} + V_{D-})/2$). This document's electrical specifications often refer to common mode peak-to-peak measurements or peak measurements, which are defined by the following equations.

$$V_{DIFFp-p} = (2 * \max | \underline{V_{D+}} - \underline{V_{D-}} |) \text{ (This applies to a symmetric differential swing)}$$

Equation 8-1 $V_{DIFFp-p}$ §

$$\underline{V_{TX-AC-CM-PP}} = \max(\underline{V_{D+}} + \underline{V_{D-}})/2 - \min(\underline{V_{D+}} + \underline{V_{D-}})/2$$

Equation 8-2 $V_{TX-AC-CM-PP}$ §

Note: The maximum value is calculated on a per unit interval evaluation with unit interval boundaries determined by the behavioral CDR. The maximum function as described is implicit for all peak-to-peak and peak common mode equations throughout the rest of this chapter.

In this section, DC is defined as all frequency components below $F_{DC} = 30$ kHz. AC is defined as all frequency components at or above $F_{DC} = 30$ kHz. These definitions pertain to all voltage and current specifications.

An example waveform is shown in § Figure 8-3. In this waveform the differential voltage (defined as $D+ - D-$) is approximately 800 mVPP, and the single-ended voltage for both $D+$ and $D-$ is approximately 400 mVPP for each. Note that while the center crossing point for both $D+$ and $D-$ is nominally at 200 mV, the corresponding crossover point for the differential voltage is at 0.0 V.

Figure 8-3 Single-ended and Differential Levels §

8.3.3 Tx Voltage Parameters §

Tx voltage parameters include equalization coefficients, equalization presets, and min/max voltage swings.

8.3.3.1 2.5 and 5.0 GT/s Transmitter Equalization §

Tx equalization at 2.5 and 5.0 GT/s is only de-emphasis. Tx equalization de-emphasis values at 2.5 and 5.0 GT/s are measured using the average ratio of transition to non-transition average eye amplitude at the 0.5 UI location using 500 repetitions of the compliance pattern.

8.3.3.2 8.0, 16.0, 32.0, and 64.0 GT/s Transmitter Equalization §

Tx voltage swing and equalization presets at 8.0, 16.0, 32.0, and 64.0 GT/s are measured by means of a low frequency pattern within the compliance pattern. The pattern consists of a sequence of 64 zeros followed by 64 ones, for 8.0, 16.0, and 32.0 GT/s and it consists of a sequence of 64 voltage level 0's followed by 64 voltage level 3's for 64.0 GT/s. The low frequency pattern permits an accurate measurement of voltage since ISI effects will have decayed and the signal will have approached a steady state. 8.0, 16.0, 32.0, and 64.0 GT/s transmitters must implement a coefficient-based equalization mode in order to support fine grained control over Tx equalization resolution. Additionally, a Transmitter must support a specified number of presets that give a coarser control over Tx equalization resolution. Both coefficient space and preset space are controllable via messaging from the Receiver via an equalization procedure. The equalization procedure operates on the same physical path as normal signaling and is implemented via extensions to the existing protocol Link layer.

All 8.0, 16.0, 32.0, and 64.0 GT/s Transmitters must implement support for the equalization procedure, whereas 8.0, 16.0, 32.0, and 64.0 GT/s Receivers may optionally make use of requests for the Transmitter on the Link partner to update Transmitter equalization. Details of the equalization procedure may be found in the Physical Layer Logical Block chapter.

Tx equalization coefficients for 8.0, 16.0, and 32.0 GT/s are based on the following FIR filter relationship as shown in § Figure 8-4. Equalization coefficients are subject to constraints limiting their max swing to \pm unity with c_{-1} and c_{+1} being zero or negative. The inclusion of the unity condition means that only two of the three coefficients need to be specified to fully define $v_{out,n}$. In this specification for 8.0, 16.0, and 32.0 GT/s the two coefficients so specified are c_{-1} and c_{+1} , where c_0 is implied. Note that the coefficient magnitude is not the same as the Tx voltage swing magnitude.

Tx equalization coefficients for 64.0 GT/s are based on the following FIR filter relationship as shown in § Figure 8-5. Equalization coefficients are subject to constraints limiting their max swing to \pm unity with c_{-2} being zero or positive, c_{-1} and c_{+1} being zero or negative.

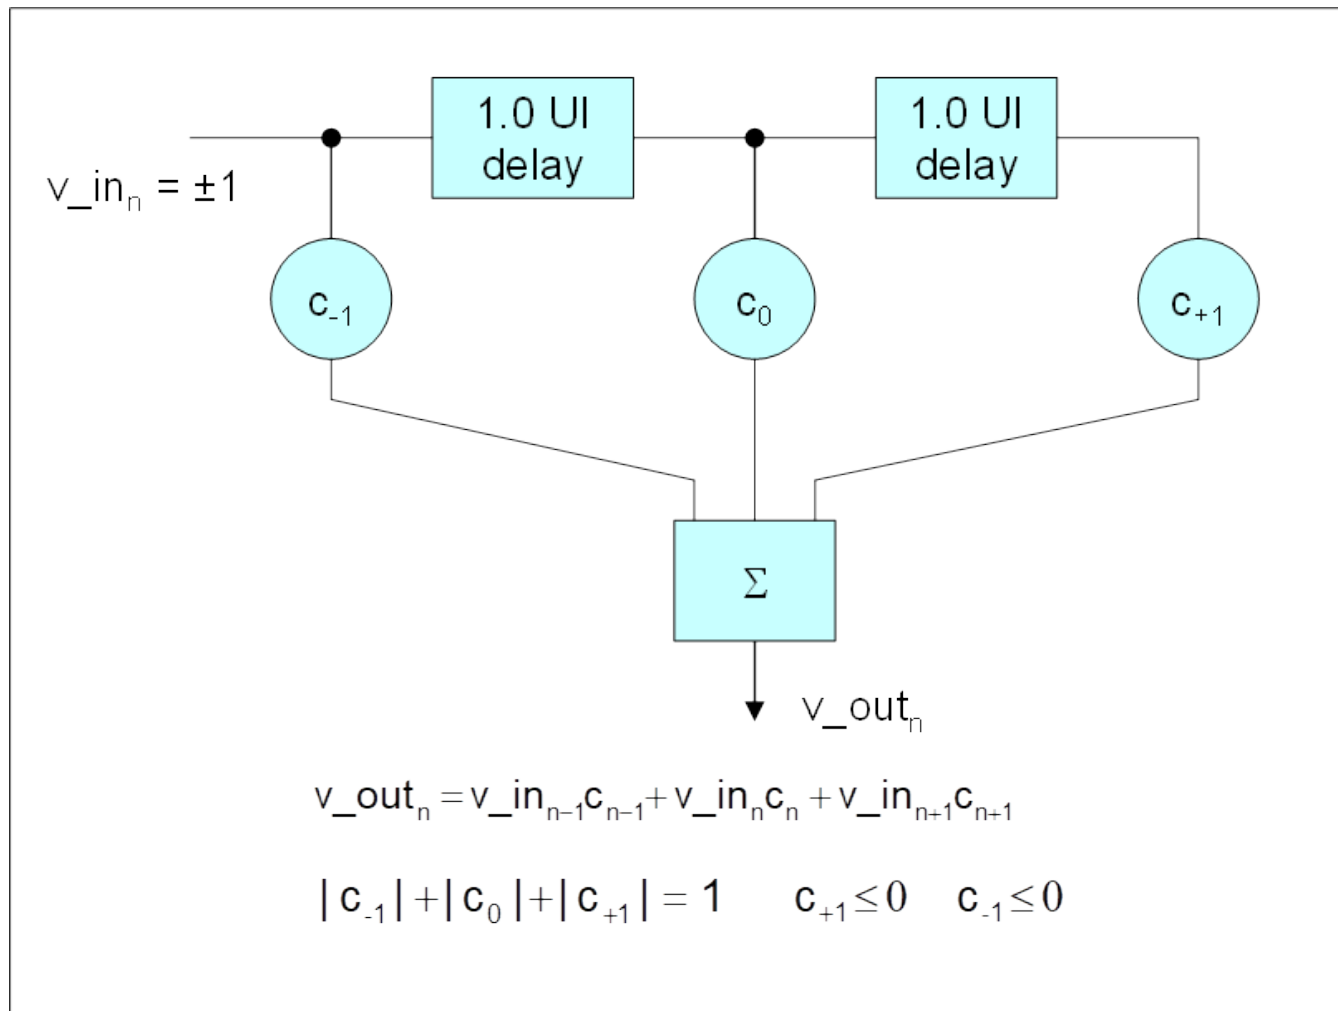

Figure 8-4 Tx Equalization FIR Representation for 8.0, 16.0, and 32.0 GT/s §

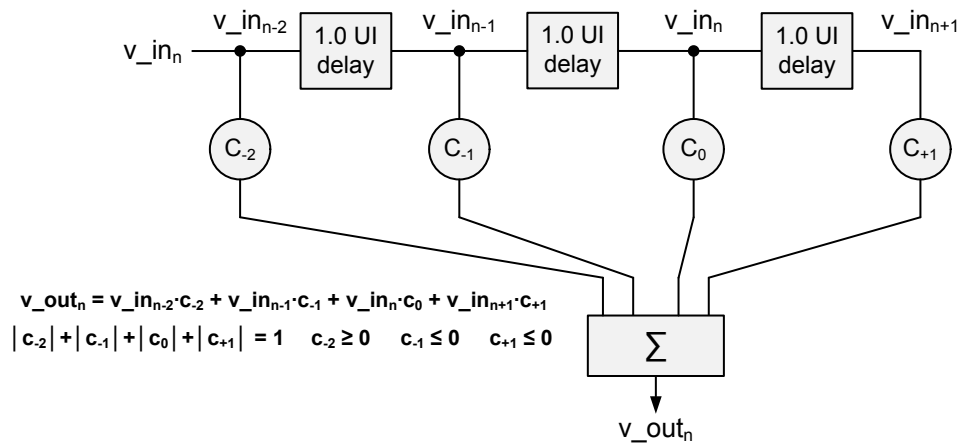

Figure 8-5 Tx Equalization FIR Representation for 64.0 GT/s §

8.3.3.3 Tx Equalization Presets for 8.0, 16.0, 32.0, and 64.0 GT/s §

When operating at 8.0 GT/s, 16.0 GT/s and 32.0 GT/s the Tx must support the full range of presets given in § Table 8-1. When operating at 64.0 GT/s, the Tx must support the full range of presets given in § Table 8-2. The data rate dependent encoding of presets has been defined in § Section 4.2.4.2. Presets are defined in terms of ratios, relating the pre-cursor and post-cursor equalization voltages. The pre-cursors (V_{c1}) and (V_{c2}) are referred to as pre-shoots, while the post-cursor (V_b) is referred to as de-emphasis. This convention permits the specification to retain the existing 2.5 GT/s and 5.0 GT/s definitions for Tx equalization, where only de-emphasis is defined, and it allows pre-shoots and de-emphasis to be defined such that each is independent of the other. The tolerances in § Table 8-1 also apply to 2.5 and 5.0 GT/s de-emphasis. The maximum swing, V_d , is also shown to illustrate that, when c_{+1} , c_{-2} , and c_{-1} are non-zero, the swing of V_a does not reach the maximum as defined by V_d . § Figure 8-6 is shown as an example of transmitter equalization, but it is not intended to represent the signal as it would appear for measurement purposes. The high frequency nature of PCIe signaling makes measurement of single UI pulse heights impractical.

The presets defined in § Table 8-1 and § Table 8-2 are numbered to match the designations in § Table 4-23.

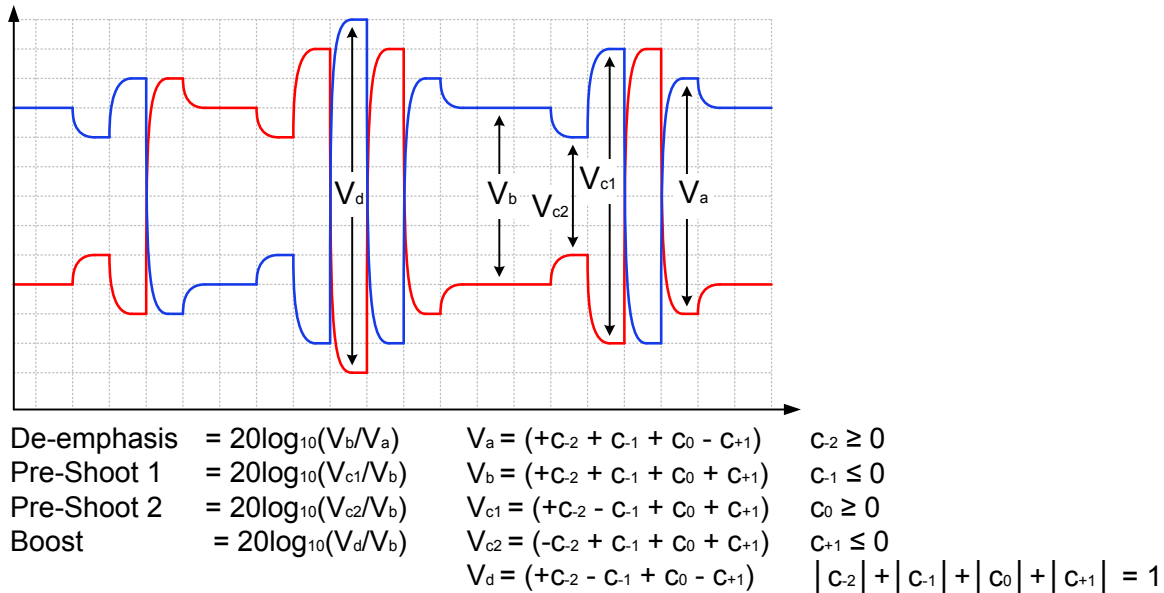

Figure 8-6 Definition of Tx Voltage Levels and Equalization Ratios §

§ Table 8-1 lists the values for presets; at 8.0 GT/s, 16.0 GT/s and 32.0 GT/s. All preset values must be supported for full swing signaling.

Table 8-1 Tx Preset Ratios and Corresponding Coefficient Values for 8.0, 16.0, and 32.0 GT/s §

Notes:

Preset #	Preshoot 2 (dB)	Preshoot 1 (dB)	De-emphasis (dB)	c_{-2}	c_{-1}	c_{+1}	Va/Vd	Vb/Vd	Vc1/Vd	Vc2/Vd
----------	-----------------	-----------------	------------------	----------	----------	----------	-------	-------	--------	--------

1. Reduced swing signaling must implement presets P4, P1, P9, P5, P6, and P3. Full swing signaling must implement all the above presets.
2. P10 boost limits are not fixed, since its de-emphasis level is a function of the LF level that the Tx advertises during training (see § Section 4.2.4.1). P10 is used for testing the boost limit of Transmitter at full swing. P1 is used for testing the boost limit of Transmitter at reduced swing.

§ Table 8-2 lists the values for presets at 64.0 GT/s. All preset values must be supported for full swing signaling.

Table 8-2 Tx Preset Ratios and Corresponding Coefficient Values for 64.0 GT/s §

Q10	0.0 ±0.5 dB	0.0 ±0.5 dB	Note 2	0.000	0.000	Note 2	1.000	Note 2	Note 2	Note 2

Notes:

1. Reduced swing signaling must implement presets Q0, Q1, Q2, Q3, and Q4. Full swing signaling must implement all the above presets.
2. Q10 boost limits are not fixed, since its de-emphasis level is a function of the LF level that the Tx advertises during training. Q10 is used for testing the boost limit of Transmitter at full swing. Q4 is used for testing the boost limit of Transmitter at reduced swing.

8.3.3.4 Measuring Tx Equalization for 2.5 GT/s and 5.0 GT/s §

Tx equalization de-emphasis values at 2.5 and 5.0 GT/s are measured using the average ratio of transition to non-transition eye heights at the 0.5 UI location using 500 repetitions of the compliance pattern.

8.3.3.5 Measuring Presets at 8.0, 16.0, 32.0, and 64.0 GT/s §

§ Figure 8-7 illustrate the methodology for measuring Tx equalization coefficients and presets. For a Tx preset to be measured, the DUT Tx transmits a Compliance Pattern with the corresponding Tx equalization coefficients. The

equalized Compliance Pattern is captured by a real-time oscilloscope and the post-processing software extracts an equalized step response waveform. The DUT Tx also transmits a Compliance Pattern with no Tx equalization. The unequalized Compliance Pattern is captured by the real-time oscilloscope and the post-processing software applies Tx equalization coefficients c_{-2} , c_{-1} , c_0 , and c_{+1} to construct an equalized step response waveform. The Tx preset coefficients are the best fit Tx equalization coefficients c_{-2} , c_{-1} , c_0 , and c_{+1} that minimize the Mean Square Error (MSE) between the measured equalized step response waveform and the reconstructed equalized step response waveform.

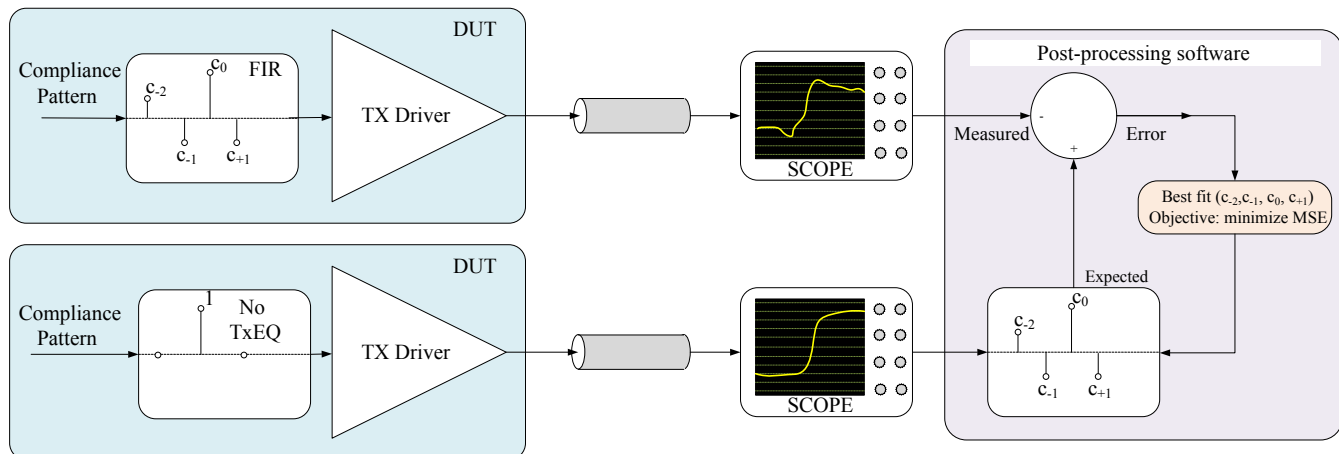

Figure 8-7 Methodology for measuring Tx equalization coefficients and presets §

8.3.3.6 Method for Measuring $V_{TX-DIFF-PP}$ at 2.5 GT/s and 5.0 GT/s §

$V_{TX-DIFF-PP}$ ($V_{TX-DIFF-PP-LOW}$ for reduced swing) at 2.5 GT/s and 5.0 GT/s are measured using the average transition eye amplitude at the 0.5 UI location using 500 repetitions of the compliance pattern.

8.3.3.7 Method for Measuring $V_{TX-DIFF-PP}$ at 8.0, 16.0, 32.0, and 64.0 GT/s §

The range for a Transmitter's output voltage swing, (specified by V_d) with no equalization is defined by $V_{TX-DIFF-PP}$ ($V_{TX-DIFF-PP-LOW}$ for reduced swing), and is obtained by setting c_{-2} , c_{-1} and c_{+1} to zero and measuring the peak-peak voltage on the 64-ones (64 PAM4 voltage level 3's at 64.0 GT/s)/64-zeros (64 PAM4 voltage level 0's at 64.0 GT/s) segment of the compliance pattern. The resulting signal effectively measures at the die pad, minus any low frequency package loss. ISI and switching effects are minimized by restricting the portion of the curve over which voltage is measured to the last few UI of each half cycle, as illustrated in § Figure 8-8. High frequency noise is mitigated by averaging over 500 repetitions of the compliance pattern.

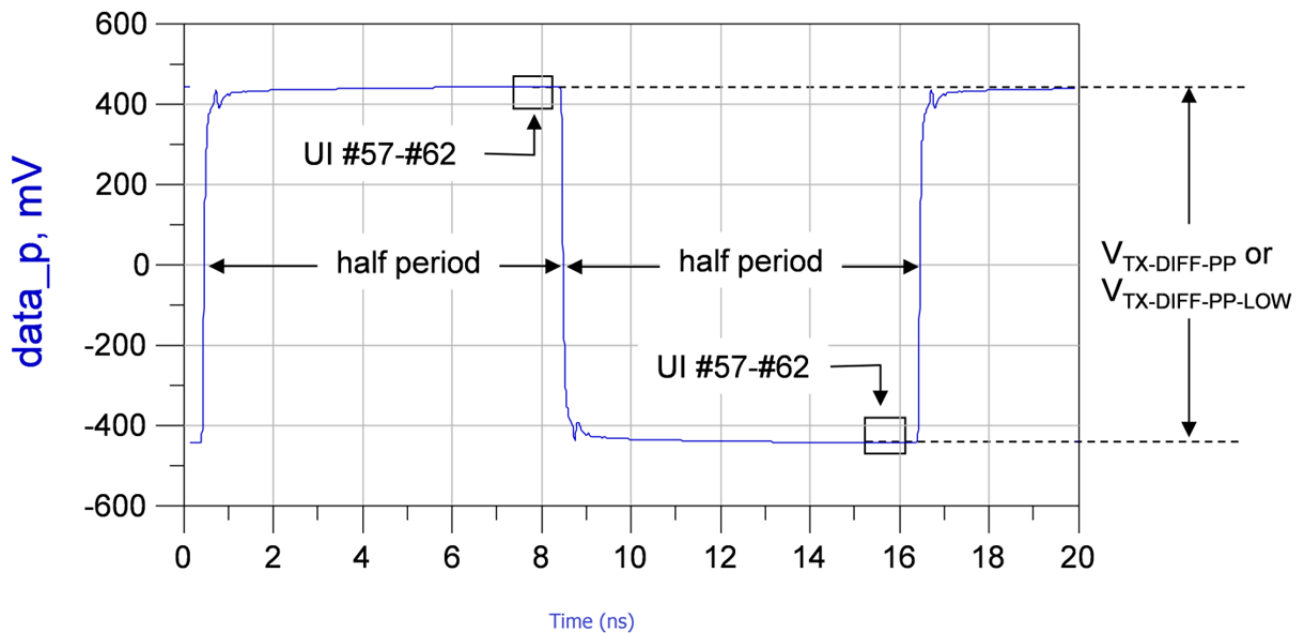

Figure 8-8 $V_{TX-DIFF-PP}$ and $V_{TX-DIFF-PP-LOW}$ Measurement §

8.3.3.8 Coefficient Range and Tolerance for 8.0, 16.0, 32.0, and 64.0 GT/s §

8.0, 16.0, 32.0, and 64.0 GT/s Transmitters are required to inform the Receiver of their coefficient range and tolerance. Coefficient range and tolerance are constrained by the following requirements.

- Coefficients must support all eleven presets and their respective tolerances as defined in § Table 8-1 and § Table 8-2
- All Transmitters must meet the full swing signaling $V_{TX-EIEOS-FS}$ limits.
- Transmitters may optionally support reduced swing, and if they do, they must meet the $V_{TX-EIEOS-RS}$ limits.
- The coefficients must meet the boost and resolution ($V_{TX-BOOST-FS}$, $V_{TX-BOOST-RS}$ and $E_{QTX-COEFF-RES}$) limits defined in § Table 8-6.

When the above constraints are applied the resulting coefficient space for 8.0, 16.0, and 32.0 GT/s with pre-shoot2 coefficient $c_2 = 0$ may be mapped onto a triangular matrix, an example of which is shown in § Figure 8-9. The matrix may be interpreted as follows: pre-shoot1 and de-emphasis coefficients are mapped onto the Y-axis and X-axes, respectively. In both cases the maximum granularity of 1/24 is assumed. Each matrix cell, corresponding to a valid combination of pre-shoot1 and de-emphasis coefficients, has three entries corresponding to pre-shoot1 (PS1), de-emphasis (DE), and boost (as shown in the upper left-hand corner). Diagonal elements are defined by the maximum boost ratio. Those cells highlighted in blue are presets required for reduced swing, while cells in either blue or orange represent presets required for full swing signaling. Note that this figure is informative only and is not intended to imply any specific Tx implementation or to alter requirements for nominal preset equalization values and allowed ranges.

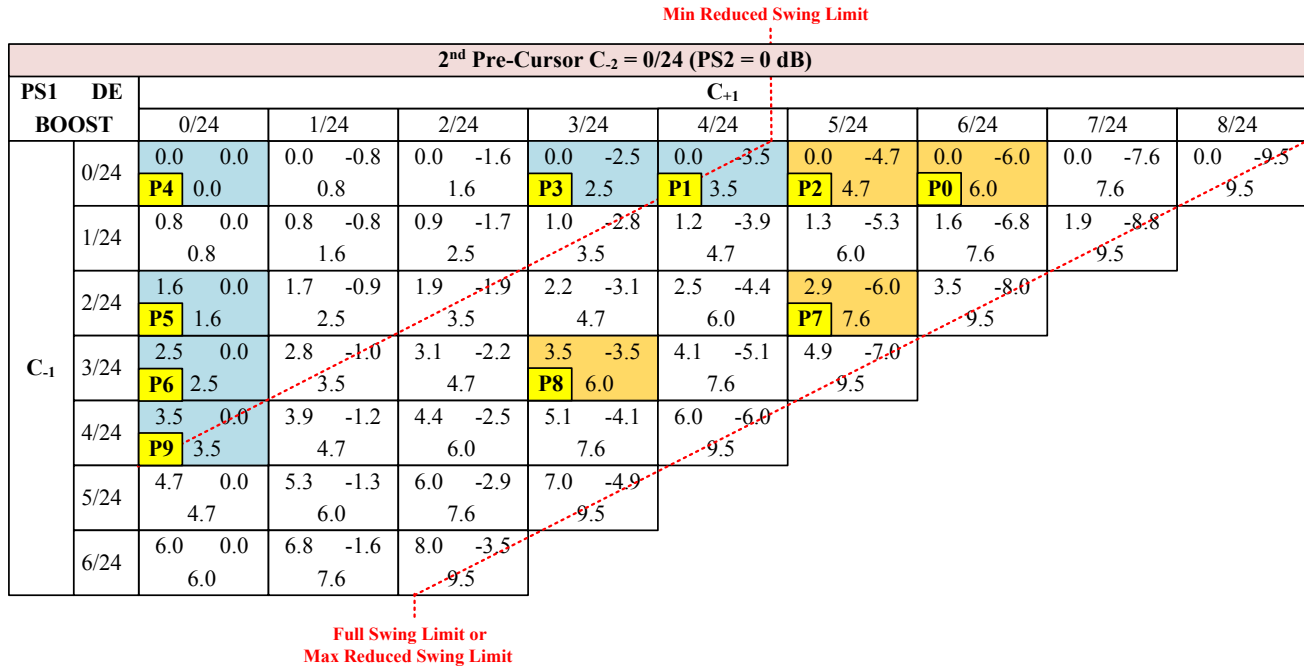

Figure 8-9 Transmit Equalization Coefficient Space Triangular Matrix Example for 8.0, 16.0, and 32.0 GT/s §

The coefficient space for 64.0 GT/s with each pre-shoot2 coefficient may be mapped onto a triangular matrix, an example of which is shown in § Figure 8-10. Maximum granularity of 1/24 is assumed for Tx equalization coefficient. Those cells highlighted in blue are presets required for reduced swing, while cells in either blue or orange represent presets required for full swing signaling. Note that this figure is informative only and is not intended to imply any specific Tx implementation or to alter requirements for nominal preset equalization values and allowed ranges.

Max Reduced Swing Limit

Figure 8-10 Transmit Equalization Coefficient Space Triangular Matrix Example for 64.0 GT/s §

8.3.3.9 EIEOS and $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$ Limits §

EIEOS signaling is defined for 5.0, 8.0, 16.0, 32.0, and 64.0 GT/s only. At 5.0 GT/s the K28.7 Symbol is used. $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$ are measured using the EIEOS sequence contained within the compliance pattern for 8.0, 16.0, 32.0, and 64.0 GT/s. At 8.0 GT/s the EIEOS pattern consists of eight consecutive ones followed by the same number of consecutive zeros, where the pattern is repeated for a total of 128 UI. At 16.0 GT/s the EIEOS pattern consists of 16 consecutive ones followed by the same number of consecutive zeros, where the pattern is repeated for a total of 128 UI. At 32.0 GT/s the EIEOS pattern consists of 32 consecutive ones followed by the same number of consecutive zeros, where the pattern is repeated for a total of 128 UI. At 32.0 GT/s the pattern is repeated for two consecutive blocks. At 64.0 GT/s the EIEOS pattern consists of 32 UI consecutive voltage level 3's followed by 32 UI consecutive voltage level 0's (see § Section 4.2.5.3).

A transmitter sends an EIEOS to cause an exit of Electrical Idle at the Receiver. This pattern guarantees the Receiver will properly detect the EI Exit condition with its squelch exit detect circuit, something not otherwise guaranteed by scrambled data. The Tx EIEOS launch voltage is defined by $V_{TX-EIEOS-FS}$ for full swing signaling and by $V_{TX-EIEOS-RS}$ for reduced swing signaling. $V_{TX-EIEOS-RS}$ is smaller than $V_{TX-EIEOS-FS}$ to reflect the fact that reduced swing is typically supported only for lower loss channels where there is less attenuation at the EIEOS signaling rate.

For full swing signaling $V_{TX-EIEOS-FS}$ is measured with a preset number P10 for 8.0, 16.0, and 32.0 GT/s, and with a preset number Q10 for 64.0 GT/s. This is equivalent to a maximum nominal boost of 9.5 dB and represents the maximum boost attainable in coefficient space. When a tolerance of ± 1.5 dB is factored in this yields the minimum boost limit of 8.0 dB appearing in § Table 8-6. For reduced swing signaling $V_{TX-EIEOS-RS}$ is measured with preset P1 for 8.0, 16.0, and 32.0 GT/s, and with a preset number Q4 for 64.0 GT/s.

A Transmitter is not always permitted to generate the maximum boost level noted above. A Transmitter that cannot drive significantly more than 800 mVPP is limited by the need to meet $V_{TX-EIEOS-FS}$. The Tx must reject any adjustments to its presets or coefficients that would violate the $V_{TX-EIEOS-FS}$ or $V_{TX-EIEOS-RS}$ limits. The EIEOS voltage limits are imposed to guarantee the EIEOS threshold of 175 mVPP at the Rx pin.

§ Figure 8-11 illustrates the de-emphasis peak as observed at the pin of a Tx for $V_{TX-EIEOS-FS}$. At the far end of a lossy channel the de-emphasis peak will be attenuated; this is why the measurement interval includes only the middle five UI at 8.0 GT/s, UI number 5-14 at 16.0 GT/s, and UI number 9-28 at 32.0 and 64.0 GT/s. The voltage is averaged over this interval for both the negative and positive halves of the waveform over 500 repetitions of the compliance pattern. $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$ are defined as the difference between the negative and positive waveform segment averages. UI boundaries are defined with respect to the edge of the recovered data clock.

Figure 8-11 Measuring $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$ at 8.0 GT/s §

8.3.3.10 Reduced Swing Signaling §

PCI Express Transmitters may optionally support a reduced swing signaling. It is left as an implementation option to define the maximum reduced swing voltage value for $V_{TX-DIFF-PP-LOW}$ anywhere up to the maximum full swing voltage. The minimum for $V_{TX-DIFF-PP-LOW}$ is captured indirectly by the constraint imposed by $V_{TX-EIEOS-RS}$, so there is no need to define a separate minimum limit for $V_{TX-DIFF-PP-LOW}$. Reduced swing limits the range of presets and the maximum boost. The boost for reduced swing must be in the region shown in § Figure 8-9 and § Figure 8-10 between the Max reduced swing limit and minimum reduced swing boost limit.

Form factors are permitted to disallow, optionally allow, or require Reduced Swing Signaling, depending on the channel requirements for the form factor. When Reduced Swing Signaling is allowed or required it is required that form factor specifications provide any additional details necessary to support interoperability.

8.3.3.11 Effective Tx Package Loss at 8.0, 16.0, 32.0, and 64.0 GT/s §

Package loss (including silicon driver bandwidth) is represented by the $ps21_{TX}$ parameter. Since both package IL and driver bandwidth affect the signal as observed at the Tx pin, the $ps21_{TX}$ parameter has the advantage of representing both of these effects, while permitting the measurement to be made at a point (TP1) that can easily be probed. It is necessary to include a package loss parameter in the Tx specification, since the voltage swing parameters ($V_{TX-DIFF-PP}$ and $V_{TX-DIFF-PP-LOW}$) are defined at an equivalent pulse frequency of 1/128 UI and purposely do not capture high frequency driver or package loss effects.

At 16.0 GT/s and 32.0 GT/s, separate $ps21_{TX}$ parameters are defined for packages containing Root Ports (Root Package) and for all other packages (Non-Root Package), based on the assumption that the former tend to be large and require socketing, while the latter are smaller and usually not socketed.

The $ps21_{TX}$ parameter is informative for 16.0 GT/s Root Package devices and for Non-Root Package devices that only support PCI Express standard form factors (i.e., CEM, M.2, etc.). The $ps21_{TX}$ parameter is normative for all 8.0, 32.0, and 64.0 GT/s devices and for 16.0 GT/s Non-Root Package devices that support captive channels. (See § Table 8-3 below).

Table 8-3 Cases that the Reference Packages and $ps21_{TX}$ Parameter are Normative §

	8.0, 32.0, and 64.0 GT/s		16.0 GT/s	
	Root Package Device	Non-Root Package Device	Root Package Device	Non-Root Package Device
Device supports captive channels	Normative	Normative	Informative	Normative
Device does not support captive channels	Normative	Normative	Informative	Informative

All implementations of PCI Express standard form factors must still meet form factor requirements. Devices for which the $ps21_{TX}$ parameter is informative, as defined above must provide a package model for use in channel compliance if they do not meet the informative $ps21_{TX}$ parameter.

Package loss is measured by comparing the 64-zeros/64-ones voltage swing (V_{111}) against a 1010 pattern (V_{101}). Tx package loss measurement is made with c_{-2} , c_{-1} , and c_{+1} set to zero. Measurements shall be made averaging over 500 repetitions of the compliance pattern.

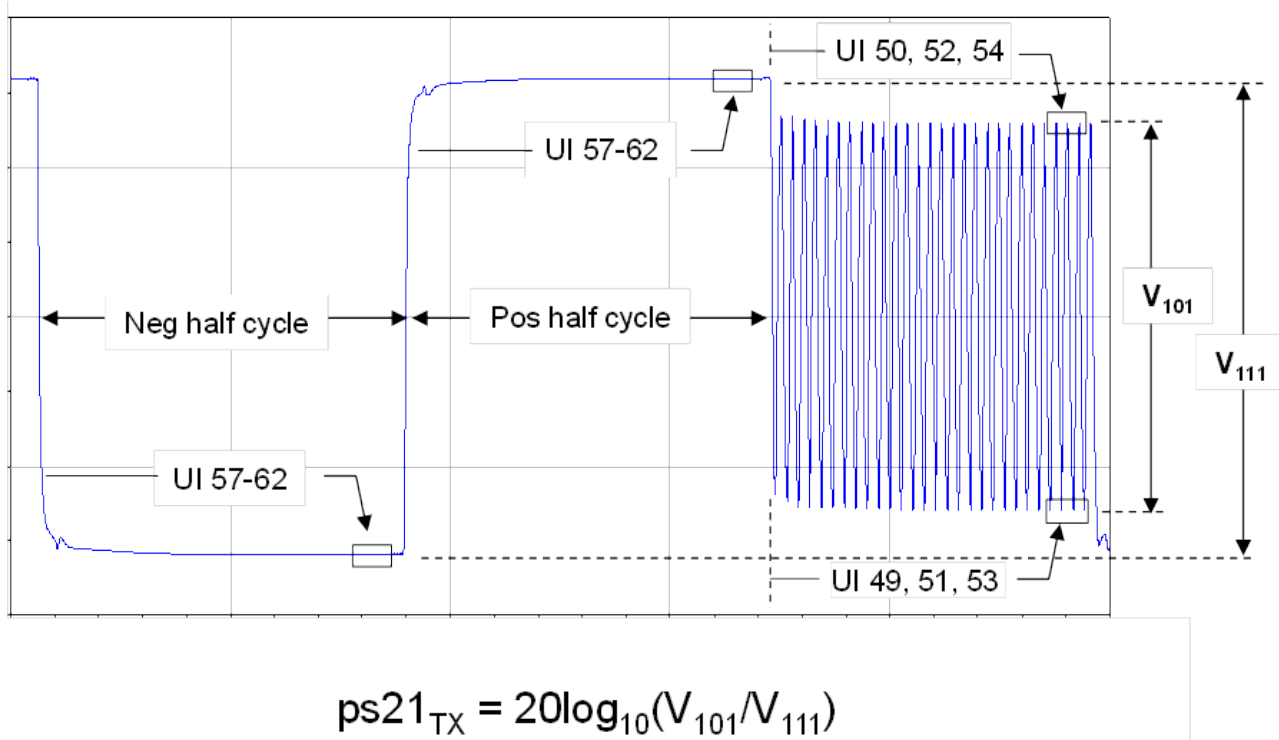

Figure 8-12 Compliance Pattern and Resulting Package Loss Test Waveform §

Measurement of V_{101} and V_{111} is made towards the end of each interval to minimize ISI and low frequency effects. V_{101} is defined as the peak-peak voltage between minima and maxima of the clock pattern. V_{111} is defined as the average voltage difference between the positive and negative levels of the two half cycles. The measurement should be averaged over 500 repetitions of the compliance pattern.

At 32.0 GT/s only the $ps21_{TX}$ parameter is calculated by filtering the captured voltage waveforms normally used for $ps21_{TX}$ measurements as follows:

- V_{111} is measured from a filtered voltage waveform with a first order (20 dB/decade) low pass filter with a -3 dB corner frequency at 1 GHz applied.
- V_{101} is measured from a filtered voltage waveform with a first order (20 dB/decade) high pass filter with a -3 dB corner frequency at 7 GHz applied.

Since the Nyquist frequency for 64.0 GT/s PAM4 signaling is 16.0 GHz, no additional measurement is necessary for 64.0 GT/s $ps21_{TX}$ spec compliance. For a PCIe 6.0 device that supports maximum data rate of 64.0 GT/s, the $ps21_{TX}$ spec parameter measured for 32.0 GT/s must be lower than the $ps21_{TX}$ spec values provided under the 64.0 GT/s column in § Table 8-6.

8.3.3.12 Transmitter Signal-to Noise and Distortion Ratio (SNDR_{TX}) for 64.0 GT/s §

Signal-to-noise and distortion ratio (SNDR) is measured at the transmitter output using the Compliance Pattern (see § Section 4.2.14) with preset Q_0 (no Tx equalization), and the lanes not under test also transmitting the Compliance Pattern with preset Q_0 . The recorded waveform must have a minimum of 250 repetitions of the compliance pattern. Measurements should be made with a 4th order Bessel-Thomson filter with a roll-off from DC value by 3 dB at 33 GHz to minimize the impact of scope high-frequency noise. The minimum scope bandwidth is 50 GHz.

A linear fit to the captured waveform and the linear fit pulse response, $p(k)$, and error vector, $e(k)$, are computed. The standard deviation of $e(k)$ is denoted by σ_e . The linear fit pulse response $p(k)$ and the error vector $e(k)$ shall be computed with the pulse length of $Np = 600$ and pulse delay $Dp = 4$. For these computations, the number of samples per PAM4 symbol, M , must be equal to or greater than 32 and resampling can be used to meet this requirement. The standard deviation of $e(k)$ is obtained from the measured PRBS portion of the compliance pattern.

The parameter σ_n measures the uncorrelated RMS amplitude noise of each symbol level (including random noise and uncorrelated bounded noise effects), while not including ISI and jitter effects. Noise for each of the four PAM4 voltage levels, σ_L , is measured by using the PAM4 symbol 61 of the 64-UI long slow pattern for the corresponding voltage level that appears once in every repeat of the Compliance Pattern. When measuring σ_L , an adjustment for uncorrelated random noise contributed by the instrumentation such as uncorrelated random scope noise shall be applied. Equivalent oscilloscope settings used for noise characterization shall be consistent with the oscilloscope settings used for waveform capture when calculating SNDR. For each voltage level L (where $L = 0,1,2,3$), the σ_L measurement is the result of eight independent measurements on eight evenly spaced sample points within the Unit Interval of symbol 61 in the run of 64 identical symbols. Each of the eight measurements denoted as $\sigma_{L,i}$ (where $i=1..8$) is calculated by using the following equations.

$$\sigma_{L,i}^2 = \frac{1}{N_k} \sum_{k=1}^{N_k} \left(V_{L,i,k} - \mu_{L,i} \right)^2$$

Equation 8-3 $\sigma_{L,i}$ §

$$\mu_{L,i} = \frac{1}{N_k} \sum_{k=1}^{N_k} V_{L,i,k}$$

Equation 8-4 $\mu_{L,i}$ §

In the above equations, N_k is the number of repetitions of the compliance pattern in the recorded waveform, $V_{L,i,k}$ is the waveform voltage at the i^{th} data sample location within the 61st symbol UI in the k^{th} repetition of the compliance pattern for each voltage level, and $\mu_{L,i}$ is the mean of N_k waveform voltage samples for the i^{th} data sample location for the corresponding voltage level.

σ_L is obtained via the following equation:

$$\sigma_L = \sqrt{\frac{\sum_{i=1}^8 \sigma_{L,i}^2}{8}}$$

Equation 8-5 σ_L §

σ_n is the average of the four σ_L measurements, one for each PAM4 voltage level, denoted as

$$\sigma_n = \frac{1}{4}(\sigma_0 + \sigma_1 + \sigma_2 + \sigma_3)$$

Equation 8-6 σ_n §

The Tx SNDR is defined by the following Equation, where p_{\max} is the maximum value of $p(k)$.

$$SNDR = 10 \times \log_{10} \left(\frac{p_{\max}^2}{\sigma_e^2 + \sigma_n^2} \right)$$

Equation 8-7 SNDR §

8.3.3.13 Transmitter Ratio of Level Mismatch (R_{LM-TX}) for 64.0 GT/s §

Transmitter linearity is defined as a function of the mean signal levels (V_0 , V_1 , V_2 , and V_3) transmitted for PAM4 2-bit symbols (see § Section 4.2.3.1.1). The ratio of level mismatch, R_{LM} , is defined as shown below:

$$V_{mid} = (V_0 + V_3) / 2$$

$$ES_1 = (V_1 - V_{mid}) / (V_0 - V_{mid})$$

$$ES_2 = (V_2 - V_{mid}) / (V_3 - V_{mid})$$

$$R_{LM} = \min\left(3 \times ES_1, 3 \times ES_2, (2 - 3 \times ES_1), (2 - 3 \times ES_2)\right)$$

Equation 8-8 R_{LM} §

The mean signal levels (V_L where $L = 0, 1, 2,$ and 3) described above are measured by following the same procedure described in § Section 8.3.3.12 and by using the following equation.

$$V_L = \frac{\sum_{i=1}^8 \mu_{L,i}}{8}$$

Equation 8-9 V_L §

8.3.4 Transmitter Margining §

Transmitters shall implement a margining procedure that allows the Tx launch voltage to be adjusted. Margining is enabled by programming a register set. Due to the larger range of Transmitter equalization, 8.0, 16.0, 32.0, and 64.0 GT/s Tx margining is subject to additional constraints: Tx margining at these speeds shall not require any coefficient or preset resolution finer than can be generated with 1/24 coefficient resolution defined for normal operation, and shall not require more Tx accuracy or capability than is required to support normal operation. It is acceptable that V_b fall below the limit set by $V_{TX-EIEOS-FS}$ or $V_{TX-EIEOS-RS}$, although proper end-to-end operation is no longer guaranteed. Transmitter equalization accuracy requirements do not need to be met during margining. A Transmitter is not required to change the FS/LF values it sends in TS1 Ordered Sets during margining from the values used in normal operation.

There are 8 encoded values for transmit margin from 000b to 111b. Encoding 000b represents the normal operating range. For all supported data rates and Tx signalling mode (full swing or reduced swing), encoding 001b must produce a $V_{TX-DIFF-PP}$ compliant with the specification limits. At least three additional encodings with monotonically decreasing values for $V_{TX-DIFF-PP}$ must be supported for each data rate and Tx swing mode. For full swing signalling there must be at least one encoding with index 100b or higher that produces a $V_{TX-DIFF-PP}$ between 200 and 400 mV. For reduced swing signalling there must be at least one encoding with value 100b or higher that produces a $V_{TX-DIFF-PP}$ between 100 and 200 mV.

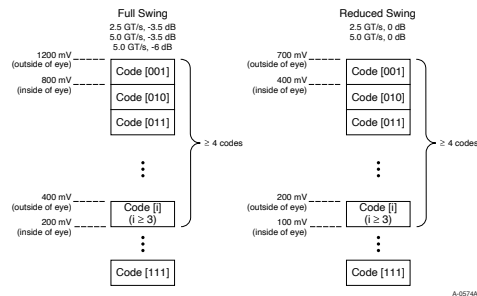

Figure 8-13 2.5 and 5.0 GT/s Transmitter Margining Voltage Levels and Codes §

8.3.5 Tx Jitter Parameters §

Jitter limits are defined identically for all data rates, although their respective values will vary with data rate. Jitter is measured at the zero-crossing point at full speed using the Compliance Pattern for 2.5, 5.0, 8.0, and 16.0 GT/s. When measuring jitter, the preset yielding the lowest jitter value should be selected. At 32.0 GT/s, the Tx under test must transmit Jitter Measurement Pattern (see § Section 4.2.13) with no Tx equalization. At 64.0 GT/s, the Tx under test must transmit Jitter Measurement Pattern (see § Section 4.2.16) with no Tx equalization for measuring the uncorrelated total jitter and deterministic jitter for all twelve transitions between the four PAM4 voltage levels. At 64.0 GT/s, the Tx under test must transmit High Swing Toggle Pattern (see § Section 4.2.17) with no Tx equalization for measuring the uncorrelated total pulse width jitter and deterministic pulse width jitter for the transitions between voltage level 0 and voltage level 3. When measuring a particular Tx Lane, it is necessary to ensure that all other PCI Express Lanes are transmitting Compliance Pattern in order to capture Tx die and package crosstalk effects. When measuring Tx jitter, it is required for the DUT to drive as many of its outputs as would occur during normal operation in a system environment. The minimum oscilloscope bandwidth for Tx jitter measurements at 32.0 and 64.0 GT/s is 50 GHz. The jitter measurements at 64.0 GT/s should be made with a 4th order Bessel-Thomson filter with a roll-off from DC value by 3 dB at 33 GHz to minimize the impact of scope high-frequency noise.

8.3.5.1 Post Processing Steps to Extract Jitter §

Measured Tx jitter is referenced to the Tx pin, and depending on what type of jitter is being measured and what reference clock architecture is being tested, is subsequently referenced to a recovered data clock, an embedded reference clock captured simultaneously with the data, or to a data edge. Data captured at TP1 requires post processing in order to remove the effects of the breakout channel and to regenerate a data clock (when an embedded reference clock is not captured simultaneously with the data).

8.3.5.2 Applying CTLE or De-embedding §

Direct probing at a Transmitter's pins is not generally feasible, so data is instead measured at TP1 of the breakout channel. By means of the replica channel it is possible to determine the loss vs. frequency characteristics of the breakout channel and de-embed this channel, resulting in measurements that are effectively referenced to the DUT's pins. Note that since de-embedding amplifies HF noise there is a practical frequency cutoff limit to de-embedding. As de-embedding amplifies HF channel and measurement noise, an HF cutoff limit must be applied to de-embedding, depending on data rate as shown in § Table 8-4.

*Table 8-4 Recommended De-embedding
Cutoff Frequency §*

Data Rate	HF Cutoff limit for de-embedding
8.0 GT/s	8 GHz - 12 GHz
16.0 GT/s	20 GHz

Jitter is decomposed into data dependent and uncorrelated terms. This separation process effectively separates the jitter caused by package effects from that caused by silicon effects such as PLL jitter and power supply noise that cannot be mitigated by equalization. As a result, the uncorrelated jitter terms define jitter as it would appear at the die pad.

As an alternative to de-embedding at 16.0 GT/s the -12 dB CTLE in the reference equalizer can be applied to the data measured at TP1 for measuring all uncorrelated jitter parameters (not DDJ).

It is recommended that s-parameters for de-embedding are measured to at least 3 times the Nyquist frequency with a frequency step size of 10 MHz.

If both de-embedding and CTLE approaches are used and given different answers only the lower values for the uncorrelated jitter parameters are used.

For 32.0 GT/s, Jitter Measurement Pattern (see § Section 4.2.13) with no Tx equalization is used to minimize the breakout channel ISI impact and avoid pessimism in jitter measurement from de-embedding and associated high frequency scope noise amplification. For further reduction of channel loss impact on jitter at 32.0 GT/s, any CTLE curve in the reference equalizer or no CTLE curve can be applied to the data measured at TP1 for measuring all uncorrelated jitter parameters (not DDJ). The CTLE or no CTLE curve that gives the lowest result for $T_{TX-UPW-TJ}$ is used.

For 64.0 GT/s, the Jitter Measurement Pattern (see § Section 4.2.16) with no Tx equalization is used for measuring the uncorrelated total jitter and the uncorrelated deterministic jitter for all twelve transitions between the four PAM4 voltage levels. The 64.0 GT/s Jitter Measurement Pattern is 52-UI long and all 12 PAM4 transitions repeat four times within the pattern resulting in 48 edge transitions. Jitter must be measured on each of the 48 edges individually and then averaged. The Q-scale associated with the 64.0 GT/s Jitter Measurement Pattern for BER of 10^{-6} is 4.8759. For mitigating channel ISI impact on jitter at 64.0 GT/s, any CTLE curve in the reference equalizer or no CTLE curve can be applied to the data measured at TP1 for measuring all uncorrelated jitter parameters (not DDJ). The CTLE or no CTLE curve that gives the lowest result for the average T_{TX-RJ} of the 48 edges is used. The uncorrelated jitter parameters for all 48 transitions must be measured and corrected for the scope noise impact. The average uncorrelated total jitter and the average uncorrelated deterministic jitter are obtained by averaging the jitter parameters of all 48 edge transitions.

For 64.0 GT/s, the High Swing Toggle Pattern (see § Section 4.2.17) with no Tx equalization is used for measuring the uncorrelated total pulse width jitter and deterministic pulse width jitter for transitions between voltage level 0 and voltage level 3. The Q-scale associated with the 64.0 GT/s High Swing Toggle Pattern for BER of 10^{-6} is 4.8916. The High Swing Toggle Pattern minimizes the breakout channel ISI impact and avoids pessimism in jitter measurement from de-embedding and associated high frequency scope noise amplification. For further reduction of channel loss impact on pulse width jitter at 64.0 GT/s, any CTLE curve in the reference equalizer or no CTLE curve can be applied to the data measured at TP1 for measuring all uncorrelated jitter parameters (not DDJ). The CTLE or no CTLE curve that gives the lowest result for $T_{TX-UPW-TJ}$ is used. The uncorrelated pulse width jitter parameters must be corrected for the scope noise impact.

8.3.5.3 Independent Refclk Measurement and Post Processing §

A Transmitter may operate in the Independent Refclk (IR) mode, in which case the Transmitter may not provide a Refclk output. In this case a single-port jitter measurement is required. The post processing algorithm must employ the appropriate model CDR for the reference clock architecture being tested.

8.3.5.4 Embedded and Non-Embedded Refclk Measurement and Post Processing §

When the transmitting PCIe device is driven from an external source to its Refclk pin it permits the Tx under test to be driven with a clean Refclk as shown in § Figure 8-1.

The specification now explicitly supports the complete matrix of Refclk options, including where the Refclk is embedded, where the reference clock is external, where the reference clock is available at the DUT's pins, and where the reference clock is not available at the DUT's pins. § Table 8-5 lists the post processing requirements for each of the four possible combinations. Embedded Refclk with Refclk available at the DUT's pin represents a special case where any jitter common to both the Refclk and the data must be removed via a two-port measurement.

If the DUT supports multiple Refclk modes, as described in § Table 8-5 then the Tx needs to be tested in each of the Refclk modes it supports.

Table 8-5 Tx Measurement and Post Processing For Different Refclks §

	Embedded Refclk	Non-Embedded Refclk
Refclk available at DUT pin and not testing SRIS mode	2-port measurement, CC CDR, PLL ¹ and 10 ns transport delay ²	1-port measurement, CC CDR, clean external Refclk
Refclk not available at DUT pin or testing SRIS mode	1-port measurement, SRIS CDR	1-port measurement, CC CDR, clean external Refclk

Notes:

1. PLL characteristics are defined in Refclk section for each data rate.
2. Refer to § Section 8.6.6 for a discussion of the transport delay

8.3.5.5 Behavioral CDR Characteristics §

A behavioral CDR filter is applied to reject low frequency jitter that would normally be tracked by the CDR in a Receiver. As such, the behavioral CDR represents a bounding function for actual CDR implementations. Roll-off characteristics of the behavioral CDR are dependent on whether the corresponding DUT supports an embedded vs. non-embedded Refclk, is operating in CC or IR mode, and whether the Refclk pin is available for probing (see § Table 8-5). In all cases the behavioral CDR represents a high pass filter function where the corner frequency depends on the Tx data rate. § Figure 8-14 shows the CC first-order CDR transfer functions for an f_{3dB} of 1.5 MHz, 5.0 MHz, and 10 MHz that corresponds to 2.5 GT/s, 5.0 GT/s, and 8.0 GT/s, respectively. The 10 MHz behavioral CDR is also used for CC Transmitter and CC Reference Clock testing for 16.0 GT/s and, optionally, for Receiver Stressed Eye calibration when 32.0 GT/s is not supported.

Figure 8-14 First Order CC Behavioral CDR Transfer Functions §

§ Figure 8-15 illustrates second order CDR transfer functions corresponding to 2.5 GT/s and 5.0 GT/s. These functions are defined by a ζ of 0.707 and an f_{3dB} of 1.5 MHz and 5.0 MHz, respectively. Behavioral transfer functions for 8.0 GT/s, 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s approximate the piecewise linear sinusoidal jitter (Sj) masks shown in § Section 8.4.2.2.1 . SRIS capable Transmitters must be evaluated using these behavioral transfer functions.

Note: The common clock (CC) and independent reference clock (IR) architectures are not interoperable - although it is possible to design a single Receiver that meets both sets of electrical requirements.

8.3.5.6 Data Dependent and Uncorrelated Jitter §

Measured at TP1 and de-embedded back to the pin, a Transmitter's jitter contains both data dependent and uncorrelated components. The data dependent components occur principally due to package loss and reflection. Uncorrelated jitter sources include PLL jitter, power supply noise, and crosstalk. The specification separates jitter into uncorrelated and data dependent bins, because such a separation matches well with the Tx and Rx equalization capabilities. Uncorrelated jitter is not mitigated by Tx or Rx equalization and represents timing margin that cannot be recovered via equalization. It is important that margin recoverable by means of equalization (data dependent) is not budgeted as non-recoverable jitter.

Once data dependent jitter has been removed from the Tx measurement it becomes possible to resolve the remaining jitter into Tj and deterministic jitter (Dual Dirac Model) (DJDD) components. High frequency jitter (which is subject to jitter amplification in the channel) is accounted for by separate $T_{TX-UPW-DJDD}$ and $T_{TX-UPW-TJ}$ parameters.

8.3.5.7 Data Dependent Jitter §

While DDJ is not explicitly defined as a parameter in the specification, it is necessary to separate DDJ in order to eliminate package loss effects and reference the jitter parameters of interest to the Tx die pad. Separation of jitter into data dependent and uncorrelated components may be achieved by averaging techniques; for example, by having the Tx repeatedly drive the compliance test pattern which is a repeating pattern.

§ Figure 8-18 illustrates the relation between Tx data, recovered clock, and the data's PDF. Data dependent jitter is defined as the time delta between the PDF's mean for each zero-crossing point and the corresponding recovered clock edge. A sufficient number of repeated patterns must be accumulated to yield stable mean values and PDF profiles for each transition. These PDFs are then utilized to extract uncorrelated jitter parameters.

Figure 8-18 Relation Between Data Edge PDFs and Recovered Data Clock §

8.3.5.8 Uncorrelated Total Jitter and Deterministic Jitter (Dual Dirac Model) (T_{TX-UTJ} and $T_{TX-UDJDD}$) §

Uncorrelated Total Jitter (UTJ) and uncorrelated deterministic jitter (Dual Dirac model) (UDJDD) are referenced to a recovered data clock generated by means of a CDR tracking function. Uncorrelated jitter may be derived after removing the DDJ component from each PDF and combining the PDFs for all edges in the pattern. By appropriately converting the PDF to a Q-scale it is possible to obtain the graphical relation shown in § Figure 8-19, from which T_{TX-UTJ} and $T_{TX-UDJDD}$ may be derived. In § Figure 8-19 note that the two PDF curves are identical but that the fitted slopes, defined by $1/RJ_{LH}$ and $1/RJ_{RH}$, may differ.

Figure 8-19 Derivation of T_{TX-UTJ} and $T_{TX-UDJDD}$ §

8.3.5.9 Random Jitter (T_{TX-RJ}) (informative) §

Random jitter is uncorrelated with respect to data dependent jitter. T_{TX-RJ} may be obtained by subtracting $T_{TX-UDJDD}$ from T_{TX-UTJ} and is included in the specification as an informative parameter only. It is typically used as a benchmark to characterize PLL performance.

8.3.5.10 Uncorrelated Total and Deterministic PWJ ($T_{TX-UPW-TJ}$ and $T_{TX-UPW-DJDD}$) §

Pulse width jitter is defined as an edge to edge phenomenon on consecutive edges nominally 1.0 UI apart. § Figure 8-20 illustrates how PWJ is defined, showing that it is typically present on both data edges of consecutive UI. To accurately quantify PWJ it is first necessary to remove the ISI contributions to PWJ. The shaded areas on either side of the unjittered edges represent the maximum amount of jitter about that edge. Note the jitter for one edge is assumed to be independent from the other.

An equivalent description of PWJ may be obtained by referencing to a fixed leading edge and having jitter contributions from both edges appear at the trailing edge. This approach yields a single PDF as shown below. Each 1 UI wide pulse in the pattern will have a different median for this PDF which is caused by ISI and F/2 jitter. The average of the medians for 1 UI wide pulses at odd and even UI numbers within the pattern are calculated, and the odd and even PDF's are normalized to the appropriate average of medians and summed to form an odd UI PDF and an even UI PDF. The final PDF is calculated from the sum of the summed odd and even UI PDFs. The key idea here is that the final PDF for uncorrelated PWJ should include F/2 or odd/even UI jitter

Figure 8-20 PWJ Relative to Consecutive Edges 1 UI Apart §

The PDF of jitter around each non-jittered edge may be converted into the Q-scale (see § Figure 8-21) from which $T_{TX-UPW-TJ}$ and $T_{TX-UPW-DJDD}$ may be derived in a manner analogous to T_{TX-UTJ} and $T_{TX-UDJDD}$. Note that the PDF may not be symmetric, and the tail of interest is RJ_{LH} , since it represents pulse compression.

Figure 8-21 Definition of $T_{TX-UPW-DJDD}$ and $T_{TX-UPW-TJ}$ Data Rate Dependent Transmitter Parameters §

8.3.6 Data Rate Dependent Parameters §

Note: the jitter margins for 2.5 GT/s and 5.0 GT/s were previously defined at the device's pins. For 2.5 GT/s the jitter was defined via a single parameter that lumped DDJ, UDJDD, UTJ, PWJ-DDJ and PWJ-TJ into a single quantity. Consequently, it is necessary to first remove the DDj jitter component. Since there was no previous UDj-UTj separation T_{TX-UTJ} and $T_{TX-UDJDD}$ are set equal to each other. Similarly, there was no UTj-PWJ separation, so it is necessary to assume that the entirety of the uncorrelated jitter is PWJ that occurs oppositely on consecutive edges of a 1 UI wide pulse.

For 5.0 GT/s a similar removal of DDj must be performed to obtain UTj. However, [PCIe-3.0] for 5.0 GT/s did specify Rj, so a distinct value for $T_{TX-UDJDD}$ can be obtained. Similarly, [PCIe-3.0] for 5.0 GT/s defined a minimum pulse width, assumed to be 100% Dj, from which $T_{TX-UPW-TJ}$ and $T_{TX-UPW-DJDD}$ may be derived. For 64.0 GT/s PAM4 signaling, the voltage parameters such as differential peak-to-peak Tx voltage swing correspond to the swing between PAM4 voltage level 0 and voltage level 3.

Table 8-6 Data Rate Dependent Transmitter Parameters §

Symbol	Parameter description	2.5 GT/s	5.0 GT/s	8.0 GT/s	16.0 GT/s	32.0 GT/s	64.0 GT/s	Units	Notes
UI (Tx)	Unit Interval	(min) 399.88 (max) 400.12 (300 PPM)	(min) 199.94 (max) 200.06 (300 PPM)	(min) 124.9625 (max) 125.0375 (300 PPM)	(min) 62.48125 (max) 62.51875 (300 PPM)	(min) 31.246875 (max) 31.253125 (100 PPM)	(min) 31.246875 (max) 31.253125 (100 PPM)	ps	Does not include SSC variations

<i>RL_{TX-CM}</i>	Tx package plus die common mode return loss	See § Figure 8-23					See § Figure 8-25	dB	Note 6

Notes:

1. A single combination of PLL BW and peaking is specified for 2.5, 32.0, and 64.0 GT/s implementations. For other data rates, two combinations of PLL BW and peaking are specified to permit designers to make a tradeoff between the two parameters.
2. The Tx PLL Bandwidth must lie between the min and max ranges given in the above table. PLL peaking must lie below the value listed above. Note: the PLL B/W extends from zero up to the value(s) specified in the above table. The PLL BW is defined at the point where its transfer function crosses the -3dB point.
3. See § Section 8.3.3.6 and § Section 8.3.3.7 for measurement details.
4. $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$ are measured at the device pin and include package loss. Voltage limits comprehend both full swing and reduced swing modes. A Transmitter must advertise a value for LF during TS1 at 8.0, 16.0, 32.0, and 64.0 GT/s that ensures that these parameters are met.
5. The numbers above consider measurement error. For some Tx package/driver combinations ps_{21TX} may be greater than 0 dB. The channel compliance methodology at 2.5 and 5.0 GT/s assumes the 8.0 GT/s package model.
6. The DUT must be powered up and DC isolated, and its data+/data- outputs must be in the low-Z state at a static value.
7. The reference plane for all parameters at 2.5 and 5.0 GT/s is the package pins.
8. These are design parameter requirements - a specific test methodology for them is not defined.
9. For PCIe 6.0 devices that do not support 32.0 and 64.0 GT/s have the option to use 2 MHz as min of $BW_{TX-PKG-PLL1}$ and $BW_{TX-PKG-PLL2}$ for both 8.0 and 16.0 GT/s. The corresponding T_{TX-UTJ} max value is 31.25 ps at 8.0 GT/s and 12.5 ps at 16.0 GT/s. The range of T_{TX-RJ} is 1.4-2.2 ps at 8.0 GT/s and 0.45-0.89 ps at 16.0 GT/s. Such devices also have the option to use 1st-order, 10 MHz CDR filter for testing Tx, Reference clock, and CC Rx.

8.3.7 Tx and Rx Return Loss for 2.5, 5.0, 8.0, 16.0, and 32.0 GT/s §

Return loss measurements for the Tx and Rx are essentially identical, so both are included in the Transmitter section. Return loss measurements are made at the end of the respective breakout channels and require that the breakout

channel's contribution to RL be de-embedded, thereby associating the return loss with the Tx or Rx pin. Return loss measurements are made with a reference impedance of 50 ohms. § Figure 8-22 defines the pass/fail mask for differential return loss for 2.5, 5.0, 8.0, 16.0, and 32.0 GT/s. Both differential and common mode are defined over a frequency range of 50 MHz to 16.0 GHz.

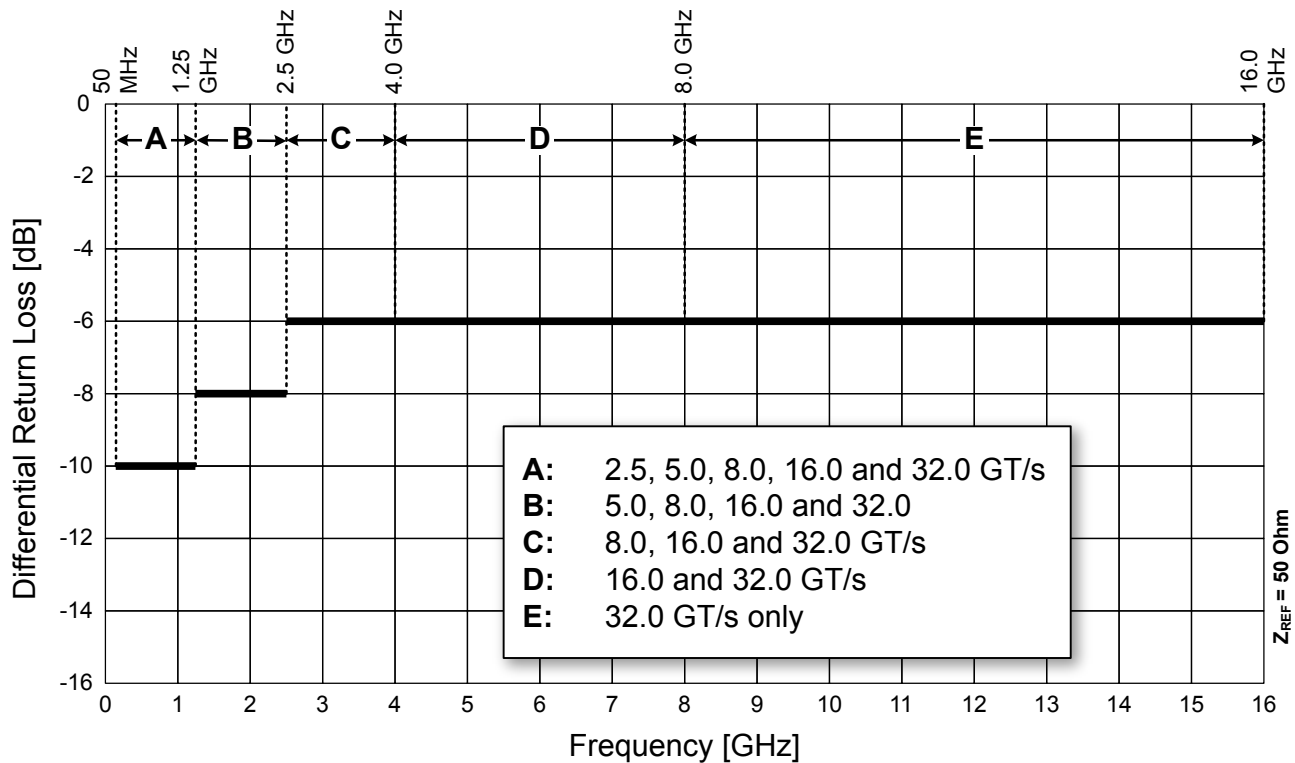

Figure 8-22 Tx, Rx Differential Return Loss Mask with 50 Ohm Reference §

The pass/fail mask for common mode return loss is shown in § Figure 8-23 for 2.5, 5.0, 8.0, 16.0, and 32.0 GT/s. Return loss measurements require that both the Tx and Rx are powered up and that their respective termination circuits are enabled.

Microprobing the package may be required to measure RL accurately.

Figure 8-23 Tx, Rx Common Mode Return Loss Mask with 50 Ohm Reference §

8.3.8 Tx and Rx Return Loss for 64.0 GT/s §

§ Figure 8-24 defines the pass/fail mask for differential return loss for 64.0 GT/s with a single-ended reference impedance of 50 ohms.

Figure 8-24 64.0 GT/s Tx, Rx Differential Return Loss Mask with 50 Ohm Reference §

§ Figure 8-25 defines the pass/fail mask for 64.0 GT/s common mode return loss with a single-ended reference impedance of 50 ohms. Return loss measurements require that both the Tx and Rx are powered up and that their respective termination circuits are enabled. Microprobing the package may be required to measure RL accurately.

Figure 8-25 64.0 GT/s Tx, Rx Common Mode Return Loss Mask with 50 Ohm Reference §

8.3.9 Transmitter PLL Bandwidth and Peaking §

8.3.9.1 2.5 GT/s and 5.0 GT/s Tx PLL Bandwidth and Peaking §

PLL bandwidth and peaking are defined for both the Transmitter and Receiver in order to place an upper limit on the amount of Refclk jitter that is propagated to the transmitted data and to the CDR. Defining PLL BW and peaking limits also guarantees a minimum degree of Tx/Rx jitter tracking in those systems utilizing a Common Refclk Rx architecture.

The 2.5 GT/s PLL characteristics have been moved from the 3.0 CEM spec to the Electrical Base Spec. A single PLL bandwidth range from 1.5 to 22 MHz is given, which is identical to that defined in the CEM spec. No range of peaking was given in the CEM spec for the 2.5 GT/s PLL. However, for the Electrical Base Spec a peaking range of 0.01 dB to 3 dB is now defined. It is necessary to place a non-zero lower limit on the peaking, both to define a corner case as well as to maintain a common mathematical expression for the PLL transfer function in terms of ω_n and ζ .

Two sets of bandwidth and peaking are defined for 5.0 GT/s: 8-16 MHz with 3 dB of peaking and 5.0-16.0 MHz with 1 dB of peaking. This gives the designer the option of trading off between a low peaking PLL design vs. a low bandwidth design.

8.3.9.2 8.0 GT/s, 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s Tx PLL Bandwidth and Peaking §

The Tx and Rx PLL bandwidth for 8.0 and 16.0 GT/s is 0.5-5 MHz with 1.0 dB of peaking or 0.5-4 MHz with 2.0 dB of peaking. The Tx and Rx PLL bandwidth for 32.0 GT/s is 0.5 to 1.8 MHz with 2.0 dB of peaking. The Tx and Rx PLL bandwidth for 64.0 GT/s is 0.5 to 1.0 MHz with 2.0 dB of peaking. The 8.0 GT/s PLL BW range is substantially lower than

the PLL bandwidths specified for 5.0 GT/s or 2.5 GT/s to reduce the amount of Refclk jitter at the sample latch of the Receiver. A non-zero value of 0.01 dB is given for the lower limit of the peaking to define all the peaking corners.

8.3.9.3 Series Capacitors §

PCI Express requires series capacitors to provide a DC block between Tx and Rx. The min/max capacitance spread has been decreased from that of the 2.5 and 5.0 GT/s standards, while the maximum value has been slightly increased. This change is necessary to minimize DC wander effects due to data scrambling implemented at 8.0 GT/s, 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s. Note that 2.5 GT/s and 5.0 GT/s signaling must also propagate through these larger value capacitors, but the small increase in capacitor size has no adverse impact on either 2.5 GT/s or 5.0 GT/s signaling or low frequency in-band signaling such as Receiver detect.

8.3.10 Data Rate Independent Tx Parameters §

Table 8-7 Data Rate Independent Tx Parameters §

Symbol	Parameter Description	Value	Units	Notes
$V_{TX-DC-CM}$	Tx DC peak-peak common mode voltage	(min) 0 (max) 3.6	V	Total single-ended voltage a Tx can supply under any conditions with respect to ground. See also the $I_{TX-SHORT}$. See Note 1
$V_{TX-CM-DC-ACTIVE-IDLE-DELTA}$	Absolute delta of DC Common Mode Voltage during L0 and Electrical Idle	(min) 0 (max) 100	mV	$ V_{TX-CM-DC} [during L0] - V_{TX-CM-Idle-DC} [during Electrical Idle] \leq 100 \text{ mV}$ $V_{TX-CM-DC} = DC_{(avg)} \text{ of } V_{TX-D+} + V_{TX-D-} / 2$ $V_{TX-CM-Idle-DC} = DC_{(avg)} \text{ of } V_{TX-D+} + V_{TX-D-} / 2 [Electrical Idle]$
$V_{TX-CM-DC-LINE-DELTA}$	Absolute Delta of DC Common Mode Voltage between D+ and D-	(min) 0 (max) 25	mV	$ V_{TX-CM-DC-D+} [during L0] - V_{TX-CM-DC-D-} [during L0] \leq 25 \text{ mV}$ $V_{TX-CM-DC-D+} = DC_{(avg)} \text{ of } V_{TX-D+} [during L0] $ $V_{TX-CM-DC-D-} = DC_{(avg)} \text{ of } V_{TX-D-} [during L0] $
$V_{TX-IDLE-DIFF-AC-p}$	Electrical Idle Differential Peak Output Voltage	(min) 0 (max) 20	mV	$V_{TX-IDLE-DIFF-AC-p} = V_{TX-Idle-D+} - V_{TX-Idle-D-} \leq 20 \text{ mV}$. Voltage must be band pass filtered to remove any DC component and HF noise. The bandpass is constructed from two first-order filters, the high pass and low pass 3 dB bandwidths are 10 kHz and 1.25 GHz, respectively.
$V_{TX-IDLE-DIFF-DC}$	DC Electrical Idle Differential Output Voltage	(min) 0 (max) 5	mV	$V_{TX-IDLE-DIFF-DC} = V_{TX-Idle-D+} - V_{TX-Idle-D-} \leq 5 \text{ mV}$. Voltage must be low pass filtered to remove any AC component. The low pass filter is first-order with a 3 dB bandwidth of 10 kHz.
$V_{TX-RCV-DETECT}$	The amount of voltage change allowed during Receiver <u>Detection</u>	(max) 600	mV	The total amount of voltage change in a positive direction that a Transmitter can apply to sense whether a low impedance Receiver is present. Note: Receivers display substantially different impedance for $V_{IN} < 0$ vs. $V_{IN} > 0$.

Symbol	Parameter Description	Value	Units	Notes
$T_{TX-IDLE-MIN}$	Minimum time spent in Electrical Idle	20 (min)	ns	The time a Tx must spend in Electrical Idle before transitioning to another state
$T_{TX-IDLE-SET-TO-IDLE}$	Maximum time to transition to a valid Electrical Idle after sending an EIOS	(max) 8	ns	After sending the required number of EIOSs, the Transmitter must meet all Electrical Idle specifications within this time. This is measured from the end of the last UI of the last EIOS to the Transmitter in Electrical Idle.
$T_{TX-IDLE-TO-DIFF-DATA}$	Maximum time to transition to valid diff signaling after leaving Electrical Idle	(max) 8	ns	Maximum time to transition to valid diff signaling after leaving Electrical Idle. This is considered a debounce time to the Tx.
$T_{CROSSLINK}$	Crosslink random timeout	(max) 1.0	ms	This random timeout helps resolve potential conflicts in the crosslink configuration.
C_{TX}	AC Coupling Capacitor	(min) 176 (max) 265	nF	All Transmitters shall be AC coupled. The AC coupling is required either within the media or within the transmitting component itself.
$Z_{TX-DIFF-DC}$	DC differential Tx impedance	(max) 120	Ω	Low impedance defined during signaling. The minimum value is bounded by $R_{LTX-DIFF}$.
$I_{TX-SHORT}$	Tx short circuit current	(max) 90	ma	Tx short circuit current. Note 1

Notes:

1. $I_{TX-SHORT}$ and $V_{TX-DC-CM}$ stipulate the maximum current/voltage levels that a Transmitter can generate and therefore define the worst case transients that a Receiver must tolerate.

8.4 Receiver Specifications §

8.4.1 Receiver Stressed Eye Specification §

All Receiver speeds are tested by means of a stressed eye applied over a calibration channel that approximates the near worst-case loss characteristics encountered in an actual channel. The recovered eye is defined at the input to the Receiver's latch. For 2.5 GT/s and 5.0 GT/s this point is equivalent to the Rx pins; for 8.0 GT/s, 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s it is equivalent to the signal at the Rx die pad after behavioral Rx equalization has been applied.

8.4.1.1 Breakout and Replica Channels §

The closest practical measurement points to the Rx DUT are the coaxial connectors at the end of a breakout channel, while the Rx reference point of interest is the pin of the Rx. By constructing a replica channel that closely matches the

electrical characteristics of the breakout channel it is possible to measure the signal as it would appear at the DUT's pin, if the DUT were an ideal termination. Impedance targets for the Rx breakout and replica channels are 85 Ω differential and 42.5 Ω single-ended, and the impedance tolerance should be maintained within $\pm 5\%$ or better. Note that the impedance target for the Tx test breakout and replica channels is still 100 Ω differential and 50 Ω single-ended

In § Figure 8-26 the stressed eye is observed at TP2 with the signal sources connected to the calibration channel. A calibration channel will be required for each data rate. Once the stressed eye has been calibrated, the signal source is applied to the DUT. Note that TP1-TP2 encompasses all the components between the signal source and the equivalent of the DUT pin, thereby capturing all non-ideal characteristics in the overall insertion loss due to cabling and replica/breakout channel, excluding Rx package. The AC and DC loss from generator to TP1 are assumed to be zero or must be otherwise de-embedded. The $V_{RX-LAUNCH}$ (differential voltage swing) and Tx Equalization of the Signal Generator are calibrated at TP3 as shown in § Figure 8-26. Some Signal Generators do factory calibration with a cable and trying to de-embed to TP1 for these calibrations can cause inaccuracies. Only the loss from TP3 onward is counted in overall calibration channel loss.

Figure 8-26 Rx Test board Topology for 16.0 and 32.0 GT/s §

8.4.1.2 Calibration Channel Insertion Loss Characteristics §

Calibration channels, each with a specified differential insertion loss at one of the PCIe data rates, provide the means of generating prescribed amounts of ISI that approximates a worst-case channel. For each data rate a single calibration channel loss mask is defined by means of two pairs of IL limits at a high and a low frequency. It is not acceptable to generate IL by means other than physical channel (PCB traces, cables, switches, small compensation delays, etc. are acceptable), such as specialized filters. The Calibration Channel needs to include all physical loss after TP3 as shown in § Figure 8-26 within the IL mask.

Figure 8-27 Example Calibration Channel IL Mask Excluding Rx Package for 8.0 GT/s §

The following table defines the calibration channel IL masks by means of four loss points at two frequency limits, thereby creating a quadrilateral shaped solution area. The calibration channel IL mask is provided as a guideline to minimize reflection so that the channel represents mostly ISI stress for the receiver test.

Table 8-8 Calibration Channel IL Limits §

Data Rate	$F_{LOW-IL-MIN}$	$F_{LOW-IL-MAX}$	$F_{HIGH-IL-MIN}$	$F_{HIGH-IL-MAX}$
2.5 GT/s	4.5 dB @ 1 GHz	5.0 dB @ 1 GHz	4.7 dB @ 1.25 GHz	5.2 dB @ 1.25 GHz
5.0 GT/s	4.5 dB @ 1 GHz	5.0 dB @ 1 GHz	10.0 dB @ 2.5 GHz	11.0 dB @ 2.5 GHz
8.0 GT/s	5 dB @ 1 GHz	8 dB @ 1 GHz	20 dB @ 4 GHz	22 dB @ 4 GHz
16.0 GT/s Root Port	4.2 dB @ 1 GHz	5.2 dB @ 1 GHz	22.5 dB @ 8 GHz	23.5 dB @ 8 GHz
16.0 GT/s Non-Root Port	4.2 dB @ 1 GHz	5.2 dB @ 1 GHz	24.5 dB @ 8 GHz	25.5 dB @ 8 GHz
32.0 GT/s Root Port	3.2 dB @ 1 GHz	4.2 dB @ 1 GHz	26.5 dB @ 16 GHz	27.5 dB @ 16 GHz
32.0 GT/s Non-Root Port	3.9 dB @ 1 GHz	4.9 dB @ 1 GHz	31.5 dB @ 16 GHz	32.5 dB @ 16 GHz

Data Rate	$F_{LOW-IL-MIN}$	$F_{LOW-IL-MAX}$	$F_{HIGH-IL-MIN}$	$F_{HIGH-IL-MAX}$
64.0 GT/s Root Port	3.0 dB @ 1 GHz	4.0 dB @ 1 GHz	23.5 dB @ 16 GHz	24.5 dB @ 16 GHz
64.0 GT/s Non-Root Port	3.6 dB @ 1 GHz	4.6 dB @ 1 GHz	27.5 dB @ 16 GHz	28.5 dB @ 16 GHz

Notes:

- Calibration channel plus Rx package is 28 dB nominally (informative) for 16.0 GT/s.
- Calibration channel plus Rx package is 36 dB nominally (informative) for 32.0 GT/s.
- Calibration channel plus Rx package is 32 dB nominally (informative) for 64.0 GT/s.
- Different reference packages are defined for devices containing Root Ports and all other device types at 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s.
- It is recommended that some validation be done with shorter channels at 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s.
- For 32.0 GT/s, a material at least as good as a Megtron-6 class material with loss of approximately 1.0 dB/inch at 16 GHz at typical room conditions must be used.
- For 64.0 GT/s, a material at least as good as a Megtron-6 class material with loss of approximately 1.0 dB/inch at 16 GHz under worst-case temperature and humidity conditions must be used to achieve system routing length of 13" for 1-connector server topologies.

The impedance targets for the Rx tolerancing interconnect environment are 100 Ω differential and 50 Ω single-ended for the 2.5, 5.0, and 8.0 GT/s channels and 85 Ω differential and 42.5 Ω single-ended for the 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s channels; the impedance tolerance should be maintained within $\pm 5\%$ or better.

The calibration channel for 16.0 GT/s must meet the following return loss mask when measured from either end of the calibration channel:

- ≤ -12 dB for < 4 GHz
- ≤ -8 dB for ≥ 4 GHz and < 12 GHz
- ≤ -6 dB for ≥ 12 GHz and ≤ 16 GHz

The calibration channel for 32.0 GT/s and 64.0 GT/s must meet the following return loss mask when measured from either end of the calibration channel:

- ≤ -12 dB for < 4 GHz
- ≤ -10 dB for ≥ 4 GHz and < 16 GHz
- ≤ -6 dB for ≥ 16 GHz and ≤ 32 GHz

A calibration channel consists of a differential pair of PCB traces terminated at both ends by coaxial connectors. For 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s the calibration channel includes a 4.0 (16.0 GT/s), 5.0 (32.0 GT/s), or 6.0 (64.0 GT/s) Card Electromechanical Specification compliant connector and edge finger placed at least 4 dB at Nyquist away from the coaxial connectors where the signal generator is connected. The calibration channel's electrical characteristics are defined in terms of differential insertion loss masks as shown in § Figure 8-27, where S_{DD21} is measured between TP3 (See § Figure 8-26) and TP2. Connections between TP4-TP5 represent cabling and are included in the S_{DD21} measurement. Loss before TP3 is effectively calibrated out by calibrating differential voltage swing and TX EQ at TP3 and is not included in the S_{DD21} measurement.

While the 8.0 GT/s, 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s S-parameter masks do not extend below 1.0 GHz, all calibration channels must be well behaved below 1.0 GHz and must not have a DC resistance in excess of 7.5 ohms, as measured by the sum of the resistances of the D+ and D- traces. This limitation on DC resistance guarantees that the calibration channel low frequency characteristic is consistent with the extrapolations of the S_{DD21} masks to DC. The calibration loss

targets for devices containing Root Ports and other devices are different because the reference package models have different losses. For 16.0 GT/s, 32.0 GT/s, and 64.0 GT/s the insertion loss range $F_{\text{HIGH-IL-MIN}}$ to $F_{\text{HIGH-IL-MAX}}$ is the nominal loss. The calibration channel must have a series of loss options covering a range from at least 2 dB below $F_{\text{HIGH-IL-MIN}}$ to 3 dB above $F_{\text{HIGH-IL-MAX}}$ (for example for the non-root case this means a loss range from -22.5 to -28.5 dB) with loss delta between consecutive options of 0.5 dB or less.

IMPLEMENTATION NOTE:

16.0 GT/S CALIBRATION CHANNEL REFERENCE DESIGN §

This section gives an example of a 16.0 GT/s calibration channel that was built and tested to meet the requirements in this specification. A high-level block diagram of the calibration channel is shown in § Figure 8-28. Note that this example fixture covers a wider loss range than required by the specification and can cover both root and non-root cases. The test fixture includes four PCBs:

16.0 GT/s Rx Calibration Base Boards

Sixteen differential pairs (85 Ohm Nominal Impedance) routed from SMA connectors to a CEM through-hole connector. There are three different base boards to achieve the following insertion loss ranges – The insertion loss of the differential pairs for the base board is varied as follows @ 8.0 GHz in 0.5 dB steps.

Low-Loss Base Board: 4-11.5 dB

Mid-Loss Base Board: 12-19.5 dB

High-Loss Base Board: 20-27.5 dB

All traces are routed as microstrip on the bottom layer. The SMA connectors and CEM connectors are optimized with layout techniques at 8.0 GHz.

16.0 GT/s Rx Calibration Riser Board

Sixteen differential pairs (85 Ohm Nominal Impedance) routed from SMA connectors to Gold Edge Fingers. The insertion loss of the differential pairs is fixed at 4 dB nominal @ 8.0 GHz for all sixteen pairs. All traces are routed as microstrip on the bottom layer. The SMA connectors and CEM connectors are optimized with layout techniques at 8.0 GHz.

Figure 8-28 Example 16.0 GT/s Calibration Channel §

The stackup for both boards is shown in § Figure 8-29 where 65% is the estimated copper fill percentage. § Figure 8-29 includes stackups for both nominal 85 Ω and 100 Ω stackups - the 85 Ω stackup is used for the calibration channel example.

IMPLEMENTATION NOTE:

32.0 GT/S CALIBRATION CHANNEL REFERENCE DESIGN §

This section gives an example of a 32.0 GT/s calibration channel that was built and tested to meet the requirements in this specification. A high-level block diagram of the calibration channel is shown in § Figure 8-32. Note this example fixture covers a wider loss range than required by the specification and can cover both root and non-root cases. The test fixture includes two PCBs:

32.0 GT/s Rx Calibration Base Boards

Sixteen differential pairs (85 Ohm Nominal Impedance) routed on a Megtron-6 PCB from MMPX connectors to a CEM surface mount connector. There are three different base boards to achieve the following insertion loss ranges - The insertion loss of the differential pairs for the base board is varied as follows @ 16.0 GHz in 0.5 dB steps.

Low-Loss Base Board: 4.0-11.5 dB

Mid-Loss Base Board: 12.0-19.5 dB

High-Loss Base Board: 20.0-27.5 dB

All traces are routed as microstrip on the top layer. The MMPX connectors and CEM connectors are optimized with layout techniques at 16.0 GHz

For information on MMPX connectors refer to Huber+Suhner microminiature connectors.

32.0 GT/s Rx Calibration Riser Board

Sixteen differential pairs (85 Ohm Nominal Impedance) routed on a Megtron-6 PCB from MMPX connectors to Gold Edge Fingers. The insertion loss of the differential pairs is fixed at 8 dB nominal @ 16.0 GHz for all sixteen pairs. All traces are routed as microstrip on the top layer. The MMPX connectors and CEM connectors are optimized with layout techniques at 16.0 GHz.

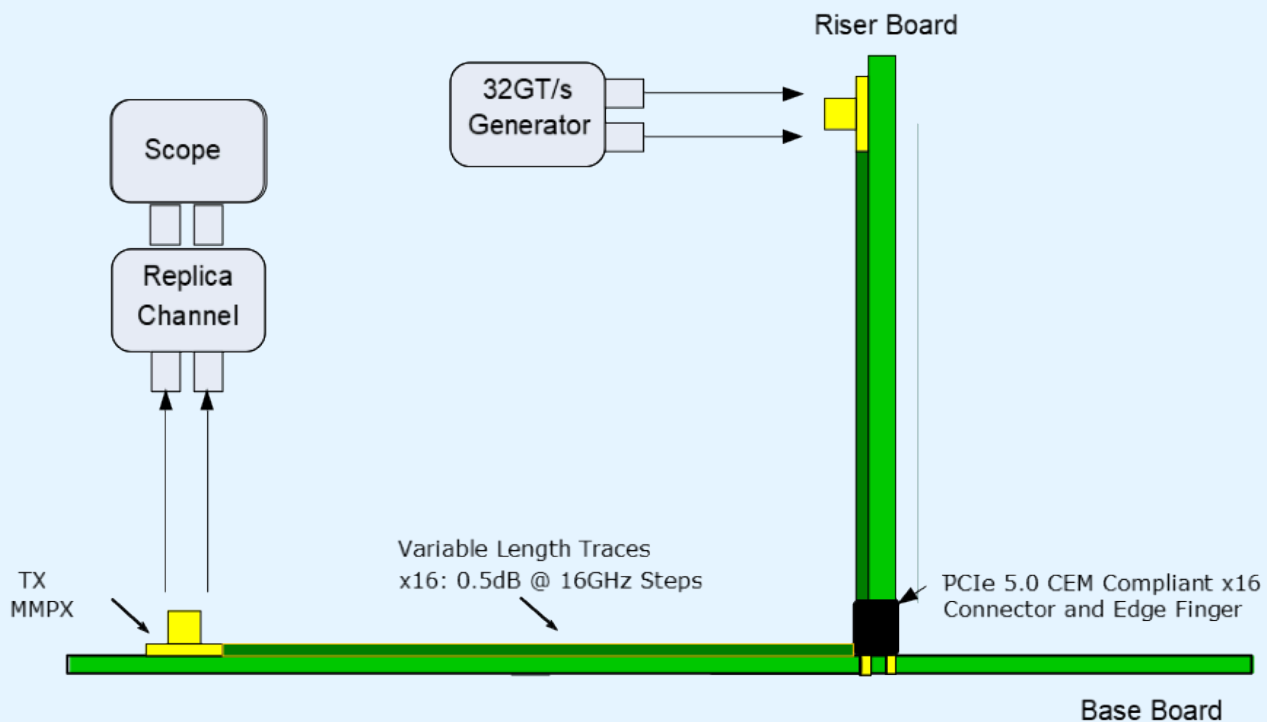

Figure 8-32 Example 32.0 GT/s Calibration Channel §

The stack-up for both 85 Ohm boards is shown in § Figure 8-33 where 65% is the estimated copper fill percentage.

Figure 8-33 Stack-up for Example 32.0 GT/s Calibration Channel §

64.0 GT/s Calibration channel reference design may be added in Rev 0.9.

8.4.1.3 Post Processing Procedures §

The Receiver test requires that the stressed eye characteristics be measured at TP2 (which is accessible) and then post-processed to yield a signal as it would appear at test point two post-processed (TP2P) (which is not accessible) for 8.0, 16.0, 32.0, and 64.0 GT/s. TP2P defines a reference point that comprehends the effects of the behavioral Rx package plus Rx equalization and represents the only location where a meaningful EH and EW limits can be defined.

8.4.1.4 Behavioral Rx Package Models §

Behavioral Rx package models are included as part of the post processing to allow the calibrated eye to comprehend package insertion loss. A separate pair of package models is defined for 8.0, 16.0, 32.0, and 64.0 GT/s eye calibration. At 8.0 GT/s, separate package models are defined for TX and RX ports to reflect the smaller CPAD capacitance typical in most receiver implementations. At 16.0, 32.0, and 64.0 GT/s, separate package models are defined for devices containing Root Ports and all other devices. This is necessary to allow a reasonable channel solution space and assumes that devices containing Root Complexes are usually large and socketed, while all other devices tend to be unsocketed and smaller. The 16.0 GT/s Root and Non-Root behavioral Rx package models have been constructed to represent respective package loss characteristics for high loss, but not worst-case loss, packages. The 32.0 and 64.0 GT/s Root and Non-Root behavioral Rx package models have been constructed to represent package loss characteristics for worst case packages.

The 8.0, 32.0, and 64.0 GT/s stressed eye test for all devices and the 16.0 GT/s stressed eye test for Non-Root Package devices that support captive channels are required to use the appropriate behavioral package (see § Section 8.3.3.11). For all other device types, if the actual Rx package performance is worse than that of the behavioral package, then the actual package models are permitted to be used. If the actual package models are used, the calibration channel must be adjusted such that the total channel loss including the embedded actual package remains at 28 dB nominal. Note that form factor overall requirements still need to be met. The Rx package performance is assessed using the methodology defined in § Section 8.5.1.2.

Details of the behavioral Rx packages are provided in § Section 8.5.1.1 of the Channel Tolerancing section. S-parameter models for the behavioral Rx package models are available as design collateral. The reference impedance at the pad side of the packages model is assumed to be $2 \times 50 \Omega$.

8.4.1.5 Behavioral CDR Model §

Post processing shall include a behavioral CDR model with a data rate dependent transfer function. A first order CDR transfer function is utilized for Receivers operating with a CC Refclk architecture except for 32.0 GT/s and 64.0 GT/s. For Receivers operating in IR Refclk mode an alternate CDR transfer function is required. For a given data rate the behavioral CDR used for Rx testing is the same as the corresponding CDR used for Tx testing. For details on behavioral CDR functions refer to § Section 8.3.5.5.

8.4.1.6 No Behavioral Rx Equalization for 2.5 and 5.0 GT/s §

The combination of worst-case channel, behavioral Rx package, and Tx jitter at 2.5 and 5.0 GT/s will yield open eyes, when the appropriate Tx presets are set. Therefore, there is no need to define a behavioral Rx equalization or to adjust the Tx equalization setting. Actual implementations of 2.5 and 5.0 GT/s receivers may, of course, include equalization.

8.4.1.7 Behavioral Rx Equalization for 8.0, 16.0, 32.0, and 64.0 GT/s §

As measured at TP2, stressed eyes at 8.0, 16.0, 32.0, and 64.0 GT/s will usually be closed, making direct measurement of the stressed eye jitter parameters unfeasible. This problem is overcome by employing a behavioral Receiver equalizer that implements both CTLE and a 1-tap DFE (8.0 GT/s) or a 2-tap DFE (16.0 GT/s) or a 3-tap DFE (32.0 GT/s) or a 16-tap DFE (64.0 GT/s).

Rx equalization algorithms of CTLE and DFE are only intended to be a means for obtaining an open eye in the presence of calibration channel ISI plus the other signal impairment terms and for channel compliance. The behavioral Rx equalization algorithms are not intended to serve as a guideline for implementing actual Receiver equalization. For example, additional DFE taps can have significant benefit in actual implementations where the CTLE may differ from the

behavioral equalizer and/or CTLE selection may not always be optimal. Channel loss characteristics can vary significantly with temperature and humidity and a real Receiver must be able to continue to function at the target BER through such variations.

8.4.1.8 Behavioral CTLE (8.0 and 16.0 GT/s) §

8.0 and 16.0 GT/s behavioral Rx equalization defines a 1st order CTLE with fixed LF and HF poles, and an adjustable DC gain (A_{DC}) specified according to the family of curves shown in § Figure 8-35. For the 8.0 GT/s rates A_{DC} is adjustable over a minimum range of -6 to -12 dB in steps of 1.0 dB.

$$H(s) = \omega_{P2} \times \frac{s + \omega_{P1} \times A_{DC}}{(s + \omega_{P1}) \times (s + \omega_{P2})}$$

$$\omega_{P1} = \text{pole 1} = 2\pi \times 2 \text{ GHz}$$

$$\omega_{P2} = \text{pole 2} = 2\pi \times 8 \text{ GHz}$$

$$A_{DC} = \text{dc gain}$$

Figure 8-34 Transfer Function for 8.0 GT/s Behavioral CTLE §

The following diagram illustrates the gain vs. frequency behavior of the CTLE as A_{DC} is varied over its minimum to maximum range in 1.0 dB steps.

Figure 8-35 Loss Curves for 8.0 GT/s Behavioral CTLE §

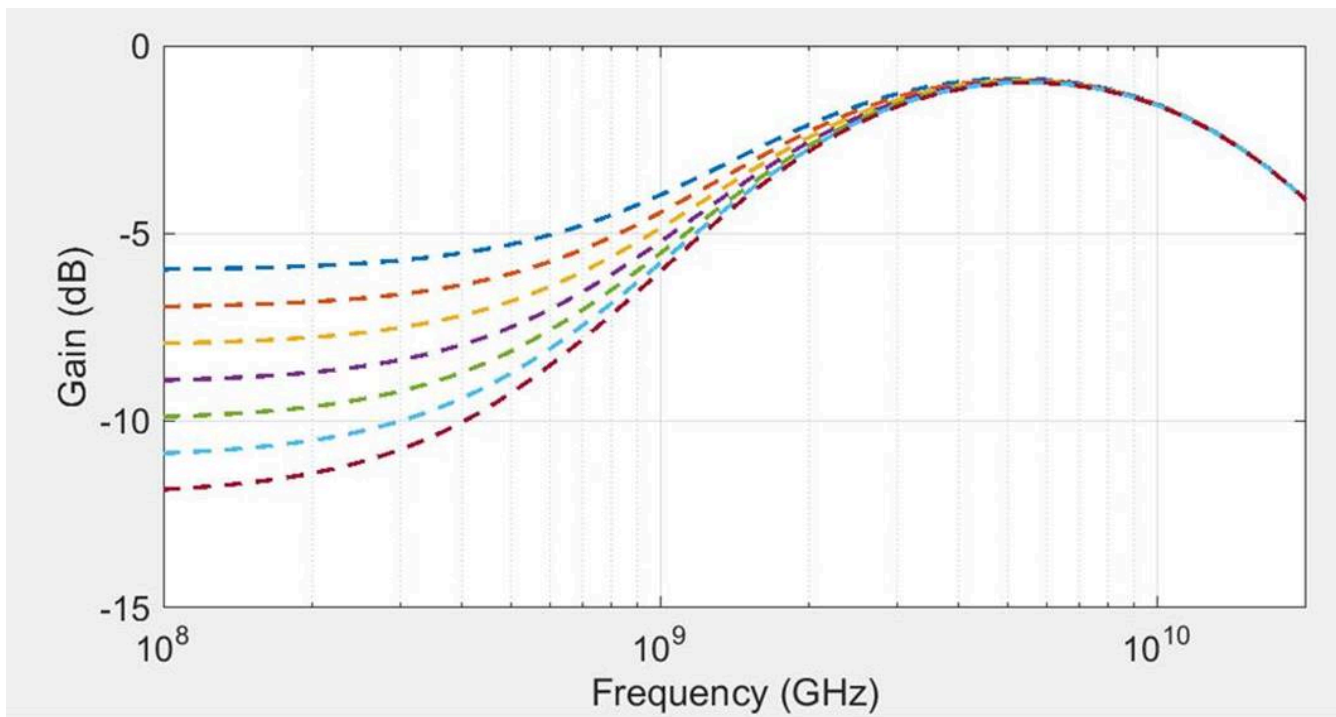

Figure 8-36 Loss Curves for 16.0 GT/s Behavioral CTLE §

A Receiver operating at 16.0 GT/s utilizes a similar set of CTLE curves with different pole locations. The difference is that $\omega_{p1} = \text{pole 1} = 2\pi * 2 \text{ GHz}$ and $\omega_{p2} = \text{pole 2} = 2\pi * 16.0 \text{ GHz}$. The range for A_{DC} remains the same as that for 8.0 GT/s.

8.4.1.9 Behavioral CTLE (32.0 and 64.0 GT/s) §

32.0 GT/s behavioral Rx equalization defines a 2nd order CTLE with fixed poles, and an adjustable DC gain (A_{DC}) specified according to the family of curves shown in § Figure 8-37. The A_{DC} is adjustable over a range of -5 to -15 dB in steps of 1.0 dB.

$$H(s) = \frac{\omega_{p1} \times \omega_{p3} \times \omega_{p4}}{\omega_{z1}} \times \frac{(s + \omega_{z1})(s + \omega_{p2} \times A_{DC})}{(s + \omega_{p1})(s + \omega_{p2})(s + \omega_{p3})(s + \omega_{p4})}$$

$$\omega_x = 2\pi \times F_x$$

$$F_{p1} = 1.65 \times F_{z1}$$

$$F_{p2} = 9.5 \text{ GHz}$$

$$F_{p3} = 28 \text{ GHz}$$

$$F_{p4} = 28 \text{ GHz}$$

$$F_{z1} = 450 \text{ MHz}$$

$$F_{z2} = \text{mag}(\text{DC gain}) \times F_{p2}$$

Equation 8-14 Behavioral CTLE at 32.0 GT/s §

§ Figure 8-37 illustrates the gain vs. frequency behavior of the CTLE as A_{DC} is varied over its minimum to maximum range in 1.0 dB steps. Note that the maximum frequency of the CTLE curves is 200 GHz which ensures accuracy in the time-domain post-processing simulation tools.

Figure 8-37 Loss Curves for 32.0 GT/s Behavioral CTLE §

64.0 GT/s behavioral Rx equalization defines a CTLE with six poles and three zeros, and an adjustable DC gain (ADC) specified according to the family of curves shown in § Figure 8-38. The ADC is adjustable over a range of -5 to -15 dB in steps of 1.0 dB. The maximum frequency of the CTLE curves is 250 GHz.

$$H(s) = \frac{\omega_{p1} \times \omega_{p3} \times \omega_{p4} \times \omega_{p5} \times \omega_{p6}}{\omega_{z1} \times \omega_{z3}} \times \frac{(s + \omega_{z1}) \times (s + \omega_{p2} \times A_{DC}) \times (s + \omega_{z3})}{(s + \omega_{p1}) \times (s + \omega_{p2}) \times (s + \omega_{p3}) \times (s + \omega_{p4}) \times (s + \omega_{p5}) \times (s + \omega_{p6})}$$

$$\omega_x = 2\pi \times F_x$$

$$F_{P1} = 1.30 \times F_{Z1}$$

$$F_{P2} = 7.7 \text{ GHz}$$

$$F_{P3} = 22.0 \text{ GHz}$$

$$F_{P4} = 28.0 \text{ GHz}$$

$$F_{P5} = 32.0 \text{ GHz}$$

$$F_{P6} = 32.0 \text{ GHz}$$

$$F_{Z1} = 250 \text{ MHz}$$

$$F_{Z2} = \text{mag}(\text{DC gain}) \times F_{P2}$$

$$F_{Z3} = 7.7 \text{ GHz}$$

Equation 8-15 Behavioral CTLE at 64.0 GT/s §

Figure 8-38 Loss Curves for 64.0 GT/s Behavioral CTLE §

8.4.1.10 Behavioral DFE (8.0, 16.0, 32.0, and 64.0 GT/s Only) §

At 8.0 GT/s the combination of a 1st order CTLE and a one-tap DFE algorithm is required for calibrating the stressed eye when employing the max length calibration channel. The DFE may be represented by the following equation and flow diagram. For 8.0 GT/s and 16.0 GT/s the limits on d_1 are ± 30 mV. For 32.0 GT/s the limit on d_1 is defined as a ratio of the tap magnitude (h_1) to the cursor strength (h_0). The h_1/h_0 ratio must be less than or equal to 0.8. Note that the h_1/h_0 limit of 0.8 is only to bound the behavior of the reference receiver and does not indicate that real implementations will be safe from error bursts due to large h_1/h_0 causing undetected data errors if the h_1/h_0 ratio is below 0.8. Implementers must do their own analysis for their specific designs on the largest safe h_1/h_0 ratio. Note that an optional precoding mechanism is provided at 32.0 GT/s that receivers can optionally enable to reduce the risk of DFE related error bursts in high transition data patterns causing silent data corruption. For 16.0 GT/s the limits on d_2 are ± 20 mV. For 32.0 GT/s the limits on d_2 and d_3 are ± 20 mV.

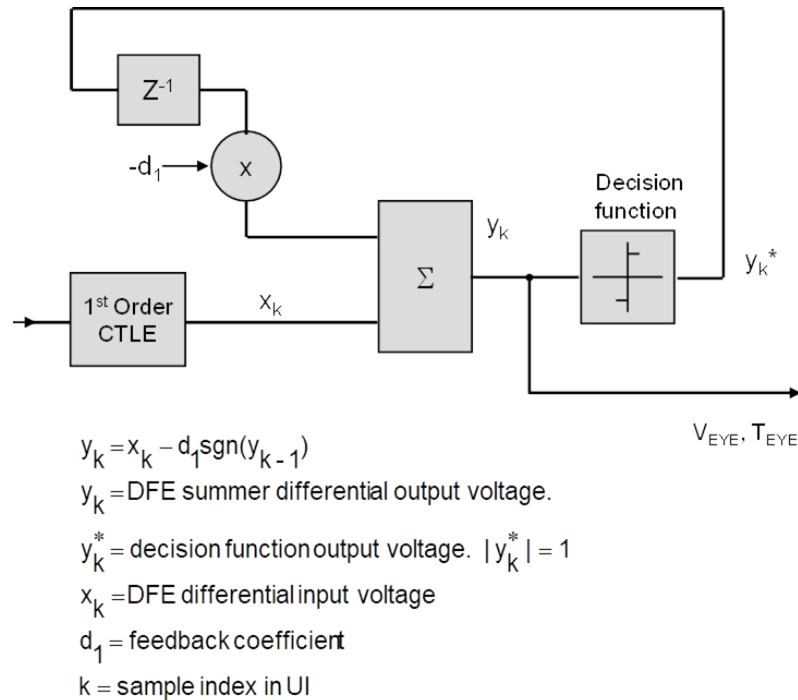

Figure 8-39 Variables Definition and Diagram for 1-tap DFE §

16.0 GT/s Receiver tolerancing utilizes a CTLE and a 2-tap behavioral DFE as illustrated below. Other than the inclusion of the second tap, it is identical to the 1-tap DFE shown above. The 32.0 GT/s Receiver tolerancing utilizes a CTLE and a 3-tap behavior DFE.

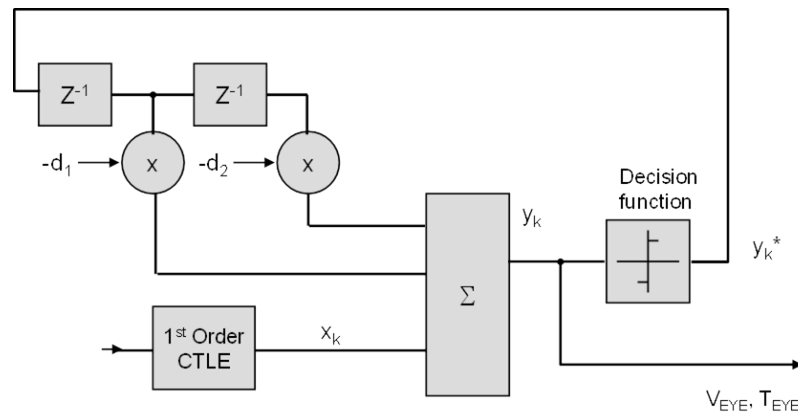

Figure 8-40 Diagram for 2-tap DFE §

For 64.0 GT/s, the feedback signal y_k^* can take values of -1, -1/3, +1/3 and +1. In this case, the limit on d_1 is defined as a ratio of the tap magnitude ($|d_1|$) to the cursor magnitude at the input of the DFE (h_0). To constrain DFE burst errors, the $|d_1/h_0|$ ratio must be less than 0.55 and the weighted-sum of the tap magnitudes defined as $(|d_1| + |d_2| + 0.85*|d_3| + 0.60*|d_4| + 0.25*|d_5| + 0.10*|d_6| + 0.05*|d_7| + 0.05*|d_8| + 0.05*|d_9| + 0.05*|d_{10}| + 0.05*|d_{11}| + 0.05*|d_{12}| + 0.05*|d_{13}| + 0.05*|d_{14}| + 0.05*|d_{15}| + 0.05*|d_{16}|)/h_0$ must be less than 0.85. The limits on DFE tap magnitudes are only to bound the behavior of the reference receiver and do not indicate that real implementations will be safe from error bursts by

ensuring the DFE tap magnitude limits specified for the reference receiver. Implementers must do their own analysis for their specific designs on the largest safe DFE tap magnitudes.

8.4.2 Stressed Eye Test §

Rx testing at 16.0, 32.0, and 64.0 GT/s requires only a single stressed voltage/stressed jitter test per data rate.

When testing a Receiver, it is required to have other PCI Express Lanes on the DUT sending or receiving data. Similarly, if the device supports other I/O, it should also be sending or receiving on these interfaces. The goal is to have the Rx test environment replicate the noise environment found in a real system as closely as possible.

8.4.2.1 Procedure for Calibrating a Stressed EH/EW Eye §

The goal of calibrating a stressed voltage/jitter eye is to present the Receiver under test with simultaneously worst case margins whose distortion characteristics are like an eye produced by a real channel. Much of the distortion consists of the ISI produced by the calibration channel. Incremental changes of R_j and differential voltage are allowed to adjust the EW and EH, respectively at 8.0 GT/s. Incremental changes of S_j , $V_{RX-DIFF-INT}$, and differential voltage swing from nominal values may be used to adjust the EW and EH at 16.0, 32.0, and 64.0 GT/s. Refer to § Table 8-11 for initial values of various stress parameters for all data rates.

The reference point where EH/EW is defined corresponds to input to the Receiver latch at 8.0, 16.0, 32.0, and 64.0 GT/s. Since this point is not physically accessible it is necessary to construct its equivalent by means of a post-processing procedure. A two million unit interval data record of compliance pattern or a step that has been averaged 1024 times at TP2 is first post processed to mathematically include the additional signal distortion caused by the behavioral Receiver package. If a compliance pattern waveform is used then all stresses except $V_{RX-CM-INT}$ are turned on if a step is used then all stresses are turned off. Then the resulting signal is recovered by means of Rx equalization, and a behavioral CDR function, resulting in an equivalent eye. The requirements for the waveform post processing tool used for the EH/EW calibration are described further in § Section 8.4.2.1.1. If the receiver calibration eye margin simulation tool uses a step response, the R_j , S_j , and $V_{RX-DIFF-INT}$ are input parameters to the simulation tool. If the receiver calibration eye margin simulation tool uses compliance pattern waveform, the R_j , S_j , and $V_{RX-DIFF-INT}$ are inputs to the waveform. In either case, the stress parameters must be calibrated.

As the calibration procedure of the signal generator output contains steps where the generator is connected directly to measurement instrumentation, the transition time of the output waveform can be very fast. Therefore, it is important that the bandwidth of instrumentation used to calibrate the generator be matched appropriately to the edge rate of the generator output. This specification requires the use of a generator for 16.0 GT/s testing whose outputs have a rise time of 14 ps-19 ps (20% / 80%) which also requires a minimum oscilloscope bandwidth of 25 GHz. This oscilloscope bandwidth is also the minimum required bandwidth for transmitter measurements at 16.0 GT/s. For 32.0 and 64.0 GT/s testing the specification requires the use of a generator whose outputs have a rise time of 7.5 - 15.0 ps (20%/80% measured with P4) which requires a minimum oscilloscope bandwidth of 50 GHz. This oscilloscope bandwidth is also the minimum required for transmitter measurements at 32.0 and 64.0 GT/s. A minimum oscilloscope sampling rate that captures at least 4 samples per unit interval is required for all data rates.

For the eye calibration process, the Tx equalization is fixed to the preset that gives the optimal eye area with the post processing tool being used for calibration. Once the testing procedure is under way the Tx preset may be adjusted to yield the best eye margins with the DUT. During EH/EW calibration S_j is initially set to 100 MHz with a nominal amplitude of 0.1 UI for 8.0, 16.0, and 32.0 GT/s, with a nominal amplitude of 0.05 UI for 64.0 GT/s. The 100 MHz S_j amplitude will be swept during the stressed eye calibration. Tx EQ and differential voltage swing calibration are done at TP3 as shown in § Figure 8-26. The coaxial cable from TP1 to TP3 is considered part of the generator and not included in the channel insertion loss measurements for 32.0 GT/s and 64.0 GT/s stressed eye calibration, but the coaxial cable is included in the total channel insertion loss measurement at 16.0 GT/s to keep consistency with the 16.0 GT/s measurement methodology adopted in PCIe 4.0. For calibration at 16.0 GT/s the following process is used to calibrate the eye:

1. Calibrate the stress values to the nominal values in § Table 8-11.
2. Select an initial test channel length that gives a loss at TP2P at 8 GHz of 27 dB±0.5 dB.
3. Measure the eye diagram for each TX EQ preset using the nominal TX Eq for the preset +/- 0.1 dB and select the TX EQ preset that gives the largest eye area.

For all EH, EW and eye area measurements performed in receiver calibration the A_{DC} in the reference receiver CTLE is varied over its minimum to maximum range in 0.25 dB steps. This is done to improve repeatability and accuracy in automated Rx calibration software and is only done for stressed eye calibration (not for channel compliance, etc.)

4. Increase the calibration channel loss to the next available length/loss and measure the new eye diagram at the selected preset. Continue to increase the length/loss until either the height or width have fallen below the targets in § Table 8-11 then the previous calibration channel length/loss is selected. If neither the height or width have fallen below the targets and the TP3 (§ Figure 8-26) to TP2P loss at 8 GHz has reached 30.0 dB then advance to the next step.
5. For the selected calibration channel length/loss, measure the eye diagram for each TX EQ preset and select the preset that gives the largest eye area. Note that this may be a different preset than step 3 due to the length/loss change.
6. Adjust S_j , $V_{RX-DIFF-INT}$, and Voltage Swing to make final adjustments to the eye by sweeping them through the following ranges:
 - a. S_j 5 to 10 ps PP.
 - b. $V_{RX-DIFF-INT}$ 10 to 25 mV at TP2.
 - c. Differential Voltage Swing 720 to 800 mV PP at TP1.
7. If the final S_j value is less than 0.1 UI then the R_j level is reduced so the eye width meets the target eye width with 0.1 UI of 100 MHz S_j .
8. If there are multiple combinations of S_j , $V_{RX-DIFF-INT}$, and Voltage Swing that give valid solutions first pick the combination that is closest to the target eye width (18.75 ps). If there are multiple S_j , $V_{RX-DIFF-INT}$, and Voltage Swing combinations that are equally close to the target eye width then pick the one with S_j closest to nominal. The selected values must give a mean eye height and width (over at least 5 measurements exact number of measurements needed for stable values will depend on lab set-up and tools) within the following ranges at BER E-12:
 - a. Eye height 15 mV +/- 1.5 mV
 - b. Eye width 18.75 ps +/- 0.5 ps

For calibration at 32.0 GT/s the following process is used to calibrate the eye:

1. Measure the eye diagram for each TX EQ preset using the nominal TX Eq for the preset +/- 0.3 dB and select the TX EQ preset that gives the largest eye area.

For all EH, EW and eye area measurements performed in receiver calibration the A_{DC} in the reference receiver CTLE is varied over its minimum to maximum range in 1.0 dB steps. Measure the eye diagram varying the following parameters with the maximum indicated step size for each variable parameter:

- a. Calibrate the stress values to the initial values in § Table 8-11. The R_j stress is kept constant.
- b. Channel loss from TP3 to TP2P varied from 34.0 to 37.0 dB with a maximum 0.5 dB step size.

Note that if your actual channel loss comes out to slightly above 37 or slightly below 34 that these cases are excluded (loss must be between 34.0 and 37.0 dB)

- c. S_j varied from 1 to 5 ps PP with a maximum 0.25 ps step size with S_j measured at TP3

- d. $V_{RX-DIFF-INT}$ 5 to 30 mV at TP2 with a maximum 2.5 mV step size
2. If the final S_j value is less than $0.1 UI$ then the R_j level is reduced so the eye width meets the target eye width with $0.1 UI$ of 100 MHz S_j .
3. If there are multiple combinations of S_j , $V_{RX-DIFF-INT}$, and channel loss that give valid solutions first pick the combination with the highest channel loss. If there are multiple combinations that work with the highest channel loss, then select the combination that is closest to the target eye height (15.0 mV). The selected values must give a mean eye height and width (over at least 5 measurements exact number of measurements needed for stable values will depend on lab set-up and tools) within the following ranges at BER E-12. A specific method for finding the combination of stress values that meet these criteria is outside the scope of this specification. If and only if no stress combinations can be found, then the voltage swing may also be varied from 720 to 800 mV:

Note that because the first tiebreaker is highest loss - most approaches will start with the highest allowed channel loss.

- a. Eye height 15 mV +/- 1.5 mV
- b. Eye width 9.375 ps +/- 0.5 ps

For calibration at 64.0 GT/s the following process is used to calibrate the eye:

1. Measure the PAM4 eye diagrams for each TX EQ preset of Q0-Q9 using the nominal TX Eq for the preset +/- 0.3 dB and select the TX EQ preset that gives the largest top eye area.

For all EH, EW and eye area measurements performed in receiver calibration the ADC in the reference receiver CTLE is varied over its minimum to maximum range in 1.0 dB steps. Measure the eye diagrams varying the following parameters with the maximum indicated step size for each variable parameter:

- a. Calibrate the stress values to the initial values in § Table 8-11. The R_j stress is kept constant.
- b. Channel loss from TP3 to TP2P varied from 30.0 to 33.0 dB with a maximum 0.5 dB step size.

Note that if your actual channel loss comes out to slightly above 33 or slightly below 30 that these cases are excluded (loss must be between 30.0 and 33.0 dB)

- c. S_j varied from 1 to 3 ps PP with a maximum 0.25 ps step size with S_j measured at TP3
- d. $V_{RX-DIFF-INT}$ 5 to 25 mV at TP2 with a maximum 2.0 mV step size
2. If the final S_j value is less than $0.05 UI$ then the R_j level is reduced so the eye width meets the target eye width with $0.05 UI$ of 100 MHz S_j .
3. If there are multiple combinations of S_j , $V_{RX-DIFF-INT}$, and channel loss that give valid solutions first pick the combination with the highest channel loss. If there are multiple combinations that work with the highest channel loss, then select the combination that is closest to the target top eye height (6.0 mV). The selected values must give a mean eye height and width (over at least 5 measurements exact number of measurements needed for stable values will depend on lab set-up and tools) within the following ranges at BER of 10⁻⁶. A specific method for finding the combination of stress values that meet these criteria is outside the scope of this specification. If and only if no stress combinations can be found, then the voltage swing between PAM4 voltage level 0 and level 3 may also be varied from 720 to 800 mV:

Note that because the first tiebreaker is highest loss - most approaches will start with the highest allowed channel loss.

- a. Top eye height 6 mV +/- 0.5 mV
- b. Top eye width 3.125 ps +/- 0.3 ps

For calibration at 64.0 GT/s, if the Differential Noise and/or Common Mode Noise are generated using an external source, any broadband differential noise introduced by the noise source should be characterized and added to the step response based calibration procedure through inclusion of SNDR in the modeling of the BERT transmitter.

Based upon the data rate at which the Rx is being tested, Rj or Sj and differential interference sources are adjusted to fall within the V_{RX-ST} and T_{RX-ST} limits. The EH and EW ranges are designed to account for post processing or measurement errors. § Figure 8-41 shows the process for calibrating the stressed jitter eye at 8.0 GT/s.

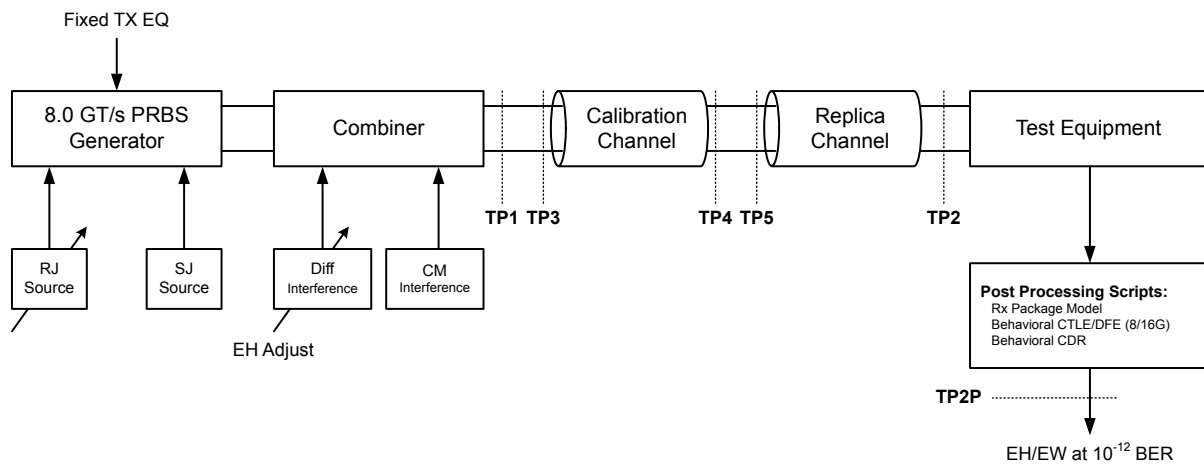

Figure 8-41 Layout for Calibrating the Stressed Jitter Eye at 8.0 GT/s §

§ Figure 8-42 shows the process for calibrating the stressed jitter eye common for 16.0, 32.0, and 64.0 GT/s data rates. The PRBS Generator provides the required data rate and the eye is calibrated to the data rate specific target EH and EW at the corresponding BER.

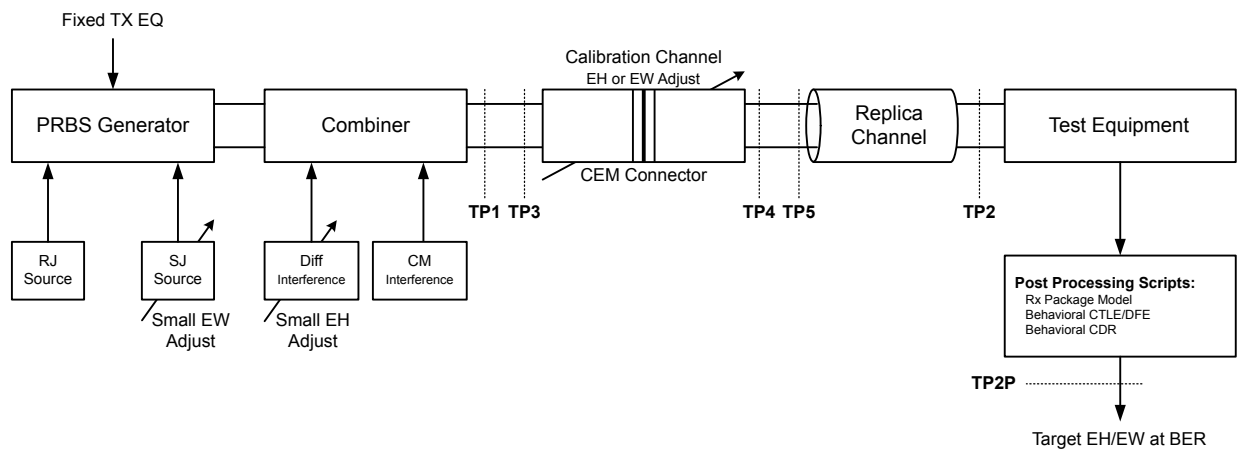

Figure 8-42 Layout for Calibrating the Stressed Jitter Eye at 16.0, 32.0, and 64.0 GT/s §

Table 8-11 Stressed Jitter Eye Parameters §

Notes:

Symbol	Parameter	2.5 GT/s	5.0 GT/s	8.0 GT/s	16.0 GT/s	32.0 GT/s	64.0 GT/s	Units	Details
									<ol style="list-style-type: none"> $V_{RX-LAUNCH}$ may be adjusted to meet V_{RX-ST} as long as the outside eye voltage at TP2 does not exceed 1300 mVPP for calibration at 2.5, 5.0, and 8.0 GT/s. $V_{RX-LAUNCH}$ is adjusted from 800 to 720 mV for 16.0, 32.0, and 64.0 GT/s calibration with 800 mV as the nominal value. Voltages shown for 2.5 GT/s and 5.0 GT/s are at the Rx pins. Eye widths shown for 2.5 GT/s and 5.0 GT/s are at the Rx pins. V_{RX-ST} and T_{RX-ST} are referenced to TP2P for 8.0, 16.0, 32.0, and 64.0 GT/s and TP2 for 2.5 and 5.0 GT/s. For 8.0, 16.0, 32.0, and 64.0 GT/s behavioral equalization are applied to the data at TP2. At 64.0 GT/s, V_{RX-ST} and T_{RX-ST} correspond to top eye height and eye width at 10^{-6} BER. $T_{RX-ST-SJ}$ may be measured at either TP1 or TP2. Only 8.0, 16.0, 32.0 and 64.0 GT/s receivers are tested with Sj mask. $T_{RX-ST-RJ}$ may be adjusted to meet the target value for T_{RX-ST} at 8.0 GT/s. Rj is measured at TP1 to prevent data-channel interaction from adversely affecting the accuracy of the Rj calibration. Rj is applied over the following range: The low frequency limit may be between 1.5 and 10 MHz, and the upper limit is 1.0 GHz. Both $T_{RX-ST-RJ}$ and $V_{RX-DIFF-INT}$ are limited to prevent the stressed eye from containing excessive amounts of jitter or noise distortion that are unrepresentative of a real channel. Too many of these distortion components produces a signal that cannot be equalized by an actual Receiver. Defined as a single tone at 120 MHz. Measurement made at TP2 without post-processing. Common mode is turned off during T_{RX-ST} and V_{RX-ST} calibration and then turned on for the stressed eye jitter test. For 2.5 GT/s and 5.0 GT/s Rx calibration variable channel loss is used to achieve the target eye height. For 2.5 GT/s Rx calibration 100 MHz Sj is used to achieve the target eye width. For 33 kHz SSC residual for common clock architecture testing only when testing at 5 GT/s. Frequency for $V_{RX-DIFF-INT}$ is chosen to be slightly above the first pole of the reference CTLE. Applied for CC testing only as a triangular phase modulation with a frequency between 30 kHz to 33 kHz when testing at 16.0 GT/s with no 32.0 GT/s and no 64.0 GT/s support and when the Sj mask of § Figure 8-50 and a first order CDR transfer function are used.

8.4.2.1.1 Post Processing Tool Requirements §

A waveform post processing tool or a channel compliance methodology tool may be used for Rx stressed eye calibration at 16.0, 32.0, or 64.0 GT/s. If a waveform post processing tool is used to calibrate the EH/EW for the RX stressed eye testing, the tool must be consistent with the channel compliance methodology tool based on a consistency test defined as follows:

- The test channel is the long Rx calibration channel with the Root reference package applied in post-processing to give a total loss of 28.0 dB at 8 GHz (16.0 GT/s), 36.0 dB at 16 GHz (32.0 GT/s), or 32.0 dB at 16 GHz (64.0 GT/s). This means that the physical channel loss is 23.0 dB (16.0 GT/s), 27.0 dB (32.0 GT/s), or 24.0 dB (64.0 GT/s).
- All measurements are done at TP2.
- A step pattern with 512 ones and zeros is captured through the test channel by averaging 1024 times on a real time oscilloscope. The step is saved with an x-axis resolution of 1 ps or less to be used as the transmit waveform for the channel compliance methodology. The step pattern is captured for each preset using the nominal Tx EQ for each preset.

- The channel compliance methodology is run with no Tx EQ applied in simulation using the nominal stress values for Rx stressed eye calibration for each of the captured steps. The Tx EQ preset that produced the largest eye area is selected for exact eye height and width calibration.
- The channel compliance methodology is used with the selected Tx EQ preset to produce an EH/EW of
 - 15 mV and 0.3 UI @ 10^{-12} BER (16.0 GT/s),
 - 15 mV and 0.3 UI @ 10^{-12} BER (32.0 GT/s), or
 - top eye height of 6.0 mV and top eye width of 0.1 UI @ 10^{-6} BER (64.0 GT/s)
 by adjusting the S_j , $V_{RX-DIFF-INT}$ and voltage swing at the Transmitter output.
- A pattern generator is calibrated to have the same jitter stress levels and Tx Swing as those used in the channel compliance simulations that produced the target eye height and eye width.
- 2 million unit interval waveforms with compliance pattern are captured at each Tx EQ at the end of the channel. The Tx EQ is calibrated to the nominal values for each preset at the pattern generator output before doing the captures.
- For the preset that gives the largest eye area with the waveform post processing tool the EH and EW (@ 10^{-12} BER for 8.0, 16.0, and 32.0 GT/s and @ 10^{-6} BER for 64.0 GT/s) & must match the target EH and EW from the channel compliance methodology within +/- 15%.

8.4.2.2 Procedure for Testing Rx DUT §

8.4.2.2.1 S_j Mask §

Once a calibrated EH and EW have been obtained, the cables are moved to connect the Rx DUT to the far end of calibration channel. For the testing of the Rx DUT, the BERT Tx must transmit Modified Compliance Pattern. The Tx equalization may then be optimized with the assumption that the DUT Rx will also optimize its equalization. S_j is set to an initial value of 0.1 UI at 100 MHz and the Receiver CDR must achieve lock. For 64.0 GT/s, S_j is set to an initial value of 0.05 UI at 100 MHz and the Receiver CDR must achieve lock. At 8.0, 16.0, 32.0, and 64.0 GT/s the 100 MHz S_j initial tone is removed and then the appropriate swept S_j profile is tested. At 16.0, 32.0, and 64.0 GT/s an additional S_j tone at 210 MHz is present for all testing. At 16.0 and 32.0 GT/s, the amplitude of this additional tone is equal to the amplitude of the 100 MHz S_j required to achieve the target eye width minus 0.1 UI. If the calibration S_j level was less than 0.1 UI then no additional tone at 210 MHz is used. At 64.0 GT/s, the amplitude of this additional tone is equal to the amplitude of the 100 MHz S_j required to achieve the target eye width minus 0.05 UI. If the calibration S_j level was less than 0.05 UI then no additional tone at 210 MHz is used. Different S_j profiles are used, depending on data rate and whether the Rx under test operates in the CC mode or the IR Refclk mode. See § Table 8-11.

The S_j (pp value) profiles shown in § Figure 8-43, § Figure 8-44, § Figure 8-45, § Figure 8-46, § Figure 8-47, § Figure 8-48, and § Figure 8-49 consist of swept tones at 33 kHz and from 400 kHz to 100 MHz, representing the swept S_j frequency range. For 8.0 and 16.0 GT/s SRIS mode with 5000 ppm SSC, the magnitude of the 33 kHz spur is 25 ns pp. For 32.0 and 64.0 GT/s SRIS mode with 3000 ppm SSC, the magnitude of the 33 kHz spur is 15 ns pp. A Receiver must meet the target BER (10^{-6} for 64.0 GT/s and 10^{-12} for all other data rates) over the entire swept S_j frequency range. It is not necessary to test a Receiver over the entire S_j frequency range, but a sufficient number of frequency points should be tested to guarantee that the Rx does not fail the target BER at some resonance frequency. The 33 kHz frequency point must be tested and treated as another frequency point. The 33 kHz frequency will not be kept on during other frequency measurements. Note that no SSC is applied at the source. Swept S_j is required only for testing Receivers at 8.0, 16.0, 32.0, and 64.0 GT/s. Receiver operation at 2.5 GT/s and 5.0 GT/s is tested using a single 33 kHz S_j tone.

Receivers operating at 8.0 GT/s in the IR mode use the S_j mask profile shown in § Figure 8-43. The magnitude of the 33 kHz spur is 25 ns pp, or 200 U_{lpp}. The equation of the swept S_j curve is shown on § Figure 8-43.

Figure 8-43 S_j Mask for Receivers Operating in IR mode at 8.0 GT/s §

Receivers operating at 16.0 GT/s in the Independent Refclk (IR) mode use the S_j mask profile shown in § Figure 8-44. The magnitude of the 33 kHz spur is 25 ns pp, or 400 U_{lpp}. The equation of the swept S_j curve is shown on the § Figure 8-44.

Figure 8-44 Sj Mask for Receivers Operating in SRIS mode at 16.0 GT/s §

Receivers operating at 16.0 GT/s in the Common Clock (CC) Refclk mode use the Sj mask profile shown in § Figure 8-45. The magnitude of the 33 kHz spur is 1 ns pp, or 16 UIpp. The equation of the swept Sj curve is shown on the § Figure 8-45. Devices that do not support 32.0 GT/s have the option to use the Sj mask defined in § Figure 8-50. In this case, a 500 ps-pp triangular SSC modulation has to be applied at the source for both channel calibration and RX compliance, as specified in § Table 8-11.

Figure 8-45 Sj Mask for Receivers Operating in CC mode at 16.0 GT/s §

Receivers operating at 32.0 GT/s in the IR mode use the Sj mask profile shown in § Figure 8-46. The magnitude of the 33 kHz spur is 15 ns pp, or 480 U_{lpp}. The equation of the swept Sj curve is shown on the § Figure 8-46.

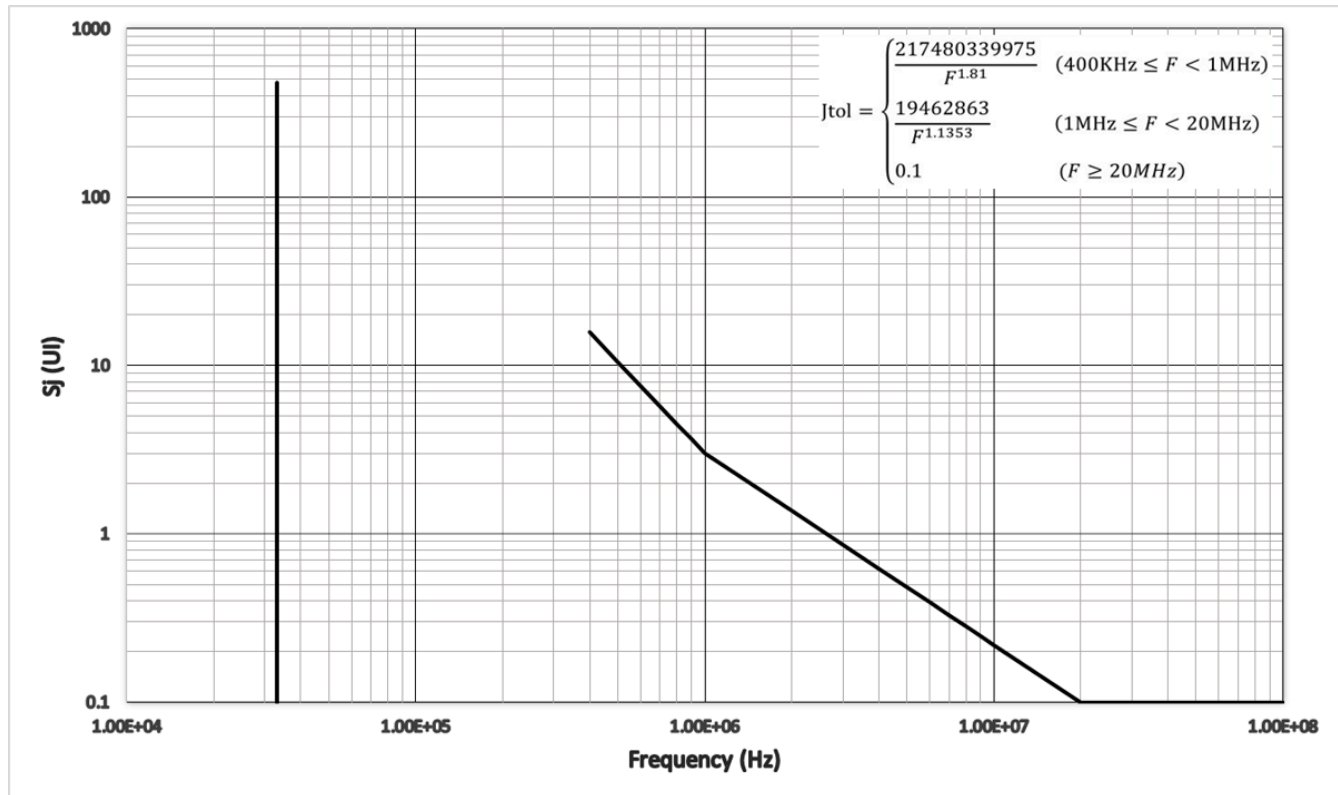

Figure 8-46 Sj Mask for Receivers Operating in SRIS mode at 32.0 GT/s §

Receivers operating at 32.0 GT/s in the CC Refclk mode use the Sj mask profile shown in § Figure 8-47. The magnitude of the 33 kHz spur is 1 ns pp, or 32 U_{pp}. The equation of the swept Sj curve is shown on the § Figure 8-47.

Figure 8-47 S_j Mask for Receivers Operating in CC mode at 32.0 GT/s §

Receivers operating at 64.0 GT/s in the IR mode use the S_j mask profile shown in § Figure 8-48. The magnitude of the 33 kHz spur is 15 ns pp, or 480 UI pp. The equation of the swept S_j curve is shown on the § Figure 8-48.

Figure 8-48 S_j Mask for Receivers Operating in SRIS mode at 64.0 GT/s §

Receivers operating at 64.0 GT/s in the CC Refclk mode use the S_j mask profile shown in § Figure 8-49. The magnitude of the 33 kHz spur is 1 ns pp, or 32 U_{pp}. The equation of the swept S_j curve is shown on the § Figure 8-49.

Figure 8-49 S_j Mask for Receivers Operating in CC mode at 64.0 GT/s §

Receivers operating in the CC Refclk mode at 8.0 GT/s shall utilize the S_j profile shown in § Figure 8-50. The testing procedure is identical to that used for the IR mode, except that the clock topology differs. See § Section 8.4.2.3 for details. Receivers operating at 16.0 GT/s in the CC Refclk mode in devices that do not support 32.0 GT/s also have the option to use the S_j mask profile shown in § Figure 8-50, with additional residual SSC applied per § Table 8-11.

Figure 8-50 S_j Masks for Receivers Operating in CC Mode at 8.0 GT/s §

8.4.2.3 Receiver Refclk Modes §

A Rx is permitted to support one or both of two clock modes: CC and IR although only one clock mode may be operational at a given time. Receivers can support more than one Refclk mode by selecting a mode at power-up or by means of strapping pins, etc.

8.4.2.3.1 Common Refclk Mode §

§ Figure 8-51 shows the Refclk connection for a receiver in the Common Clock Refclk mode. A single Refclk source drives both the Generator and the DUT. This test utilizes the S_j mask specified in § Section 8.4.2.2.1 .

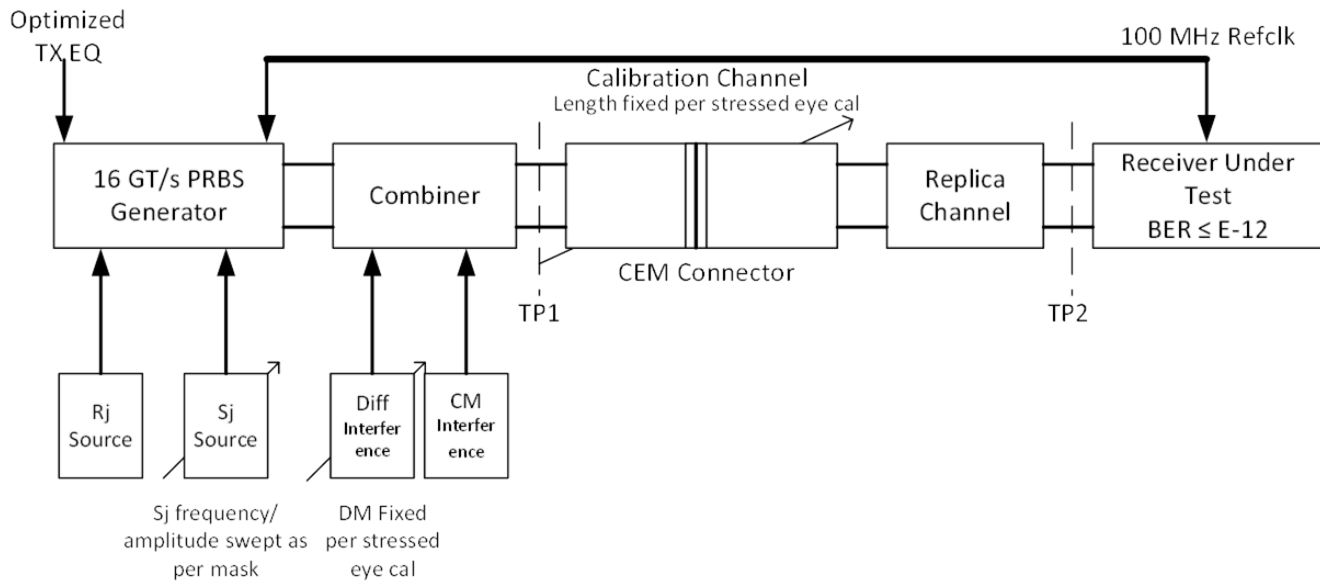

Figure 8-51 Layout for Jitter Testing Common Refclk Rx at 16.0 GT/s §

8.4.2.3.2 Independent Refclk Mode §

§ Figure 8-52 illustrates the configuration for testing a Receiver in the IR Refclk mode. A Refclk source with SSC is required for the DUT. The test utilizes the Sj mask specified in § Section 8.4.2.2.1. The generator must be able to produce a large 33 KHz Sj tone while Sj is swept as shown in § Section 8.4.2.2.1.

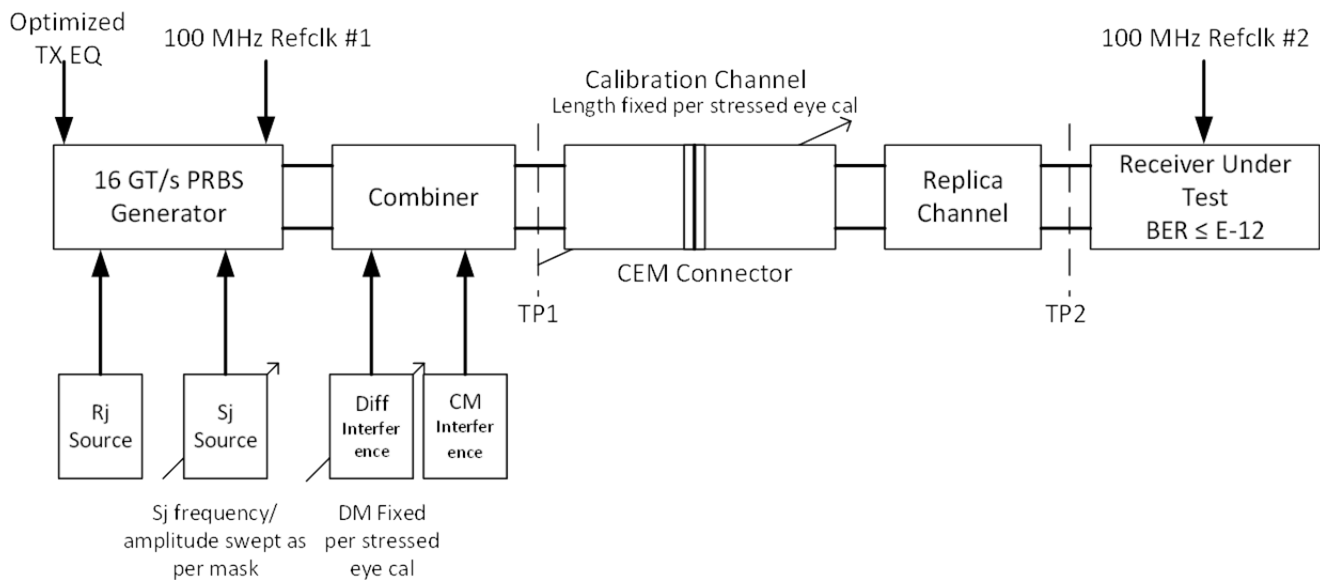

Figure 8-52 Layout for Jitter Testing for Independent Refclk Rx at 16.0 GT/s §

8.4.3 Common Receiver Parameters §

§ Table 8-12 lists the common Receiver parameters that are not directly associated with stressed eye tolerancing. Values are separately defined for the four data rates.

Table 8-12 Common Receiver Parameters §

Symbol	Parameter	2.5 GT/s value	5.0 GT/s value	8.0 GT/s value	16.0 GT/s value	32.0 GT/s value	64.0 GT/s value	Units	Notes	
UI (Rx)	Unit Interval	(min) 399.88 (max) 400.12 (300 PPM)	(min) 199.94 (max) 200.06 (300 PPM)	(min) 124.9625 (max) 125.0375 (300 PPM)	(min) 62.48125 (max) 62.51875 (300 PPM)	(min) 31.246875 (max) 31.253125 (100 PPM)	(min) 31.246875 (max) 31.253125 (100 PPM)	ps	UI tolerance does not include SSC effects	
BW_{RX}-PKG-PLL1	Rx PLL bandwidth corresponding to <u>PKG_{RX}-PLL1</u>	(max) 22 (min) 1.5	(max) 16.0 (min) 8	(max) 4.0 (min) 0.5	(max) 4.0 (min) 0.5	(max) 1.8 (min) 0.5	(max) 1.0 (min) 0.5	MHz	Second order PLL transfer bounding function. See Note 1.

PKG_{RX}-PLL1	Maximum Rx PLL peaking corresponding to <u>BW_{RX}-PKG-PLL1</u>	(max) 3.0	3.0	2.0	2.0	2.0	2.0	dB	Second order PLL transfer bounding function. See Note 1.	
PKG_{RX}-PLL2	Maximum Rx PLL peaking corresponding to <u>BW_{RX}-PKG-PLL2</u>	Not specified	1.0	1.0	1.0	N/A	N/A	dB	Second order PLL transfer bounding function. See Note 1.	
RL_{RX-DIFF}	Differential receiver return loss	See § Figure 8-22					See § Figure 8-24		dB	Note 2
RL_{RX-CM}	Common mode receiver return loss	See § Figure 8-23					See § Figure 8-25		dB	Note 2
T_{RX-GND-FLOAT}	Rx termination float time			(max) 500	(max) 500	(max) 500	(max) 500	µs	Note 5	
V_{RX-CM-AC-P}	Rx AC common Mode Voltage	(max) 150	(max) 150	(max) 75	(max) 75	(max) 75	(max) 37.5	mVP	Measured at Rx pins into a pair of 50Ω terminations to ground	
Z_{RX-DC}	Receiver DC single ended impedance	(min) 40 (max) 60	(min) 40 (max) 60	Not specified	Not specified	Not specified	Not specified	Ω	DC impedance limits are needed to guarantee Receiver detect. For 8.0,	

Symbol	Parameter	2.5 GT/s value	5.0 GT/s value	8.0 GT/s value	16.0 GT/s value	32.0 GT/s value	64.0 GT/s value	Units	Notes
									16.0, 32.0, and 64.0 GT/s it is bounded by $\underline{RL_{RX-CM}}$. See Note 3.
Z_{RX-HIGH-IMP-DC-POS}	DC input CM input impedance for $V \geq 0$ during Reset or power-down	$\geq 10K$ (0-200 mV) $\geq 20K$ (> 200 mV)	$\geq 10K$ (0-200 mV) $\geq 20K$ (> 200 mV)	$\geq 10K$ (0-200 mV) $\geq 20K$ (> 200 mV)	$\geq 10K$ (0-200 mV) $\geq 20K$ (> 200 mV)	$\geq 10K$ (0-200 mV) $\geq 20K$ (> 200 mV)	$\geq 10K$ (0-200 mV) $\geq 20K$ (> 200 mV)	Ω	Voltage measured wrt. ground. Parameters may not scale with process technology. See Note 4.
Z_{RX-HIGH-IMP-DC-NEG}	DC input CM input impedance for $V < 0$ during Reset or power-down	1.0K (min)	1.0K (min)	1.0K (min)	1.0K (min)	1.0K (min)	1.0K (min)	Ω	Voltage measured over the range of -150 mV to 0 mV wrt. ground. Parameters may not scale with process technology. See Note 4.
V_{RX-IDLE-DET-DIFF-PP}	Electrical Idle Detect threshold	(min) 65 (max) 175	(min) 65 (max) 175	(min) 65 (max) 175	(min) 65 (max) 175	(min) 65 (max) 175	(min) 65 (max) 175	mV	V_{RX-IDLE-DET-DIFFp-p} = $2 \times V_{RX-D+} - V_{RX-D-} $
T_{RX-IDLE-DET-DIFF-ENTERTIME}	Unexpected Electrical Idle Enter Detect Threshold Integration Time	(max) 10	(max) 10	(max) 10	(max) 10	(max) 10	(max) 10	ms	An unexpected Electrical Idle ($V_{RX-IDLE-DET-DIFF-PP} < \underline{V_{RX-IDLE-DET-DIFFp-p}}$) must be recognized no longer than $\underline{T_{RX-IDLE-DET-DIFF-ENTER-TIME}}$ to signal an unexpected idle condition.
L_{RX-SKEW}	Lane to Lane skew	(max) 20	(max) 8	(max) 6	(max) 5	(max) 5	(max) 5	ns	Across all Lanes on a Port. $\underline{L_{RX-SKEW}}$ comprehends Lane-Lane variations due to channel and repeater delay differences.

Notes:

- Two combinations of PLL BW and peaking are specified at 5.0 GT/s to permit designers to make tradeoffs between the two parameters. If the PLL's min BW is ≥ 8 MHz, then up to 3.0 dB of peaking is permitted. If the PLL's min BW is relaxed to ≥ 5.0 MHz, then a tighter peaking value of 1.0 dB must be met. Note: a PLL BW extends from zero up to the value(s) defined as the min or max in the above table. For 2.5 GT/s a single PLL bandwidth and peaking value of 1.5-22 MHz and 3.0 dB are defined.
- Measurements must be made for both common mode and differential return loss. In both cases the DUT must be powered up and DC isolated, and its D+/D- inputs must be in the low-Z state.

Symbol	Parameter	2.5 GT/s value	5.0 GT/s value	8.0 GT/s value	16.0 GT/s value	32.0 GT/s value	64.0 GT/s value	Units	Notes
3.	The Rx DC single ended impedance must be present when the Receiver terminations are first enabled to ensure that the Receiver Detect occurs properly. Compensation of this impedance is permitted to start immediately and the Rx Common Mode Impedance (constrained by RL_{RX-CM} to $50 \Omega \pm 20\%$) must be within the specified range by the time Detect is entered.								
4.	$Z_{RX-HIGH-IMP-DC-NEG}$ and $Z_{RX-HIGH-IMP-DC-POS}$ are defined respectively for negative and positive voltages at the input of the Receiver. Transmitter designers need to comprehend the large difference between >0 and <0 Rx impedances when designing Receiver detect circuits.								
5.	Defines the time for the Receiver's input pads to settle to new common-mode on 2.5/5.0 GT/s transition to 8.0, 16.0, 32.0, and 64.0 GT/s.								

8.4.3.1 5.0 GT/s Exit From Idle Detect (EFI) §

It is difficult to scale the capabilities of the EFI detect circuits with data rate, and for this reason the 5.0, 8.0, 16.0, 32.0, and 64.0 GT/s specification defines different data patterns in the FTS and the TS1 and TS2 Ordered Sets than are defined for 2.5 GT/s operation. In particular, repeated K28.7 patterns are defined to guarantee sufficient voltage and time requirements, as illustrated in the figure below. Concatenated EIE Symbols yield alternating one/zero run lengths of five UI each.

Figure 8-53 Exit from Idle Voltage and Time Margins §

8.4.3.2 Receiver Return Loss §

The measurement methodology and frequency binning for differential and common mode Rx RL is identical to that for the Tx. For details refer to § Figure 8-22, § Figure 8-24, § Figure 8-23, and § Figure 8-25.

8.4.4 Lane Margining at the Receiver - Electrical Requirements §

PCI Express components including Retimers that support the 16.0 GT/s or higher rate are required to support Lane margining at the Receiver when operating at 16.0 GT/s or higher. Lane Margining enables system software to get the margin information of a given Lane while the Link is in L0 state. For NRZ signaling, the margin information includes both voltage and time, in either direction from the current Receiver position. For PAM4 signaling, the margin information includes both voltage and time for all the three eyes. The margin feature is not permitted to require any additional external hardware to function. Support of Lane margining for voltage is optional at 16.0 GT/s and required at 32.0 GT/s or higher. Support of independent timing margin to the left or to the right is optional for all data rates. Support of independent voltage margin for up or for down is optional for all data rates that support voltage margining. For

simplicity, the margin commands and requirements described in § Section 4.2.18 are described in terms of moving the data sample location - but the actual margining method is implementation specific. For example - the timing margin could be implemented on the actual data sampler or an independent error sampler. Further the timing margin can be achieved by injecting an appropriate amount of stress/jitter to the data sample location, or by moving the data/error sample location. The parameters in § Table 8-13 are reported for 16.0, 32.0, or 64.0 GT/s and all are allowed to be different for each of those data rates, though some are required to be different for NRZ vs. PAM4 data rates.

Figure 8-54 Allowed Ranges for Maximum NRZ Timing and Voltage Margin §

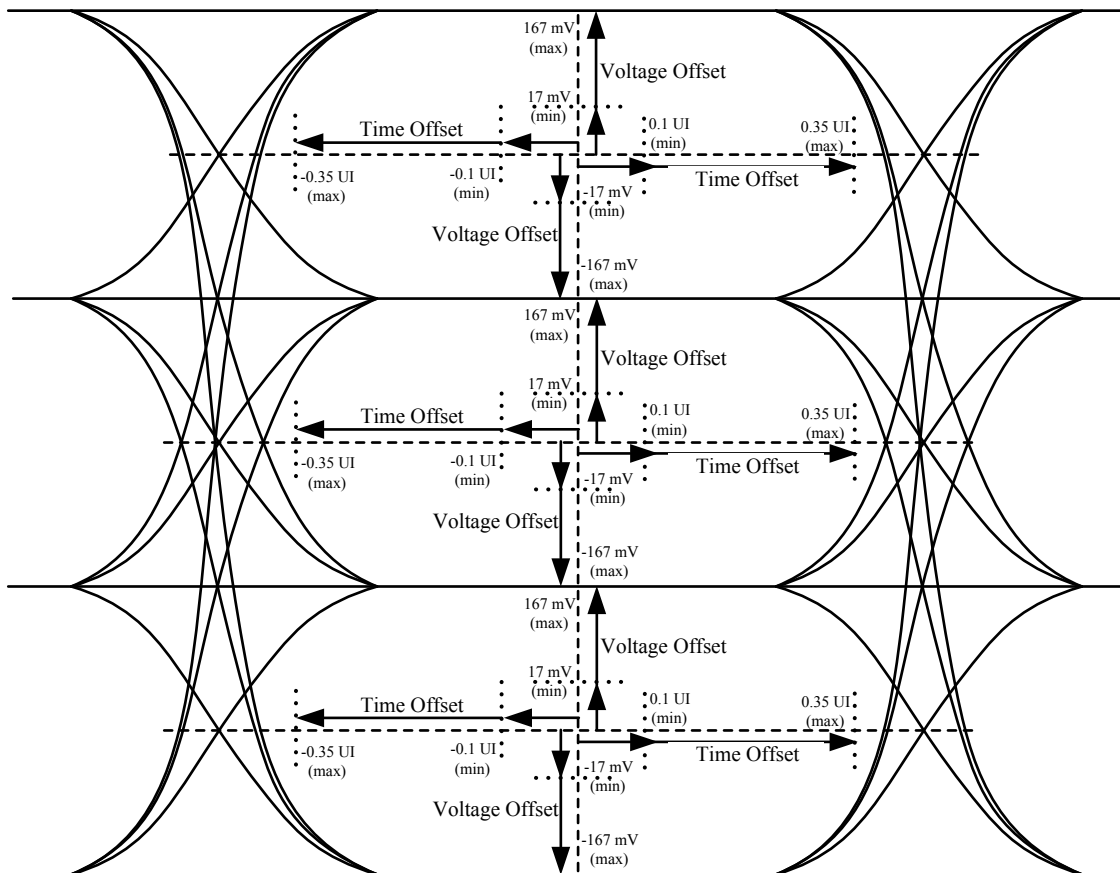

Figure 8-55 Allowed Ranges for Maximum PAM4 Timing and Voltage Margins §

Table 8-13 Lane Margining §

Parameter Name	Min	Max	Description
<i>M</i>NumTimingSteps	6	63	<p>Number of time steps from default (to either left or right), range must be at least +/-0.2 UI</p> <p>Timing offset must increase monotonically</p> <p>The number of steps in both positive (toward the end of the unit interval) and negative (toward the beginning of the unit interval) must be identical</p>
<i>M</i>MaxTimingOffset	20 %	50 %	<p>Offset from default at maximum step value as percentage of a nominal UI</p> <p>A 0 value may be reported if the vendor chooses not to report the offset</p>
<i>M</i>NumVoltageSteps	32	127	<p>Number of voltage steps from default (either up or down), minimum range +/-50 mV as measured by the reference equalizer</p> <p>Voltage offset must increase monotonically</p> <p>The number of steps in both positive and negative direction from the default sample location must be identical</p>

Parameter Name	Min	Max	Description
			This value is undefined if $M_{VoltageSupported}$ is 0b
$M_{MaxVoltageOffset}$	5 %	50 %	Offset from default at maximum step value as percentage of one volt A 0 value may be reported if the vendor chooses not to report the offset when $M_{VoltageSupported}$ is 1b This value is undefined if $M_{VoltageSupported}$ is 0b
$M_{NumTimingStepsPAM4}$	10	63	Number of time steps from default (to either left or right), range must be at least +/-0.1 UI Timing offset must increase monotonically The number of steps in both positive (toward the end of the unit interval) and negative (toward the beginning of the unit interval) must be identical
$M_{MaxTimingOffsetPAM4}$	10 %	35 %	Offset from default at maximum step value as percentage of a nominal UI A 0 value may be reported if the vendor chooses not to report the offset
$M_{NumVoltageStepsPAM4}$	64	127	Number of voltage steps from default (either up or down), minimum range +/-17 mV as measured by the reference equalizer Voltage offset must increase monotonically The number of steps in both positive and negative direction from the default sample location must be identical
$M_{MaxVoltageOffsetPAM4}$	5 %	50 %	Offset from default at maximum step value as percentage of one third volt
$M_{SamplingRateVoltage}$	0	63	The ratio of bits tested to bits received during voltage margining. A value of 0 is a ratio of 1:64 (1 bit of every 64 bits received), and a value of 63 is a ratio of 64:64 (all bits received).
$M_{SamplingRateTiming}$	0	63	The ratio of bits tested to bits received during timing margining. A value of 0 is a ratio of 1:64 (1 bit of every 64 bits received), and a value of 63 is a ratio of 64:64 (all bits received).
$M_{VoltageSupported}$	0	1	1b indicates that voltage margining is supported
$M_{IndLeftRightTiming}$	0	1	1b indicates independent left/right timing margin supported
$M_{IndUpDownVoltage}$	0	1	1b independent up and down voltage margining supported
$M_{IndErrorSampler}$	0	1	1b Margining will not produce errors (change in the error rate) in data stream (ie. error sampler is independent) 0b Margining may produce errors in the data stream
$M_{MaxLanes}$	0	31	Maximum number of Lanes minus 1 that can be margined at the same time. It is recommended that this value be greater than or equal to the number of Lanes in the Link minus 1. Encoding Behavior is undefined if software attempts to margin more than $M_{MaxLanes}+1$ at the same time.

Parameter Name	Min	Max	Description
			Note: This value is permitted to exceed the number of Lanes in the Link minus 1.
<i>M_{SampleReportingMethod}</i>	0	1	Indicates whether sampling rates (<u>M_{SamplingRateVoltage}</u> and <u>M_{SamplingRateTiming}</u>) are supported (1) or a sample count is supported (0). One of the two methods is supported by each device.
<i>M_{ErrorCount}</i>	0	63	If <u>M_{IndErrorSampler}</u> is 1b this is a count of the actual bit errors since margining started. If <u>M_{IndErrorSampler}</u> is 0b this is the actual count of the logical errors since margining started. See the Physical Layer Logical Block chapter for the definition of what errors are counted. The count saturates at 63.
<i>M_{SampleCount}</i>	0	127	Value = $3 * \log_2$ (number of bits margined). Where number of bits margined is a count of the actual number of bits tested during margining. The count stops when margining stops. The count saturates at 127 (after approximately 5.54×10^{12} bits). The count resets to zero when a new margin command is received.

8.4.5 Low Frequency and Miscellaneous Signaling Requirements §

8.4.5.1 ESD Standards §

All PCI Express signal and power supply pins must be tested for ESD protection levels to the Human Body Model (HBM) and the Charged Device Model (CDM) standards in accordance with [ESDA-JEDEC-JS-001-2010] (for HBM) and in accordance with [JEDEC-JESD22-C101] (for CDM). Pins must meet or exceed the minimum levels recommended in [JEDEC-JEP155-JEP157] (HBM/CDM) or JEDEC approved superseding documents.

8.4.5.2 Channel AC Coupling Capacitors §

Each Lane of a PCI Express Link must be AC coupled. The minimum and maximum values for the capacitance are given in § Table 8-7. Capacitors must be placed on the Transmitter side of an interface that permits adapters to be plugged and unplugged. In a topology where everything is located on a single substrate, the capacitors may be located anywhere along the channel. External capacitors are assumed because the values required are too large to feasibly construct on-chip.

8.4.5.3 Short Circuit Requirements §

All Transmitters and Receivers must support surprise hot insertion/removal without damage to the component. The Transmitter and Receiver must be capable of withstanding sustained short circuit to ground of D+ and D-.

8.4.5.4 Transmitter and Receiver Termination §

- The Transmitter is required to meet $RL_{TX-DIFF}$ and RL_{TX-CM} (see § Figure 8-22, § Figure 8-24, § Figure 8-23 and § Figure 8-25) any time functional differential signals are being transmitted.
- The Transmitter is required only to meet $I_{TX-SHORT}$ (see § Table 8-7) any time functional differential signals are not being transmitted.
- Note: The differential impedance during this same time is not defined.
- The Receiver is required to meet $RL_{RX-DIFF}$ and RL_{RX-CM} (see § Table 8-12) during all LTSSM states excluding only times during when the device is powered down, Fundamental Reset is asserted, or when explicitly specified.
- The Receiver is required to meet $Z_{RX-HIGH-IMP-DC-NEG}$ and $Z_{RX-HIGH-IMP-DC-POS}$ (see § Table 8-12) any time adequate power is not provided to the Receiver, Fundamental Reset is asserted, or when explicitly specified.

8.4.5.5 Electrical Idle §

Electrical Idle is a steady state condition where the Transmitter D+ and D- voltages are held constant at the same value. Electrical Idle is primarily used in power saving and inactive states (e.g., Disabled).

Before a Transmitter enters Electrical Idle, it must always send the required number of EIOSs except for the LTSSM substates explicitly exempted from this requirement. After sending the last Symbol of the last of the required number of EIOSs, the Transmitter must be in a valid Electrical Idle state within the time as specified by $T_{TX-IDLE-SET-TO-IDLE}$ in § Table 8-7.

The successful reception of an EIOS occurs based on the rules defined in the Physical Layer Logical Block chapter. It should be noted that in substates (e.g., Loopback.Active for a Loopback Follower) where multiple consecutive EIOSs are expected, the Receiver must receive the appropriate number of EIOS sequences comprising of COM, IDL, IDL, IDL.

The low impedance common mode and differential Receiver termination values (see § Table 8-7 and § Table 8-12) must be met in Electrical Idle. The Transmitter can be in either a low or high impedance mode during Electrical Idle.

Any time a Transmitter enters Electrical Idle it must remain in Electrical Idle for a minimum of $T_{TX-IDLE-MIN}$. The Receiver should expect the last EIOS followed by a minimum amount of time in Electrical Idle ($T_{TX-IDLE-MIN}$) to arm its Electrical Idle Exit detector.

When the Transmitter transitions from Electrical Idle to a valid differential signal level it must meet the output return loss specifications described in § Figure 8-22, § Figure 8-24, § Figure 8-23, and § Figure 8-25.

Electrical Idle Exit shall not occur if a signal smaller than $V_{RX-IDLE-DET-DIFF-p}$ minimum is detected at a Receiver. Electrical Idle Exit shall occur if a signal larger than $V_{RX-IDLE-DET-DIFF-p}$ maximum is detected at a Receiver. Electrical Idle may be detected on the received signal regardless of its frequency components, or it may be detected only when the received signal is switching at a frequency of 125 MHz or higher.

8.4.5.6 DC Common Mode Voltage §

The Receiver DC common mode voltage is nominally 0 V when operating at 2.5 GT/s or 5.0 GT/s.

Transmitter DC common mode voltage is held at the same value during all states unless otherwise specified. The range of allowed Transmitter DC common mode values is specified in § Table 8-7 ($V_{TX-DC-CM}$).

8.4.5.7 Receiver Detection §

The Receiver Detection circuit is implemented as part of a Transmitter and must correctly detect whether a load impedance equivalent to a DC impedance implied by the Z_{RX-DC} parameter (40 Ω -60 Ω) is present. Note: Support for Rx detect, which only occurs at 2.5 GT/s, is the reason why 2.5 GT/s Receivers impedance at DC is specified.

The recommended behavior of the Receiver Detection sequence is described below:

Step 1. A Transmitter must start at a stable voltage prior to the detect common mode shift.

Step 2. A Transmitter changes the common mode voltage on D+ and D- consistent with meeting the $V_{TX-RCV-DETECT}$ parameter and consistent with detection of Receiver high impedance which is bounded by parameters $Z_{RX-HIGH-IMP-DC-POS}$, $Z_{RX-HIGH-IMP-DC-NEG}$ in § Table 8-12. Receiver is detected based on the rate that the lines change to the new voltage.

- a. The Receiver is not present if the voltage at the Transmitter charges at a rate dictated only by the Transmitter impedance and the capacitance of the interconnect and series capacitor.
- b. The Receiver is present if the voltage at the Transmitter charges at a rate dictated by the Transmitter impedance, the series capacitor, the interconnect capacitance, and the Receiver termination.

If the Receiver Detection circuit performs the detect sequence on each conductor of the differential pair (both D+ and D-) and detects a load impedance greater than Z_{RX-DC} on either conductor, the Receiver Detection circuit shall interpret this as no termination load present and respond as if neither load were present.

It is required that the detect sequence be performed on both conductors of a differential pair.

8.5 Channel Tolerancing §

8.5.1 Channel Compliance Testing §

This section of the specification is relevant only for those cases where a platform design comprehends the relevant channel between Transmitter device pins and Receiver device pins. These types of platform designs are called “captive channels”. Designs that are not captive channels shall refer to the appropriate form factor (CEM is one example) specification, since in this case the form factor specification takes precedence over this specification and splits the channel between two different types of components.

The key components and processes of channel tolerancing are illustrated in § Figure 8-56 and § Figure 8-57. The major difference lies in the complexity of the Behavioral Tx and Rx equalization, which depends on the data rate. 2.5 and 5.0 GT/s utilize fixed Tx presets and assume no Rx equalization, whereas 8.0, 16.0, 32.0, and 64.0 GT/s assume multi-valued, adjustable Tx presets and a combination of Rx DFE and CTLE.

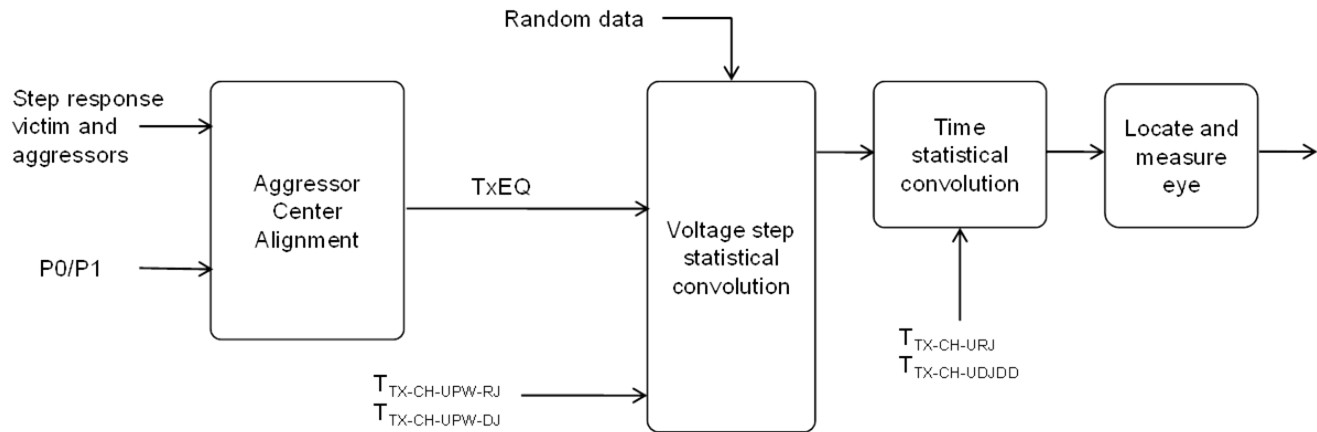

Figure 8-56 Flow Diagram for Channel Tolerancing at 2.5 and 5.0 GT/s §

The basic channel compliance approach is to first acquire the channel's characteristics, usually by means of s-parameters or equivalent model. Behavioral Tx and Rx package models are then appended to the channel model to yield a die pad to die pad topology. The model shall include both victim path and a sufficient number of aggressor paths to accurately capture channel crosstalk effects. Using the Tx voltage and jitter limits defined in the Transmitter specification section it is possible to transform these parameters to what would appear at the die pad of a Tx.

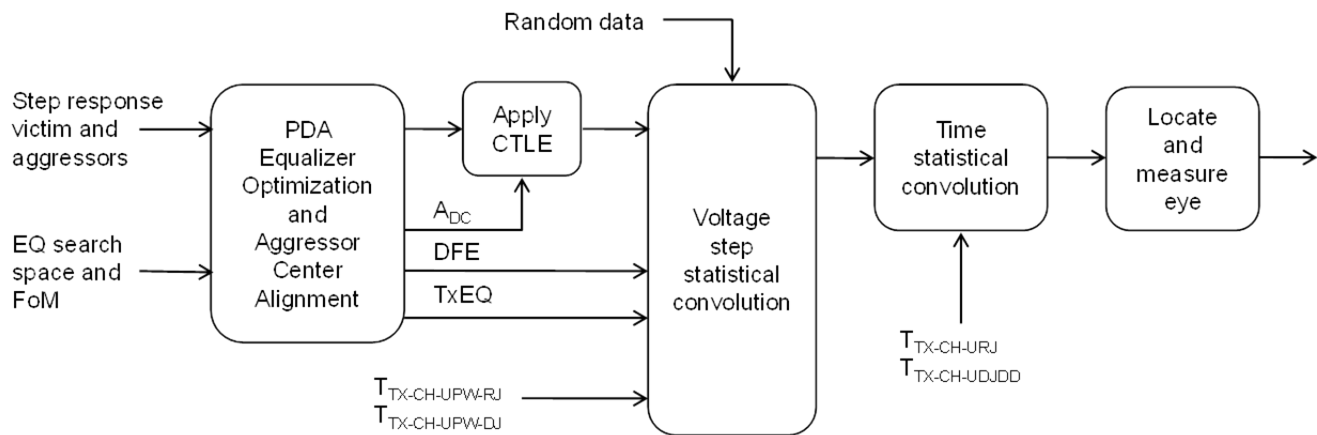

Figure 8-57 Flow Diagram for Channel Tolerancing at 8.0 and 16.0 GT/s §

The resulting model is analyzed via simulation, yielding voltage and jitter at a point equivalent to the input latch of the Receiver. The signal observed at the Receiver's latch is referenced to a recovered data clock from which an eye diagram may be constructed.

For 8.0, 16.0, 32.0, and 64.0 GT/s testing the simulation process must properly account for Tx and Rx equalization optimization as must be supported by a minimum capability Tx/Rx pair. This means the simulation process must be able to select the optimum values for the Tx presets or coefficients and Rx equalization settings based upon:

- a 1st order CTLE and a 1-tap DFE for 8.0 GT/s,
- a 1st order CTLE and a 2-tap DFE for 16.0 GT/s,

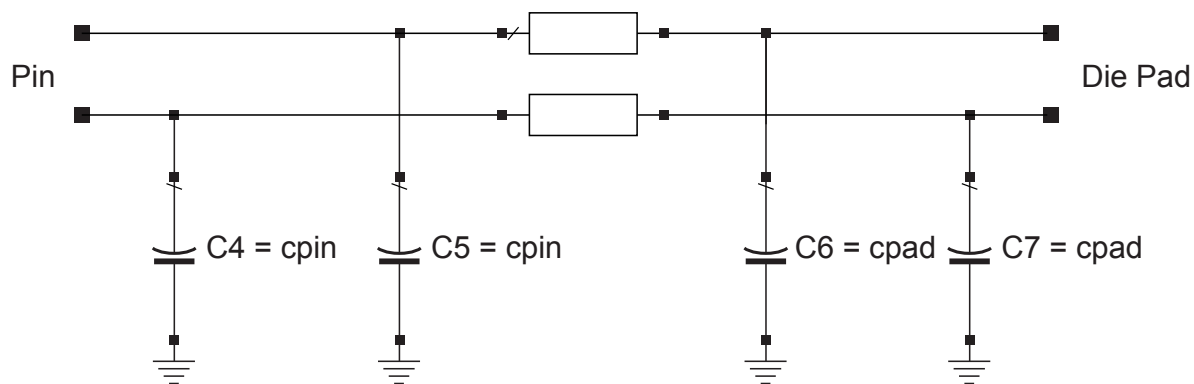

- a 2nd order CTLE and a 3-tap DFE for 32.0 GT/s, and
- a CTLE transfer function with six poles and three zeros and a 16-tap DFE for 64.0 GT/s.

8.5.1.1 Behavioral Transmitter and Receiver Package Models §

Behavioral package models are defined in this specification to represent the combined die and package loss that is expected to interoperate with the targeted range of channels. Note that at 16.0 GT/s, the behavioral packages represent a high, but not worst-case, loss for many devices. (see § Section 8.3.3.11 and § Section 8.4.1.5)

A separate pair of package models are defined for 8.0, 16.0, 32.0, and 64.0 GT/s. At 8.0 GT/s, separate package models are defined for TX and RX ports to reflect the smaller CPAD capacitance typical in most receiver implementations. At 16.0, 32.0, and 64.0 GT/s, separate package models are defined for devices containing Root Ports and all other devices to reflect the large and socketed nature of most devices containing Root Complexes. Channel testing for all three data rates typically requires testing in both directions.

The package models are included with the specification as design collateral. Each model for 8.0 and 16.0 GT/s comprehends C_{PIN} and C_{PAD} parasitic capacitances plus a differential t-line element as illustrated in § Figure 8-58.

A-0838A

Figure 8-58 Tx/Rx Behavioral Package Models §

The C_{PIN} and C_{PAD} values used in the package model generation are provided for informative purposes only.

Table 8-14 Package Model Capacitance Values §

	8.0 GT/s Tx	8.0 GT/s Rx	16.0 GT/s
C_{PIN}	0.25 pF	0.25 pF	0.25 pF
C_{PAD}	1.0 pF	0.8 pF	0.5 pF

For ease of incorporation into the post processing flow the 8.0 and 16.0 behavioral package models are specified as 4-port s-parameter files. The files are specified with port designations, frequency range and granularity as listed below. The reference impedance for the s-parameters is 50 Ω . File format is Touchstone.

A-0839A

Figure 8-59 Behavioral Tx and Rx S-Port Designation for 8.0 and 16.0 GT/s Packages §

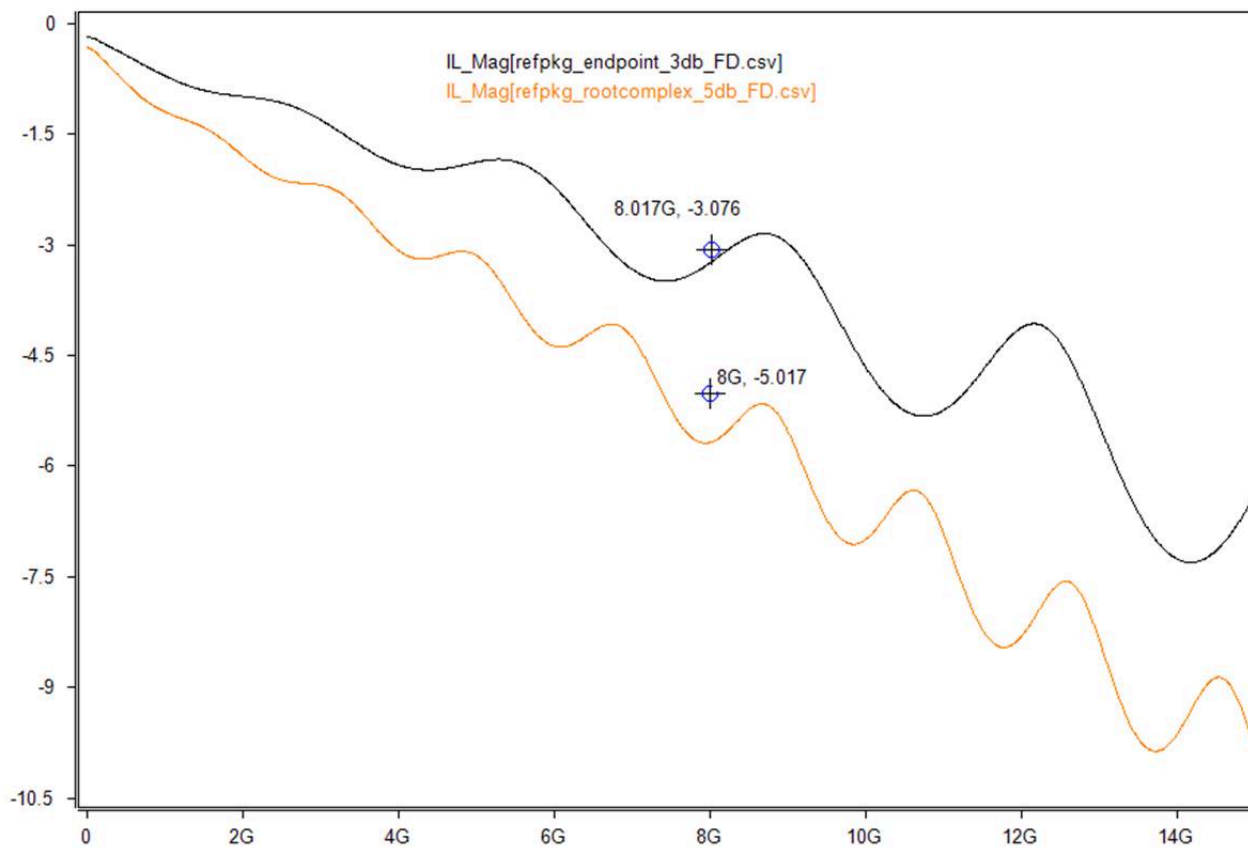

Figure 8-60 SDD21 Plots for Root and Non-Root Packages for 16.0 GT/s §

For 32.0 and 64.0 GT/s the package models are based on real package and socket models for the root package and package and BGA models for the non-root package.

For 32.0 GT/s, reference package models the die capacitive loads are included in the models. For 64.0 GT/s, the effective die cap has been replaced by the S-parameter representation of an on-die network that represents the insertion and

return loss characteristics of on-die pad for a typical design. The reference impedance for the 32.0 and 64.0 GT/s reference package model s-parameters is 50 Ω . Figures below show 32.0 and 64.8 GT/s reference package insertion loss, return loss, FEXT, and NEXT S-parameter plots based on 50 Ω impedance. To account for the on-die inductive coil DC loss of about 3 Ω , the Tx and Rx DC termination should be set to 47 Ω in 64.0 GT/s channel compliance simulations.

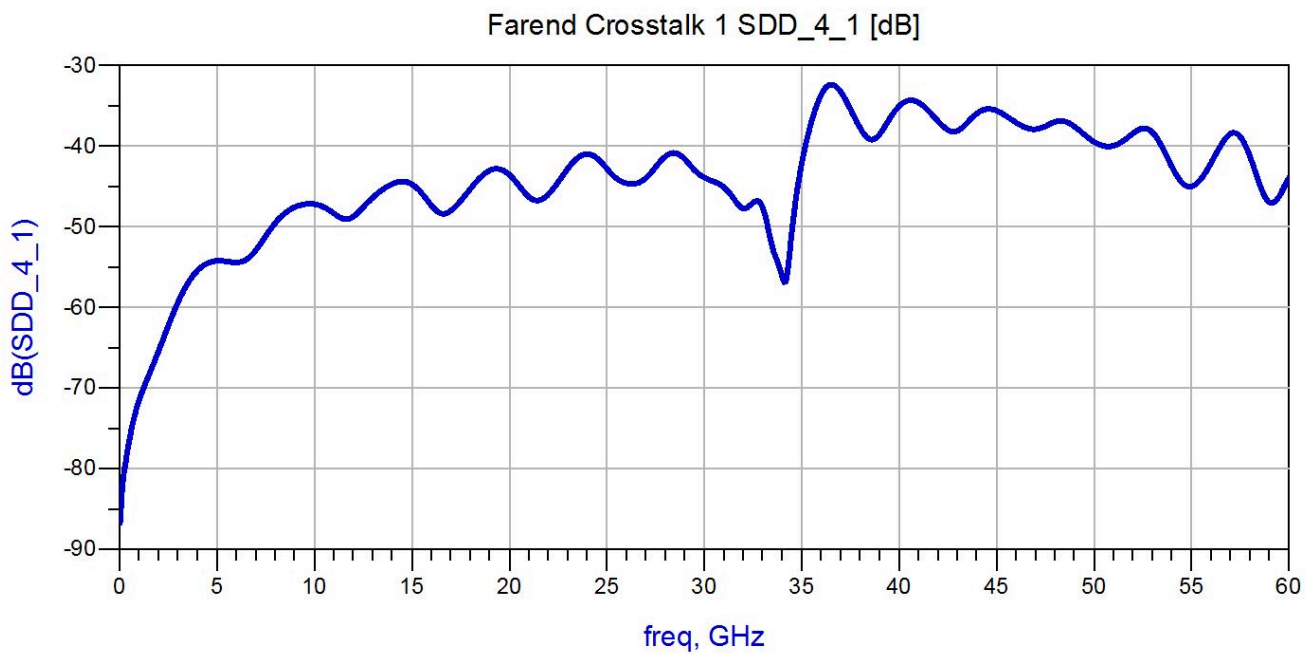

Figure 8-76 FEXT for Non-Root Reference Package (Worst Case) for 64.0 GT/s ⁵

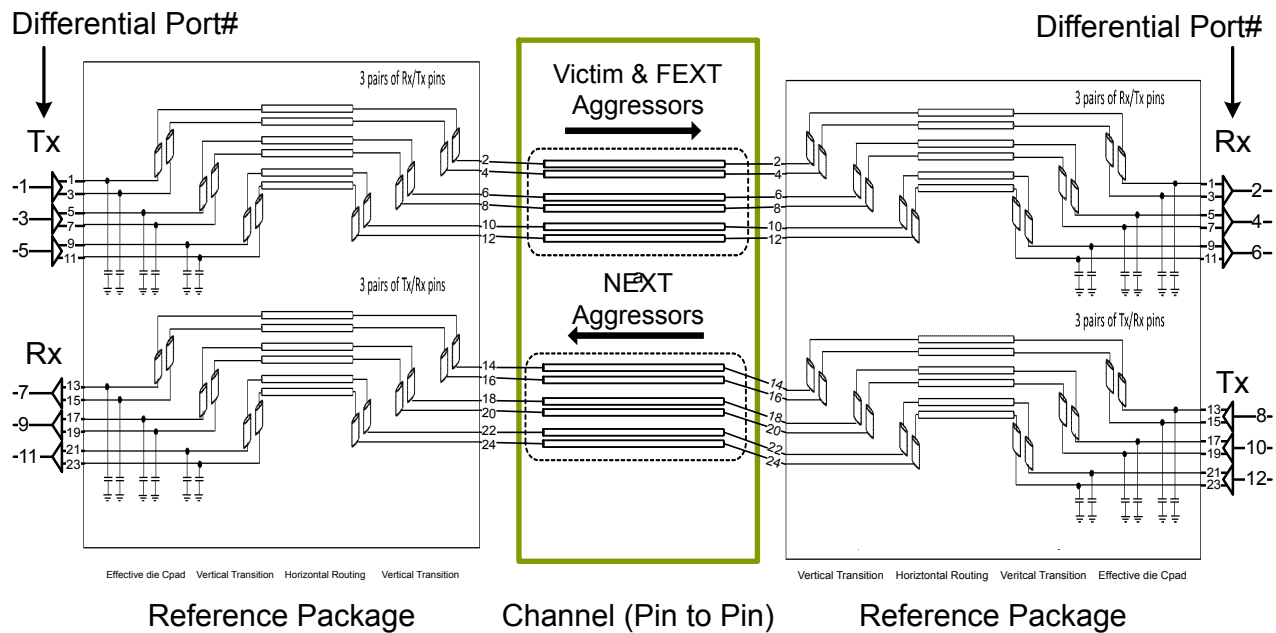

Figure 8-77 32.0 and 64.0 GT/s Reference Package Port Connections for Pin to Pin Channel Evaluation §

§ Figure 8-77 shows the port connections for using the 32.0 and 64.0 GT/s reference packages to evaluate a pin to pin channel using the channel compliance methodology. Both directions (root transmitting and non-root transmitting) must be evaluated. The lane labeled channel 3 to channel 4 is intended as the worst-case victim channel and must be evaluated in both directions. Other channels in the reference package model are intended only for use as cross-talk aggressors (not victim channels).

8.5.1.2 Measuring Package Performance (16.0 GT/s only) §

Package insertion loss at 16.0 GT/s is an informative spec parameter. Some implementations at 16.0 GT/s (see § Section 8.3.3.11) are allowed to have packages that exceed reference packages in insertion loss and/or cross-talk. Actual package performance must be assessed by performing channel compliance with reference channels provided with the specification on the PCI-SIG website. A set of channel compliance simulations are run on the reference channels with one of the reference packages being replaced by the package that is being evaluated. If the eye height or eye width is smaller for any of the channels with the package that is being evaluated, then the package is considered to have worse performance than the reference package. An implementation with a package that has worse performance than the reference package must use the implementation package model in the channel compliance methodology and may optionally use the implementation package in the Receiver stressed eye calibration. Note that form factor and channel compliance (for a captive channel) overall requirements still need to be met regardless of package characteristics.

8.5.1.3 Simulation Tool Requirements §

Channel tolerancing is implemented by means of simulation, where the pass/fail criteria are defined in terms of a time domain eye diagram. The simulation tool must accept a prescribed set of inputs, including the channel under

consideration and then simulate based upon a set of post processing requirements. This specification does not stipulate the use of any specific tool for simulating channels. However, any simulation tool must meet the following requirements.

8.5.1.3.1 Simulation Tool Chain Inputs §

- Channel characteristics defined as S-parameters or equivalent model. The model must include the victim differential Lane plus as many aggressors as required to accurately capture crosstalk. In most cases this will be between 2 and 4 additional differential Lanes. Note that 32.0 and 64.0 GT/s are most likely to require additional aggressors to accurately capture worst-case cross-talk and most likely to require several NEXT aggressors to capture crosstalk accurately.
- Behavioral Root and Non-Root package models. The models will be included as part of the specification in the form of s-parameter files (see § Section 8.5.1.1).
- Transmitter Jitter and voltage: The voltage and jitter parameters input to the simulator may be directly obtained from a combination of the Transmitter and Refclk jitter. Since these parameters are fixed the simulation tool may choose to hard code their values.
- Transmitter and Receiver Termination Impedance: The simulator shall use a $2 \times 50 \Omega$ termination for both the Transmitter and Receiver. This value matches the assumptions which are implicit in generating and measuring the stressed eye for Rx tolerancing.

8.5.1.3.2 Processing Steps §

- Time domain representation of the end-to-end connectivity: Included are the behavioral Tx and Rx packages and the channel under test.
- Tx voltage and jitter: Voltage and jitter parameters defined for the Transmitter but have been recalculated to properly comprehend high and low frequency jitter components, and also include Refclk jitter contributions.
- Behavioral Transmitter Equalization: The simulator shall replicate the Transmitter equalization capabilities defined in the Transmitter section.
- Behavioral Rx CTLE: The simulation tool shall implement a behavioral CTLE that replicates the CTLE function employed for Rx tolerancing.
- Behavioral DFE: The simulation tool shall implement a 1-tap (8.0 GT/s), a 2-tap (16.0 GT/s), a 3 tap DFE (32.0 GT/s), and a 16-tap DFE (64.0 GT/s), where the dynamic range for the feedback coefficient is defined in § Section 8.4.1.10 .
- Optimizing Tx equalization and Rx DFE/CTLE settings: The simulation tool shall implement an optimization algorithm that selects the combination of Tx equalization and Rx CTLE and DFE settings that yields a maximum value for the eye height (at the data sample point) multiplied by the eye width at the far end of the channel. For details refer to § Section 8.4.1.8 .
- Statistical Treatment of jitter: In order to avoid overestimating the effect of channel-data and channel-jitter interactions, the tool shall use a statistical analysis of these parameters to generate voltage/jitter eye margins.

8.5.1.3.3 Simulation Tool Outputs §

Output eye parameters: The simulator shall generate a statistically defined output that displays the eye width and eye height. EH will be measured as the peak eye height at the data sample location, while EW shall be measured at the zero-crossing line. Additionally the simulator shall have the capability to adjust the data sample point by ± 0.1 UI from the mean center of the UI for 8.0 and 16.0 GT/s as shown in § Figure 8-79. For 32.0 GT/s the simulator shall adjust the sample point up to 0.30 UI to the left of the mean center of the UI sample position in 0.05 UI increments, computing the

DFE coefficients for each sample location and selecting the result producing the maximum value for the eye height (at the data sample point) multiplied by the eye width. For 64.0 GT/s the simulator shall adjust the sample point up to 0.30 UI to the left of the mean center of the UI sample position in 0.015 UI increments, computing the DFE coefficients for each sample location and selecting the result producing the maximum value for the eye height (at the data sample point) multiplied by the eye width.

8.5.1.3.4 Open Source Simulation Tool §

An open source simulation tool shall be provided with the specification as design collateral. The tool will provide a turnkey capability, where the user provides the channel characteristics at the Receiver's die pad as step responses, and the tool calculates a statistical eye showing pass/fail.

8.5.1.4 Behavioral Transmitter Parameters §

8.5.1.4.1 Deriving Voltage and Jitter Parameters §

This section is for informative purposes. The voltage and jitter parameters may be derived from the Transmitter voltage and jitter parameters but are referenced to the die pad. This is necessary to allow the channel simulation to include a behavioral Tx package and drive the package from the die pads. Additionally, the Tj terms must be decomposed into separate Rj and DjDD terms.

- $V_{TX-CH-FS-NO-EQ}$ and $V_{TX-CH-RS-NO-EQ}$: These two parameters define the minimum peak-peak voltage corresponding to Vd in § Figure 8-6.
- The jitter parameters are derived based on the following set of equations. Algebraic manipulation is used to extract the Rj implicitly defined by the combination of Tj and DjDD terms. The following numbers are based on 8.0 GT/s Tx jitter parameters based on values specified in § Table 8-6. The same approach is used to extract jitter parameters for 2.5, 5.0, 16.0, 32.0, and 64.0 GT/s where it is assumed that maximum data rate supported by the PCIe 6.0 device is 64.0 GT/s and the jitter values in § Table 8-6 are used in the extraction process.

$$\begin{aligned} \text{jit_hfrj_nui} &= (T_{TX-UTJ} - T_{TX-UDJ-DD})/14.06 = 1.11\text{ps} \\ T_{TX-CH-UPW-RJ} &= (T_{TX-UPWJ-TJ} - T_{TXUPWJ-DJDD})/14.06 = 1.00\text{ps} \\ T_{TX-CH-UPW-DJ} &= T_{TXUPWJ-DJDD} = 10.0\text{ps} \\ T_{TX-CH-URJ} &= \sqrt{(\text{jit_hfrj_nui})^2 - (T_{TX-CH-UPW-RJ} * 0.707)^2 + T_{REFCLK-RMS}^2} = 1.31\text{ps} \\ T_{TX-CH-UDJDD} &= T_{TX-UDJ-DD} - (T_{TXUPWJ-DJDD})/2 = 7.00\text{ps} \end{aligned}$$

A-0840A

Figure 8-78 Example Derivation of 8.0 GT/s Jitter Parameters for § Table 8-15 §

A channel must be tested at all data rates, with the corresponding Tx jitter parameters, that it is intended to support during normal operation. For example, a channel intended to support a maximum data rate of 8.0 GT/s must be tested at 2.5, 5.0, and 8.0 GT/s.

Table 8-15 Jitter/Voltage Parameters for Channel Tolerancing §

Symbol	Parameter	Value	Units	Notes
$V_{TX-CH-FS-NO-EQ}$	Full swing Tx voltage	804	mVPP	Full swing, No Tx Eq.

Symbol	Parameter	Value	Units	Notes
<i>V_{TX-CH-RS-NO-EQ}</i>	Reduced swing Tx voltage	402	mVPP	Reduced swing, No Tx Eq.

2.5 GT/s Jitter Parameters and Voltage Parameters

<i>T_{TX-CH-URJ-2.5G}</i>	Tx uncorrelated Rj	3.45	ps RMS	See Note 1
<i>T_{TX-CH-UDJDD-2.5G}</i>	Tx uncorrelated DjDD	20	ps PP	
<i>T_{TX-CH-UPW-RJ-2.5G}</i>	Uncorrelated PW Rj	1.42	ps RMS	See Note 2
<i>T_{TX-CH-UPW-DJ-2.5G}</i>	PW DDj	80	ps PP	
<i>T_{TX-DIEPAD-EDGERATE-2.5G}</i>	Signal edge rate at behavioral Tx die pad	140	ps	Measured 10% to 90% using a gaussian lowpass filter to shape the edge. See Note 3.

5.0 GT/s Jitter Parameters and Voltage Parameters

<i>T_{TX-CH-URJ-5G}</i>	Tx uncorrelated Rj	3.45	ps RMS	See Note 1
<i>T_{TX-CH-UDJDD-5G}</i>	Tx uncorrelated DjDD	20-	ps PP	
<i>T_{TX-CH-UPW-RJ-5G}</i>	Uncorrelated PW Rj	1.42	ps RMS	
<i>T_{TX-CH-UPW-DJ-5G}</i>	PW DDj	40	ps PP	See Note 2.
<i>T_{TX-DIEPAD-EDGERATE-5G}</i>	Signal edge rate at behavioral Tx die pad	70	ps	Measured 10% to 90% using a gaussian lowpass filter to shape the edge. See Note 3.

8.0 GT/s Jitter Parameters and Voltage Parameters

<i>T_{TX-CH-URJ-8G}</i>	Tx uncorrelated Rj	1.31	ps RMS	No DDj of HF jitter. See Note 1.
<i>T_{TX-CH-UDJDD-8G}</i>	Tx uncorrelated DjDD	7.0	ps PP	No DDj of HF jitter
<i>T_{TX-CH-UPW-RJ-8G}</i>	Uncorrelated PW Rj	1.0	ps RMS	
<i>T_{TX-CH-UPW-DJ-8G}</i>	PW DDj	10	ps PP	See Note 2.
<i>T_{TX-DIEPAD-EDGERATE-8G}</i>	Signal edge rate at behavioral Tx die pad	43.75	ps	Measured 10% to 90% using a gaussian lowpass filter to shape the edge. See Note 3.

16.0 GT/s Jitter Parameters and Voltage Parameters

<i>T_{TX-CH-URJ-16G}</i>	Tx uncorrelated Rj	0.71	ps RMS	See Note 1.
<i>T_{TX-CH-UDJDD-16G}</i>	Tx uncorrelated DjDD	3.75	ps PP	
<i>T_{TX-CH-UPW-RJ-16G}</i>	Uncorrelated PW Rj	0.54	ps RMS	
<i>T_{TX-CH-UPW-DJ-16G}</i>	PW DDj	5.0	ps PP	See Note 2.
<i>T_{TX-DIEPAD-EDGERATE-16G}</i>	Signal edge rate at behavioral Tx die pad	21.875	ps	Measured 10% to 90% using a gaussian lowpass filter to shape the edge. See Note 3.

Symbol	Parameter	Value	Units	Notes
32.0 GT/s Jitter Parameters and Voltage Parameters				
$T_{TX-CH-URJ-32G}$	Tx uncorrelated Rj	0.276	ps RMS	See Note 1.
$T_{TX-CH-UDJDD-32G}$	Tx uncorrelated DjDD	1.875	ps PP	
$T_{TX-CH-UPW-RJ-32G}$	Uncorrelated PW Rj	0.27	ps RMS	
$T_{TX-CH-UPW-DJ-32G}$	PW DDj	2.5	ps PP	See Note 2.
$T_{TX-DIEPAD-EDGERATE-32G}$	Signal edge rate at behavioral Tx die pad	10.94	ps	Measured 10% to 90% using a gaussian lowpass filter to shape the edge. See Note 3.

64.0 GT/s Jitter Parameters and Voltage Parameters				
$T_{TX-CH-URJ-64G}$	Tx uncorrelated Rj	0.215	ps RMS	See Note 1.
$T_{TX-CH-UDJDD-64G}$	Tx uncorrelated DjDD	0.938	ps PP	
$T_{TX-CH-UPW-RJ-64G}$	Uncorrelated PW Rj	0.289	ps RMS	
$T_{TX-CH-UPW-DJ-64G}$	PW DDj	1.25	ps PP	See Note 2.
$T_{TX-DIEPAD-EDGERATE-64G}$	Signal edge rate at behavioral Tx die pad	10.94	ps	Measured 10% to 90% using a gaussian lowpass filter to shape the edge. See Note 3.

Notes:

1. Includes low frequency (non F/2) Rj components from the Transmitter and Rj from the Refclk.
2. Applied on a per edge basis as a dual Dirac model.
3. Does not include parasitic die pad capacitance. See § Figure 8-58 for details of behavioral package.

8.5.1.4.2 Optimizing Tx/Rx Equalization (8.0, 16.0, 32.0, and 64.0 GT/s only) §

The behavioral receiver selects the combination of Transmitter Equalization, CTLE, DFE and sample location (32.0 and 64.0 GT/s only) that produces the optimal eye area (eye width multiplied by eye height).

8.5.1.4.3 Pass/Fail Eye Characteristics §

The output of the simulation tool shall be in the form of pass/fail characteristics as defined by an eye mask as shown in § Figure 8-79. EH and EW must meet respectively the voltage and jitter parameters defined in § Table 8-16. Eye margins are defined at the die pad of the Receiver after the appropriate Tx and Rx equalization algorithms have been applied. In the case where the channel is being designed for a specific pair of silicon devices and the package models of these silicon devices including cross-talk aggressors are known the actual device packages may be used instead of the reference packages in running the pad to pad channel pass/fail compliance simulations.

A-0841A

Figure 8-79 EH, EW Mask §

Note that the pass/fail EH and EW limits shown in § Figure 8-79 are identical to the limits defined for Rx testing in § Table 8-11 for 8.0 and 16.0 GT/s. For 32.0 and 64.0 GT/s, the pass/fail EH and EW limits are still identical but they are computed at the optimal sample location. For 2.5 and 5.0 GT/s the limits for Rx testing are referenced to the package pins and the limits for channel tolerancing in this table are referenced to the Receiver pad after applying the same reference package used for 8.0 GT/s channel tolerancing.

Table 8-16 Channel Tolerancing Eye Mask Values §

Symbol	Parameter	Value	Units	Comments
2.5 GT/s Eye Margins				
$V_{RX-CH-EH-2.5G}$	Eye height	<130 (min)	mVPP	Eye height at BER=10 ⁻¹² . Note 1
$T_{RX-CH-EW-2.5G}$	Eye width at zero-crossing	<0.35 (min)	UI	Eye width at BER=10 ⁻¹²
$T_{RX-DS-OFFSET-2.5G}$	Peak EH offset from UI center	±0.1	UI	See § Figure 8-79 for details.
5.0 GT/s Eye Margins				
$V_{RX-CH-EH-5G}$	Eye height	< 85 (min)	mVPP	Eye height at BER=10 ⁻¹² . Note 1
$T_{RX-CH-EW-5G}$	Eye width at zero-crossing	<0.30 (min)	UI	Eye width at BER=10 ⁻¹²
$T_{RX-DS-OFFSET-5G}$	Peak EH offset from UI center	±0.1	UI	See § Figure 8-79 for details.
8.0 GT/s Eye Margins				

Symbol	Parameter	Value	Units	Comments
<i>V_{RX-CH-EH-8G}</i>	Eye height	25 (min)	mVPP	Eye height at BER=10 ⁻¹² . Note 1.
<i>T_{RX-CH-EW-8G}</i>	Eye width at zero-crossing	0.3 (min)	<u>UI</u>	Eye width at BER=10 ⁻¹²
<i>T_{RX-DS-OFFSET-8G}</i>	Peak EH offset from <u>UI</u> center	±0.1	<u>UI</u>	See § Figure 8-79 for details.
<i>V_{RX-DFE-D1-8G}</i>	Range for DFE d ₁ coefficient	±30	mV	

16.0 GT/s Eye Margins

<i>V_{RX-CH-EH-16G}</i>	Eye height	15 (min)	mVPP	Eye height at BER=10 ⁻¹² . Note 1.
<i>T_{RX-CH-EW-16G}</i>	Eye width at zero-crossing	0.3 (min)	<u>UI</u>	Eye width at BER=10 ⁻¹²
<i>T_{RX-DS-OFFSET-16G}</i>	Peak EH offset from <u>UI</u> center	±0.1	<u>UI</u>	See § Figure 8-79 for details.
<i>V_{RX-DFE-D1-16G}</i>	Range for DFE d ₁ coefficient	±30	mV	
<i>V_{RX-DFE-D2-16G}</i>	Range for DFE d ₂ coefficient	±20	mV	

32.0 GT/s Eye Margins

<i>V_{RX-CH-EH-32G}</i>	Eye height	15 (min)	mVPP	Eye height at BER=10 ⁻¹² . Note 1.
<i>T_{RX-CH-EW-32G}</i>	Eye width at zero-crossing	0.3 (min)	<u>UI</u>	Eye width at BER=10 ⁻¹²
<i>T_{RX-DS-OFFSET-32G}</i>	Peak EH offset from <u>UI</u> center	N/A	<u>UI</u>	See § Figure 8-79 for details.
<i>T_{RX-SAMPLE-OFFSET-32G}</i>	Max sample location offset to the left from <u>UI</u> center	0.30	<u>UI</u>	Note 2
<i>T_{RX-SAMPLE-GRANULARITY-32G}</i>	Granularity for sample location offset	0.05	<u>UI</u>	Note 2
<i>V_{RX-DFE-D1-32G}</i>	Range for DFE d ₁ coefficient	d ₁ / d ₀ (cursor amplitude) ≤ 0.8		
<i>V_{RX-DFE-D2-32G}</i>	Range for DFE d ₂ coefficient	±20	mV	
<i>V_{RX-DFE-D3-32G}</i>	Range for DFE d ₃ coefficient	±20	mV	

64.0 GT/s Eye Margins

Symbol	Parameter	Value	Units	Comments
<i>V_{RX-CH-TOP-EH-64G}</i>	Top Eye height	6 (min)	mVPP	Eye height at BER=10 ⁻⁶ . Note 1.
<i>T_{RX-CH-TOP-EW-64G}</i>	Top Eye width at zero-crossing	0.1 (min)	UI	Eye width at BER=10 ⁻⁶
<i>T_{RX-DS-OFFSET-64G}</i>	Peak EH offset from UI center	N/A	UI	
<i>T_{RX-SAMPLE-OFFSET-64G}</i>	Max sample location offset to the left from UI center	0.30	UI	Note 2
<i>T_{RX-SAMPLE-GRANULARITY-64G}</i>	Granularity for sample location offset	0.015	UI	Note 2
<i>V_{RX-DFE-D1-64G}</i>	Range for DFE d1 coefficient	$ d_1 / d_0$ (cursor amplitude) < 0.55		
<i>V_{RX-DFE-TAPS-WEIGHTED-SUM-64G}</i>	Range for weighted sum of absolute values of DFE d1-d16 coefficients	$(d_1 + d_2 + 0.85 \times d_3 + 0.6 \times d_4 + 0.25 \times d_5 + 0.1 \times d_6 + 0.05 \times \{ d_7 + d_8 + d_9 + d_{10} + d_{11} + d_{12} + d_{13} + d_{14} + d_{15} + d_{16} \}) / d_0 < 0.85$	mV	

Notes:

1. ***V_{RX-CH-EH}*** is defined as max EH within an aperture of ± 0.1 UI from mean UI center.
2. The optimal eye area is computed at each offset from mean UI center -0.30 UI to mean UI center with the specified granularity.

8.5.1.4.4 Characterizing Channel Common Mode Noise §

A channel must meet the common mode requirements as they are defined in the receiver specification. In general, it is not possible to accurately simulate all the channel's common mode noise contributions due to the large number of mechanisms that can generate CM noise, including the Transmitter. Typically channel common mode noise is a budgeted parameter, and the limits defined below assume a budgeting process. The channel's CM limit is defined as the amount of CM noise that a channel can add and still meet the Rx CM limits assuming the worst-case Tx CM.

Note that the Tx and channel CM noise parameters cannot simply be added to obtain the Rx CM limit. This is due to the fact that a channel will attenuate some of high frequency Tx CM noise while propagating Tx LF CM noise through with little loss. The channel may also contribute both high and low frequency CM components of its own.

8.5.1.4.5 Verifying $V_{CH-IDLE-DET-DIFF-pp}$ §

$V_{CH-IDLE-DET-DIFF-pp}$ is defined to guarantee that, when a Transmitter issues an EIEOS sequence, the Receiver is guaranteed to detect it. Potentially larger Transmitter equalization boost ratios at 8.0, 16.0, 32.0, and 64.0 GT/s necessitate that this parameter be verified; this procedure was not necessary for 2.5 or 5.0 GT/s, where the max Transmitter equalization boost is smaller. Defining the launch and detect voltages at the Tx/Rx die pad permits $V_{CH-IDLE-DET-DIFF-pp}$ to be verified with the same channel and Tx/Rx package models used to determine eye margins. It is also acceptable to simulate from Tx pin to Rx pin (excluding the Tx and Rx behavioral package models), in which case the EIEOS and idle detect parameters defined in the Tx and Rx sections are applicable.

Long channels, where $V_{TX-EIEOS-FS}$ is applicable, are characterized by driving the channel under test with the EIEOS pattern and -11.0 dB de-emphasis and zero dB preshoot. For short channels, where $V_{TX-EIEOS-RS}$ is applicable, -4.5 dB of de-emphasis and zero dB of preshoot are applied.

Table 8-17 EIEOS Signaling Parameters §

Parameter	Description	Value	Units	Comments
$V_{CH-IDLE-EXIT-pp}$	Idle detect voltage seen at the Rx die pad	172	mVPP	Assuming Rx RTERM of $2 \times 50 \Omega$
$V_{CH-EIEOS-FS-vb}$	PP voltage during Vb interval at behavioral Tx die pad for full swing signaling	255	mVPP	Assuming Tx RS of $2 \times 50 \Omega$
$V_{CH-EIEOS-RS-vb}$	PP voltage during Vb interval at behavioral Tx die pad for reduced swing signaling	237	mVPP	Assuming Tx RS of $2 \times 50 \Omega$

8.6 Refclk Specifications §

This version of the specification consolidates and streamlines the Refclk requirements. The 2.5 GT/s Refclk parameters are moved from the CEM spec to this spec so that all Refclk parameters for all data rates (2.5, 5.0, 8.0, 16.0, 32.0, and 64.0 GT/s) are now contained in this section.

8.6.1 Refclk Test Setup §

The test setup for the Refclk assumes that only the Refclk generator itself is present. Provision is made in the test setup to account for signal degradation that occurs between the pins of the Refclk generator and the Transmitter or Receiver in an actual system. The above described setup emulates the worst case signal degradation that is likely to occur at the pins of a PCI Express device. Note that the Refclk signal is tested into a load that represents the series (open) termination appearing at the Refclk input pins of a PCIe device for all requirements except 32.0 and 64.0 GT/s reference clock jitter. For 32.0 and 64.0 GT/s, the reference clock jitter is measured with an oscilloscope, and is tested with the reference clock terminated by 50 Ohm terminations without a channel.

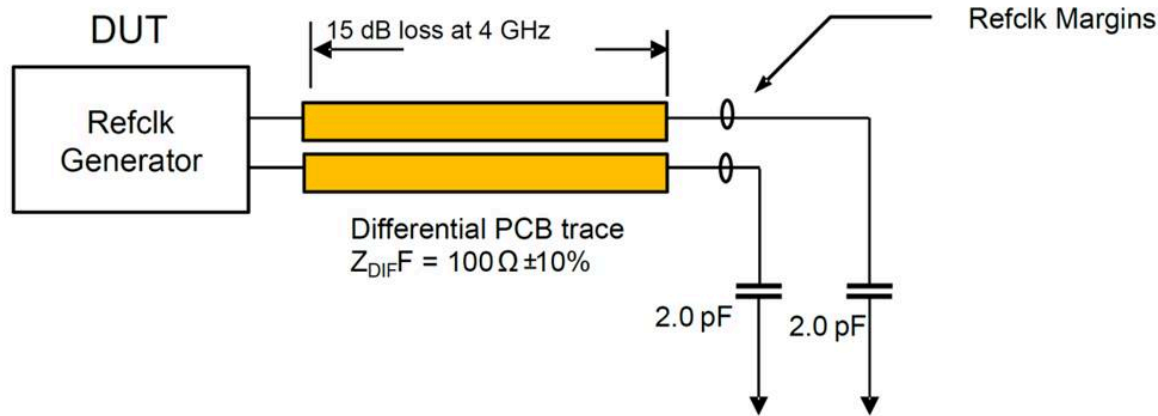

Figure 8-80 Oscilloscope Refclk Test Setup for All Cases Except Jitter at 32.0 and 64.0 GT/s §

8.6.2 REFCLK AC Specifications §

All specifications in § Table 8-18 are to be measured using a test configuration as described in Note 11 with a circuit as shown in § Figure 8-80.

Table 8-18 REFCLK DC Specifications and AC Timing Requirements §

Symbol	Parameter	100 MHz Input		Unit	Note
		Min	Max		
Rising Edge Rate	Rising Edge Rate	0.6	4.0	V/ns	2, 3
Falling Edge Rate	Falling Edge Rate	0.6	4.0	V/ns	2, 3
V_{IH}	Differential Input High Voltage	+150		mV	2
V_{IL}	Differential Input Low Voltage		-150	mV	2
V_{CROSS}	Absolute crossing point voltage	+250	+550	mV	1, 4, 5
V_{CROSS DELTA}	Variation of <u>V_{CROSS}</u> over all rising clock edges		+140	mV	1, 4, 9
V_{RB}	Ring-back Voltage Margin	-100	+100	mV	2, 12
T_{STABLE}	Time before <u>V_{RB}</u> is allowed	500		ps	2, 12
T_{PERIOD AVG}	Average Clock Period Accuracy	-300	+2800	ppm	2, 10, 13
T_{PERIOD AVG_32G_64G_CC}	Average Clock Period Accuracy for devices that support 32.0 and 64.0 GT/s in CC Mode at any speed	-100	+2600	ppm	2, 10, 13

Symbol	Parameter	100 MHz Input		Unit	Note
		Min	Max		
<i>T_{PERIOD}</i> <i>AVG_32G_64G_SRIS</i>	Average Clock Period Accuracy for devices that support 32.0 and 64.0 GT/s in SRIS Mode at any speed	-100	+1600	ppm	2, 10, 13
<i>T_{PERIOD}</i> <i>ABS</i>	Absolute Period (including Jitter and Spread Spectrum modulation)	9.847	10.203	ns	2, 6
<i>T_{PERIOD}</i> <i>ABS_32G_64G_CC</i>	Absolute Period (including Jitter and Spread Spectrum modulation) for devices that support 32.0 and 64.0 GT/s in CC Mode at any speed	9.849	10.201	ns	2, 6
<i>T_{PERIOD}</i> <i>ABS_32G_64G_SRIS</i>	Absolute Period (including Jitter and Spread Spectrum modulation) for devices that support 32.0 and 64.0 GT/s in SRIS Mode at any speed	9.849	10.181	ns	2, 6
<i>T_{CCJITTER}</i>	Cycle to Cycle jitter		150	ps	2
<i>V_{MAX}</i>	Absolute Max input voltage		+1.15	V	1, 7
<i>V_{MIN}</i>	Absolute Min input voltage		-0.3	V	1, 8
<i>Duty Cycle</i>	Duty Cycle	40	60	%	2
<i>Rise-Fall Matching</i>	Rising edge rate (REFCLK+) to falling edge rate (REFCLK-) matching		20	%	1, 14
<i>Z_{C-DC}</i>	Clock source DC impedance	40	60	Ω	1, 11

Notes:

1. Measurement taken from single ended waveform.
2. Measurement taken from differential waveform.
3. Measured from -150 mV to +150 mV on the differential waveform (derived from REFCLK+ minus REFCLK-). The signal must be monotonic through the measurement region for rise and fall time. The 300 mV measurement window is centered on the differential zero-crossing. See § Figure 8-85.
4. Measured at crossing point where the instantaneous voltage value of the rising edge of REFCLK+ equals the falling edge of REFCLK-. See § Figure 8-81.
5. Refers to the total variation from the lowest crossing point to the highest, regardless of which edge is crossing. Refers to all crossing points for this measurement. See § Figure 8-81.
6. Defines as the absolute minimum or maximum instantaneous period. This includes cycle to cycle jitter, relative PPM tolerance, and spread spectrum modulation. See § Figure 8-84.
7. Defined as the maximum instantaneous voltage including overshoot. See § Figure 8-81.
8. Defined as the minimum instantaneous voltage including undershoot. See § Figure 8-81.
9. Defined as the total variation of all crossing voltages of Rising REFCLK+ and Falling REFCLK-. This is the maximum allowed variance in V_{CROSS} for any system. See § Figure 8-82.
10. Note deleted.
11. REFCLK+ and REFCLK- are to be measured at the load capacitors C_L . Single ended probes must be used for measurements requiring single ended measurements. Either single ended probes with math or differential probe can be used for differential measurements. Test load $C_L = 2$ pF.
12. T_{STABLE} is the time the differential clock must maintain a minimum ± 150 mV differential voltage after rising/falling edges before it is allowed to droop back into the $V_{RB} \pm 100$ mV differential range. See § Figure 8-86.

Symbol	Parameter	100 MHz Input		Unit	Note
		Min	Max		

13. PPM refers to parts per million and is a DC absolute period accuracy specification. 1 PPM is 1/1,000,000th of 100.000000 MHz exactly or 100 Hz. For example, for 300 PPM, then we have an error budget of 100 Hz/PPM × 300 PPM = 30 kHz. The period is to be measured with a frequency counter with measurement window set to 100 ms or greater.
14. Matching applies to rising edge rate for REFCLK+ and falling edge rate for REFCLK-. It is measured using a ±75 mV window centered on the median cross point where REFCLK+ rising meets REFCLK- falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations. The Rise Edge Rate of REFCLK+ should be compared to the Fall Edge Rate of REFCLK-; the maximum allowed difference should not exceed 20% of the slowest edge rate. See § Figure 8-83.

8.6.3 Data Rate Independent Refclk Parameters §

A number of Refclk parameters are data rate independent and are listed in the table below. $T_{\text{TRANSPORT-DELAY}}$ is defined in § Section 8.6.6 and illustrated in § Figure 8-89. It is relevant only for the Common Refclk architecture. For the SRIS mode the source of the SSC modulation is implementation dependent.

Table 8-19 Data Rate Independent Refclk Parameters §

Symbol	Description	Limits	Units	Notes
F_{REFCLK}	Refclk Frequency	99.97 (min) 100.03 (max)	MHz	
$F_{\text{REFCLK_32G_64G}}$	Refclk Frequency for devices that support 32.0 and 64.0 GT/s	99.99 (min) 100.01 (max)	MHz	
F_{SSC}	SSC frequency range	30 (min) 33 (max)	kHz	3
$T_{\text{SSC-FREQ-DEVIATION}}$	SSC deviation	-0.5 (min) 0.0 (max)	%	3
$T_{\text{SSC-FREQ-DEVIATION_32G_64G_SRIS}}$	SSC deviation for devices that support 32.0 and 64.0 GT/s and SRIS when operating in SRIS mode at all speeds	-0.3 (min) 0.0 (max)	%	3
$T_{\text{TRANSPORT-DELAY}}$	Tx-Rx transport delay	12 (max)	ns	1, 4
$T_{\text{SSC-MAX-FREQ-SLEW}}$	Max SSC df/dt	1250	ppm/ μ s	2, 3

Notes:

- Parameter is relevant only for Common Refclk architecture.
- Measurement is made over 0.5 μ s time interval with a 1st order LPF with an f_c of 60x the modulation frequency.

Symbol	Description	Limits	Units	Notes
	3. When testing the a device configured for the IR reference clock architecture the SSC related parameters must be tested with the Tx output data instead of the reference clock.			
	4. There are form factors (for example topologies including long cables) that may exceed the transport delay limit. Extra jitter from the large transport delay must be accounted by these form factor specifications.			

8.6.3.1 Low Frequency Refclk Jitter Limits §

Refclks supporting SSC must meet an additional jitter limit over a range of low frequencies. Low frequency Refclk jitter limits are defined as a continuous, piece-wise linear graph from 30 kHz to 500 kHz as shown below. Unfiltered Refclk phase jitter must fall below this graph over the frequency range of interest.

Figure 8-87 Limits for phase jitter from the Reference with 5000 ppm SSC §

8.6.4 Refclk Architectures Supported §

Two Refclk architectures are supported: **Common Refclk (CC)** and **Independent Refclk (IR)**. The CC clock architecture is described in terms of its topology and its corresponding jitter transfer function based on PLL and CDR characteristics. Finally, the corresponding Refclk jitter limits are given for each data rate. The jitter transfer function and corresponding

jitter limits are not defined for the IR clock architecture. It is up to the implementer to trade off reference clock jitter and PLL characteristics to ensure that Transmitter requirements are met in the IR clocking mode.

8.6.5 Filtering Functions Applied to Raw Data §

Two types of filtering are applied to the raw Refclk data. The first, edge filtering, minimizes the measurement-induced jitter due to the finite sampling rate of the test equipment. The second, replicates the jitter filtering that is inherent in the combination of Tx/Rx PLLs, the Rx CDR and (where applicable) the transport delay. The combination of the preceding filter functions yields the effective Refclk jitter as it appears at the sample latch of the Receiver.

Note that the PLL and CDR filter functions represent minimally capable approximations to actual Receiver implementations and are not intended to define actual PLL or CDR implementations.

8.6.5.1 PLL Filter Transfer Function Example §

All PLLs are behaviorally modeled with a second order transfer function, $H(s)$, as defined in § Figure 8-89. The parameters defining the transfer function include the damping factor ζ and the natural frequency ω_n .

The relation between the 2nd order PLL (lowpass) natural frequency, ω_n and the 3 dB point ω_{3dB} , is given by the following expression:

$$\frac{\omega_{3dB}}{\omega_n} = \sqrt{\sqrt{\left(\left(2\zeta^2 + 1\right)^2 + 1\right)} + 2\zeta^2 + 1}$$

Equation 8-16 Relationship between 2nd order PLL natural frequency and 3 dB point §

The following plot of a 2nd order PLL illustrates the transfer function with an f_{3dB} of 5.0 MHz and 1.0 dB of peaking. This corresponds to $\zeta = 1.15$, and $\omega_n = 11.55$ Mrad/sec.

Figure 8-88 5 MHz PLL Transfer Function Example §

8.6.5.2 CDR Transfer Function Examples §

Depending on the Refclk architecture and data rate, either a first or higher order transfer function shall be used as a behavioral CDR bounding limit.

For behavioral CDR functions refer to § Section 8.3.5.5

8.6.6 Common Refclk Rx Architecture (CC) §

This architecture utilizes a single Refclk source that is distributed to both the Tx and Rx. Most of the SSC jitter sourced by the Refclk is propagated equally through Tx and Rx PLLs, and so intrinsically tracks LF jitter. This is particularly true for SSC which tends to be low frequency. § Figure 8-89 illustrates the Common Refclk Rx architecture, showing key jitter, delay, and PLL and CDR transfer function sources for all data rates except 32.0 and 64.0 GT/s. At 32.0 and 64.0 GT/s the only difference in the figure is Behavioral CDR transfer function as defined in § Section 8.3.5.5. The amount of jitter appearing at the CDR is then defined by the difference function between the Tx and Rx PLLs multiplied by the CDR highpass characteristic.

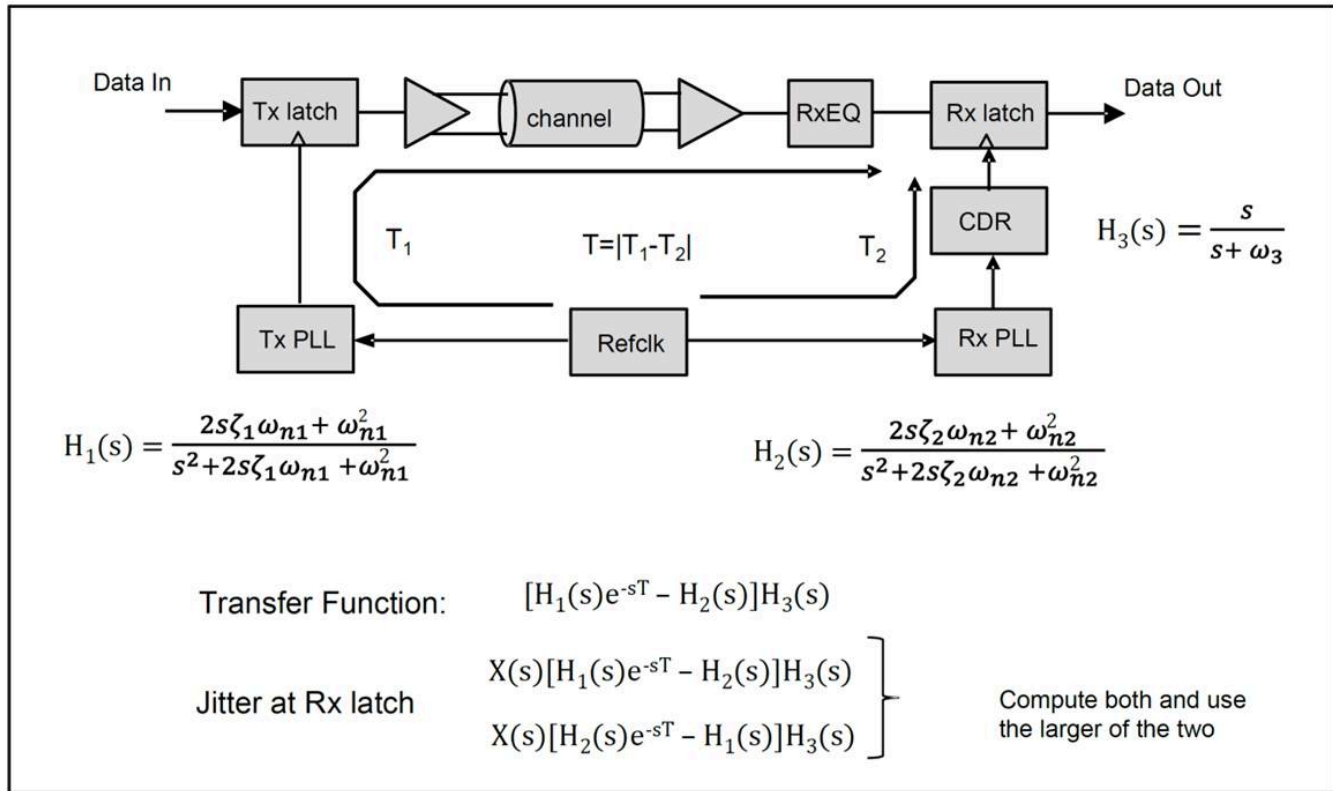

Figure 8-89 Common Refclk Rx Architecture for all Data Rates Except 32.0 and 64.0 GT/s §

Based on the above clock architecture, it is possible to define a difference function that corresponds to the worst case mismatch between Tx and Rx PLLs. Second order PLL transfer functions are assumed, (even though most PLL transfer functions are 3rd order or higher), since a 2nd order function tends to yield a slightly conservative difference function vis-a-vis most actual PLL implementations.

In the Common Refclk Rx architecture it is also necessary to comprehend a maximum Transmitter to Receiver transport delay difference. This delay delta is illustrated in § Figure 8-89 and represents the delay difference between the Transmitter data and recovered Receiver clock as seen at the inputs to the receiver's data latch.

8.6.6.1 Determining the Number of PLL BW and peaking Combinations §

A Tx or Rx PLL is defined by the combination of min/max bandwidth and peaking, making for a total of four possible limits. In the CC architecture both the Tx and Rx PLLs contribute to the jitter transfer function. At 2.5 GT/s only one set of BW/peaking limits is defined. If the combinations for the Tx and Rx PLLs limits are defined by the sets $(A_{TX}, B_{TX}, C_{TX}, D_{TX})$, $(A_{RX}, B_{RX}, C_{RX}, D_{RX})$ then it's easily demonstrated that there are a total of ten ways of selecting one element from each set. The delay term e^{-sT} can be applied to either $H_1(s)$ or $H_2(s)$, adding another six possibilities. Only six, as opposed to ten, terms are added when the delay term is considered because terms like A_{TX}, A_{RX} , are identical to A_{RX}, A_{TX} .

At 5.0 GT/s and higher data rates, two possible sets of limits of PLL bandwidth and peaking are defined, which may be defined by the sets $(A_{TX}, B_{TX}, C_{TX}, D_{TX})$ and $(E_{RX}, F_{RX}, G_{RX}, H_{RX})$. In this case the number of unique 2-element combinations from the above 4-element sets is 36, which increases to 64 when the delay term is considered.

8.6.6.2 CDR and PLL BW and Peaking Limits for Common Refclk §

The Common Refclk architecture filter function is dependent on the difference function defined by the BW and peaking of Tx and the Rx PLLs, plus the CDR high-pass characteristic. It is necessary to consider all corner case combinations of Tx and Rx PLL peaking and bandwidth plus the CDR characteristics at their minimum and maximum peaking values.

This procedure must be applied to all six data rates.

§ Figure 8-90 lists the PLL BW and CDR BW/peaking values that need to be applied as filter functions for 2.5 GT/s data rates. It is necessary to assign a min and a max value for peaking for the 2.5 GT/s PLL. The values of 0.01 dB and 3.0 dB represent best estimates of realistic PLL implementations.

The minimum peaking for 2.5 and 5.0 GT/s has been reduced to 0.01 dB to bring it into line with the 8.0 and 16.0 GT/s cases. Note that the Rx CDR is 1st order, so its natural frequency, ω_n can be directly obtained from its BW, unlike the 2nd order CDRs, where ω_n is a function of both BW and peaking. For 32.0 GT/s, a 2nd-order CDR filter with 20 MHz BW described by § Equation 8-13 must be used.

PLL #1, PLL #2	0.01 dB peaking	3.0 dB peaking	<div style="border: 1px solid black; padding: 2px;"> $BW_{CDR}(\min) = 1.5$ MHz, 1st order </div> CDR
$BW_{PLL}(\min) = 1.5$ MHz	$\omega_{n1} = .336$ Mrad/s $\zeta_1 = 14$	$\omega_{n1} = 5.09$ Mrad/s $\zeta_1 = 0.54$	
$BW_{PLL}(\max) = 22$ MHz	$\omega_{n1} = 4.93$ Mrad/s $\zeta_1 = 14$	$\omega_{n1} = 74.68$ Mrad/s $\zeta_1 = 0.54$	
16 combinations			2.5 GT/s

Figure 8-90 Common Refclk PLL and CDR Characteristics for 2.5 GT/s §

PLL and CDR jitter and peaking characteristics for 5.0, 8.0, and 16.0 GT/s yield a larger number of possible combinations because two sets of PLL BW and peaking limits are given. This choice to support two sets of BW and peaking was made to give designers as much latitude as possible when designing PLL circuits.

PLL #1	0.01 dB peaking	1.0 dB peaking	PLL #2	0.01 dB peaking	3.0 dB peaking
$BW_{PLL}(\min) = 5.0$ MHz	$\omega_{n1} = 1.12$ Mrad/s $\zeta_1 = 14$	$\omega_{n1} = 11.01$ Mrad/s $\zeta_1 = 1.16$	$BW_{PLL}(\min) = 8.0$ MHz	$\omega_{n2} = 1.79$ Mrad/s $\zeta_2 = 14$	$\omega_{n2} = 26.86$ Mrad/s $\zeta_2 = 0.54$
$BW_{PLL}(\max) = 16$ MHz	$\omega_{n1} = 3.58$ Mrad/s $\zeta_1 = 14$	$\omega_{n1} = 35.26$ Mrad/s $\zeta_1 = 1.16$	$BW_{PLL}(\max) = 16$ MHz	$\omega_{n2} = 3.58$ Mrad/s $\zeta_2 = 14$	$\omega_{n2} = 53.73$ Mrad/s $\zeta_2 = 0.54$
<div style="border: 1px solid black; padding: 2px;"> $BW_{CDR}(\min) = 5$ MHz, 1st order </div>			64 combinations		5 GT/s

Figure 8-94 Common Refclk PLL and CDR Characteristics for 64.0 GT/s §

8.6.7 Jitter Limits for Refclk Architectures §

§ Table 8-20 lists the jitter limits for the CC Refclk architecture at each of the four data rates.

Jitter at 2.5 GT/s is measured as a peak to peak jitter value, because a substantial proportion of the jitter is SSC harmonics which appears at the receiver as Dj. The combination of the 2.5 GT/s PLL and CDR bandwidths passes a significant amount of SSC residual, where it appears Dj.

For 5.0, 8.0, and 16.0 GT/s jitter is specified as an RMS (Rj) value. These signaling speeds utilize a lower PLL BW and a higher CDR BW, and the effect is to suppress SSC harmonics such that almost all the jitter appears as Rj.

Table 8-20 Jitter Limits for CC Architecture §

Data Rate	CC jitter Limit	Notes
2.5 GT/s	86 ps pp	1, 2
5.0 GT/s	3.1 ps RMS	1, 2

Data Rate	CC jitter Limit	Notes
8.0 GT/s	1.0 ps RMS	1, 2
16.0 GT/s	0.5 ps RMS	1, 2, 3, 4
32.0 GT/s	0.15 ps RMS	1, 2, 3, 5
64.0 GT/s	0.1 ps RMS	1, 2, 3, 6

Notes:

1. The Refclk jitter is measured after applying the filter function in § Figure 8-89
2. Jitter measurements shall be made with a capture of at least 100,000 clock cycles captured by a real time oscilloscope (RTO) with a sample rate of 20 GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately - Jitter measurements may be used with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200 MHz (at 300 MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5 GT/s data rate the RMS jitter is converted to peak to peak jitter using a multiplication factor of 8.83. In the case where real time oscilloscope and PNA measurements have both been done and produce different results the RTO result must be used.
3. For the 16.0, 32.0, and 64.0 GT/s CC measurements SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2 MHz taking care to minimize removal of any non-SSC content.
4. Note that 0.7 ps RMS is to be used in channel simulations to account for additional noise in a real system.
5. Note that 0.25 ps RMS is to be used in channel simulations to account for additional noise in a real system.
6. Note that 0.15 ps RMS is to be used in channel simulations to account for additional noise in a real system.

8.6.8 Form Factor Requirements for RefClock Architectures §

Each form factor specification must include the following table (see § Table 8-21) to provide a clear summary of the clocking architecture requirements for devices that support the form factor specification. For each clocking architecture the table indicates whether that architecture is required, optional, or not allowed for this form factor. Note that this refers to the operation of the device not the underlying silicon capabilities.

A form factor must provide the CLKREQ# signal if it supports L1 PM Substates. Form factor specifications must indicate if the CLKREQ# signal is required, optional, or not allowed.

Table 8-21 Form Factor Clocking Architecture Requirements §

Clock Architecture	System Board (Motherboard)	Add-in Card (Module)	Retimer
Common	**	**	**
SRNS	**	**	**
SRIS	**	**	**

** Each entry in the table must be filled in with one of: Required, Optional, or Not Allowed

If the Common Reference Clock architecture is required or optional for the form factor, then there must be an additional table (see § Table 8-22) providing details for the common clock. Each entry in the table is marked required, optional, not allowed, or NA. “Clock Source” indicates the source of the common reference clock, if applicable. “SSC” indicates whether the clock source is spread.

Table 8-22 Form Factor Common Clock Architecture Details §

Common Clock Details	System Board (Motherboard)	Add-in Card (Module)	Retimer
Clock Source			
SSC			

If a form factor has clocking requirements that cannot be provided in this simple one or two table form then careful consideration must be given to ensure that the form factor requirements are supported by this specification.

As an example the populated tables are shown for a hypothetical form factor that requires all components use the common clock architecture and does not allow the use of any other clocking architecture (see § Table 8-23 and § Table 8-24). The common clock source is required to be provided by the motherboard component and may optionally have SSC. L1 PM Substates are not supported and therefore CLKREQ# is not defined as a connector signal for this example form factor.

Table 8-23 Form Factor Clocking Architecture Requirements Example §

Clock Architecture	System Board (Motherboard)	Add-in Card (Module)	Retimer
Common	Required	Required	Required
SRNS	Not Allowed	Not Allowed	Not Allowed
SRIS	Not Allowed	Not Allowed	Not Allowed

Table 8-24 Form Factor Common Clock Architecture Details Example §

Common Clock Details	System Board (Motherboard)	Add-in Card (Module)	Retimer
Clock Source	Required	Not Allowed	Not Allowed
SSC	Optional	N/A	N/A

It is important for form factor specifications to recognize that the CLKREQ# signal is required if L1 PM Substates are to be supported, and that for L1 PM Substates the CLKREQ# signal is used even if there is no common reference clock.

If a form factor has clocking requirements that cannot be provided in this simple one or two table form then careful consideration must be given to ensure that the form factor requirements are supported by this specification.

9. Single Root I/O Virtualization and Sharing §

9.1 SR-IOV Architectural Overview §

Within the industry, significant effort has been expended to increase the effective hardware resource utilization (i.e., application execution) through the use of virtualization technology. Single Root I/O Virtualization and Sharing (SR-IOV) enables multiple System Images (SI) to share PCI hardware resources.

To illustrate how this technology can be used to increase effective resource utilization, consider the generic platform configuration illustrated in § Figure 9-1.

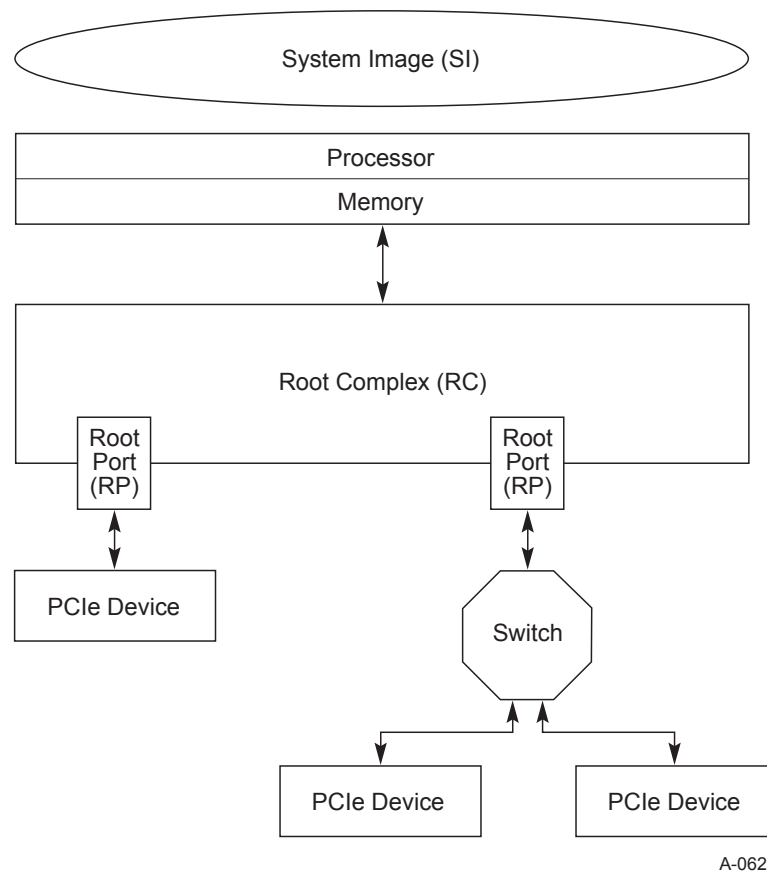

Figure 9-1 Generic Platform Configuration §

The generic platform configuration is composed of the following components:

- PCIe Root Complex (RC), which includes:
 - Processor - general purpose, embedded, or specialized processing element
 - Memory - general purpose or embedded

- Root Complex Integrated Endpoints (RCiEPs)
- PCIe Root Ports (RP) - Each RP represents a separate hierarchy.
- PCIe Switch - provides I/O fan-out and connectivity
 - PCIe Device - multiple I/O device types, (e.g., network, storage, etc.)
 - System Image - software such an operating system that is used to execute applications or trusted services, (e.g., a shared or non-shared I/O device driver).

In order to increase the effective hardware resource utilization without requiring hardware modifications, multiple SI can be executed. Software termed a Virtualization Intermediary (VI) is interposed between the hardware and the SI as illustrated in § Figure 9-2.

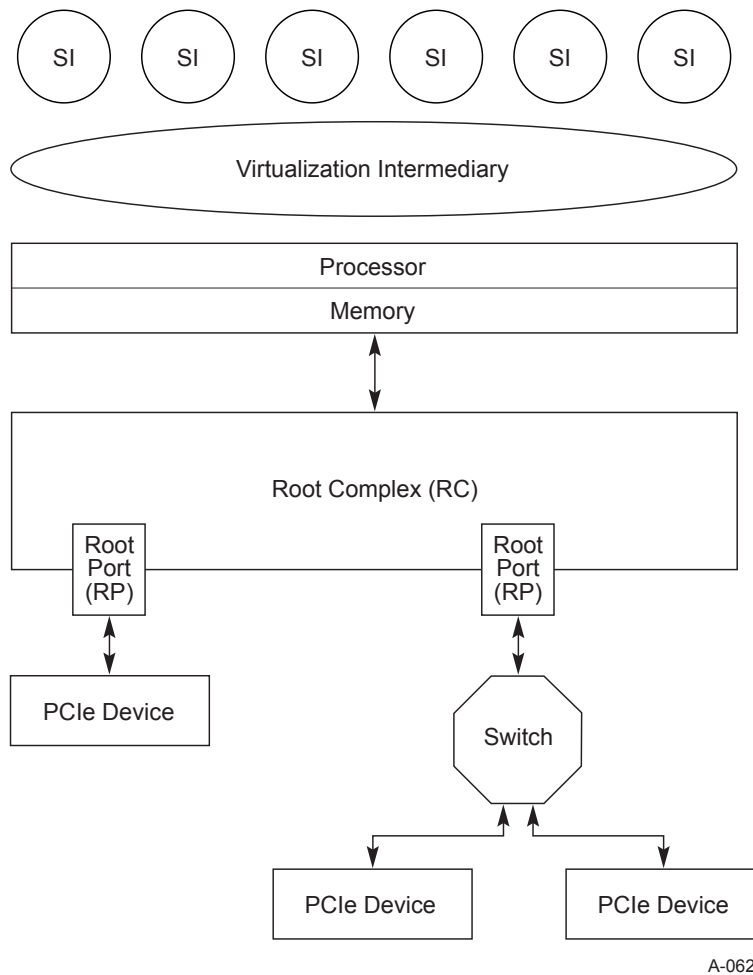

Figure 9-2 Generic Platform Configuration with a VI and Multiple SI §

The VI takes sole ownership of the underlying hardware. Using a variety of methods outside of the scope of this specification, the VI abstracts the hardware to present each SI with its own virtual system. The actual hardware resources available to each SI can vary based on workload or customer-specific policies. While this approach works well for many environments, I/O intensive workloads can suffer significant performance degradation. Each I/O operation - inbound or outbound - must be intercepted and processed by the VI adding significant platform resource overhead.

SR-IOV provides tools to reduce these platform resources overheads. The benefits of SR-IOV are:

- The ability to eliminate VI involvement in main data movement actions - DMA, Memory space access, interrupt processing, etc. Elimination of VI interception and processing of each I/O operation can provide significant application and platform performance improvements.
- Standardized method to control SR-IOV resource configuration and management through Single Root PCI Manager (SR-PCIM).
 - Due to a variety of implementation options - system firmware, VI, operating system, I/O drivers, etc. - SR-PCIM implementation is outside the scope of this specification.
- The ability to reduce the hardware requirements and associated cost with provisioning potentially a significant number of I/O Functions within a device.
- The ability to integrate SR-IOV with other I/O virtualization technologies such as Address Translation Services (ATS), **Address Translation and Protection Table (ATPT)** technologies, and interrupt remapping technologies to create robust, complete I/O virtualization solutions.

§ Figure 9-3 illustrates an example SR-IOV capable platform.

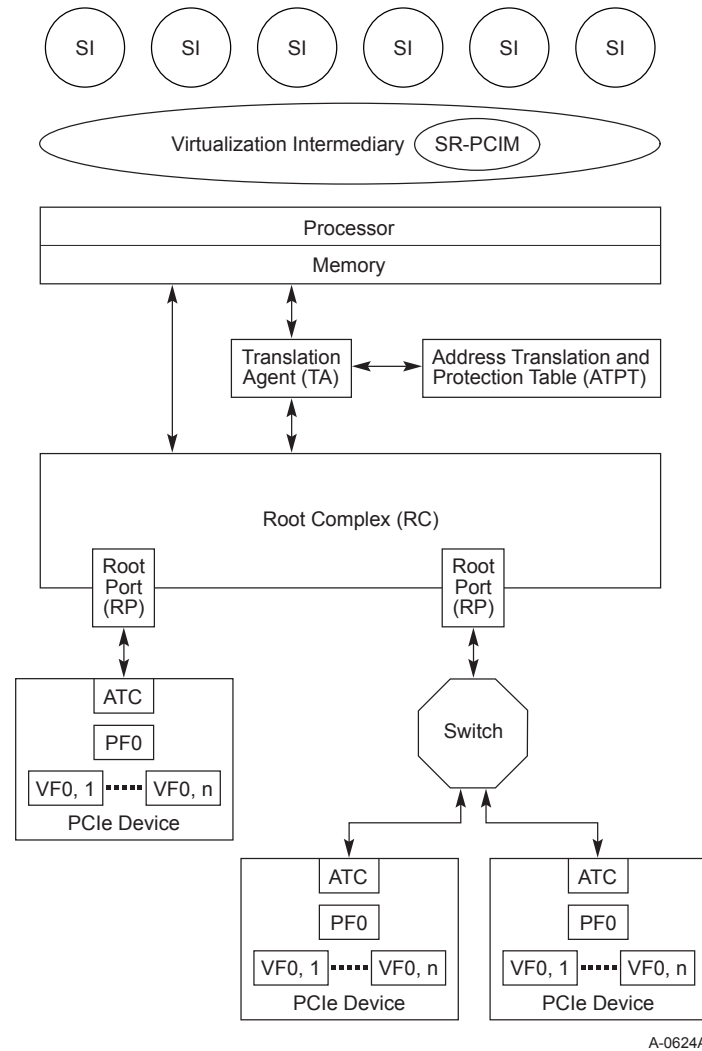

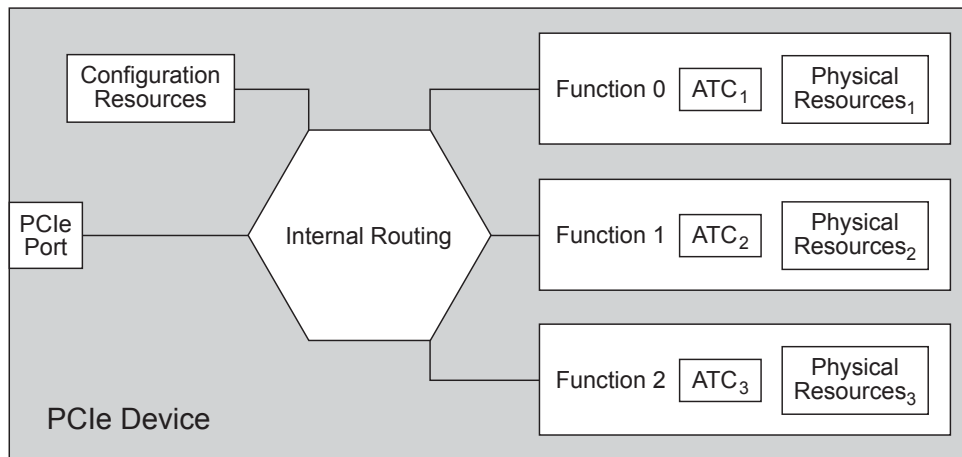

Figure 9-3 Generic Platform Configuration with SR-IOV and IOV Enablers §

The SR-IOV generic platform configuration is composed of the following additional functional elements:

- SR-PCIM - Software responsible for the configuration of the SR-IOV Extended Capability, management of Physical Functions and Virtual Functions, and processing of associated error events and overall device controls such as power management and hot-plug services.
- Optional Translation Agent (TA) - A TA is hardware or a combination of hardware and software responsible for translating an address within a PCIe transaction into the associated platform physical address. A TA may contain an Address Translation Cache (ATC) to accelerate translation table access. A TA may also support Address Translation Services (ATS) which enables a PCIe Function to obtain address translations *a priori* to DMA access to the associated memory. See § Chapter 10. for more details on ATS benefits and operation.
- Optional Address Translation and Protection Table (ATPT) - An ATPT contains the set of address translations accessed by a TA to process PCIe requests - DMA Read, DMA Write, or interrupt requests. See Address Translation Services (§ Chapter 10.) for additional details.

- In PCIe, interrupts are treated as memory write operations. Through the combination of a Requester Identifier and the address contained within a PCIe transaction, an interrupt can be routed to any target (e.g., a processor core) transparent to the associated I/O Function.
- DMA Read and Write requests are translated through a combination of the Routing ID and the address contained within a PCIe transaction.
- **Optional Address Translation Cache (ATC)** - An ATC can exist in two locations within a platform - within the TA which can be integrated within or sit above an RC - or within a PCIe Device. Within an RC, the ATC enables accelerated translation look ups to occur. Within a Device, the ATC is populated through ATS technology. PCIe transactions that indicate they contain translated addresses may bypass the platform's ATC in order to improve performance without compromising the benefits associated with ATPT technology. See Address Translation Services (§ Chapter 10.) for additional details.
- **Optional Access Control Services (ACS)** - ACS defines a set of control points within a PCI Express topology to determine whether a TLP should be routed normally, blocked, or redirected. In a system that supports SR-IOV, ACS may be used to prevent device Functions assigned to the VI or different SIs from communicating with one another or a peer device. Redirection may permit a Translation Agent to translate Upstream memory TLP addresses before a peer-to-peer forwarding decision is made. Selective blocking may be provided by the optional ACS P2P Egress Control. ACS is subject to interaction with ATS. See § Section 6.12 for additional details.
- **Physical Function (PF)** - A PF is a PCIe Function that supports the SR-IOV Extended Capability and is accessible to an SR-PCIM, a VI, or an SI.
- **Virtual Function (VF)** - A VF is a “light-weight” PCIe Function that is directly accessible by an SI.
 - Minimally, resources associated with the main data movement of the Function are available to the SI. Configuration resources should be restricted to a trusted software component such as a VI or SR-PCIM.
 - A VF can be serially shared by different SI, (i.e., a VF can be assigned to one SI and then reset and assigned to another SI).
 - A VF can be optionally migrated from one PF to another PF. The migration process itself is outside the scope of this specification but is facilitated through configuration controls defined within this specification.
- All VFs associated with a PF must be the same device type as the PF, (e.g., the same network device type or the same storage device type).

To compare and contrast a PCIe Device with a PCIe SR-IOV capable device, examine the following set of figures. § Figure 9-4 illustrates an example PCIe-compliant Device.

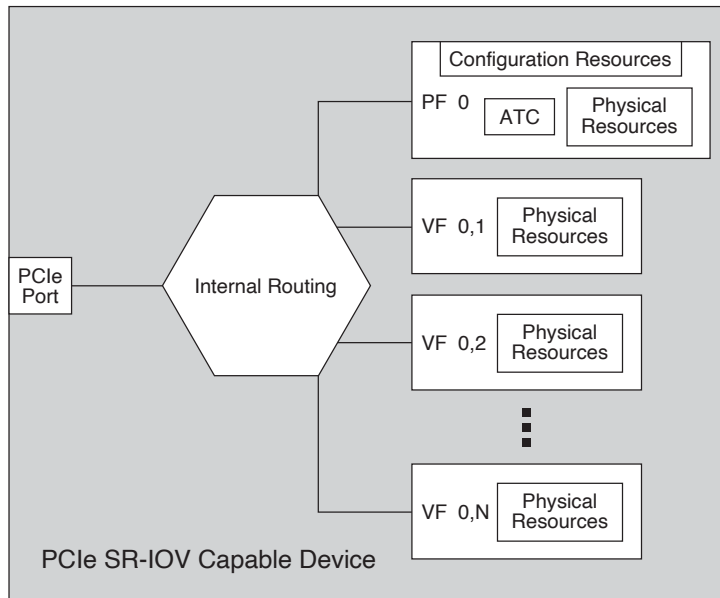

A-0625

Figure 9-4 Example Multi-Function Device §

This figure illustrates an example multi-Function PCIe Device with the following characteristics:

- The PCIe Device shares a common PCIe Link. The Link and PCIe functionality shared by all Functions is managed through Function 0.
 - While this figure illustrates only three Functions, with the use of the Alternative Routing Identifier (ARI) capability, a PCIe Device can support up to 256 Functions.
 - All Functions use a single Bus Number captured through the PCI enumeration process.
- In this example, each PCIe Function supports the ATS capability and therefore has an associated ATC to manage ATS obtained translated addresses.
- Each PCIe Function has a set of unique physical resources including a separate configuration space and BAR.
- Each PCIe Function can be assigned to an SI. To prevent one SI from impacting another, all PCIe configuration operations should be intercepted and processed by the VI.

As this figure illustrates, the hardware resources scale with the number of Functions provisioned. Depending upon the complexity and size of the device, the incremental cost per Function will vary. To reduce the incremental hardware cost, a device can be constructed using SR-IOV to support a single PF and multiple VFs as illustrated in § [Figure 9-5](#).

A-0626A

Figure 9-5 Example SR-IOV Single PF Capable Device §

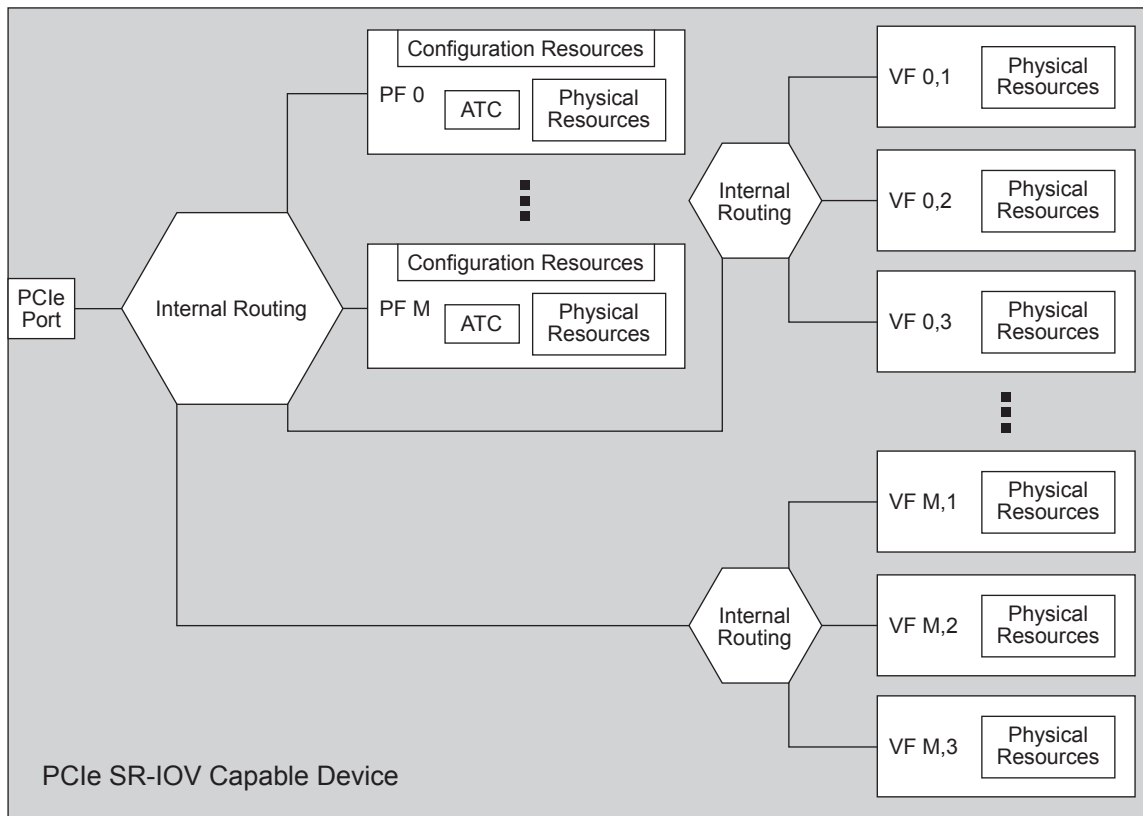

The example in § Figure 9-5 illustrates a single PF with N VFs. Key observations to note:

- The PF is a PCIe-compliant.
 - Initially and after a conventional reset, a PCIe Function that supports the SR-IOV capabilities defined in this specification shall have the SR-IOV capabilities disabled.
 - To discover the page sizes supported by a PF and its associated VF, the Supported Page Sizes configuration field is read. For additional information on how this field can be used to align PF or VF Memory space apertures on a system page boundary, see § Section 9.2.1.1.1.
- PF nomenclature **PF M** designates the PF at Function number M.
- VF nomenclature **VF M,N** designates the Nth VF associated with PF M. VFs are numbered starting with 1 so the first VF associated with PF M is VF M,1.
- Each VF shares a number of common configuration space fields with the PF; (i.e., where the fields are applicable to all VF and controlled through a single PF. Sharing reduces the hardware resource requirements to implement each VF).
 - A VF uses the same configuration mechanisms and header types as a PF.
 - All VFs associated with a given PF share a VF BAR set (see § Section 9.3.3.14) and share a VF Memory Space Enable (MSE) bit in the SR-IOV extended capability (see § Section 9.3.3.3.4) that controls access to the VF Memory space. That is, if the VF MSE bit is Clear, the memory mapped space allocated for all VFs is disabled.
 - The InitialVFs and TotalVFs fields (see § Section 9.3.3.5 and § Section 9.3.3.6) are used to discover the maximum number of VFs that can be associated with a PF.
 - TotalVFs and InitialVFs shall contain the same value¹⁸⁵.

185. InitialVFs and TotalVFs could have had different values due to MR-IOV (now deprecated).

- Each Function, PF, and VF is assigned a unique Routing ID. The Routing ID for each PF is constructed as per § Section 2.2.4.2 . The Routing ID for each VF is determined using the Routing ID of its associated PF and fields in that PF's SR-IOV Extended Capability.
- All PCIe and SR-IOV configuration access is assumed to be through a trusted software component such as a VI or an SR-PCIM.
- Each VF contains a non-shared set of physical resources required to deliver Function-specific services, (e.g., resources such as work queues, data buffers, etc.) These resources can be directly accessed by an SI without requiring VI or SR-PCIM intervention.
- One or more VF may be assigned to each SI. Assignment policies are outside the scope of this specification.
- While this example illustrates a single ATC within the PF, the presence of any ATC is optional. In addition, this specification does not preclude an implementation from supporting an ATC per VF within the Device.
- Internal routing is implementation specific.
- While many potential usage models exist regarding PF operation, a common usage model is to use the PF to bootstrap the device or platform strictly under the control of a VI. Once the SR-IOV Extended Capability is configured enabling VF to be assigned to individual SI, the PF takes on a more supervisory role. For example, the PF can be used to manage device-specific functionality such as internal resource allocation to each VF, VF arbitration to shared resources such as the PCIe Link or the Function-specific Link (e.g., a network or storage Link), etc. These policy, management, and resource allocation operations are outside the scope of this specification.

Another example usage model is illustrated in § Figure 9-6. In this example, the device supports multiple PFs each with its own set of VFs.

A-0627

Figure 9-6 Example SR-IOV Multi-PF Capable Device §

Key observations to note:

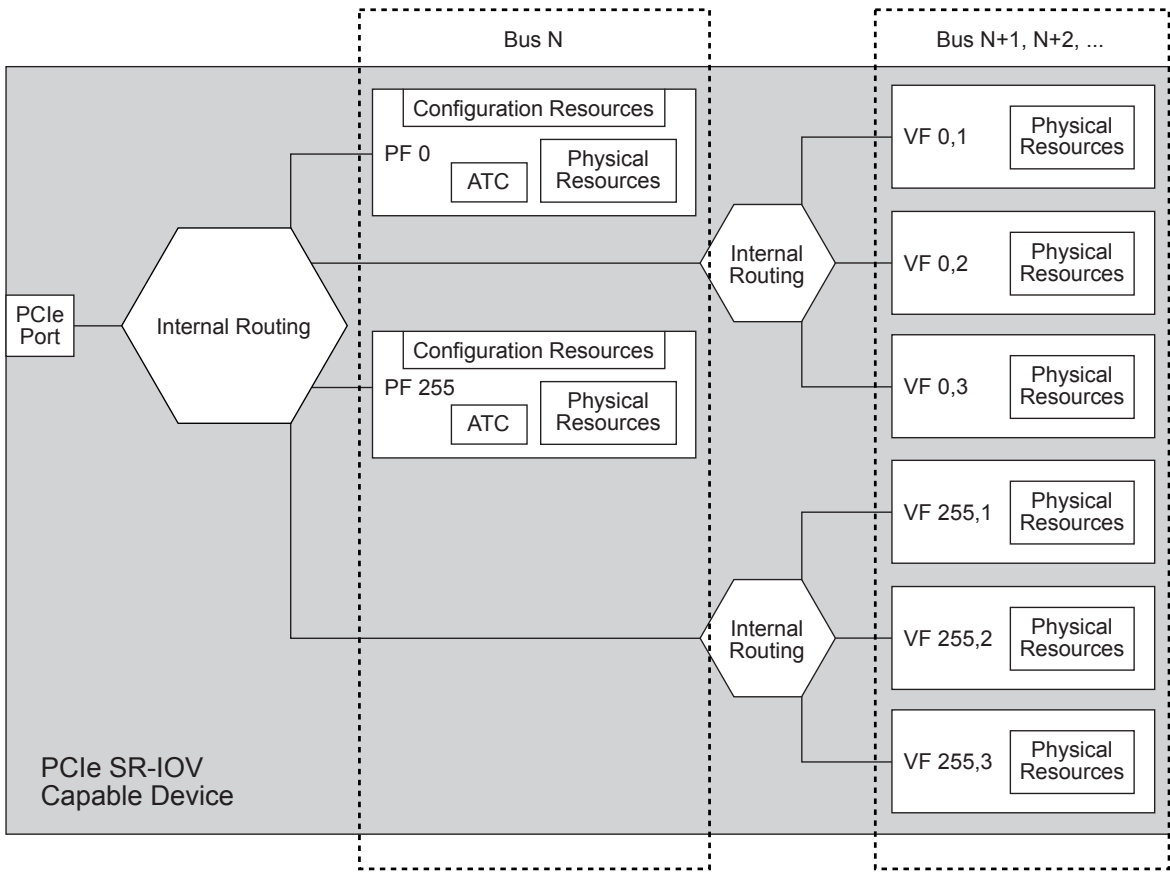

- Each PF can be assigned zero or more VFs. The number of VFs per PF is not required to be identical for all PFs within the device.
- The ARI Extended Capability enables Functions to be assigned to Function Groups and defines how Function Group arbitration can be configured. PFs and VFs can be assigned to Function Groups and take advantage of the associated arbitration capabilities. Within each Function Group, though, arbitration remains implementation specific.
- Internal routing between PFs and VFs is implementation specific.
- For some usage models, all PFs may be the same device type; (e.g., all PFs deliver the same network device or all deliver the same storage device functionality). For other usage models, each PF may represent a different device type; (e.g., in § Figure 9-6, one PF might represent a network device while another represents an encryption device).
 - In situations where there is a usage model dependency between device types, such as for each VF that is a network device type, each SI also requires a VF that is an encryption device type. The SR-IOV Extended Capability provides a method to indicate these dependencies. The policies used to construct these dependencies as well as assign dependent sets of VF to a given SI are outside the scope of this specification.

As seen in the prior example, the number of PF and VF can vary based on usage model requirements. To support a wide range of options, an SR-IOV Device can support the following number and mix of PF and VF:

- Using the Alternative Routing Identifier (ARI) capability, a device may support up to 256 PFs. Function Number assignment is implementation specific and may be sparse throughout the 256 Function Number space.
- A PF can only be associated with the Device's captured Bus Number as illustrated in § Figure 9-7.
- SR-IOV Devices may consume more than one Bus Number. A VF can be associated with any Bus Number within the Device's Bus Number range - the captured Bus Number plus any additional Bus Numbers configured by software. See § Section 9.2.1.2 for details.
 - Use of multiple Bus Numbers enables a device to support a very large number of VFs - up to the size of the Routing ID space minus the bits used to identify intervening busses.
 - If software does not configure sufficient additional Bus Numbers, then the VFs implemented for the additional Bus Numbers may not be visible.

IMPLEMENTATION NOTE: FUNCTION CO-LOCATION §

The ARI Extended Capability enables a Device to support up to 256 Functions - Functions, PFs, or VFs in any combination - associated with the captured Bus Number. If a usage model does not require more than 256 Functions, implementations are strongly encouraged to co-locate all Functions, PFs, and VFs within the captured Bus Number and not require additional Bus Numbers to access VFs.

A-0628

Figure 9-7 Example SR-IOV Device with Multiple Bus Numbers §

In this last example, § Figure 9-8, a device implementation may mix any number of Functions, PFs, and VFs.

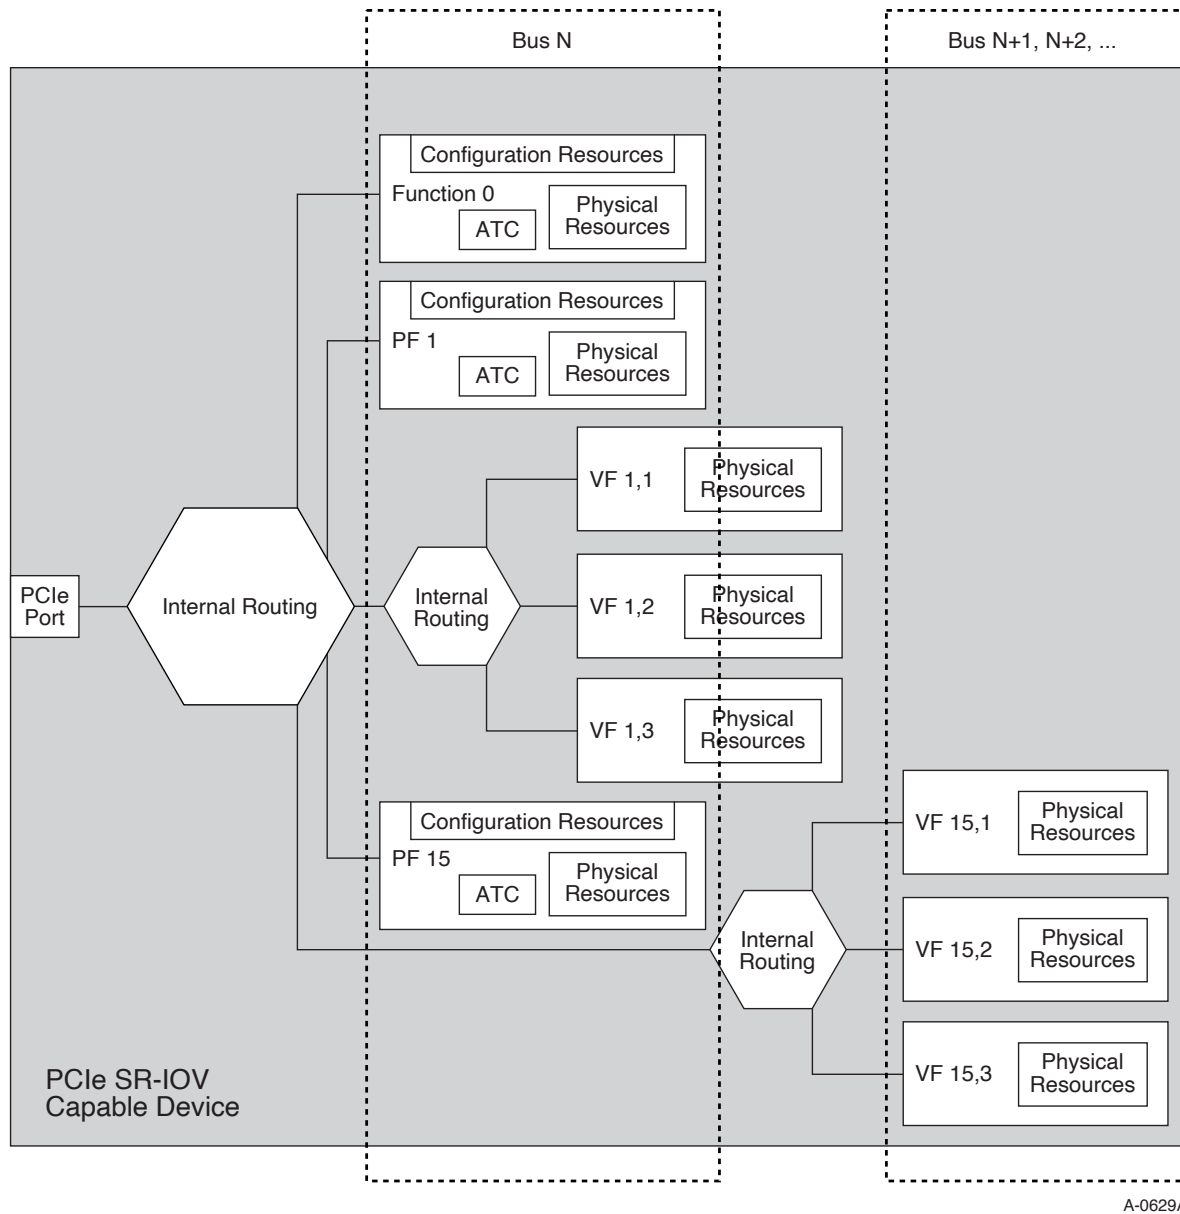

Figure 9-8 Example SR-IOV Device with a Mixture of Function Types §

Key observations to note:

- Each Device must contain a Function 0. Function 0 may be a PF (i.e., it may include the SR-IOV extended capability).
- Any mix of Functions can be associated with the captured Bus Number.
 - Non-VFs can only be associated with the captured Bus Number.
- If the ARI Extended Capability is supported, Functions can be assigned to Function Groups. The assignment policy is outside the scope of this specification. If the ARI Extended Capability is not supported, Functions can still use the Function arbitration capabilities as defined in § Section 6.3.3.4 .

9.2 SR-IOV Initialization and Resource Allocation §

9.2.1 SR-IOV Resource Discovery §

The following sections describe how software determines that a Device is SR-IOV capable and subsequently identifies VF resources through Virtual Function Configuration Space.

9.2.1.1 Configuring SR-IOV Capabilities §

This section describes the fields that must be configured before enabling a PF's IOV Capabilities. The VFs are enabled by Setting the PF's VF Enable bit (see § Section 9.3.3.3.1) in the SR-IOV extended capability.

The NumVFs field (see § Section 9.3.3.7) defines the number of VFs that are enabled when VF Enable is Set in the associated PF.

9.2.1.1.1 Configuring the VF BAR Mechanisms §

This section describes how the VF BARs are configured to map memory space. VFs do not support I/O Space and thus VF BARs shall not indicate I/O Space.

The System Page Size field (see § Section 9.3.3.13) defines the page size the system will use to map the VF's PCIe memory addresses when the PF's IOV Capabilities are enabled. The System Page Size field is used by the PF to align the Memory space aperture defined by each VF BAR to a system page boundary. The value chosen for the System Page Size must be one of the Supported Page Sizes (see § Section 9.3.3.12) in the SR-IOV extended capability.

The behavior of VF BARs is the same as the normal PCI Memory Space BARs (see § Section 7.5.1.2.1), except that a VF BAR describes the aperture for each VF, whereas a PCI BAR describes the aperture for a single Function. The attributes for some of the bits in the VF BARs are affected by the VF Resizable BAR Extended Capability (see § Section 7.8.7) if it is implemented.

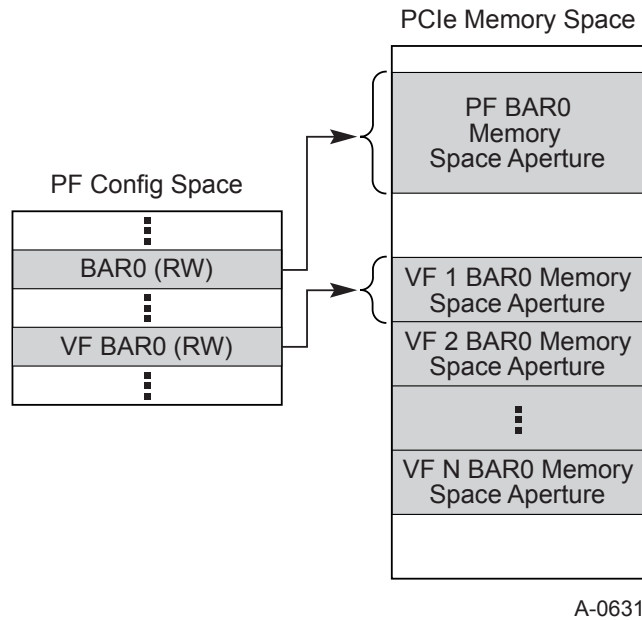

- The behavior described in § Section 7.5.1.2.1 for determining the memory aperture of a Function's BAR applies to each VF BAR. That is, the size of the memory aperture required for each VF BAR can be determined by writing all "1"s and then reading the VF BAR. The results read back must be interpreted as described in § Section 7.5.1.2.1 .
- The behavior for assigning the starting memory space address of each BAR associated with the first VF is also as described in § Section 7.5.1.2.1 . That is, the address written into each VF BAR is used by the Device for the starting address of the first VF.
- The difference between VF BARs and BARs described in § Section 7.5.1.2.1 is that for each VF BAR, the memory space associated with the second and higher VFs is derived from the starting address of the first VF and the memory space aperture. For any given VF_v, the starting address of its Memory space aperture for any implemented BAR_b) is calculated according to the following formula:

$$\text{BAR}_b \text{ VF}_v \text{ starting address} = \text{VF BAR}_b + (v - 1) \times (\text{VF BAR}_b \text{ aperture size})$$

where VF BAR_b aperture size is the size of VF BAR_b as determined by the usual BAR probing algorithm as described in § Section 9.3.3.14 .

VF memory space is not enabled until both VF Enable and VF MSE have been Set (see § Section 9.3.3.3.1 and § Section 9.3.3.3.4). Note that changing System Page Size (see § Section 9.3.3.13) may affect the VF BAR aperture size.

§ Figure 9-9 shows an example of the PF and VF Memory space apertures.

A-0631

Figure 9-9 BAR Space Example for Single BAR Device §

9.2.1.2 VF Discovery §

The First VF Offset and VF Stride fields in the SR-IOV extended capability are 16-bit Routing ID offsets. These offsets are used to compute the Routing IDs for the VFs with the following restrictions:

- The value in NumVFs in a PF (§ Section 9.3.3.7) may affect the values in First VF Offset (§ Section 9.3.3.9) and VF Stride (§ Section 9.3.3.10) of that PF.
- The value in ARI Capable Hierarchy (§ Section 9.3.3.3.5) in the lowest-numbered PF of the Device (for example PF₀) may affect the values in First VF Offset and VF Stride in all PFs of the Device.
- NumVFs of a PF may only be changed when VF Enable (§ Section 9.3.3.3.1) of that PF is Clear.
- ARI Capable Hierarchy (§ Section 9.3.3.3.5) may only be changed when VF Enable is Clear in all PFs of a Device.

IMPLEMENTATION NOTE: NUMVFS AND ARI CAPABLE HIERARCHY §

After configuring NumVFs and ARI Capable Hierarchy where applicable, software may read First VF Offset and VF Stride to determine how many Bus Numbers would be consumed by the PF's VFs. The additional Bus Numbers, if any, are not actually used until VF Enable is Set.

§ Table 9-1 describes the algorithm used to determine the Routing ID associated with each VF.

Table 9-1 VF Routing ID Algorithm §

VF Number	VF Routing ID
VF 1	$(\text{PF Routing ID} + \text{First VF Offset}) \text{ Modulo } 2^{16}$
VF 2	$(\text{PF Routing ID} + \text{First VF Offset} + \text{VF Stride}) \text{ Modulo } 2^{16}$
VF 3	$(\text{PF Routing ID} + \text{First VF Offset} + 2 * \text{VF Stride}) \text{ Modulo } 2^{16}$
...	...
VF N	$(\text{PF Routing ID} + \text{First VF Offset} + (N-1) * \text{VF Stride}) \text{ Modulo } 2^{16}$
...	...
VF NumVFs (last one)	$(\text{PF Routing ID} + \text{First VF Offset} + (\text{NumVFs}-1) * \text{VF Stride}) \text{ Modulo } 2^{16}$

All arithmetic used in this Routing ID computation is 16-bit unsigned dropping all carries.

All VFs and PFs must have distinct Routing IDs. The Routing ID of any PF or VF must not overlap with the Routing ID of any other PF or VF given any valid setting of NumVFs across all PFs of a device.

VF Stride and First VF Offset are constants. Except as stated earlier in this section, their values may not be affected by settings in this or other Functions of the Device.

VFs may reside on different Bus Number(s) than the associated PF. This can occur if, for example, First VF Offset has the value 0100h. A VF shall not be located on a Bus Number that is numerically smaller than its associated PF. A VF that is located on the same Bus Number as its associated PF shall not be located on a Device Number that is numerically smaller than the PF¹⁸⁶.

VFs of an SR-IOV RCiEP Device are associated with the same Root Complex Event Collector (if any) as their PF. Such VFs are not reported in the Root Complex Event Collector Endpoint Association Extended Capability of the Root Complex Event Collector.

As per § Section 2.2.6.2, SR-IOV capable Devices that are associated with an Upstream Port capture the Bus Number from any Type 0 Configuration Write Request. SR-IOV capable Devices do not capture the Bus Number from any Type 1 Configuration Write Requests. SR-IOV capable RCiEPs use an implementation specific mechanism to assign their Bus Numbers.

Note: Bus Numbers are a constrained resource. Devices are strongly encouraged to avoid leaving “holes” in their Bus Number usage to avoid wasting Bus Numbers.

All PFs must be located on the Device’s captured Bus Number.

186. SR-IOV Devices immediately below a Downstream Port always have a Device Number of 0 and thus always satisfy this condition.

IMPLEMENTATION NOTE: VFS SPANNING MULTIPLE BUS NUMBERS §

As an example, consider an SR-IOV Device that supports a single PF. Initially, only PF 0 is visible. Software Sets ARI Capable Hierarchy. From the SR-IOV Extended Capability it determines: InitialVFs is 600, First VF Offset is 1 and VF Stride is 1.

- If software sets NumVFs in the range [0 ... 255], then the Device uses a single Bus Number.
- If software sets NumVFs in the range [256 ... 511], then the Device uses two Bus Numbers.
- If software sets NumVFs in the range [512 ... 600], then the Device uses three Bus Numbers.

PF 0 and VF 0,1 through VF 0,255 are always on the first (captured) Bus Number. VF 0,256 through VF 0,511 are always on the second Bus Number (captured Bus Number plus 1). VF 0,512 through VF 0,600 are always on the third Bus Number (captured Bus Number plus 2).

Software should configure Switch Secondary and Subordinate Bus Number fields to route enough Bus Numbers to the Device. If sufficient Bus Numbers are not available, software should reduce a Device's Bus Number requirements by not enabling SR-IOV and/or reducing NumVFs for some or all PFs of the Device prior to enabling SR-IOV.

After VF Enable is Set in some PF n , the Device must Enable VF $n,1$ through VF n,m (inclusive) where m is the smaller of InitialVFs and NumVFs. A Device receiving a Type 0 Configuration Request targeting an Enabled VF located on the captured Bus Number must process the Request normally. A Device receiving a Type 1 Configuration Request targeting an Enabled VF not located on the captured Bus Number must process the Request normally. A Device receiving a Type 1 Configuration Request targeting the Device's captured Bus Number must follow the rules for handling Unsupported Requests. Additionally, if VF MSE is Set, each Enabled VF must respond to PCIe Memory transactions addressing the memory space associated with that VF.

Functions that are not enabled (i.e., Functions for VFs above m) do not exist in the PCI Express fabric. As per § Section 2.3.1, addressing Functions that do not exist will result in Unsupported Request (UR) being returned. This includes Functions on additional Bus Numbers.

IMPLEMENTATION NOTE: MULTI-FUNCTION DEVICES WITH PFS AND SWITCH FUNCTIONS §

SR-IOV devices may consume multiple bus numbers. Additional bus numbers beyond the first one are consecutive and immediately follow the first bus number assigned to the device. If an SR-IOV device also contains PCI-PCI Bridges (with Type 1 Configuration Space Headers), the SR-IOV usage must be accounted for when programming the Secondary Bus Number for those Bridges. Software should determine the last Bus Number used by VFs first and then configure any co-located Bridges to use Bus Numbers above that value.

9.2.1.3 Function Dependency Lists §

PCI Devices may have vendor-specific dependencies between Functions. For example, Functions 0 and 1 might provide different mechanisms for controlling the same underlying hardware. In such situations, the Device programming model might require that these dependent Functions be assigned to SIs as a set.

Function Dependency Lists are used to describe these dependencies (or to indicate that there are no Function dependencies). Software should assign PFs and VFs to SIs such that the dependencies are satisfied.

See § [Section 9.3.3.8](#) for details.

9.2.1.4 Interrupt Resource Allocation §

PFs and VFs support either MSI, MSI-X interrupts, or both if interrupt resources are allocated. VFs shall not implement INTx. MSI and MSI-X interrupts are described in § [Section 6.1.4](#).

For MSI-X interrupts, special address range isolation requirements apply for the MSI-X structures in PF and VF MMIO regions. See in § [Section 7.7.2](#).

9.2.2 SR-IOV Reset Mechanisms §

This section describes how reset mechanisms defined in § [Section 6.6](#) affect Devices that support SR-IOV. It also describes the mechanisms used to reset a single VF and a single PF with its associated VFs.

9.2.2.1 SR-IOV Conventional Reset §

A Conventional Reset to a Device that supports SR-IOV shall cause all Functions (including both PFs and VFs) to be reset to their original, power-on state as per the rules in § [Section 6.6.1](#). § [Section 9.3](#) describes the behavior for the fields defined.

Note: Conventional Reset clears [VF Enable](#) in the PF. Thus, VFs no longer exist after a Conventional Reset.

9.2.2.2 FLR That Targets a VF §

VFs must support [Function Level Reset \(FLR\)](#).

Note: Software may use FLR to reset a VF. FLR to a VF affects a VF's state but does not affect its existence in PCI Configuration Space or PCI Bus address space. The VFs BARn values (see § [Section 9.3.3.14](#)) and VF MSE (see § [Section 9.3.3.3.4](#)) in the PF's SR-IOV extended capability, and the VF Resizable BAR capability values (see § [Section 7.8.7](#)) are unaffected by FLRs issued to the VF.

9.2.2.3 FLR That Targets a PF §

PFs must support [FLR](#).

FLR to a PF resets the PF state as well as the SR-IOV extended capability including [VF Enable](#) which means that VFs no longer exist.

9.2.3 IOV Re-initialization and Reallocation §

If [VF Enable](#) is Cleared after having been Set, all of the VFs associated with the PF no longer exist and must no longer issue PCIe transactions or respond to Configuration Space or Memory Space accesses. VFs must not retain any architected state after [VF Enable](#) has been Cleared (including sticky bits). For security, unarchitected VF state configured through the VF must be cleared or randomized, with the exception of persistent storage data.

Unarchitected VF state configured through the PF or SR-PCIM interface is permitted to persist across VF instances.

Architected VF state configured through the PF or SR-PCIM interface is permitted to be restored to earlier values or set to new values. That is, when VF Enabled is Set again, instances of VFs are permitted to have a different set of architected capabilities and/or their attributes (e.g., MSI-X Table size) from previous instances.

9.3 Configuration §

9.3.1 SR-IOV Configuration Overview §

This section provides SR-IOV-added requirements for implementing PFs and VFs.

PFs are discoverable in configuration space, as with all Functions. PFs contain the SR-IOV Extended Capability described in § Section 9.3.3 . PFs are used to discover, configure, and manage the VFs associated with the PF and for other things described in this specification.

9.3.2 Configuration Space §

PFs that support SR-IOV shall implement the SR-IOV Extended Capability as defined in the following sections. VFs shall implement configuration space fields and capabilities as defined in the following sections.

9.3.3 SR-IOV Extended Capability §

The SR-IOV Extended Capability defined here is a PCIe extended capability that must be implemented in each PF that supports SR-IOV. This Capability is used to describe and control a PF's SR-IOV Capabilities.

For Multi-Function Devices, each PF that supports SR-IOV shall provide the Capability structure defined in this section. This Capability structure may be present in any Function with a Type 0 Configuration Space Header. This Capability must not be present in Functions with a Type 1 Configuration Space Header.

§ Figure 9-10 shows the SR-IOV Extended Capability structure.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Byte Offset

Figure 9-10 SR-IOV Extended Capability §

9.3.3.1 SR-IOV Extended Capability Header (Offset 00h) §

§ Table 9-2 defines the SR-IOV Extended Capability header. The Capability ID for the SR-IOV Extended Capability is 0010h.

Figure 9-11 SR-IOV Extended Capability Header §

Table 9-2 SR-IOV Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the SR-IOV Extended Capability is 0010h.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh.	RO

9.3.3.2 SR-IOV Capabilities Register (04h) §

§ Table 9-3 defines the layout of the SR-IOV Capabilities field.

Figure 9-12 SR-IOV Capabilities Register §

Table 9-3 SR-IOV Capabilities Register §

Bit Location	Register Description	Attributes
0	VF Migration Capable - If Set, the PF is Migration Capable and operating under a Migration Capable MR-PCIM. Deprecated. New designs should hardwire this bit to 0b.	RO
1	ARI Capable Hierarchy Preserved <i>PCI Express Endpoint:</i> If Set, the ARI Capable Hierarchy bit is preserved across certain power state transitions. <i>RCiEP:</i> Not applicable - this bit <i>MUST@FLIT</i> be hardwired to 0b.	RO
2	VF 10-Bit Tag Requester Supported - If Set, all VFs associated with this PF must support 10-Bit Tag Requester capability. If Clear, VFs must not support 10-Bit Tag Requester capability.	HwInit

Bit Location	Register Description	Attributes
	If the <u>10-Bit Tag Requester Supported</u> bit in the PF's <u>Device Capabilities 2</u> register is Clear, this bit must be Clear.	
3	VF 14-Bit Tag Requester Supported - If Set, all VFs associated with this PF must support 14-Bit Tag Requester capability. If Clear, VFs must not support 14-Bit Tag Requester capability. If the <u>14-Bit Tag Requester Supported</u> bit in the PF's <u>Device Capabilities 3</u> register is Clear, this bit must be Clear.	HwInit
31:21	VF Migration Interrupt Message Number - Indicates the MSI/MSI-X vector used for migration interrupts. The value in this field is undefined if <u>VF Migration Capable</u> is Clear. VF Migration is a feature associated with the deprecated MR-IOV. New designs should hardwire this field to 0.	RO

9.3.3.2.1 VF Migration Capable §

VF Migration Capable is Set to indicate that the PF supports VF Migration. If Clear, the PF does not support VF Migration.

VF Migration is a feature associated with the deprecated [MR-IOV]. This bit should be hardwired to 0b in new designs.

9.3.3.2.2 ARI Capable Hierarchy Preserved §

ARI Capable Hierarchy Preserved is Set to indicate that the PF preserves the ARI Capable Hierarchy bit across certain power state transitions (see § Section 9.3.3.3.5). Components must either Set this bit or Set the No_Soft_Reset bit (see § Section 5.10.2). It is recommended that components set this bit even if they also set No_Soft_Reset.

ARI Capable Hierarchy Preserved is only present in the lowest-numbered PF of a Device (for example PF0). ARI Capable Hierarchy Preserved is Read Only Zero in other PFs of a Device.

ARI Capable Hierarchy Preserved does not apply to RCiEPs, and its value is undefined (see § Section 9.3.3.3).

9.3.3.2.3 VF Larger-Tag Requester Support §

If a PF and/or its associated VFs support UIO as a Completer, 14-bit Tags must be supported.

Otherwise, if a PF supports one or both larger-Tag Requester capabilities, its associated VFs are permitted to support the associated larger-Tag Requester capabilities as well, but this is optional. Especially for usage models where the bulk of the traffic is spread across several VFs concurrently, it may not be necessary for individual VFs to use larger Tags so they can support >256 outstanding Non-Posted Requests each.

For a given PF, it is required that either all or none of its associated VFs support larger-Tag Requester capabilities. This avoids unnecessary implementation and management complexity. See VF 14-Bit Tag Requester Supported and VF 10-Bit Tag Requester Supported.

VFs that support larger-Tag Requester capabilities have additional requirements and recommendations beyond other Function types in order to simplify error handling and reduce the possibility of larger-Tag related errors with one VF impacting other traffic.

- If one of the VF larger-Tag Requester Enable bits in the SR-IOV Control Register is Set, then each VF must use the associated larger Tags for all Non-Posted Requests that it generates. If both bits are Set at the same time, the result is undefined.
- As documented in § Table 2-11, the permitted range with 10-bit Tags enabled is 256 to 1023, and the recommended range with 14-bit Tags enabled is 1024 to 16383. The keep-out range for 10-bit Tags is Tag[9:8] being 00b, and the recommended keep-out range for 14-bit Tags is Tag[13:10] being 0000b.
- For each outstanding larger-Tag Request, if the VF receives a Completion that matches the outstanding Request other than all Tag bits in the implemented keep-out Tag bit range being zero, then the Tag is invalid, and it is strongly recommended that the VF prevent that Request from (eventually) generating a Completion Timeout error, and instead handle the error via a device-specific mechanism that avoids data corruption.

It is strongly recommended that software not configure Unexpected Completion errors to be handled as Uncorrectable Errors. This avoids them triggering System Errors or hardware error containment mechanisms like Downstream Port Containment (DPC).

IMPLEMENTATION NOTE:

NO VF LARGER-TAG COMPLETER SUPPORTED BITS §

There are no VF 14-bit or VF 10-Bit Tag Completer Supported bits. If a PF supports one or both larger-Tag Completer capabilities, then all of its associated VFs are required support the associated Tag Completer capabilities as stated in 14-Bit Tag Completer Supported and 10-Bit Tag Completer Supported. This helps avoid the complexity of PCIe hierarchies where some Completers support larger-Tag capability and some do not.

9.3.3.2.4 VF Migration Interrupt Message Number §

VF Migration is associated with the now deprecated MR-IOV. New designs should hardwire this field to 0.

9.3.3.3 SR-IOV Control Register (Offset 08h) §

§ Table 9-4 defines the layout of the SR-IOV Control fields.

Figure 9-13 SR-IOV Control Register §

Table 9-4 SR-IOV Control Register §

Bit Location	Register Description	Attributes
0	VF Enable - Enables/Disables VFs. Default value is 0b.	<u>RW</u>
1	VF Migration Enable - Enables/Disables VF Migration Support. Default value is 0b. See § Section 9.3.3.3.2.	<u>RW or RO</u> (see description)
2	VF Migration Interrupt Enable - Enables/Disables VF Migration State Change Interrupt. Default value is 0b.	<u>RW</u>

9.3.3.3.1 VF Enable §

VF Enable manages the assignment of VFs to the associated PF. If VF Enable is Set, the VFs associated with the PF are accessible in the PCI Express fabric. When Set, VFs respond to and may issue PCI Express transactions following the rules for PCI Express Endpoint Functions.

If VF Enable is Clear, VFs are disabled and not visible in the PCI Express fabric; requests to these VFs shall receive UR and these VFs shall not issue PCI Express transactions.

To allow components to perform internal initialization, after changing the VF Enable bit from Cleared to Set, the system is not permitted to issue Requests to the VFs which are enabled by that VF Enable bit until one of the following is true:

- At least 100 ms has passed
- An FRS Message has been received from the PF with a Reason Code of VF Enabled
- At least VF Enable Time has passed. VF Enable Time is either (1) the Reset Time value in the Readiness Time Reporting capability associated with the VF, or (2) a value determined by system software / firmware¹⁸⁷.

The Root Complex and/or system software must allow at least 1.0 s after Setting the VF Enable bit, before it may determine that a VF which fails to return a Successful Completion Status for a valid Configuration Request is broken. After Setting the VF Enable bit, the VFs enabled by that VF Enable bit are permitted to return a Configuration RRS status in response to Configuration Requests up to the 1.0 s limit, if they are not ready to provide a Successful Completion Status for a valid Configuration Request. After a PF transmits an FRS Message with a Reason Code of VF Enabled, no VF associated with that PF is permitted to return Configuration RRS in response to a Configuration Request without an intervening VF disable or other valid reset condition. After returning a Successful Completion to any Request, no VF is permitted to return Configuration RRS in response to a Configuration Request without an intervening VF disable or other valid reset condition.

Since VFs don't have an MSE bit (MSE in VFs is controlled by the VF MSE bit in the SR-IOV Extended Capability in the PF), it's possible for software to issue a Memory Request before the VF is ready to handle it. Therefore, Memory Requests must not be issued to a VF until at least one of the following conditions has been met:

- The VF has responded successfully (without returning RRS) to a Configuration Request.
- After issuing an FLR to the VF, at least one of the following is true:

¹⁸⁷. For example, ACPI tables.

- At least 1.0 s has passed since the FLR was issued.
- The VF supports FRS and, after the FLR was issued, an FRS Message has been received from the VF with a Reason Code of FLR Completed.
- At least FLR Time has passed since the FLR was issued. FLR Time is either (1) the FLR Time value in the Readiness Time Reporting capability associated with the VF or (2) a value determined by system software / firmware¹⁵³.
- After Setting VF Enable in a PF, at least one of the following is true:
 - At least 1.0 s has passed since VF Enable was Set.
 - The PF supports FRS and, after VF Enable was Set, an FRS Message has been received from the PF with a Reason Code of VF Enabled.
 - At least VF Enable Time has passed since VF Enable was Set. VF Enable Time is either (1) the Reset Time value in the Readiness Time Reporting capability associated with the VF or (2) a value determined by system software / firmware¹⁸⁸.

The VF is permitted to silently drop Memory Requests after an FLR has been issued to the VF or VF Enable has been Set in the associated PF's SR-IOV Extended Capability until the VF responds successfully to any Request (excluding the return of RRS in response to a Configuration Request).

Clearing VF Enable effectively destroys the VFs. Setting VF Enable effectively creates VFs. Setting VF Enable after it has previously been Cleared shall result in a new set of VFs. If the PF is in the D0 power state, the new VFs are in the D0_uninitialized state. If the PF is in a lower power state behavior is undefined (see Sections 9.6.1 and 9.6.2).

When Clearing VF Enable, a PF that supports FRS shall send an FRS Message with FRS Reason VF Disabled to indicate when this operation is complete. The PF is not permitted to send this Message if there are outstanding Non-Posted Requests issued by the PF or any of the VFs associated with the PF. The FRS Message may only be sent after these Requests have completed (or timed out).

After VF Enable is Cleared no field in the SR-IOV Extended Capability may be accessed until either:

- At least 1.0 s has elapsed after VF Enable was Cleared.
- The PF supports FRS and after VF Enable was Cleared, an FRS Message has been received from the PF with a Reason Code of VF Disabled.

§ Section 9.3.3.7 NumVFs, § Section 9.3.3.5 InitialVFs, § Section 9.3.3.6 TotalVFs, § Section 9.3.3.9 First VF Offset, § Section 9.3.3.13 System Page Size, and § Section 9.3.3.14 VF BARx describe additional semantics associated with this field.

9.3.3.3.2 VF Migration Enable §

VF Migration Enable must be Set to allow VF Migration on this PF.

VF Migration is associated with the now-deprecated [MR-IOV]. New designs should hardwire this bit to 0b.

9.3.3.3.3 VF Migration Interrupt Enable §

VF Migration is associated with the now-deprecated MR-IOV. New designs should hardwire this bit to 0b.

188. For example, ACPI tables.

9.3.3.3.4 VF MSE (Memory Space Enable) §

VF MSE controls memory space enable for all Active VFs associated with this PF, as with the Memory Space Enable bit in a Function's PCI Command register. The default value for this bit is 0b.

When VF Enable is Set, VF memory space will respond only when VF MSE is Set. VFs shall follow the same error reporting rules as defined in the [PCIe] if an attempt is made to access a Virtual Function's memory space when VF Enable is Set and VF MSE is Clear.

IMPLEMENTATION NOTE: VF MSE AND VF ENABLE §

VF memory space will respond with Unsupported Request when VF Enable is Clear. Thus, VF MSE is “don't care” when VF Enable is Clear; however, software may choose to Set VF MSE after programming the VF BARn registers, prior to Setting VF Enable.

9.3.3.3.5 ARI Capable Hierarchy §

For Devices associated with an Upstream Port, ARI Capable Hierarchy is a hint to the Device that ARI has been enabled in the Root Port or Switch Downstream Port immediately above the Device. Software should set this bit to match the ARI Forwarding Enable bit in the Root Port or Switch Downstream Port immediately above the Device.

ARI Capable Hierarchy is only present in the lowest-numbered PF of a Device (for example PF₀) and affects all PFs of the Device. ARI Capable Hierarchy is Read Only Zero in other PFs of a Device.

A Device may use the setting of ARI Capable Hierarchy to determine the values for First VF Offset (see § Section 9.3.3.9) and VF Stride (see § Section 9.3.3.10). The effect of changing ARI Capable Hierarchy is undefined if VF Enable is Set in any PF. This bit must be set to its default value upon Conventional Reset. This bit is not affected by FLR of any PF or VF. If either ARI Capable Hierarchy Preserved is Set (see § Section 9.3.3.2.2) or No_Soft_Reset is Set (see § Section 5.10.2), a power state transition of this PF from D3_{Hot} to D0 does not affect the value of this bit (see § Section 5.10.2).

ARI Capable Hierarchy does not apply to RCiEPs.

IMPLEMENTATION NOTE: ARI CAPABLE HIERARCHY §

For a Device associated with an Upstream Port, that Device has no way of knowing whether ARI has been enabled. If ARI is enabled, the Device can conserve Bus Numbers by assigning VFs to Function Numbers greater than 7 on the captured Bus Number. ARI is defined in § Section 6.13.

Since RCiEPs are not associated with an Upstream Port, ARI does not apply, and VFs may be assigned to any Function Number within the Root Complex permitted by First VF Offset and VF Stride (see § Section 9.3.3.8 and § Section 9.3.3.9).

9.3.3.4 SR-IOV Status Register (Offset 0Ah) §

§ Table 9-5: defines the layout of the SR-IOV Status field.

Figure 9-14 SR-IOV Status §

Table 9-5 SR-IOV Status §

Bit Location	Register Description	Attributes
0	VF Migration Status - VF Migration is associated with the now-deprecated [MR-IOV]. New designs should hardwire this bit to 0b.	RW1C

9.3.3.4.1 VF Migration Status §

VF Migration is associated with the now-deprecated [MR-IOV]. New designs should hardwire this bit to 0b.

9.3.3.5 InitialVFs (Offset 0Ch) §

VF Migration is associated with the now deprecated MR-IOV. New designs should encode this field as Hwlnit with a value equal to TotalVFs.

9.3.3.6 TotalVFs (Offset 0Eh) §

TotalVFs indicates the maximum number of VFs that are associated with the PF.

The minimum value of TotalVFs is 0.

This field is Hwlnit and must contain the same value as InitialVFs.

9.3.3.7 NumVFs (Offset 10h) §

NumVFs controls the number of VFs that are visible. SR-PCIM sets NumVFs as part of the process of creating VFs. This number of VFs shall be visible in the PCI Express fabric after both NumVFs is set to a valid value and VF Enable is Set.

The results are undefined if NumVFs is set to a value greater than TotalVFs.

NumVFs may only be written while VF Enable is Clear. If NumVFs is written when VF Enable is Set, the results are undefined.

The initial value of NumVFs is undefined.

9.3.3.8 Function Dependency Link (Offset 12h) §

The programming model for a Device may have vendor-specific dependencies between sets of Functions. The Function Dependency Link field is used to describe these dependencies.

This field describes dependencies between PFs. VF dependencies are the same as the dependencies of their associated PFs.

If a PF is independent from other PFs of a Device, this field shall contain its own Function Number.

If a PF is dependent on other PFs of a Device, this field shall contain the Function Number of the next PF in the same Function Dependency List. The last PF in a Function Dependency List shall contain the Function Number of the first PF in the Function Dependency List.

If PF_p and PF_q are in the same Function Dependency List, then any SI that is assigned VF_{p,n} shall also be assigned to VF_{q,n}.

IMPLEMENTATION NOTE: FUNCTION DEPENDENCY LINK EXAMPLE §

Consider the following scenario:

SR-IOV Field	PF 0	PF 1	PF 2
Function Dependency Link	1	0	2
NumVFs	4	4	6
First VF Offset	4	4	4
VF Stride	3	3	3

Function Number	Description	Independent
0	PF 0	No
1	PF 1	No
2	PF 2	Yes
3	Function not present	
4	VF 0,1 (aka PF 0 VF 1)	No
5	VF 1,1 (aka PF 1 VF 1)	No
6	VF 2,1 (aka PF 2 VF 1)	Yes
7	VF 0,2	No
8	VF 1,2	No
9	VF 2,2	Yes
10	VF 0,3	No
11	VF 1,3	No
12	VF 2,3	Yes
13	VF 0,4	No
14	VF 1,4	No
15	VF 2,4	Yes
16 to 17	Functions not present	
18	VF 2,5	Yes
19 to 20	Functions not present	
21	VF 2,6	Yes

Function Number	Description	Independent
22 to 255	Functions not present	

In this example, Functions 4 and 5 must be assigned to the same SI. Similarly, Functions 7 and 8, 10 and 11, and 13 and 14 must be assigned together. If PFs are assigned to SIs, Functions 0 and 1 must be assigned together as well. Functions 2, 6, 9, 12, 15, 18, and 21 are independent and may be assigned to SIs in any fashion.

All PFs in a Function Dependency List shall have the same values for the InitialVFs and TotalVFs fields.

SR-PCIM shall ensure that all PFs in a Function Dependency List have the same values for the NumVFs and VF Enable fields before any VF in that Function Dependency List is assigned to an SI.

VF Mapping operations occur independently for every VF. SR-PCIM shall not assign a VF to an SI until it can assign all dependent VFs.

Similarly, SR-PCIM shall not remove a VF from an SI until it can remove all dependent VFs.

9.3.3.9 First VF Offset (Offset 14h) §

First VF Offset is a constant and defines the Routing ID offset of the first VF that is associated with the PF that contains this Capability structure. The first VF's 16-bit Routing ID is calculated by adding the contents of this field to the Routing ID of the PF containing this field ignoring any carry, using unsigned, 16-bit arithmetic.

A VF shall not be located on a Bus Number that is numerically smaller than its associated PF.

This field may change value when the lowest-numbered PF's ARI Capable Hierarchy value changes or when this PF's NumVFs value changes.

Note: First VF Offset is unused if NumVFs is 0. If NumVFs is greater than 0, First VF Offset must not be zero.

9.3.3.10 VF Stride (Offset 16h) §

VF Stride defines the Routing ID offset from one VF to the next one for all VFs associated with the PF that contains this Capability structure. The next VF's 16-bit Routing ID is calculated by adding the contents of this field to the Routing ID of the current VF, ignoring any carry, using unsigned 16-bit arithmetic.

This field may change value when the lowest-numbered PF's ARI Capable Hierarchy value changes or when this PF's NumVFs value changes.

Note: VF Stride is unused if NumVFs is 0 or 1. If NumVFs is greater than 1, VF Stride must not be zero.

9.3.3.11 VF Device ID (Offset 1Ah) §

This field contains the Device ID that should be presented for every VF to the SI.

VF Device ID may be different from the PF Device ID. A VF Device ID must be managed by the vendor. The vendor must ensure that the chosen VF Device ID does not result in the use of an incompatible device driver.

9.3.3.12 Supported Page Sizes (Offset 1Ch) §

This field indicates the page sizes supported by the PF. This PF supports a page size of 2^{n+12} if bit n is Set. For example, if bit 0 is Set, the PF supports 4-KB page sizes. PFs are required to support 4-KB, 8-KB, 64-KB, 256-KB, 1-MB, and 4-MB page sizes. All other page sizes are optional.

The page size describes the minimum alignment requirements for VF BAR resources as described in § Section 9.3.3.13.

IMPLEMENTATION NOTE: NON-PREFETCHABLE ADDRESS SPACE §

Non-prefetchable address space is limited to addresses below 4 GB. Pre-fetch address space in 32-bit systems is also limited. Vendors are strongly encouraged to utilize the System Page Size feature to conserve address space while also supporting systems with larger pages.

9.3.3.13 System Page Size (Offset 20h) §

This field defines the page size the system will use to map the VFs' memory addresses. Software must set the value of the System Page Size to one of the page sizes set in the Supported Page Sizes field (see § Section 9.3.3.12). As with Supported Page Sizes, if bit n is Set in System Page Size, the VFs associated with this PF are required to support a page size of 2^{n+12} . For example, if bit 1 is Set, the system is using an 8-KB page size. The results are undefined if System Page Size is zero. The results are undefined if more than one bit is Set in System Page Size. The results are undefined if a bit is Set in System Page Size that is not Set in Supported Page Sizes.

When System Page Size is set, the VF associated with this PF is required to align all BAR resources on a System Page Size boundary. Each VF BAR n or VF BAR n pair (see § Section 9.3.3.14) shall be aligned on a System Page Size boundary. Each VF BAR n or VF BAR n pair defining a non-zero address space shall be sized to consume an integer multiple of System Page Size bytes. All data structures requiring page size alignment within a VF shall be aligned on a System Page Size boundary.

VF Enable must be zero when System Page Size is written. The results are undefined if System Page Size is written when VF Enable is Set.

Default value is 0000 0001h (i.e., 4 KB).

9.3.3.14 VF BAR0 (Offset 24h), VF BAR1 (Offset 28h), VF BAR2 (Offset 2Ch), VF BAR3 (Offset 30h), VF BAR4 (Offset 34h), VF BAR5 (Offset 38h) §

These fields must define the VF's Base Address Registers (BARs). These fields behave as normal PCI BARs, as described in § Section 7.5.1. They can be sized by writing all 1s and reading back the contents of the BARs as described in § Section 7.5.1.2.1, complying with the low order bits that define the BAR type fields.

These fields may have their attributes affected by the VF Resizable BAR Extended Capability (see § Section 7.8.7) if it is implemented.

The amount of address space decoded by each BAR shall be an integral multiple of System Page Size.

Each VF BAR n , when "sized" by writing 1s and reading back the contents, describes the amount of address space consumed and alignment required by a single Virtual Function, per BAR. When written with an actual address value, and

VF Enable and VF MSE are Set, the BAR maps NumVFs BARs. In other words, the base address is the address of the first VF BAR n associated with this PF and all subsequent VF BAR n address ranges follow as described below.

VF BARs shall only support 32-bit and 64-bit memory space. PCI I/O Space is not supported in VFs. Bit 0 of any implemented VF BAR x must be RO 0b except for a VF BAR x used to map the upper 32 bits of a 64-bit memory VF BAR pair.

The alignment requirement and size read is for a single VF, but when VF Enable is Set and VF MSE is Set, the BAR contains the base address for all (NumVFs) VF BAR n .

The algorithm to determine the amount of address space mapped by a VF BAR n differs from the standard BAR algorithm as follows:

1. Resize the BAR via the VF Resizable BAR Extended Capability (see § Section 7.8.7) if it is implemented.
2. After reading the low order bits to determine if the BAR is a 32-bit BAR or 64-bit BAR pair, determine the size and alignment requirements by writing all 1s to VF BAR n (or VF BAR n and VF BAR $n+1$ for a 64-bit BAR pair) and reading back the contents of the BAR or BAR pair. Convert the bit mask returned by the read(s) to a size and alignment value as described in § Section 7.5.1.2.1. This value is the size and alignment for a single VF.
3. Multiply the value from step 2 by the value set in NumVFs to determine the total amount of space the BAR or BAR pair will map after VF Enable and VF MSE are Set.

For each VF BAR n field, n corresponds to one of the VFs BAR spaces. § Table 9-8 shows the relationship between n and a Function's BAR.

Table 9-8 BAR Offsets §

n	BAR Offset in a Type 0 Header
0	10h
1	14h
2	18h
3	1Ch
4	20h
5	24h

The contents of all VF BAR n registers are indeterminate after System Page Size is changed.

9.3.3.15 VF Migration State Array Offset (Deprecated) (Offset 3Ch) §

VF Migration is associated with the now deprecated [MR-IOV]. New designs should hardwire this register to 0000 0000h.

9.3.4 PF/VF Configuration Space Header §

This section's material in previous versions of this specification has been integrated into § Section 7.5.1.

9.3.5 PCI Express Capability Changes §

This section's material in previous versions of this specification has been integrated into § Section 7.5.3.

9.3.6 PCI Standard Capabilities §

SR-IOV usage of PCI Standard Capabilities is described in § Table 9-9. Items marked n/a are not applicable to PFs or VFs.

Table 9-9 SR-IOV Usage of PCI Standard Capabilities §

Capability ID	Description	PF Attributes	VF Attributes
00h	Null Capability	Base	Base
01h	PCI Power Management Interface	Base	Optional. See § Section 5.10 .
02h	AGP	n/a	n/a
03h	VPD	Base	Optional. See § Section 7.9.18 .
04h	Slot Identification	n/a	n/a
05h	MSI	Base	See § Section 9.2.1.4 .
06h	CompactPCI Hot Swap	n/a	n/a

10. Address Translation Services (ATS) §

10.1 ATS Architectural Overview §

Most contemporary system architectures make provisions for translating addresses from DMA (bus mastering) I/O Functions. In many implementations, it has been common practice to assume that the physical address space seen by the CPU and by an I/O Function is equivalent. While in others, this is not the case. The address programmed into an I/O Function is a “handle” that is processed by the Root Complex (RC). The result of this processing is often a translation to a physical memory address within the central complex. Typically, the processing includes access rights checking to insure that the DMA Function is allowed to access the referenced memory location(s).

The purposes for having DMA address translation vary and include:

- Limiting the destructiveness of a “broken” or misprogrammed DMA I/O Function
- Providing for scatter/gather
- Ability to redirect message-signaled interrupts (e.g., MSI or MSI-X) to different address ranges without requiring coordination with the underlying I/O Function
- Address space conversion (32-bit I/O Function to larger system address space)
- Virtualization support

Irrespective of the motivation, the presence of DMA address translation in the host system has certain performance implications for DMA accesses.

Depending on the implementation, DMA access time can be significantly lengthened due to the time required to resolve the actual physical address. If an implementation requires access to a main-memory-resident translation table, the access time can be significantly longer than the time for an untranslated access. Additionally, if each transaction requires multiple memory accesses (e.g., for a table walk), then the memory transaction rate (i.e., overhead) associated with DMA can be high.

To mitigate these impacts, designs often include address translation caches in the entity that performs the address translation. In a CPU, the address translation cache is most commonly referred to as a translation look-aside buffer (TLB). For an I/O TA, the term address translation cache or ATC is used to differentiate it from the translation cache used by the CPU.

While there are some similarities between TLB and ATC, there are important differences. A TLB serves the needs of a CPU that is nominally running one thread at a time. The ATC, however, is generally processing requests from multiple I/O Functions, each of which can be considered a separate thread. This difference makes sizing an ATC difficult depending upon cost models and expected technology reuse across a wide range of system configurations.

The mechanisms described in this specification allow an I/O Device to participate in the translation process and provide an ATC for its own memory accesses. The benefits of having an ATC within a Device include:

- Ability to alleviate TA resource pressure by distributing address translation caching responsibility (reduced probability of “thrashing” within the TA)
- Enable ATC Devices to have less performance dependency on a system’s ATC size
- Potential to ensure optimal access latency by sending pretranslated requests to central complex

This specification will provide the interoperability that allows PCIe Devices to be used in conjunction with a TA, but the TA and its Address Translation and Protection Table (ATPT) are treated as implementation specific and are outside the

scope of this specification. While it may be possible to implement ATS within other PCIe Components, this specification is confined to PCIe Devices and PCIe Root Complex Integrated Endpoints (RCiEPs).

§ Figure 10-1 illustrates an example platform with a TA and ATPT, along with a set of PCIe Devices and RC Integrated Endpoints with integrated ATC. A TA and an ATPT are implementation specific and can be distinct or integrated components within a given system design.

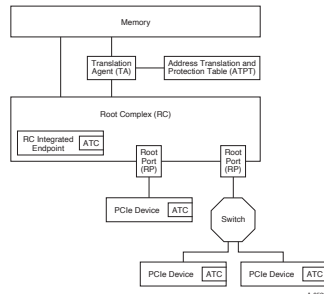

Figure 10-1 Example Illustrating a Platform with TA, ATPT, and ATC Elements §

10.1.1 Address Translation Services (ATS) Overview §

The ATS chapter provides a new set of TLP and associated semantics. ATS uses a request-completion protocol between a Device¹⁸⁹ and a Root Complex (RC) to provide translation services. In addition, a new AT field is defined within the Memory Read and Memory Write TLP. The new AT field enables an RC to determine whether a given request has been translated or not via the ATS protocol.

§ Figure 10-2 illustrates the basic flow of an ATS Translation Request operation.

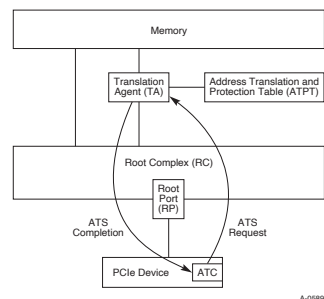

Figure 10-2 Example ATS Translation Request/Completion Exchange §

In this example, a Function-specific work request is received by a single-Function PCIe Device. The Function determines through an implementation specific method that caching a translation within its ATC would be beneficial. There are a number of considerations a Function or software can use in making such a determination; for example:

- Memory address ranges that will be frequently accessed over an extended period of time or whose associated buffer content is subject to a significant update rate

189. All references within this chapter to a Device apply equally to a PCIe Device or a Root Complex Integrated Endpoint. ATS does not delineate between these two types in terms of requirements, semantics, configuration, error handling, etc. From a software perspective, an ATS-capable Root Complex Integrated Endpoint must behave the same as an ATS-capable non-integrated Device.

- Memory address ranges, such as work and completion queue structures, data buffers for low-latency communications, graphics frame buffers, host memory that is used to cache Function-specific content, and so forth

Given the variability in designs and access patterns, there is no single criteria that can be applied.

The Function generates an ATS Translation Request which is sent upstream through the PCIe hierarchy to the RC which then forwards it to the TA. An ATS Translation Request uses the same routing and ordering rules as defined in this specification. Further, multiple ATS Translation Requests can be outstanding at any given time; i.e., one may pipeline multiple requests on one or more TC. Each TC represents a unique ordering domain and defines the domain that must be used by the associated ATS Translation Completion.

Upon receipt of an ATS Translation Request, the TA performs the following basic steps:

1. Validates that the Function has been configured to issue ATS Translation Requests.
2. Determines whether the Function may access the memory indicated by the ATS Translation Request and has the associated access rights.
3. Determines whether a translation can be provided to the Function. If yes, the TA issues a translation to the Function.
 - a. ATS is required to support a variety of page sizes to accommodate a range of ATPT and processor implementations.
 - i. Page sizes are required to be a power of two and naturally aligned.
 - ii. The minimum supported page size is 4096 bytes. ATS capable components are required to support this minimum page size.
 - b. A Function must be informed of the minimum translation or invalidate size it will be required to support to provide the Function an opportunity to optimize its resource utilization. The smallest minimum translation size must be 4096 bytes.
4. The TA communicates the success or failure of the request to the RC which generates an ATS Translation Completion and transmits via a Response TLP through a RP to the Function.
 - a. An RC is required to generate at least one ATS Translation Completion per ATS Translation Request; i.e., there is minimally a 1:1 correspondence independent of the success or failure of the request.
 - i. A successful translation can result in one or two ATS Translation Completion TLPs per request. The Translation Completion indicates the range of translation covered.
 - ii. An RC may pipeline multiple ATS Translation Completions; i.e., an RC may return multiple ATS Translation Completions and these ATS Translation Completions may be in any order relative to ATS Translation Requests.
 - iii. The RC is required to transmit the ATS Translation Completion using the same TC (Traffic Class) as the corresponding ATS Translation Request.
 - b. The requested address may not be valid. The RC is required to issue a Translation Completion indicating that the requested address is not accessible.

When the Function receives the ATS Translation Completion and either updates its ATC to reflect the translation or notes that a translation does not exist. The Function proceeds with processing its work request and generates subsequent requests using either a translated address or an untranslated address based on the results of the Completion.

- a. Similar to Read Completions, a Function is required to allocate resource space for each completion(s) without causing backpressure on the PCIe Link.
- b. A Function is required to discard Translation Completions that might be “stale”. Stale Translation Completions can occur for a variety of reasons.

As one can surmise, ATS Translation Request and Translation Completion processing is conceptually similar and, in many respects, identical to PCIe Read Request and Read Completion processing. This is intentional to reduce design complexity and to simplify integration of ATS into existing and new PCIe-based solutions. Keeping this in mind, ATS requires the following:

- ATS capable components must interoperate with [PCIe-1.1] compliant components.
- ATS is enabled through a new Capability and associated configuration structure. To enable ATS, software must detect this Capability and enable the Function to issue ATS TLP. If a Function is not enabled, the Function is required not to issue ATS Translation Requests and is required to issue all DMA Read and Write Requests with the TLP AT field set to “untranslated”.
- ATS TLPs are routed using either address-based or ID-based routing.
- ATS TLPs are required to use the same ordering rules as specified in this specification.
- ATS TLPs are required to flow unmodified through [PCIe-1.1] compliant Switches.
- A Function is permitted to intermix translated and untranslated requests.
- ATS transactions are required not to rely upon the address field of a memory request to communicate additional information beyond its current use as defined by the PCI-SIG.

IMPLEMENTATION NOTE: ADDRESS RANGE OVERLAP §

While significant overlap is expected, a system is not required to make Untranslated and Translation/Translated sequences interchangeable for all address ranges. For example, it is permitted for a Root Complex to require Untranslated Requests for interrupt behavior (MSI/MSI-X).

In contrast to the prior example, § Figure 10-3 illustrates an example Multi-Function Device. In this example Device, there are three Functions. Key points to note in § Figure 10-3 are:

- Each ATC is associated with a single Function. Each ATS-capable Function must be able to source and sink at least one of each ATS Translation Request or Translation Completion type.
- Each ATC is configured and accessed on a per Function basis. A Multi-Function Device is not required to implement ATS on every Function.
- If the ATC implementation shares resources among a set of Functions, then the logical behavior is required to be consistent with fully independent ATC implementations.

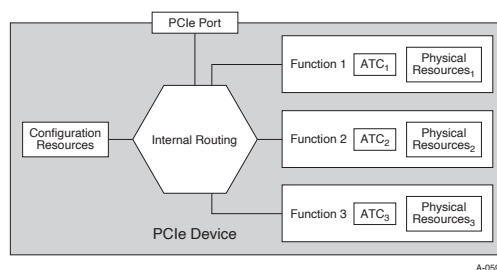

Figure 10-3 Example Multi-Function Device with ATC per Function §

Independent of the number of Functions within a Device, the following are required:

- A Function is required not to issue any TLP with the AT field set unless the address within the TLP was obtained through the ATS Translation Request and Translation Completion protocol.
- Each ATC is required to only be populated using the ATS protocol; i.e., each entry within the ATC must be filled via an ATS Translation Completion in response to the Function issuing an ATS Translation Request for a given address.
- Each ATC cannot be modified except through the ATS protocol. That is:
 - Host system software cannot modify the ATC other than through the protocols defined in this specification except to invalidate one or more translations in an ATC. A Device or Function reset would be an example of an operation performed by software to change the contents of the ATC, but a reset is only allowed to invalidate entries not modify their contents.
 - It must not be possible for host system software to use software executing on the Device to modify the ATC.

When a TA determines that a Function should no longer maintain a translation within its ATC, the TA initiates the ATS invalidation protocol. The invalidation protocol consists of a single Invalidation Request and one or more Invalidate Completions.

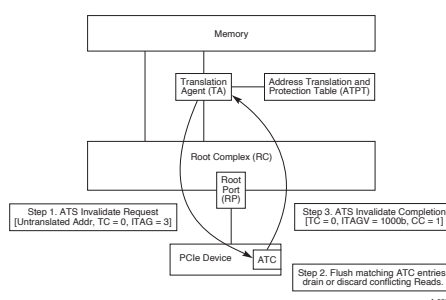

Figure 10-4 Invalidation Protocol with a Single Invalidation Request and Completion §

As § Figure 10-4 illustrates, there are essentially three steps in the ATS Invalidation protocol:

1. The system software updates an entry in the tables used by the TA. After the table is changed, the TA determines that a translation should be invalidated in an ATC and initiates an Invalidation Request TLP which is transmitted from the RP to the example single-Function Device. The Invalidate Request communicates an untranslated address range, the TC, and an RP unique tag which is used to correlate Invalidate Completions with the Invalidation Request.
2. The Function receives the Invalidate Request and invalidates all matching ATC entries. A Function is not required to immediately flush all pending requests upon receipt of an Invalidate Request. If transactions are in a queue waiting to be sent, it is not necessary for the Function to expunge requests from the queue even if those transactions use an address that is being invalidated.
 - a. A Function is required not to indicate the invalidation has completed until all outstanding Read Requests or Translation Requests that reference the associated translated address have been retired or nullified.
 - b. A Function is required to ensure that the Invalidate Completion indication to the RC will arrive at the RC after any previously posted writes that use the “stale” address.
3. When a Function has ascertained that all uses of the translated address are complete, it issues one or more ATS Invalidate Completions.

- a. An Invalidate Completion is issued for each TC that may have referenced the range invalidated. These completions act as a flush mechanism to ensure the hierarchy is cleansed of any in-flight transactions which may contain references to the translated address.
 - i. The number of Completions required is communicated within each Invalidate Completion. A TA or RC implementation can maintain a counter to ensure that all Invalidate Completions are received before considering the translation to no longer be in use.
 - ii. If more than one Invalidation Complete is sent, the Invalidate Completion sent in each TC must be identical in the fields detailed in § Section 10.3.2 .
- b. An Invalidate Completion contains the ITAG from Invalidate Request to enable the RC to correlate Invalidate Requests and Completions.

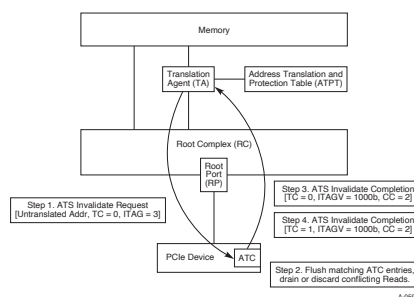

Figure 10-5 Single Invalidate Request with Multiple Invalidate Completions §

10.1.2 Page Request Interface Extension §

ATS improves the behavior of DMA based data movement. An associated Page Request Interface (PRI) provides additional advantages by allowing DMA operations to be initiated without requiring that all the data to be moved into or out of system memory be pinned.¹⁹⁰ The overhead associated with pinning memory may be modest, but the negative impact on system performance of removing large portions of memory from the pageable pool can be significant.

PRI is functionally independent of the other aspects of ATS. That is, a device that supports ATS need not support PRI, but PRI is dependent on ATS's capabilities.

Intelligent I/O devices can be constructed to make good use of a more dynamic memory interface. Pinning will always have the best performance characteristics from a device's perspective—all the memory it wants to touch is guaranteed to be present. However, guaranteeing the residence of all the memory a device might touch can be problematic and force a sub-optimal level of device awareness on a host. Allowing a device to operate more independently (to page fault when it requires memory resources that are not present) provides a superior level of coupling between device and host.¹⁹¹

The mechanisms used to take advantage of a Page Request Interface are very device specific. As an example of a model in which such an interface could improve overall system performance, let us examine a high-speed LAN device. Such a device knows its burst rate and need only have as much physical buffer space available for inbound data as it can receive within some quantum. A vector of unpinned virtual memory pages could be made available to the device, that the device then requests as needed to maintain its burst window. This minimizes the required memory footprint of the device and simplifies the interface with the host, both without negatively impacting performance.

The ability to page, begs the question of page table status flag management. Typical TAs associate flags (e.g., dirty and access indications) with each untranslated address. Without any additional hints about how to manage pages mapped

190. Locked in place so that it cannot be swapped out by the system's dynamic paging mechanism.

191. The alternative is a private interface between a device and its driver that is used to communicate device state so that the driver can ensure the availability of pinned memory resources.

to a Function, such TAs would need to conservatively assume that when they grant a Function permission to read or write a page, that Function will use the permission. Such writable pages would need to be marked as dirty before their translated addresses are made available to a Function.

This conservative dirty-on-write-permission-grant behavior is generally not a significant issue for Functions that do not support paging, where pages are pinned and the cost of saving a clean page to memory will seldom be paid. However, Functions that support the Page Request Interface could pay a significant penalty if all writable pages are treated as dirty, since such Functions operate without pinning their accessible memory footprints and may issue speculative page requests for performance. The cost of saving clean pages (instead of just discarding them) in such systems can diminish the value of otherwise attractive paging techniques. This can cause significant performance issues and risk functional issues in circumstances where the backing store is unable to be written, such as a CD-ROM.

The No Write (NW flag in Translation Requests indicates that a Function is willing to restrict its usage to only reading the page, independent of the access rights that would otherwise have been granted.

If a device chooses to request only read access by issuing a Translation Request with the NW flag Set and later determines that it needs to write to the page, then the device must issue a new Translation Request.

Upon receiving a Translation Request with the NW flag Clear, TAs are permitted to mark the associated pages dirty. Functions *MUST@FLIT* not issue such Requests unless they have been given explicit write permission. An example of write permission is where the host issues a command to a Function to load data from a storage device and write that data into memory.

10.1.3 Process Address Space ID (PASID) §

Certain TLPs can optionally be associated with a Process Address Space ID (PASID). This value is conveyed using the PASID TLP Prefix (NFM) or OHC-A (FM). The PASID TLP Prefix is defined in § Section 6.20 .

PASID is permitted for the following types of TLPs:

- Memory Requests (including AtomicOp Requests) with Address Type (AT) of Untranslated or Translated
- Address Translation Requests (i.e., MRd with AT=01b)
- Page Request Messages
- ATS Invalidation Request Messages
- PRG Response Messages
- Address routed messages in Flit Mode

Usage of PASID for Untranslated Memory Requests is defined in § Section 6.20 . This section describes PASID for the remaining TLPs.

Each Function has an independent set of PASID values. The PASID field is 20 bits wide, although typically the number of active PASID values will be significantly lower than 2^{20} . PASID values may be allocated sparsely. If the usable width is constrained by the TA or the ATC, the unused upper bits of the PASID value must be 0b. All $2^{\text{usable_width}}$ PASID values are usable. Function hardware is not permitted to assume there are “reserved” PASID values.

An ATC may optionally support Translated Requests with PASID. The Translated Requests with PASID feature is enabled when the Translated Requests with PASID Enable bit is Set. When Translated Requests with PASID Enable is Set, an ATC is permitted to issue Translated Requests with a PASID. When enabled, if the ATC obtained a translation using a Translation Request with PASID, the corresponding Translated Request must carry the same PASID as the Translation Request, the Privileged Mode Requested bit must match the Privileged Mode Access bit in the Translation Response, and the Execute Requested bit is permitted to be Set only if the Execute Permitted bit in the Translation Response was Set. Similarly, if the ATC obtained a translation using a Translation Request without a PASID, the corresponding Translated Request must not carry a PASID. If these rules are not followed the resulting system behavior is undefined.

10.1.4 ATS Memory Attributes §

ATS Memory Attributes (AMAs) provide hints for performing memory operations such as cache management. The AMAs may be supplied to an Endpoint device by a Translation Completion and stored in the ATC. If the ATS Memory Attributes Enable bit is Set, the Endpoint function retrieves the AMAs from the ATC and is permitted to provide AMAs with Memory Read/Write TLPs using the TPH TLP Prefix. This serves as a performance optimization by preventing the TA from having to perform a look-up. The TA and ATC are permitted to support AMAs. If the ATC does not support AMAs but the TA does, then the TA is permitted to perform a lookup to obtain AMAs when processing Memory Read/Write TLPs received from the Endpoint device. A TA that supports AMAs is permitted to always return AMAs in all ATS Translation Completions to all Endpoints.

10.2 ATS Translation Services §

A TA does translations. An ATC can cache those translations. If an ATC is separated from the TA by PCIe, the memory request from an ATC will need to be able to indicate if the address in the transaction is translated or not. The modifications to the memory transactions are described in this section, as are the transactions that are used to communicate translations between a remote ATC and a central TA.

When Shadow Functions are enabled, the TA must treat identically all Requests from the “main” Function and its Shadows (See Section 7.9.21). This usually involves ensuring that system software configures the translation tables used by the TA provide identical answers for the “main” Function and its Shadows. Depending on the architecture of a specific TA, more work may be required (e.g., managing dirty bits, ensuring caches are consistent, etc.). Such work is outside the scope of this specification.

10.2.1 Memory Requests with Address Type §

A Function with an ATC can send Memory Requests that contain either translated or untranslated addresses. The Address Type (AT) field is used to indicate the type of address that is present in the request header (see § Figure 10-6, § Figure 10-7, § Figure 10-8, and § Figure 10-9).

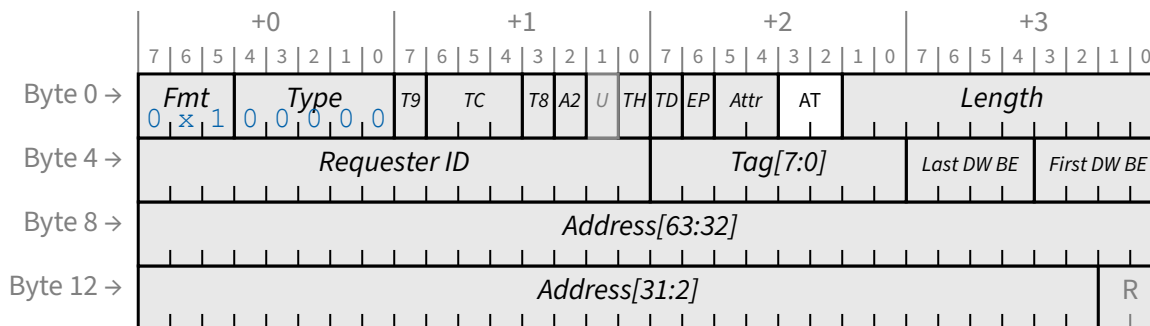

Figure 10-6 Memory Request Header with 64-bit Address Highlighting AT field §

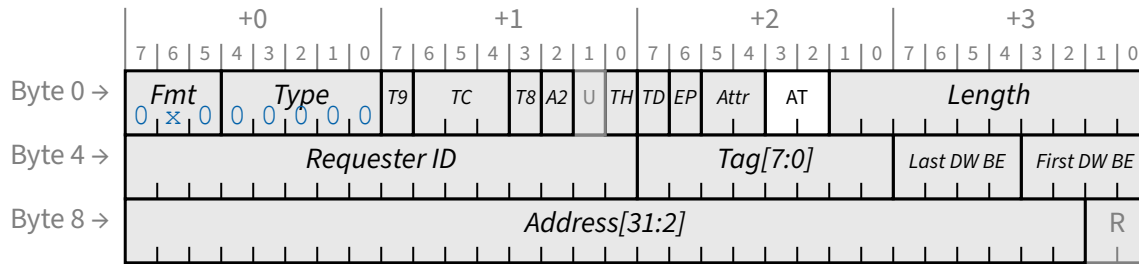

Figure 10-7 Memory Request Header with 32-bit Address Highlighting AT field §

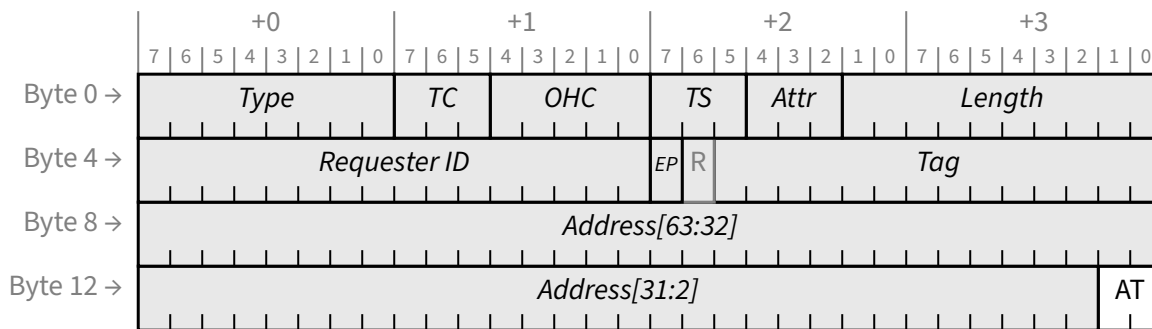

Figure 10-8 Memory Request Header with 64-bit Address Highlighting AT field - FLIT Mode §

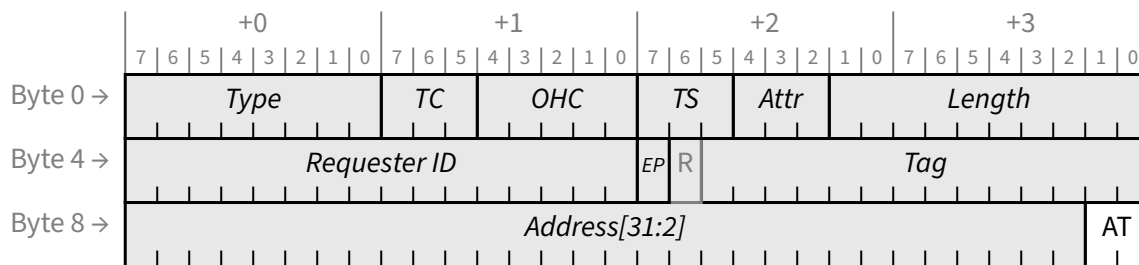

Figure 10-9 Memory Request Header with 32-bit Address Highlighting AT field - FLIT Mode §

In NFM, the AT field in the Requests is a redefinition of a reserved field in earlier version of this specification.

Functions that do not implement an ATC will continue to set the AT field to its defined reserved value (00b). Functions that implement an ATC will set the AT field as listed in Table 10-1.

Table 10-1 Address Type (AT) Field Encodings §

AT[1:0] Coding	Mnemonic	Meaning
00b	Untranslated	A TA may treat the address as either virtual or physical.
01b	Translation Request	The TA will return the translation of the address contained in the address field of the request as a read completion. This value only has meaning for an explicit Translation Request (see <u>Section 10.2.2</u>). The TA

AT[1:0] Coding	Mnemonic	Meaning
		will signal an Unsupported Request (UR) if it receives a TLP with the <u>AT</u> field set to 01b in a Memory Request other than Memory Read.
10b	Translated	The address in the transaction has been translated by an ATC. If the Function associated with the SourceID is allowed to present physical addresses to the system memory, then the TA might not translate this address. If the Function is not allowed to present physical addresses, then the TA may treat this as an UR.
11b	Reserved	The TA will signal an Unsupported Request (UR) if it receives a Memory Request TLP with the <u>AT</u> field set to 11b.

The AT field is only defined for Memory Requests and in Flit Mode, Address Routed Messages. The field remains reserved for other TLPs.

10.2.2 Translation Requests §

A Translation Request has a format that is similar to that of a Memory Read¹⁹² (MRd TLP Type) in either FM or NFM. The AT field must be set to the value defined for "Translation Request" to differentiate a Translation Request from a normal Memory Read (see § Figure 10-10, § Figure 10-11, § Figure 10-12, and § Figure 10-13). In Flit Mode, OHC-A1 must be included, and the No Write (NW flag is contained in OHC-A1).

Translation Requests have the same completion timeout intervals as Read Requests.

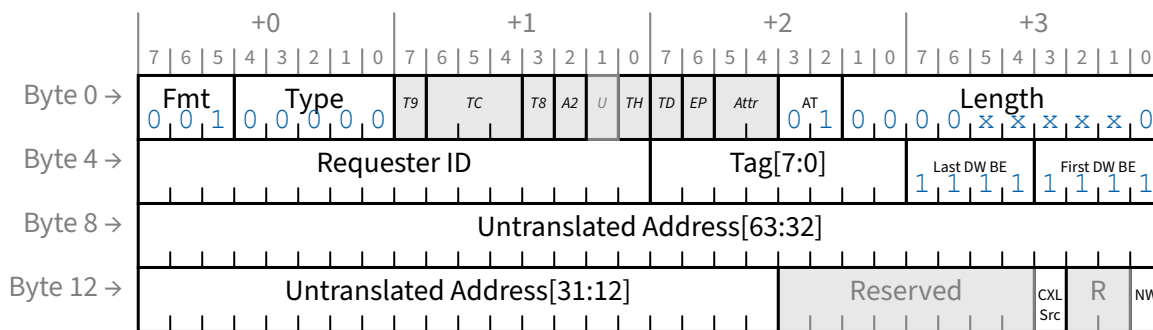

Figure 10-10 Translation Request with 64-bit Address - Non-Flit Mode §

192. Translation Requests are not defined for UIO Memory Reads (UIOMRd TLP Type).

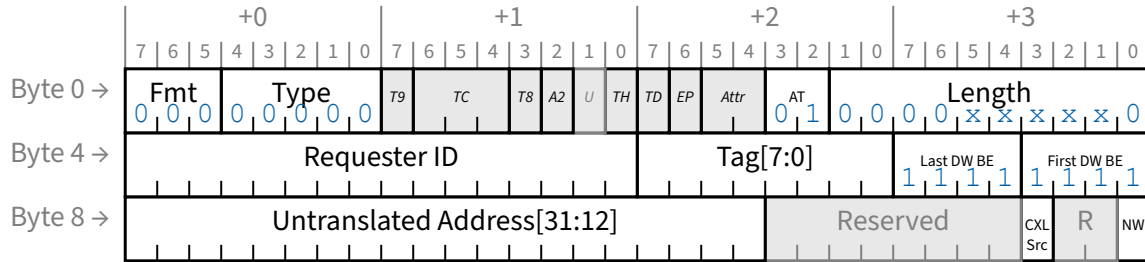

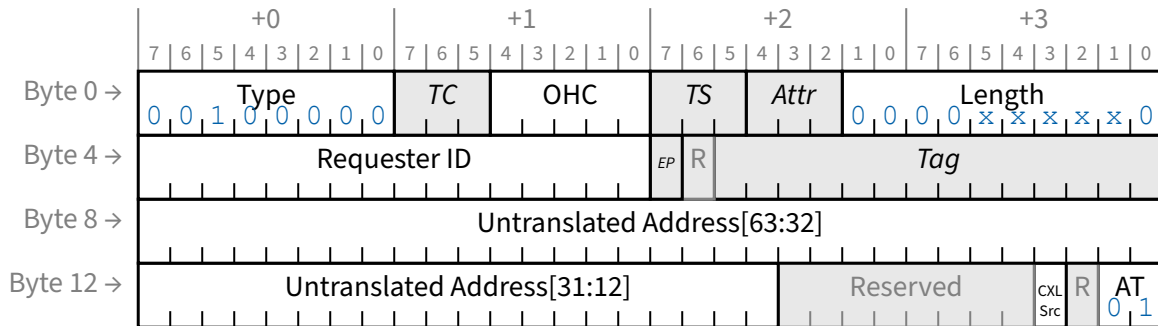

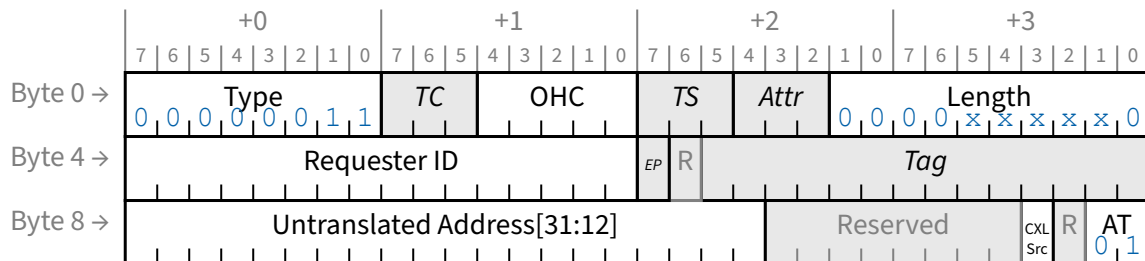

Figure 10-11 Translation Request with 32-bit Address - Non-Flit Mode §

Figure 10-12 Translation Request with 64-bit Address - Flit Mode¹⁹³ §Figure 10-13 Translation Request with 32-bit Address - Flit Mode¹⁹⁴ §

10.2.2.1 Attribute Field §

For a Translation Request, the Relaxed Ordering (RO) bit is applicable and permitted to be Set, where it affects the ordering of its associated Translation Completions. The remainder of the Attr field is Reserved. The Requester of a Translation Request must not depend on the TA to guarantee any specific ordering relationship between Translation Completions and any other Requests or Completions. There are no ordering requirements for a Translation Request. A TA may reorder a Translation Request with respect to any other request.

193. The NW bit is located in OHC-A1.

194. The NW bit is located in OHC-A1.

IMPLEMENTATION NOTE: TRANSLATION REQUEST ORDERING §

Because no ordering can be assumed between Translation Requests and other types of Requests, a Translation Request does not make an effective flushing/ordering primitive.

10.2.2.2 Length Field §

The Length field is set to indicate how many translations may be returned in response to this request. Each translation is 8 bytes in length and represents one or more STUs (Smallest Translation Unit). The maximum setting for the Length field is the RCB of the Root Port as determined by Read Completion Boundary (RCB) in the Link Control Register. The Length field in a Translation Request must always indicate an even number of DWORDs. If Length is set to indicate a value greater than allowed, or if the least-significant bit of the Length field is non-zero, then the resulting handling by the TA is undefined.¹⁹⁵

If the Length field has a value greater than two, then the Function is requesting translations for a range of memory greater than a single STU. The additional translations, if provided, are assumed to be for sequentially-increasing, equal-sized, STU-aligned regions, starting at the requested address.

10.2.2.3 Tag Field §

The Tag field has the same meaning as in a Memory Read Request.

10.2.2.4 Untranslated Address Field §

A Translation Request includes either a 32-bit or a 64-bit Untranslated Address field. This field indicates the address to be translated. The TA will make decisions about the validity of the request, based on the address in the translation request. The TA is permitted to return fewer translations than requested, but it will not return more.

When multiple translations are requested, the TA will not return a translation if the range of that translation does not overlap the implied range of the Translation Request (this would only apply to translations after the initial value). The implied range of the Translation Request is $[2^{\text{STU}+12} * (\text{Length}/2)]$ bytes.

The Untranslated Address field in the Translation Request is any address in the range of the first STU. Address bits 11:0 are not present in the Translation Request and are implied to be zero. If a Requester has Page Aligned Request Set (see § Section 7.8.9.2), it must ensure that bits 11:2 are zero. If a Requester has Page Aligned Request Clear, it is permitted to supply any value for bits 11:2.¹⁹⁶ The TA must ignore bits 11:2 as well as any low-order bits not required to determine the translation.

For example, if using 64-bit addressing for a Function with the Page Aligned Request bit Set that is programmed with an STU of 1 (i.e., 8192-byte pages), bits 63:13 are significant, bit 12 is ignored by the TA and bits 11:0 are implied to be zero.

¹⁹⁵. Due to ambiguous text in earlier versions of this document, it should be assumed that an unrecoverable error condition may occur.

¹⁹⁶. Note: The Page Aligned Request bit was added in Revision 1.1 of the ATS Specification.

10.2.2.5 No Write (NW) Flag §

The No Write flag, when Set, indicates that the Function is requesting read-only access for this translation.¹⁹⁷

The TA may ignore the No Write Flag, however, if the TA responds with a translation marked as read-only then the Function must not issue Memory Write transactions using that translation. In this case, the Function may issue another translation request with the No Write flag Clear, which may result in a new translation completion with or without the W (Write) bit Set.

Upon receiving a Translation Request with the NW flag Clear, TAs are permitted to mark the associated pages dirty. Functions *MUST@FLIT* not issue such Requests unless they have been given explicit write permission.

In Flit Mode, the NW bit is part of OHC-A1.

10.2.2.6 PASID on Translation Request §

If a Translation Request has a PASID, the Untranslated Address Field is an address within the process address space indicated by the PASID field.

If a Translation Request has a PASID with either the Privileged Mode Requested or Execute Requested bit Set, these may be used in constructing the Translation Completion Data Entry.

The PASID Extended Capability indicates whether a Function supports and is enabled to send and receive TLPs with the PASID.

10.2.2.7 CXL Src §

This bit is assigned for use by [CXL]. In non-CXL systems, this bit is Reserved.

10.2.3 Translation Completion §

A Translation Completion (either a Cpl or a CplD) is sent by a TA for each Translation Request. This specification describes the meaning of fields in Translation Completions. Fields not defined in this chapter have the same meanings proscribed for Read Completions in Chapter 2. For a Translation Completion, the Relaxed Ordering (RO) bit is applicable and permitted to be Set if the corresponding Translation Request RO bit was set. The remainder of the Attr field is Reserved.

If the TA was not able to perform the requested translation, a Completion with no data (Cpl) must be returned.

197. Note: The No Write Flag was added in Revision 1.1 of the ATS Specification.

IMPLEMENTATION NOTE: BYTE COUNT FIELD FOR UNSUCCESSFUL TRANSLATION COMPLETIONS WITH NO DATA §

Previous versions of this specification indicated the Byte Count and Lower Address field should be 0000 0000 0000b for Unsuccessful Translation Completions with No Data. It is strongly recommended that implementations do not depend on the Byte Count and Lower Address field being set to any particular value in Unsuccessful Translation Completions with No Data.

Note that in Flit Mode, the Byte Count and Lower Address Fields are not present.

The values and meaning for the Completion Status field are listed in § Table 10-2, where return values other than *Success* indicate an error.

Table 10-2 Translation Completion with No Data Status Codes §

Value	Status	Meaning
000b	Success	Indicates that the TA is returning one or more Translation Completion entries (including entries with R=W=0b).
001b	Unsupported Request (UR)	Indicates there is a problem, potentially correctable by system software, that prevents the TA from returning any Translation Completion entries. It is permitted for a Function that receives this Completion code to disable its ATC and not send requests using translated addresses until the ATC is re-enabled. The mechanism a Function receiving this code uses to report this condition is outside the scope of this specification. The TA detecting this error is a "Completer Sending a Completion with UR/CA Status" and shall behave as defined in this specification.
010b	RRS	This value is not allowed in any Completion to a Translation Request initiated by a PCI Express Function. If received by a Function, it is permitted to be handled as a Malformed TLP.
100b	Completer Abort (CA)	The TA was not able to translate the address because of an error in the TA. This status indicates a more serious error condition than UR. Returning CA nominally causes an error to be reported to the device driver associated with the ATC. See AER in this specification.
All others	Reserved	A Translation Completion with a Reserved Completion Status value is treated as if the Completion Status was Unsupported Request (001b).

Completion header fields must be set in accordance with § Section 2.2.9 and § Section 2.3 .

Translation Completions must be sent using the same TC as the Translation Request. The Function is not required to verify that the same TC was used. A TA may optionally copy the RO bit of a Translation Request to the Translation Completion in accordance to the rule specified for the attribute field of completions in § Section 2.2.9 . It is strongly recommended that the TA copy the RO bit. However, if a TA does not copy the RO bit of a Translation Request to the Translation Completion, the TA must clear the RO bit in the Translation Completion.

A Translation Completion with RO Set must follow the ordering rules for Relaxed Ordered Completions as specified in § Section 2.4.1 . A Function that initiates a Translation Request with the RO bit Set but receives the associated Translation Completion with the RO bit Clear is permitted to order associated Translation Completions as if the RO bit is Set.

A Function that initiates a Translation Request with the RO bit Set, must not report an error if the associated Translation Completion has the RO bit Clear.

IMPLEMENTATION NOTE: ATTRIBUTE FIELD COMPATIBILITY IN TRANSLATION COMPLETIONS §

Some implementations of TA may not copy the Attribute field from the request to the completion as required by § Section 2.2.9 , since the Attr field is defined as Reserved in previous versions of this specification. Therefore, the following situations may occur and are handled as follows:

- A TA that does not copy the RO bit (as is typically done for completions as indicated in § Section 2.2.9) by forcing RO to 0 is coupled with a Function conforming to this specification that allows RO to be Set in the request. The Function will accept a Translation Completion with RO Clear and not log an error.
- A TA that conforms to the Attr copy rule (in § Section 2.2.9) is coupled with a Function that does not support RO in Translation Requests. Translation Completions will return with RO Clear as the Function expects.

Therefore, the use of RO is made fully backward compatible. However, it is strongly recommended that the TA support the copy of the RO bit conforming to the rules in § Section 2.2.9 .

The Lower Address field contains a computed value that makes the packet consistent with RCB semantics. If the result is returned in a single packet, Lower Address contains RCB minus Byte Count. If the results are returned in two packets, Lower Address for the first packet contains RCB minus (Total Completion Length * 4) Lower Address for subsequent packets contains 000 0000b. See § Section 10.2.4 for additional requirements for multiple packet completions.

If the Completion Status field is 000b, then the translation was successful and a data payload will follow the header. The contents of the data payload are shown in § Figure 10-14.

Figure 10-14 Translation Completion Data Entry §

Table 10-3 Translation Completion Data Fields §

Field	Meaning
S	Size of translation - This field is 0b if the translation applies to a 4096-byte range of memory. If this field is 1b, then the translation applies to a range of memory that is larger than 4096 bytes (see § Section 10.2.3.1).
N	Non-snooped accesses - If this field is 1b, then the read and write requests that use this translation must Clear the No Snoop bit in the Attribute field. If it is 0b, then the Function may use other means to determine if <u>No Snoop</u> should be Set.
CXL.io	This bit is assigned for use by [CXL]. In non-CXL systems, this bit is Reserved.
AMA	ATS Memory Attributes (AMAs) - If the ATS Memory Attributes Supported bit is Set, the ATC is permitted to cache this AMA value.

Field	Meaning				
	<table border="1"> <thead> <tr> <th>AMA</th> <th>ATS Memory Attributes</th> </tr> </thead> <tbody> <tr> <td>000b - 111b</td> <td>ATS Memory Attribute values (implementation specific). The default value is 000b.</td> </tr> </tbody> </table>	AMA	ATS Memory Attributes	000b - 111b	ATS Memory Attribute values (implementation specific). The default value is 000b.
AMA	ATS Memory Attributes				
000b - 111b	ATS Memory Attribute values (implementation specific). The default value is 000b.				
Global	<p>Global Mapping - If this bit is Set, the ATC is permitted to cache this mapping entry in all PASIDs. If Clear, the ATC is permitted to cache this mapping entry only in the PASID associated with the requesting PASID. This bit may only be Set if the associated Translation Request had a PASID.</p>				
Exe	<p>Execute Permitted - If this bit is Set, the requesting Function is permitted to execute code contained in the associated memory range.</p> <p>This bit may be Set only if the associated Translation Request had the <u>Execute Requested</u> bit Set. If this bit is Set, R must also be Set.</p> <p>The Priv bit indicates the Privilege level associated with the Exe bit. If Priv is Set, the Exe bit indicates permissions associated with Privileged Mode entities in the Function. If Priv is Clear, the Exe bit indicates permissions associated with Non-Privileged Mode entities in the Function.</p> <p>This value may be cached if R is Set.</p>				
Priv	<p>Privileged Mode Access - If this bit is Set, R, W and Exe refer to permissions associated with Privileged Mode entities. If this bit is Clear, R, W and Exe refer to permissions associated with Non-Privileged Mode entities.</p> <p>This bit may only be Set if the associated Translation Request had the <u>Privileged Mode Requested</u> bit Set.</p> <p>This value must be cached any of the R, W or Exe values are cached.</p>				
U	<p>Untranslated access only - When this field is Set, the indicated range may only be accessed using untranslated addresses, and the Translated Address field of this Translation Completion Data Entry may not be used in a subsequent Read/Write Request with <u>AT</u> set to Translated. This value may be cached if R or W is Set.</p> <p>Future revisions of this specification are expected to deprecate the U bit.</p>				
R,W	<p>Read, Write - These two fields indicate the transaction types that are allowed for requests using the translation. The encodings are:</p> <p>00b Neither read nor write transactions are allowed. This translation is considered not to be valid. The contents of the Translated Address, N, AMA, U, and Exe fields are undefined. A translation with this value must not be cached in the ATC (see § Section 10.2.3.5).</p> <p>01b Write Requests that target this range are allowed, but Read Requests are not unless they are zero-length reads.</p> <p>10b Read Requests that target this range are allowed (including zero-length reads), but Write Requests are not.</p> <p>11b Read and Write Requests that target this range are allowed.</p> <p>The Priv bit indicates the Privilege level associated with R and W. If Priv is Set, R and W indicate permissions associated with Privileged Mode entities in the Function. If Priv is Clear, R and W indicate permissions associated with Non-Privileged Mode entities in the Function.</p> <p>If AMA is enabled (AMAE bit is 1b), a zero-length Read Request using a translated address must include AMAs in the TPH TLP Prefix.</p>				

10.2.3.1 Translated Address Field §

If the R and W fields are both Clear, or if U is Set, then the Translated Address field may not be used by the Function for any purpose.

If either the R or W field is Set, and the U field is Clear, then the Translated Address field contains an address that can be used by the Function in a Memory Request with the AT field set to Translated and the Function may cache the Translated Address. When cached, the R and W fields must be stored with the same value as the Translation Completion entry. The address that is cached must be a subset of the address range indicated in the Translation Completion (the subset may include the entire range).

While the Translated Address is cached in the Function's ATC, it shall not be possible for the Function to modify the entry other than to delete it. The entry must be deleted from the ATC when an Invalidation Request is received that has an indicated range that overlaps any portion of the cached address.

A Function is not allowed to make an entry into its ATC unless the entry is in a Translation Completion and the E (Enable) field within the ATS Capability is Set. Entries in an ATC cache that are written before the E field is Set must not be used in Memory Request. They must either be invalidated when the E field is Set or ignored and not used.

10.2.3.2 Translation Range Size (S) Field §

If S is Set, then the translation applies to a range that is larger than 4096 bytes. If S = 1b, then bit 12 of the Translated Address is used to indicate whether or not the range is larger than 8192 bytes. If bit 12 is 0b, then the range size is 8192 bytes, but it is larger than 8192 bytes if Set. If S = 1b and bit 12 = 1b, then bit 13 is used to determine if the range is larger than 16384 bytes or not. If bit 13 is 0b, then the range size is 16384 bytes, but it is larger than 16384 bytes if Set.

Low-order address bits are consumed in sequence to indicate the size of the range associated with the translation.

Note: This encoding method is also used to indicate the size of the memory range being invalidated.

Examples for different translation sizes are shown in § Table 10-5.

Table 10-5 Examples of Translation Size Using S Field §

Address Bits																				S	Translation Range Size in Bytes	
63:32 *	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13			12
x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	4 K
x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	1	8 K
x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	1	1	16 K
x	x	x	x	x	x	x	x	x	x	x	x	0	1	1	1	1	1	1	1	1	1	2 M
x	x	x	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1 G
x	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	4 G

Note:

* Upper address bits are used to indicate the size for ranges larger than 4 GB.

The size field is set to indicate the range size in multiples of 4096 bytes regardless of the setting of STU. For example, if STU is set to indicate that the minimum translation is 8192 bytes, then S should be Set on all translation returned in a

Translation Completion and in all Invalidate Requests. If STU is set to indicate a 16384-byte minimum, then S and bit 12 would both be Set in all translation and invalidate ranges.

If S is Set and bits 63:12 are all 1b, then the behavior is undefined. If S is Set and bit 63 is 0b, and bits 62:12 are all 1b, then the request is to invalidate all translations.

If a Function receives a Translation Completion with a Translation Size field smaller than the Function's programmed STU value, it shall treat the Translation Completion as if it had Completion Status UR.

10.2.3.3 Non-snooped (N) Field §

This field is Set to indicate that Read and Write Requests that target memory in the range of this translation must Clear the No Snoop Attribute bit in the Request header. When this field is 0b, the Function is allowed to Set the No Snoop Attribute bit in a Function-specific manner.

Note: When this field is Cleared, the Function is not allowed to Set No Snoop in a Memory Request if the Enable No Snoop field in the Device Control register is Cleared.

The N bit may be cached by the ATC if either R or W is Set.

When U is Set, the meaning of this field is undefined, and the TA may set this field to any value. A translation has a single value for the N field that is not affected by privilege level. An ATC is permitted to cache the N field without regard to the value of the Priv bit.

10.2.3.4 Untranslated Access Only (U) Field §

Future revisions of this specification are expected to deprecate the U bit.

This field is Set when the Function is not allowed to access the implied range of memory using a translated address (the range is implied by the untranslated address in the Translation Request and the offset of the translation in the Translation Completion). The Function may use untranslated addresses to access the range as long as the accesses are allowed by the R and W fields. The Function may cache this translation value if either R or W is Set. If the U field is Set, the Translated Address field in the translation is not necessarily a valid memory address and the Function may not use the value in a Read or Write Request with AT set to Translated.

Note: One of the possible uses of this field is to avoid unnecessary invalidations. If a Function uses translated requests for some portions of memory, but not others, then the U field can be used on the portions for which translated requests are not used. When a translation changes if the U field is Set, then it will not necessarily be required that an Invalidate Request be sent to the Function. An example of this use is a Function with a ring buffer that is used for commands. The ring buffer may be allocated for a long period of time and have very high re-use (locality). For this reason, it is useful for the Function to use translated addresses in its memory request that target the command buffer. The same Function might access data buffers that have poor locality and low reuse. Accesses to the data buffers might best be handled by using untranslated Requests. Setting the U field for the data buffer translations ensures that the Function will not attempt to use a translated value to access the data buffer so, when the data buffer mappings are changed, no Invalidation Request is required. When U is Set and either R or W is Set, the ATC is permitted to cache U, R, W Exe, and Priv, as well as the Translation Range Size (see § Section 10.2.3.2). An Invalidation Request is required if these values change.

10.2.3.5 Read (R) and Write (W) Fields §

These fields indicate if the returned translation value may be used in a read or write memory request. The ATC is not permitted to issue a non-zero length read request using the translation value if the R field is Cleared. The ATC is not

permitted to issue a write request using the translation value if the *W* field is Cleared. The ATC may not issue any type of request using the translation value if neither the *R* nor *W* fields are Set. If both *R* and *W* fields are Cleared, the range of the translation is still indicated, but the meaning of the other values in the translation is undefined.

Note: The range of a Translation entry is indicated even if *R* = *W* = 0b in order to allow a “hole” in the Translation Completion. For example, if the Translation Request has a Length of six DWs, then up to three translations could be included in the Translation Completion. The first and third translations may have Set *R* or *W* but the second could have *R* = *W* = 0b. To avoid ambiguity about the size of the indicated gap, the range of the gap is indicated in the Translation Completion even if *R* = *W* = 0b.

The *R* = 0b, *W* = 0b state is used to indicate that the ATC is not permitted to use address field in the translation to form a translated address value for a subsequent request.

When the host changes a translation in the TA from not valid to valid, the host is not required to send an invalidation indication to the ATC. As such the ATC will not be notified of such changes and thus the ATC is not permitted to cache a translation value of *R* = *W* = 0b.

When the host changes permissions associated with a translation in the TA, to grant additional permission (e.g., *R* = 1, *W* = 0b to *R* = *W* = 1b), the host is not required to send an invalidation indication to the ATC. As such, the ATC will not be notified of such changes. When the ATC requires permissions greater than the cached ATC entry, the ATC is permitted to request a fresh translation.

When the host changes permissions associated with a translation in the TA, to remove permission (e.g., *R* = *W* = 1b to *R* = 1b, *W* = 0b), the host is required to send an invalidation indication to the ATC. The subsequent invalidation completion tells the host that the ATC has stopped using the previously granted permissions.

If no table entry is found for the requested address, the TA must return a CplD with a single translation value with *R* = *W* = 0b.

Note: Implementations should not assume that receiving a translation response with the *R* or *W* bits Set (*independent of the value of the U bit*) implies that a subsequent read or write request with the same **untranslated** address will succeed. Although it may be possible for a device and its controlling software to ensure this property, the method for doing so is outside the scope of this specification.

When ACS Direct Translated P2P is enabled, Translated and Untranslated requests may take different paths between Requester and Completer. As such, PCI Express Ordering between Translated and Untranslated requests is not guaranteed. For transaction sequences that require ordering, Functions should avoid using a mixture of Translated and Untranslated Requests.

The *Priv* bit is used to qualify *R* and *W*. If *Priv* is Set, *R* and *W* indicate permissions granted to Privileged Mode entities in the Function. If *Priv* is Clear, *R* and *W* indicate permissions granted to Non-Privileged Mode entities in the Function. The *R* and *W* values for the two privilege levels are independent. The ATC must not assume any correlation between the Privileged Mode and Non-Privileged Mode permissions associated with a translation.

10.2.3.6 Execute Permitted (Exe) §

If *Exe* is Set, the requesting Function is permitted to execute code in the implied range of memory. If *Exe* is Clear, the requesting Function is not permitted to execute code in the implied range of memory.

The definition of what it means for a Function to execute code is outside the scope of this specification. Various system components may have different instruction sets. Behavior within the requesting Function when it attempts to execute code that is not permitted by this bit is outside the scope of this specification.

The Exe bit may only be Set if the TA supports Execute permissions, the associated Translation Request had an effective value of 1b for the Execute Requested bit¹⁹⁸ and R is Set in the Translation Completion Data Entry. Otherwise, the Exe bit must be Clear.

This value may be cached if R is Set.

The Priv bit is used to qualify the Exe bit. If Priv is Set, the Exe bit indicates permission granted to Privileged Mode entities in the Function. If Priv is Clear, the Exe bit indicates permission granted to Non-Privileged Mode entities in the Function. The Exe bit values for the two privilege levels are independent. The ATC must not assume any correlation between the Privileged Mode and Non-Privileged Mode permissions associated with a translation.

Functions may optionally check that:

- If the Execute Requested bit is Clear in a Translation Request, the Exe bits in the associated Translation Completion Data Entries are also Clear.
- If Exe is Set, R is also Set.

If either optional check fails, the Function shall signal Unexpected Completion (UC). These checks are independently optional.

10.2.3.7 Privileged Mode Access (Priv) §

If Priv is Set, R, W, and Exe refer to permissions granted to entities operating in Privileged Mode in the requesting Function. If Priv is Clear, R, W, and Exe refer to permissions granted to entities operating in Non-Privileged Mode in the requesting Function.

The meaning of Privileged Mode and Non-Privileged Mode and what it means for an entity to be operating as in Privileged Mode or in Non-Privileged Mode depends on the protection model of the system and is outside the scope of this specification.

Behavior is outside the scope of this specification when an entity in the requesting Function attempts to access memory that it is not permitted to access.

The Priv bit may only be Set if the TA supports Privileged Mode and the associated Translation Request had a PASID TLP Prefix (NFM) or OHC-A1 with an effective value of 1b for the Privileged Mode Requested¹⁹⁹ bit. Otherwise, the Priv bit must be Clear.

The Privileged and Non-Privileged Mode versions of R, W and Exe are independent. An ATC may cache either or both versions of R, W and Exe. An ATC that receives a translation with R=W=0b for one privilege level may not assume anything about what it might receive for the other privilege level.

This value may be cached if R or W is Set. This value must be cached when the corresponding R, W, or Exe values are cached.

Note: Since the Priv bit is Set only when the requesting Function Sets the Privileged Mode Requested bit, Functions that never set that bit should always receive the Priv bit Clear and thus don't need to cache it.

Functions may optionally check that when the Privileged Mode Requested bit is Clear in a Translation Request, the Priv bits in the associated Translation Completion Data Entries are also Clear. If this optional check fails, the Function shall signal Unexpected Completion (UC).

198. The effective value of the bit is 0b unless the bit in the PASID TLP Prefix (NFM) or OHC-A1 is 1b and usage of the bit is enabled for the request.

199. The effective value of the bit is 0b unless the bit in the in the PASID TLP Prefix (NFM) or OHC-A1 is 1b and usage of the bit is enabled for the request.

IMPLEMENTATION NOTE: EXECUTE PERMISSION AND PRIVILEGE MODE ENFORCEMENT §

The requesting Function determines whether a particular Memory Request needs Execute permission or is associated with a Privileged Mode or Non-Privileged Mode entity. The ATC implements the protection checks indicated by the Exe and Priv bits.

10.2.3.8 Global Mapping (Global) §

If Global is Set, the requesting Function is permitted to create a Global Mapping entry in the ATC for this translation. If Global is Clear, the requesting Function is not permitted to create a Global Mapping entry in the ATC for this translation. Global Mapping entries apply to all PASIDs of the Function. They permit the ATC to reduce the number of translation requests needed and to reduce the memory needed for caching the results.

A Function is permitted to ignore this bit and always create non-Global Mapping entries in the ATC. This could result in multiple translations being requested for the same Untranslated Address under different PASIDs.

Functions that use this bit must also have the Global Invalidate Supported bit Set (see § [Section 10.5.1.2](#)).

IMPLEMENTATION NOTE: TLP LENGTH, ADDRESS, AND BYTE OFFSET VALUES FOR TRANSLATION REQUEST COMPLETIONS §

The intention behind the rules for Translation Completions containing multiple translations is to make the TLPs look similar to those contained in a Memory Read Completion.

For single TLP Translation Completions, the goal is to make the Completion look as though it is a Memory Read Completion that ends on an RCB. As such, the Length and Byte Count will indicate the same value, and the Lower Address will contain the value that makes the TLP appear to end on an RCB.

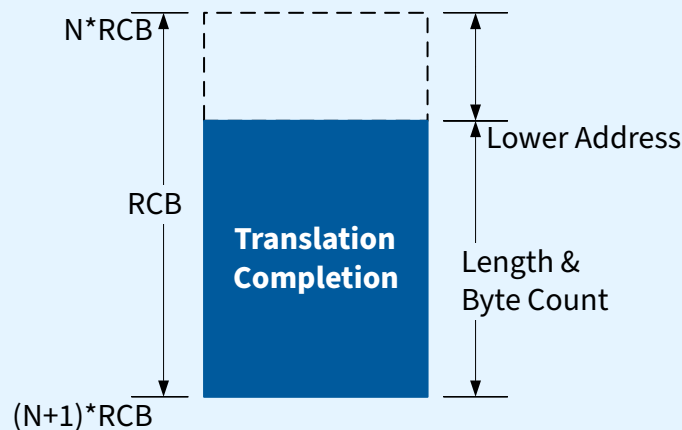

Figure 10-15 Example Translation Completion with 1 TLP §

To intermediate components (which do not track the transaction) this TLP will be indistinguishable from a Memory Read Completion ending on an RCB.

For Translation Completions consisting of two TLPs, the goal is to make the Completion look as though it is a Memory Read Completion that crosses an RCB. As Such, the first Completion TLP will contain Lower Address & Length values which make the TLP appear to end on an RCB. The Byte Count of the first TLP will indicate the total length of all the Translation Completions sent in this transaction. For the second TLP, the Length and Byte Count fields will indicate the same value, and the Lower Address value will be 0.

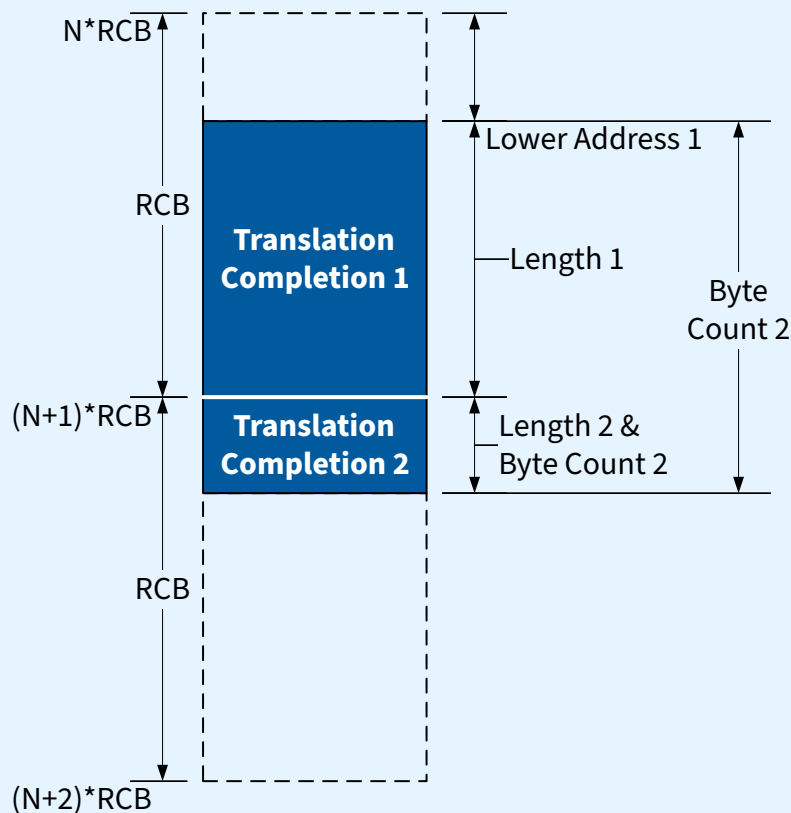

Figure 10-16 Example Translation Completion with 2 TLPs §

To intermediate components (which do not track the transaction) this Completion transaction will be indistinguishable from a Memory Read Completion that crosses an RCB.

Note that the Length field is measured in DWORDs, whereas the Lower Address and Byte Offset fields are measured in Bytes.

Provided the TLPs are properly formatted, a TA may choose to split the Translation Completion between any 2 Translation Completion Data Entries. Because an ATC cannot request more translations than can fit within a single RCB, the architectural maximum number of Translation Completion Data Entries can be sent in a single Completion TLP.

10.2.3.9 ATS Memory Attributes §

AMA values are associated with the Completer and are implementation specific. AMA values are opaque to the Requester, the Requester's ATC and the TA.

The method for detecting support of, and for enabling, the AMA mechanism in a TA is implementation specific. When the AMA mechanism is not enabled in both the Requester and the TA, the default AMA value is 000b. Behavior of the Completer for this case is implementation specific.

An ATC that supports AMA, caches AMA values along with other ATC information (Translated Address, Read, Write permission etc.) If the AMA value changes, for a page that could be cached in an ATC, software must issue an ATS Invalidation covering that page to ensure the ATC flushes the stale AMA value.

IMPLEMENTATION NOTE: ATS MEMORY ATTRIBUTES §

ATS Memory Attributes (AMAs) are used with bus transactions on the Internal Coherent Bus (ICB) of devices as shown in the figure below. AMAs simplify processing at the TA. AMAs are simply passed through to the ICB avoiding a look-up at the TA.

AMAs may be supplied by a Translation Completion and stored in the ATC. The Endpoint may provide AMAs in Memory Read/Write TLPs using a TPH TLP Prefix. AMAs may also be provided using Vendor-Defined Messages, however such methods are outside the scope of this specification.

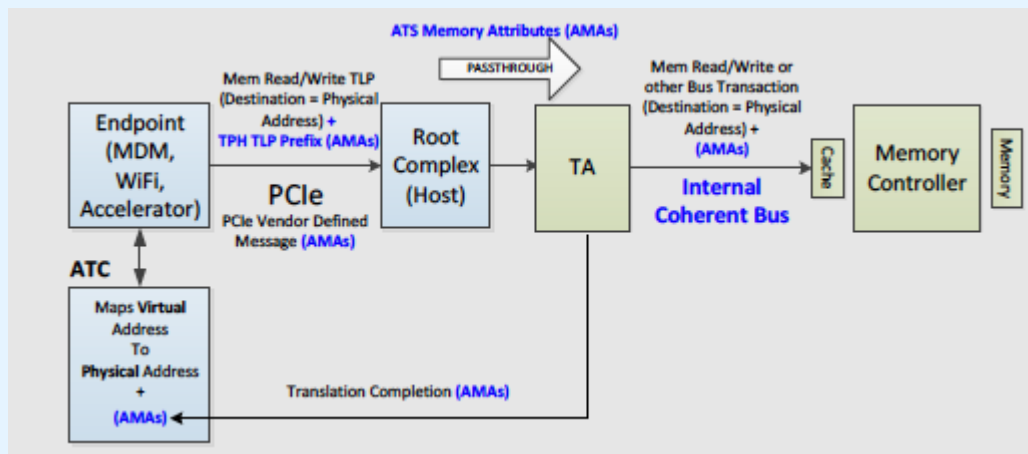

Figure 10-17 ATS Memory Attributes Example §

AMAs provide hints on performing cache management as well as behavior on the ICB for a particular transaction. For example, AMAs may hint:

- Data is cacheable or non-cacheable.
- Write-hit policy. “Write back” may indicate that on a cache hit, update the cache, do not update memory. Mark the cache as dirty.
- Write-miss policy. “Write allocate” may indicate that on a cache miss, update memory, bring the data block to the cache (allocate).

AMAs are similar to TLP Processing Hints but should be considered independent. Hence all permutations of AMAs and TLP Processing Hints are permitted. However, AMAs may convey different semantics than what is provided by TLP Processing Hints. The cache behavior conveyed by AMAs and TLP Processing Hints may not align. Additionally, AMAs may convey semantics not addressed by TLP Processing Hints. For example, handling of transactions on the ICB when caching is not in use, such as, “reordering permitted/not permitted”, “early write acknowledgement permitted/not permitted.”

AMAs may be transmitted in peer-to-peer transactions. It is recommended that an application programming interface (API) be provided to enable AMAs to be configured into the Translation Agent (TA). Note: the TA might not be collocated with the Completer.

An example of memory attributes such as “strongly ordered device normal” may be found at <http://infocenter.arm.com>.

10.2.4 Completions with Multiple Translations §

An ATC is allowed to request that the TA provide translations for a virtually contiguous range of addresses. It does this by setting the Length field in the Translation Request to a value that is two times the number of requested translations as long as the request size (Total Completion Length * 4) is not larger than Read Completion Boundary (RCB) in the Link Control Register.

If multiple translations are requested, the TA may return one or more translations as long as the number of translations does not exceed the number of requested translations. It is not an error for the TA to return fewer translations than requested and no error indication is sent unless there is an error in accessing the data.

If the Translation Completion contains multiple translations, all translations must have the same indicated size. Also, successive translations must apply to the virtual address range that abuts the previous translation in the same completion.

If a translation has both R = 0b and W = 0b, the TA must still set the Size field and the lower bits of the Translated Address field used to encode the completion size to appropriate values.

Each translation in a Translation Completion will have some overlap with the implied memory range of the Translation Request (see § Section 10.2.2).

A successful Translation Completion must consist of one or two CplDs. Each CplD must contain an integral number of Translations (i.e., Length must be a multiple of 2).

The TA is permitted to choose:

- the number of translations it returns for each Translation Request (e.g., Byte Count of the first or only CplD)
- if it returns more than one translation, whether it uses one or two CplDs
- if it returns two CplDs, how many translations are returned in each CplD

The Byte Count and Length fields in each CplD is used to convey these choices to the ATC. The Lower Address field should not be needed by the ATC (its value is computed as defined in Section 10.2.3 to satisfy RCB rules but the field otherwise conveys no additional information).

- If a Translation Completion CplD has a Byte Count that is greater than four times the Length field, then this is the first of two CplDs for the transaction.
- If a Translation Completion CplD has a Byte Count that is equal to four times the Length field, then this is the second or only CplD for the request.

Note: There are multiple reasons that the TA may truncate the results of the completion. For example, the request might ask for a range of addresses, not all of which are defined. This could occur if the first translation is valid but located at the end of a page of translations. The TA, in looking up the next page of translations, may find that the page is not valid so the addresses are not valid. The range of addresses that are valid would be returned and no error indicated. When truncating a Translation Completion the TA is not allowed to pad the response with invalid entries (R = 0b, W = 0b).

Note: There are multiple reasons that the TA may break a Translation Completion into multiple TLPs. As an example, if the virtual address of the Translation Completion resolves to a table access that crosses an implementation specific address boundary, the completion to the TA may be broken into two completions. Rather than require that the TA accumulate the results, the TA is permitted to send each portion of the Translation Completion to a Function when it is received from memory.

10.3 ATS Invalidation §

ATS uses the messages shown in this section to maintain consistency between the TA and the ATC. This specification assumes there is a single TA associated with each ATC. The TA (in conjunction with its associated software) must ensure that the address translations cached in the ATC are not stale by issuing Invalidate Requests.

10.3.1 Invalidate Request §

When a translation is changed in the TA and that translation might be contained within an ATC in a Function, the TA (in conjunction with its associated software) must send an Invalidate Request to the ATC to maintain proper synchronization between the ATPT and the ATC. An Invalidate Request is used to clear a specific subset of the address range from the ATC. Invalidate Requests are constrained to cover power of 2 multiple of 4096-byte pages.

The format of an Invalidate Request is shown in § Figure 10-18 and § Figure 10-19.

Figure 10-18 Invalidate Request Message - Non-Flit Mode §

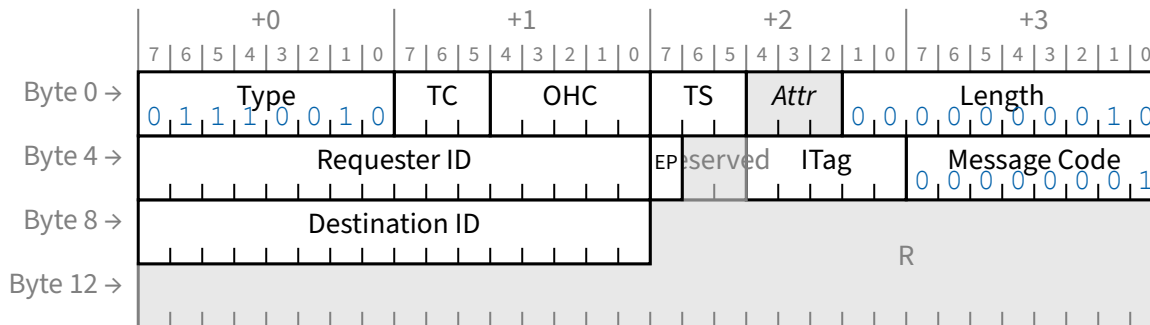

Figure 10-19 Invalidate Request Message - Flit Mode §

The Invalidate Request is a MsgD transaction with 64 bits of data. Invalidate Request messages may be sent in any TC. Invalidation Request Messages optionally include a PASID (see § Section 10.3.8)

- In Non-Flit Mode, PASID is included when a PASID TLP Prefix is present. The Execute Requested and Privileged Mode Requested bits in this PASID TLP Prefix are Reserved.
- In Flit Mode, PASID is included when OHC-A4 is present and the PV is Set. PASID is not included if either OHC-A4 is not present or if PV is Clear. OHC-A4 also contains Destination Segment if DSV is Set²⁰⁰.

200. Invalidation Request Messages are issued by the TA through a specific RP. Since everything below a given RP is part of the same segment, the Destination Segment field in the message is not required unless needed by the RC to determine the appropriate RP.

The ITag field is used by the TA to uniquely identify Invalidate Requests it issues. A TA must ensure that once an ITag is used, it is not reused for the same Destination ID until either released by the corresponding Invalidate Completions or by a vendor-specific timeout mechanism (see below). A TA is permitted to use the same ITag value for Invalidate Requests that target different Destination IDs. See the Invalidation Queue Depth field in the ATS Extended Capability for additional considerations.

The address range specified in an Invalidate Request may span one or more STU 4096-byte pages. Invalidation ranges are required to be naturally aligned and should not be smaller than STU 4096-byte pages. Upon receiving an Invalidate Request with a range less than STU an ATC may either (1) signal an Unsupported Request (not recommended) or (2) round the range of the request up to a value greater than or equal to the STU.

IMPLEMENTATION NOTE: INVALIDATE COMPLETION TIMEOUT §

Devices should respond to Invalidate Requests within 1 minute (+50% -0%). Having a bounded time permits an ATPT to implement Invalidate Completion Timeouts and reuse the associated ITag values. ATPT designs are implementation specific. As such, Invalidate Completion Timeouts and their associated error handling are outside the scope of this specification.

The content of the payload is the untranslated address range to be invalidated. The payload format is shown in § Figure 10-20.

Figure 10-20 Invalidate Request Message Body §

The S field is used to indicate if the range being invalidated is greater than 4096 bytes. Its meaning is the same as for the Translation Completion (see § Section 10.2.3.1 and § Section 10.2.3.2).

The Global Invalidate bit indicates that the Invalidation Request Message affects all PASID values (see § Section 10.3.8). This bit is Reserved unless the Invalidation Request has a PASID. The bit is ignored by the ATC if Global Invalidate Supported bit is Clear (see § Section 10.3.8).

IMPLEMENTATION NOTE: INVALIDATION REQUESTS AND FUNCTION LEVEL RESET & DEVICE POWER STATE TRANSITIONS §

Invalidation requests received while a Function is undergoing Function Level Reset, or is in (or transitioning to) non-D0 device state, may be dropped by the Function. Similarly, invalidation requests already received but pending at the time of receiving initiate FLR or D-state transition request may be dropped the Function.

System software can avoid ATS invalidation race conditions on Function Level Reset and Device Power State transitions in a variety of ways. For example:

1. When disabling ATS on a Function, system software quiesces ATS invalidations to the Function (i.e., either responses are received for all invalidation requests issued to the Function, or any pending invalidation requests to the Function have timed out).
2. Software ensures no invalidations are issued to a Function when its ATS capability is disabled.
3. Before initiating the FLR (or Device power state transitions), software disables ATS as described in item 1. above.

10.3.2 Invalidate Completion §

When a Function completes an Invalidate operation, it will send one or more Invalidate Completion messages to the TA. These messages must be tagged with information extracted from the Invalidate Request to enable the TA to associate the Invalidate Completions with the Invalidate Request.

The format of the Invalidate Completion message is shown in § Figure 10-21 and § Figure 10-22.

A-0586A

Figure 10-21 Invalidate Completion Message Format - Non-Flit Mode §

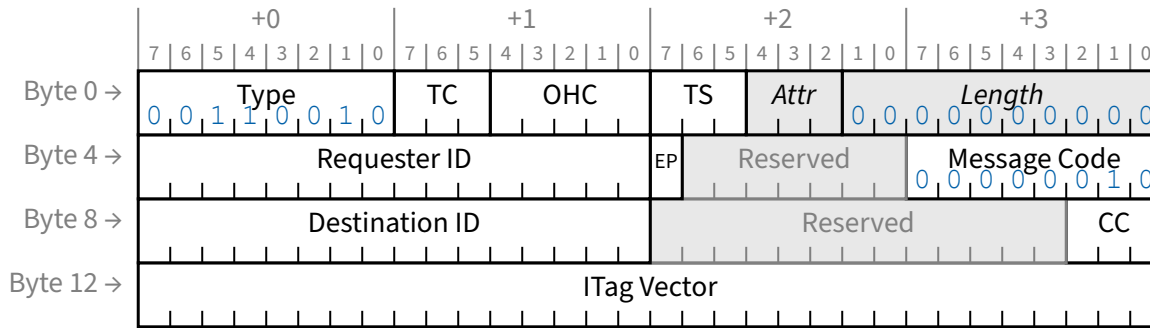

Figure 10-22 Invalidate Completion Message - Flit Mode §

The Invalidate Completion message is a Msg transaction routed by ID. The Requester ID field of the Invalidate Completion message is set to the Requester ID of the Function containing the ATC. The Device ID field of the Invalidate Completion is set to the Requester ID of the TA. The ATC may derive the Requester ID of the TA from the Requester ID field of the corresponding Invalidate Request. Alternatively, since the ATC is only associated with a single TA, the ATC may sample and store the Requester ID from the first Invalidate Request following a Fundamental Reset or FLR. Subsequent Invalidate Completion messages may use this value to set the Device ID field of Invalidate Completion messages.

In Flit Mode, Invalidation Completion messages optionally contain OHC-A4 when a Destination Segment is needed (e.g., the TA and the ATC are in different segments). The PASID is Reserved. PV must be 0b.

The Completion Count (CC) field indicates the number of individual Invalidate Completion messages that must be sent for the associated Invalidate Request. Setting the CC field to 0 indicates that eight responses must be sent. The TA is responsible for collecting all the responses associated with a given Tag before considering the corresponding Invalidate Request to be complete.

Invalidate Completion messages may be sent on any TC, independent of the TC the originating Invalidate Request was received. This enables implementations to utilize the Invalidate Completion to push outstanding transactions to the TA to guarantee the required invalidation semantics are met. Implementations that utilize a single Upstream TC are required to send a single Invalidate Completion in the utilized TC.

The ITag Vector field is used to indicate which Invalidate Request has been completed. Each of the 32 possible ITag field values from the Invalidation Request is represented by a single bit in the ITag Vector field. The least significant bit (bit 0; i.e., the right-most bit in the schematic representation of the Invalidate Completion message shown in § Figure 10-21 and § Figure 10-22) of the ITag Vector field corresponds to the ITag field value of 0. The most significant bit (bit 31) of the ITag Vector field corresponds to the ITag field value of 31. Implementations are allowed to coalesce multiple Invalidate Completions by setting multiple ITag Vector bits in a single message provided the following conditions are met:

- The Invalidate Completions flow in the same TC.
- The Invalidate Completions have the same CC value.
- All fragments of an Invalidate Completion must have identical Request ID, CC, and ITag Vector fields.

A TA that receives an Invalidation Completion for an ITag that has no outstanding Invalidation Request shall report this error using implementation specific mechanisms. One possible such mechanism is to report the Invalidation Completion as an Unexpected Completion (UC).

Functions that do not support ATS will treat an Invalidate Request as UR.

Functions supporting ATS are required to send an Invalidate Completion in response to a Invalidate Request independent of whether the Bus Master Enable bit is Set or not. Note that the above conditions must be satisfied even when Bus Master Enable is Cleared. The method for a device to achieve this is implementation dependent.

IMPLEMENTATION NOTE: BUS MASTER ENABLE CHANGE §

When Bus Master Enable changes from Set to Clear, no further memory requests should be queued. It is possible that queued write requests are present when BME is Cleared. These requests could block an Invalidate Completion. These requests must be either sent or dropped. This will ensure that all outstanding write transactions that are potentially dependent upon the outstanding invalidation are complete.

10.3.3 Invalidate Completion Semantics §

Before an ATC can return an Invalidate Completion for a given Invalidate Request, it must ensure the following conditions are satisfied with respect to stale addresses:

- All new Translated Memory Requests initiated by the Function (or its Shadows) will not utilize stale address translations.
- All expected Completions for Translated Memory Requests initiated by the Function (or its Shadows) and referencing stale addresses must be received.
- All expected Translation Completions for Translation Requests initiated by the Function (or its Shadows) and referencing stale addresses must be received or tagged to be discarded.
- All outstanding non-UIO Posted Translated Memory Requests initiated by the Function (or its Shadows) and referencing stale addresses must be ensured to be transmitted ahead of the associated Invalidate Completion(s).

The ATC is required to send a copy of the Invalidate Completion message in each TC in which a non-UIO Posted Translated Memory Request has been issued but not known to have been pushed to observability on the fabric through the TA. The CC field must be set to the same value in each copy of the Invalidate Completion message indicating number of copies sent. The TA is responsible for collecting all sent responses before considering the invalidation to be complete. The ATC must send at least one Invalidation Completion message.

The ATC must not send copies of the Invalidation Completion message in UIO VCs (Posted Message TLPs are not defined for UIO VCs). When all traffic affected by an ATS Invalidation Request is UIO, it is implementation specific how the ATC picks a non-UIO TC to use for the Invalidation Completion message.

A TA must ensure forward progress of Requests without dependence on receiving Invalidation Completions.

Invalidate Completion Messages must contain the Requester ID used in the associated Invalidate Request.

When Shadow Functions are enabled, it is sufficient to issue a single Invalidate Request message targeting either the Function or one of its Shadows. It is recommended that system software issue an Invalidate Request Message to the “main” Function instead of a Shadow Function. Since IDO is Clear, the Invalidation Completion resulting from that Invalidation Request will push to the TA any earlier Posted Writes for both the Function and its Shadows.

Invalidation Completion behavior is independent of whether the associated Invalidate Request was issued to the Function or one of its Shadows.

IMPLEMENTATION NOTE: IMPLIED TC FLUSHING §

When making the decision as to which TC to send Invalidate Completions, an ATC may infer, in an implementation specific manner, that an issued posted write has been pushed to the TA. For example, a Function that has sent a read transaction to a destination above the TA and received its corresponding response may infer that any preceding posted writes issued in the same TC have been pushed to the TA.

Independent of this optimization, the ATC is required to send at least one Invalidation Completion.

10.3.4 Request Acceptance Rules §

In accord with the request acceptance rules enumerated in this section, a Function is not allowed to create a dependency in which the acceptance of a posted transaction is dependent upon the transmission of a posted transaction. Given Invalidate Requests and Invalidate Completions both are posted transactions, Functions must not make the acceptance of an Invalidate Request dependent upon the transmission of an Invalidate Completion. The method for achieving this is implementation specific.

A Function with an ATS capability in its configuration space must be able to accept Invalidate Requests and send Invalidate Completions even if ATS is not enabled.

IMPLEMENTATION NOTE: INVALIDATE QUEUE DEPTH §

An ATC is only associated with a single TA. Each TA is limited to a total of 32 outstanding invalidations to any given ATC. This limits the number of outstanding Invalidation Requests active to a single ATC to 32. To avoid a post-to-post dependency, an ATC is required to accept up to 32 Invalidation Requests.

An ATC may choose to implement a maximally sized input queue holding Invalidate Requests. Alternatively, an ATC may choose to implement a maximally sized output queue holding Invalidate Completions. Note that queuing Invalidate Completions requires significantly less state per entry resulting in a potentially more efficient implementation than input queue buffering.

Note that the choice of whether to implement input queuing or output queuing (or a hybrid of both) has no impact on ensuring deadlock free behavior. But implementation choices with regard to queuing may have a significant impact on performance (see § Section 10.3.5).

10.3.5 Invalidate Flow Control §

Due to the variety of caching architectures and queuing strategies, implementations may vary greatly with respect to invalidation latency and throughput. It is possible that a TA may generate Invalidate Requests at a rate that exceeds the average ATC service rate. When this happens, the credit based flow control mechanisms will throttle the TA issue rate. A side effect of this is congestion spreading to other channels and Links through the credit based flow control mechanism. Depending on the frequency and duration of this congestion, performance may suffer. It is strongly recommended that TA and its associated software implement higher level flow control mechanisms.

To assist with the implementation of Invalidate Flow Control, an ATC must publish the number of Invalidate Requests it can buffer before back pressuring the Link. This field applies to all invalidations serviced by the Function, independent of the size of the invalidation. This value is communicated in the Invalidate Queue Depth field in the ATS capability structure (see § Section 7.8.9). A value of 0 0000b indicates that invalidate flow control is not necessary to this Function.

IMPLEMENTATION NOTE: INVALIDATE FLOW CONTROL §

A Function may indicate that invalidate flow control is not required when one or more of the following is true:

1. The Function can handle invalidations at the maximum arrival rate of Invalidate Requests.
2. The Function will not or very rarely cause Link backpressure (performance loss is negligible).
3. The Function can fully buffer the maximum number of incoming invalidations without back pressuring the Link.

Each Function is required to implement sufficient queuing to ensure it can hold the maximum number of outstanding Invalidation Requests from a TA (using either input or output queuing). However, with an SR-IOV device, all VFs associated with a PF share a single Invalidation Request queue in the PF. To implement Invalidation flow control, the TA must ensure that the total number of outstanding Invalidate Requests targeting the shared PF queue does not exceed the value in the PF's Invalidate Queue Depth field.

10.3.6 Invalidate Ordering Semantics §

Invalidate Requests and Translation Completions may be sent using different TC and are, therefore, unordered with respect to each other (from the Link's perspective). An ATC must ensure that the proper invalidation behavior is maintained when an Invalidate Request bypasses a Translation Completion to an overlapping region.

An ATC must “snoop” its outstanding translation request queue against all arriving Invalidate Requests. When snooping a request for a $N \times \text{STU}$ sized translation (N is a power of 2), the ATC must snoop the range of addresses starting at the STU aligned region containing the specified address and ending $(N-1)$ STU size pages later.

If an Invalidate Request overlaps the address range in an outstanding Translation Request, the Translation Request must be tagged as invalid and the results of its corresponding Translation Response must be discarded prior to transmission of the Invalidate Completion. If the Translation Response is received before the Invalidate Completion is sent, an implementation is free to issue requests utilizing the translation result provided the Invalidate Completion Semantics (see § Section 10.3.3) are satisfied.

IMPLEMENTATION NOTE: REQUEST RANGE OVERLAP IN INVALIDATIONS §

In the description above, N is the number of STU sized translations that were requested in the Translation Request. This is equal to (Length field in Translation Request)/2.

As an example:

STU is 00 0010b indicating 16384-byte pages.

An outstanding Translation Request has a Length field of 00 0000 0100b indicating two translations covering a range of 32768 bytes.

The high-order 48 bits of the Translation Request are 0000 0FFF FFFFh.

The low-order 16 bits of the address in the request are 11xx xxxx xxxx xxxb indicating that the translation request covers a range that overlaps a 32768-byte boundary (in fact, the request crosses a 16-TB boundary).

If two translations are returned, they would cover the two STU sized regions at 0000 0FFF FFFF C000h and 0000 1000 0000 0000h.

An Invalidate Request is received with the high-order 48 bits of 0000 1000 0000h and the low-order 16 bits of 0001 1xxx xxxx xxxb.

The ATC must detect that a translation associated with a portion of the Translation Request is now invalidated and the Translation Completion associated with the invalidated region must be discarded (for simplification, the ATC is allowed to discard all of the Translation Completion).

It should be noted that, processing of the Invalidate Requests is simplified if Translation Requests do not cross alignment boundaries of the request. The Translation Request from the above example is not aligned to a 32768-byte boundary. If it were broken into two requests, it would be simpler to associate the range of the Invalidate Request with the address in the Translation Request. Breaking the Translation Requests into aligned requests is not a requirement.

10.3.7 Implicit Invalidation Events §

The following events will cause the invalidation of all ATC entries:

- Conventional Reset (all forms)
- Function Level Reset
- E field in ATS Capability changes from Clear to Set

The following events will cause the invalidation of all non-Global Mapping ATC entries that were requested using a specific PASID:

- Stopping the use of a PASID as defined in this specification.

No explicit Invalidate Completion message is sent when these implied invalidate events occur.

IMPLEMENTATION NOTE:

IMPLICIT INVALIDATION AND PASID §

Software may not change any of the PASID enable bits when the E field in the ATS Capability is Set. The invalidation that occurs when software Sets the E field also invalidates ATC entries with an associated PASID value.

10.3.8 PASID and Global Invalidate §

The requirements in this section apply to Functions that support the PASID. For Invalidation Requests that have a PASID, the ATC shall:

- Optionally signal Unsupported Request (UR) if the associated PASID value is greater than or equal to $2^{\text{Max PASID Width}}$. This error may be signaled anytime an out of range PASID value is present, even when the PASID value is ignored (see below).
- Return an Invalidation Completion if PASID Enable is Clear.
- If the Function supports Global Invalidate (see § Section 7.8.9.2):
 - If the Global Invalidate bit in the Request is Set, invalidate Global and non-Global Mapping entries in the ATC within the indicated memory range associated with any PASID value and return an Invalidation Completion. The PASID value in the PASID is ignored.
 - If the Global Invalidate bit in the Request is Clear, invalidate only non-Global Mapping entries in the ATC within the indicated memory range that were requested using the associated PASID value and return an Invalidation Completion.

Global Mapping entries in the ATC for some or all of the indicated memory range may be retained.

- If the Function does not support Global Invalidate (see § Section 7.8.9.2), invalidate entries in the ATC within the indicated memory range that were requested using the associated PASID value and return an Invalidation Completion.
- If no matching entries are present in the ATC, invalidate no ATC entries and return an Invalidation Completion.

For Invalidation Requests that do not have a PASID, the ATC shall:

- Invalidate ATC entries within the indicate memory range that were requested without a PASID value.
- Invalidate ATC entries at all addresses that were requested with any PASID value.

10.4 Page Request Services §

The general model for a page request is as follows:

1. A Function determines that it requires access to a page for which an ATS translation is not available.
2. The Function causes the associated Page Request Interface to send a Page Request Message to its RC. A Page Request Message contains a page address and a Page Request Group (PRG) index. The PRG index is used to identify the transaction and is used to match requests with responses.

3. When the RC determines its response to the request (which will typically be to make the requested page resident), it sends a PRG Response Message back to the requesting Function.
4. The Function can then employ ATS to request a translation for the requested page(s).

A Page Request Message is a PCIe Message Request that is Routed to the Root Complex with a Message Code of 4 (0000 0100b). The mechanism employed at the RC to buffer requests is implementation specific. The only requirement is that an RC not silently discard requests.

All Page Request Messages and PRG Response Messages travel in PCIe Traffic Class 0. A Page Request Message or PRG Response Message with a Traffic Class other than 0 shall be treated as Malformed TLPs by the RC or endpoint that receives the same. Intermediate routing elements (e.g., Switches) shall not detect this error.

The Relaxed Ordering and ID-Based Ordering bits in the Attr field of Page Request Messages and PRG Response messages may be used. The No Snoop bit in the Attr field is reserved.

The page request service allows grouping of page requests into Page Request Groups (PRGs). A PRG can contain one or more page requests. All pages in a PRG are responded to en mass by the host. Individual pages within a PRG are requested with independent Page Request Messages and are recognized as belonging to a common PRG by sharing the same PRG index. The last request of a PRG is marked as such within its Page Request Message. One request credit is consumed per page request (not per PRG).

A PRG Response Message is a PCIe Message Request that is Routed by ID back to the requesting Function. It is used by system software to alert a Function that the page request(s) associated with the corresponding PRG has (have) been satisfied. The page request mechanism does not guarantee any request completion order and all requests are inherently independent of all other concurrently outstanding requests. If a Function requires that a particular request be completed before another request, the initial request will need to complete before the subsequent request is issued. It is valid for a Function to speculatively request a page without ascertaining its residence state and/or to issue multiple concurrently outstanding requests for the same page.

A Page Request Interface is allocated a specific number of page request message credits. An RC (system software) can divide the available credits in any manner deemed appropriate. Any measures the host chooses to employ to ensure that credits are correctly metered by Page Request Interfaces (a Page Request Interface is not using more than its allocation) is an implementation choice. A Page Request Interface is not allowed to oversubscribe the available number of requests (doing so can result in the page request mechanism being disabled if the buffer limit is exceeded at the root). A Page Request Interface's page request allocation is static. It is determined when the Page Request Interface is enabled and can only be changed by disabling and then re-enabling the interface.

10.4.1 Page Request Message §

A Function uses a Page Request Message to send page requests to its associated host. A page request indicates a page needed by the Function. The Page Request Interface associated with a Function is given a specific Page Request allocation. A Page Request Interface shall not issue page requests that exceed its page request allocation.

A page request contains the untranslated address of the page that is needed, the access permissions needed for that page, and a PRG index. A PRG Index is a 9-bit scalar that is assigned by the Function to identify the associated page request. Multiple pages may be requested using a single PRG index. When more than a single page is to be associated with a given PRG, the Last flag in the Page Request Record is cleared in all the requests except the last request associated with a given PRG (the flag is set in the last request). Page requests are responded to en mass. No response is possible (except for a Response Failure error) until the last request of a PRG has been received by the root. The number of PRGs that a Function can have outstanding at any given time is less than or equal to the associated Page Request Interface's Outstanding Page Request Allocation. It is valid for a request group to contain multiple requests for the same page and for multiple outstanding PRGs to request the same page.

A Page Request Interface applies to the “main” Function and its enabled Shadow Functions (where the “main” is the Function that contains both the Page Request Extended Capability and the Shadow Function Extended Capability). All Page Request Messages of a single PRG must have the same Requester ID. When Shadow Functions are enabled, it is recommended that Page Request Messages use the Requester ID of the “main” Function

The first two DWs of a Page Request Message contain a standard PCIe message header. The second two DWs of the message contain page request specific data fields.

Figure 10-23 Page Request Message - Non-Flit Mode §

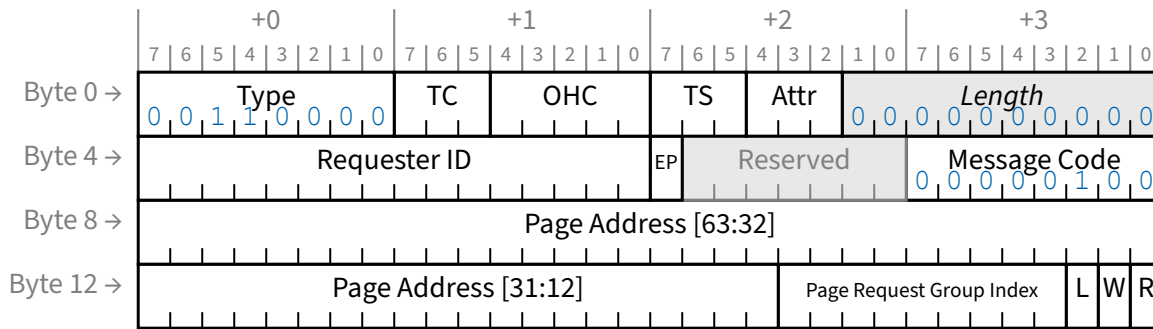

Figure 10-24 Page Request Message - Flit Mode §

Table 10-6 Page Request Message Data Fields §

Field	Meaning
R	<p>Read Access Requested - This field, when Set, indicates that the requesting Function seeks read access to the associated page. When Clear, this field indicates that the requesting Function will not read the associated page.</p> <p>The R field must be Set for Page Requests with a PASID and that have the <u>Execute Requested</u> bit Set.</p> <p>If R and W are both Clear and L is Set, this is a Stop Marker (see § Section 10.4.1.2.1).</p>
W	<p>Write Access Requested - This field, when Set, indicates that the requesting Function seeks write access and/or zero-length read access to the associated page. When Clear, this field indicates that the requesting Function will not write to the associated page.</p> <p>Upon receiving a Page Request Message with the W field Set, the host is permitted to mark the associated page dirty. Thus, Functions must not issue such Requests unless the Function has been given explicit write permission.</p> <p>If R and W are both Clear and L is Set, this is a Stop Marker (see § Section 10.4.1.2.1).</p>

Field	Meaning
L	<p>Last Request in PRG - This field, when Set, indicates that the associated page request is the last request of the associated PRG. A PRG can have a single entry, in which case the PRG consists of a single request in which this field is Set. When Clear, this field indicates that additional page requests will be posted using this record's PRG Index.</p> <p>If R and W are both Clear and L is Set, this is a Stop Marker (see § Section 10.4.1.2.1).</p>
Page Request Group Index	<p>Page Request Group Index - This field contains a Function supplied identifier for the associated page request. A Function need not employ the entire available range of PRG index values. A host shall never respond with a PRG Index that has not been previously issued by the Function and that is not currently an outstanding request PRG Index (except when issuing a Response Failure, in which case the host need not preserve the associated request's PRG Index value in the error response).</p>
Page Address	<p>Page Address - This field contains the untranslated address of the page to be loaded. For pages larger than 4096 bytes, the least significant bits of this field are ignored. For example, the least significant bit of this field is ignored when an 8096-byte page is being requested.</p>

IMPLEMENTATION NOTE: LAST BIT AND RELAXED ORDERING §

If multiple page requests are associated with a single PRG index, the last page request of a PRG should have the Relaxed Ordering attribute bit Clear in addition to having the Last flag Set. All other page request messages may have the Relaxed Ordering attribute bit set to any value.

10.4.1.1 PASID Usage §

The PASID Extended Capability indicates whether a Function supports PASID TLP Prefixes (NFM) or OHC-A1 with PASID (FM), and whether it is enabled to send and receive them.

Functions that support PASID are permitted to send a PASID on Page Request Messages. The PASID field contains the process address space of the page being requested and the Execute Requested and Privileged Mode Requested bits indicate the access being requested. In FM, the NW bit and the Last DW BW / 1st DW BE fields in the OHC-A1 are Reserved.

If one Page Request Message in a PRG has a PASID, all Page Request Messages in that PRG must contain identical PASID values. Behavior is undefined when the PASID values are inconsistent.

Functions that support PASID and have the PRG Response PASID Required bit Set (see § Section 10.5.2.3), expect that PRG Response Messages will contain a PASID if the associated Page Request Message had a PASID. For such PRG Response Messages, the Execute Requested and Privileged Mode Requested bits are reserved and the PASID field contains the PASID from the associated Page Request Message.

10.4.1.2 Managing PASID Usage on PRG Requests §

There are rules for stopping and starting the use of a PASID.

This section describes additional rules that apply to Functions that have issued Page Request Messages in a PASID that is being stopped. No additional rules are required to start the usage of the Page Request Interface for a PASID.

When stopping the use of a particular PASID, a Stop Marker Message may be optionally used to avoid waiting for PRG Response Messages before the Function indicates that the stop request for a particular PASID has completed.

To stop without using a Stop Marker Message, the Function shall:

1. Stop queueing new Page Request Messages for this PASID.
2. Finish transmitting any multi-page Page Request Messages for this PASID (i.e., send the Page Request Message with the L bit Set).
3. Wait for PRG Response Messages associated any outstanding Page Request Messages for the PASID.
4. Indicate that the PASID has stopped using a device specific mechanism. This mechanism must indicate that a Stop Marker Message will not be generated.

To stop with the use of a Stop Marker Message the Function shall:

1. Stop queueing new Page Request Messages for this PASID.
2. Finish transmitting any multi-page Page Request Messages for this PASID (i.e., send the Page Request Message with the L bit Set).
3. Internally mark all outstanding Page Request Messages for this PASID as stale. PRG Response Messages associated with these requests will return Page Request Allocation credits and PRG Index values but are otherwise ignored.²⁰¹
4. Indicate that the PASID has stopped using a device specific mechanism. This mechanism must indicate that a Stop Marker Message will be generated.
5. Send a Stop Marker Message to indicate to the host that all subsequent Page Request Messages for this PASID are for a new use of the PASID value.

Note: Steps 4 and 5 may be performed in either order, or in parallel.

10.4.1.2.1 Stop Marker Messages §

A Stop Marker Message indicates that a Function has stopped using the Page Request Interface and has transmitted all pending Page Request Messages for a specific PASID. Stop Marker Messages are strongly ordered with respect to Page Request Messages and serve to push Page Request Messages toward the Host. When the Host receives the Stop Marker Message, this indicates that all Page Request Messages associated with the PASID being stopped have been delivered and that any subsequent Page Request Message with the same PASID value are associated with a new incarnation of that PASID value.

Stop Marker Messages do not have a response. They do not have a PRG Index and do not consume Page Request allocation (see § Section 10.5.2.5).

The Stop Marker Message bit layout is shown in § Figure 10-25.

201. Page Request Allocation is shared across all PASIDs of the Function (see § Section 10.5.2.5). If PRG Response PASID Required is Clear, PRG Index values are shared across all PASIDs of the Function (see § Section 10.5.2.3).

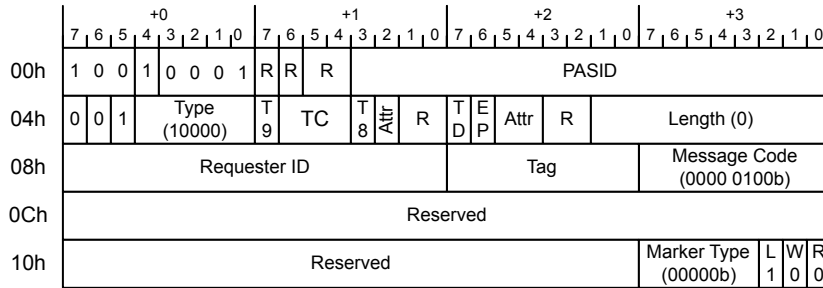

Figure 10-25 Stop Marker Message - Non-Flit Mode §

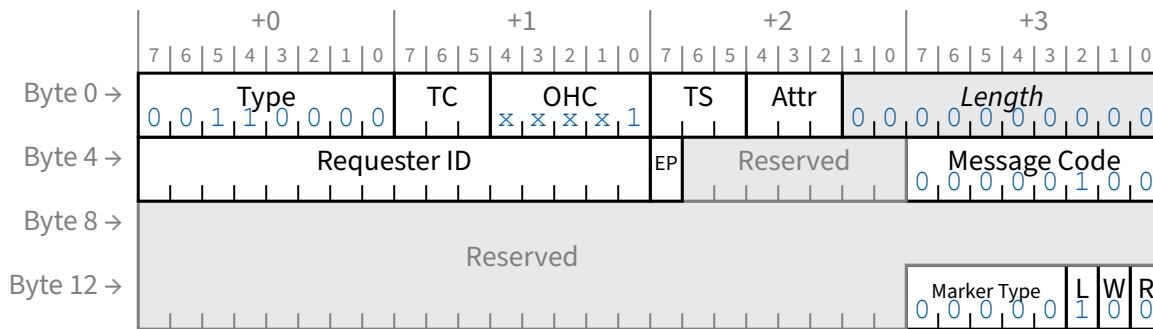

Figure 10-26 Stop Marker Message - Flit Mode §

A Stop Marker Message is encoded as a Page Request Message for which:

- In NFM, includes a PASID TLP Prefix. The Execute Requested and Privileged Mode Requested bits are Reserved.
- In FM, includes OHC-A1 with PASID. The Execute Requested bit, Privileged Mode Requested bit, and Last DW BW / 1st DW BE fields in the OHC-A1 are Reserved.
- The L, W and R fields contain 1b, 0b and 0b respectively.
- The Untranslated Address field and upper bits of the PRG Index field are Reserved.
- The Marker Type field contains 0 0000b to indicate that this is a Stop Marker Message.
- The Traffic Class must be 0.
- The Relaxed Ordering attribute bit must be Clear.
- The ID-Based Ordering attribute bit may be Set.

Behavior is undefined if a Stop Marker Message is received and any of the following are true:

- Marker Type not equal to 0 0000b.
- No PASID TLP Prefix is present (NFM).
- The PASID value does not match an outstanding stop request.
- An incomplete Page Request Message for the PASID is outstanding (i.e., for some PRG Index, the most recently received Page Request Message did not have the L bit Set).

10.4.2 Page Request Group Response Message §

System hardware and/or software communicate with a Function's page request interface via PRG Response Messages. A PRG Response Message is used by a host to signal the completion of a PRG, or the catastrophic failure of the interface. A single PRG Response Message is issued in response to a PRG, independent of the number of page requests associated with the PRG. There is no mechanism for indicating a partial request completion or partial request failure. If any of the pages associated with a given PRG cannot be satisfied, then the request is considered to have failed and the reason for the failure is supplied in the PRG Response Message. The host has no obligation to partially satisfy a multi-page request. If one of the requested pages cannot be made resident, then the entire request can, but need not, be discarded. That is, the residence of pages that share a PRG with a failed page request, but that are not associated with the failure, is indeterminate from the Function's perspective.

There are four possible Page Request failures:

1. The requested page is not a valid Untranslated Address.
2. PASID support exists, the Page Request has a PASID, and either PASID usage is not enabled for this request, the PASID value is not valid, or the Execute Requested bit is Set when R is Clear.²⁰²
3. The requested page does not have the requested access attributes (including Execute permission and/or Privileged Mode access when those bits are present).
4. The system is, for an unspecified reason, unable to respond to the request. This response is terminal (the host may no longer respond to any page requests and may not supply any further replies to the Function until the Function's page request interface has been reset). For example, a request that violates a Function's assigned request limit or overflows the RC's buffering capability may cause this type of failure.

A Function's response to Page Request failure cases 1, 2, and 3 above is implementation dependent. The failure is not necessarily persistent, that is, a failed request may, in some instances succeed if re-issued. The range of possibilities precludes the precise specification of a generalized failure behavior, though on a per Function basis, the response to a failure will be an implementation dependent behavior.

All responses are sent to their associated Functions via PRG Response Messages. A Function must be capable of sinking multiple consecutive messages without losing any information. To avoid deadlock, a Function must be able to process PRG Response Messages for all of the Function's outstanding Page Request Messages without depending on the Function sending or receiving any other TLP.²⁰³ A PRG Response Message is an ID routed PCIe message. The only Page Request Interface specific fields in this message are the Response Code and PRG. All other fields are standard PCIe message fields. (Note: these messages are routed based on the ID in bytes 8 and 9; with bytes 4 and 5 containing the host's Requester ID.)

Receipt of a PRG Response Message that contains a PRG Index that is not currently outstanding at a Function shall result in the UPRGI flag in the Page Request Extended Capability being Set, contingent upon the TLP otherwise being error free. Because of ambiguous language in earlier versions of this specification, it is permitted (though discouraged) to handle this case as an Unsupported Request (UR) or Unexpected Completion (UC) by the Function containing the Page Request Extended Capability, but otherwise no other error is permitted to be logged or signaled.

In order to prevent overflow, it is recommended to size Page Request queuing appropriately so that it does not overflow under expected behavior. If an overflow condition occurs, it is permitted to recover and resynchronize Page Request accounting as follows:

- The TA, upon detecting the overflow condition, stops accepting all incoming Page Requests for the queue and generates Page Request Group Responses with a Response Code of Success to Page Requests with L=1.

202. Behavior when PASID support does not exist is defined in § Section 6.20.1 .

203. For example, processing a PRG Response Message that causes the Function to send a TLP Upstream must not block processing of subsequent downstream TLPs even if the Upstream TLP is delayed by flow control.

- Software processes all entries in the queue and generates Page Request Group Responses with a Response Code of Success to all Page Requests with L=1.
- Software clears the overflow condition to re-enable Page Request acceptance for the queue in the TA after all entries in the queue have been processed.

Figure 10-27 PRG Response Message - Non-Flit Mode §

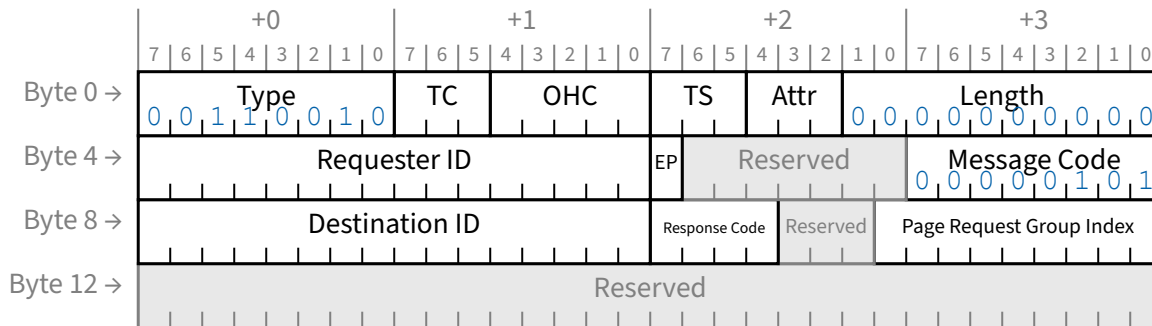

Figure 10-28 PRG Response Message - FLIT Mode §

Table 10-7 PRG Response Message Data Fields §

Field	Meaning
Page Request Group Index	Page Request Group Index - This field contains a Function supplied index to which the RC is responding. A given PRG Index will receive exactly one response per instance of PRG (with the possible exception of a Response Failure).
Response Code	Response Code - This field contains the response type of the associated PRG. The encodings are presented in § Section 10.4.2.1.

10.4.2.1 Response Code Field §

The values and meaning for the Response Code field are listed in § Table 10-8.

Table 10-8 Response Codes §

Value	Status	Meaning
0000b	Success	All pages within the associated PRG were successfully made resident.
0001b	Invalid Request	One or more pages within the associated PRG do not exist or requests access privilege(s) that cannot be granted. Unless the page mapping associated with the Function is altered, re-issuance of the associated request will never result in success.

Value	Status	Meaning
1110b:0010b	Unused	Unused Response Code values. A Function receiving such a message shall process it as if the message contained a Response Code of Response Failure.
1111b	Response Failure	One or more pages within the associated request group have encountered/caused a catastrophic error. This response disables the Page Request Interface at the Function. Any pending page requests for other PRGs will be satisfied at the convenience of the host. The Function shall ignore any subsequent PRG Response Messages, pending re-enablement of the Page Request Interface.

10.4.2.2 PASID Usage on PRG Responses §

If a Page Request has a PASID, the corresponding PRG Response Message may optionally contain one as well.

If the PRG Response PASID Required bit is Clear, PRG Response Messages do not have a PASID.

If the PRG Response PASID Required bit is Set, PRG Response Messages have a PASID if the Page Request also had one. The Function is permitted to use the PASID value from the prefix in conjunction with the PRG Index to match requests and responses.

When a PASID is attached to PRG Response Messages, the Execute Requested and Privileged Mode Requested bits are Reserved and the PASID value is copied from the PASID value of the Page Request.

10.5 ATS Configuration §

10.5.1 ATS Extended Capability §

Each Function that supports ATS (capable of generating Translation Requests) must have the ATS Extended Capability structure in its Extended Configuration Space. It is permitted to be implemented by Endpoint Functions or RCiEPs.

ATS support is optional in SR-IOV devices. If a VF implements an ATS capability, its associated PF must implement an ATS capability. The ATS Capabilities in VFs and their associated PFs are permitted to be enabled independently.

§ Figure 10-29 details allocation of the register fields in the ATS Extended Capability structure.

Figure 10-29 ATS Extended Capability Structure §

10.5.1.1 ATS Extended Capability Header (Offset 00h) §

§ Figure 10-30 details allocation of the register fields in the ATS Extended Capability Header; § Table 10-9 provides the respective field definitions.

Figure 10-30 ATS Extended Capability Header §

Table 10-9 ATS Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - Indicates the ATS Extended Capability structure. This field must return a Capability ID of "000Fh" indicating that this is an ATS Extended Capability structure.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be "1h" for this version of the specification.	RO
31:20	Next Capability Offset - The offset to the next PCI Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	RO

10.5.1.2 ATS Capability Register (Offset 04h) §

§ Figure 10-31 details the allocation of register fields of an ATS Capability Register; § Table 10-10 provides the respective bit definitions.

Figure 10-31 ATS Capability Register (Offset 04h) §

Table 10-10 ATS Capability Register (Offset 04h) §

Bit Location	Register Description	Attributes
4:0	Invalidate Queue Depth - The number of Invalidate Requests that the Function can accept before putting backpressure on the Upstream connection. A value of Zero in a non-VF Function indicates that it can accept 32 Invalidate Requests.	RO VF ROZ

Bit Location	Register Description	Attributes
	For VFs, this field must be hardwired to Zero. VFs share the queue of the associated PF. See § Section 10.3.5 .	
5	Page Aligned Request - If Set, indicates the Untranslated Address is always aligned to a 4096 byte boundary. This field permits software to distinguish between implementations compatible with this specification and those compatible with an earlier version of this specification in which a Requester was permitted to supply anything in bits [11:2]. It is strongly recommended that this bit be Set.	<u>RO</u>
6	Global Invalidate Supported - If Set, the Function supports Invalidation Requests that have the Global Invalidate bit Set. If Clear, the Function ignores the Global Invalidate bit in all Invalidate Requests (see § Section 10.3.8). It is strongly recommended that this bit be Clear. This bit must be hardwired to Zero if the Function does not support PASID.	<u>RO</u>
7	Relaxed Ordering Supported - If Set, indicates this Function is permitted to Set the RO bit in Translation Requests when Enable Relaxed Ordering bit is Set.	<u>RO</u>
8	ATS Memory Attributes Supported - If Set, the Function supports using AMA values from ATS Translation Completions in the Function ATC. When Clear, the Function ignores the AMA field in ATS Translation Completions.	<u>RO</u>

10.5.1.3 ATS Control Register (Offset 06h) §

§ Figure 10-32 details the allocation of register fields of an ATS Control Register; § Table 10-11 provides the respective bit definitions.

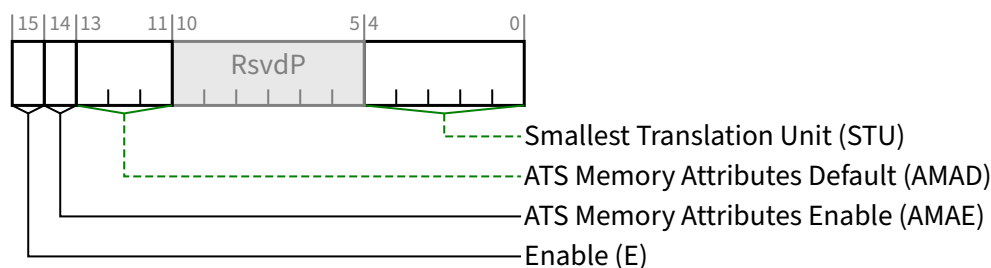

Figure 10-32 ATS Control Register §

Table 10-11 ATS Control Register §

Bit Location	Register Description	Attributes
4:0	Smallest Translation Unit (STU) - This value indicates to the Function the minimum number of 4096-byte blocks that is indicated in a Translation Completions or Invalidate Requests. This is a power of 2 multiplier and the number of blocks is 2^{STU} . A value of 0 0000b indicates one block and a value of 1 1111b indicates 2^{31} blocks (or 8 TB total)	<u>RW</u> <u>VF ROZ</u>

Bit Location	Register Description	Attributes				
	For VFs, this field must be hardwired to Zero. The associated PF's value applies. Default value is 0 0000b.					
13:11	<p>ATS Memory Attributes Default (AMAD) – When Set, as a performance optimization, and when AMAE is Set, the Requester is permitted to provide only non-default AMA values in Requests using the TPH TLP Prefix.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>AMAD</th> <th>ATS Memory Attributes</th> </tr> </thead> <tbody> <tr> <td>000b-111b</td> <td>ATS Memory Attribute values.</td> </tr> </tbody> </table> <p>This field is permitted to be hardwired to 000b if ATS Memory Attributes Supported is Clear. Default value is 000b.</p>	AMAD	ATS Memory Attributes	000b-111b	ATS Memory Attribute values.	<u>RW/RO</u>
AMAD	ATS Memory Attributes					
000b-111b	ATS Memory Attribute values.					
14	<p>ATS Memory Attributes Enable (AMAE) - When Set, the Requester is permitted to provide AMA values in Requests using the TPH TLP Prefix.</p> <p>This bit is permitted to be hardwired to 0b if the ATS Memory Attributes Supported bit is Clear. Default value is 0b.</p>	<u>RW/RO</u>				
15	<p>Enable (E) - When Set, the Function is enabled to cache translations.</p> <p>Behavior is undefined if this Endpoint Function supports PASID, this bit is Set and any bit in the associated <u>PASID Control Register</u> is changed (see § <u>Section 7.8.9.3</u>) Default value is 0b.</p>	<u>RW</u>				

10.5.2 Page Request Extended Capability Structure §

A Page Request Extended Capability Structure is used to configure the Page Request Interface mechanism. A Multi-Function Device or RCiEP Device may implement a Page Request Interface and the associated capability on any Endpoint Function within the Device. For SR-IOV devices, a single Page Request Interface is permitted for the PF and is shared between the PF and its associated VFs, in which case the PF implements this capability and its VFs must not. Every Page Request Interface mechanism operates independently.

For an SR-IOV device, even though the Page Request Interface is shared between its PFs and VFs, it sends the requesting Function's ID (PF or VF) in the Requester ID field of the Page Request Message, and the requesting Function's ID must be in the Destination Device ID field of the resulting PRG Response Message.

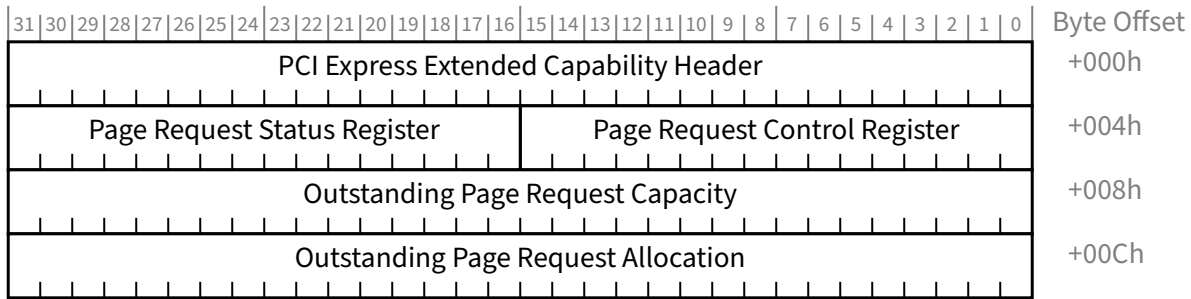

Figure 10-33 Page Request Extended Capability Structure §

10.5.2.1 Page Request Extended Capability Header (Offset 00h) §

§ Figure 10-34 details allocation of the register fields in the Page Request Extended Capability Header; § Table 10-13 provides the respective field definitions.

Figure 10-34 Page Request Extended Capability Header §

Table 10-13 Page Request Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - Indicates that the associated extended capability structure is a Page Request Extended Capability. This field must return a Capability ID of "0013h".	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be "1h" for this version of the specification.	RO
31:20	Next Capability Offset - The offset to the next PCI Extended Capability structure or 000h if no other items exist in the linked list of capabilities.	RO

10.5.2.2 Page Request Control Register (Offset 04h) §

§ Figure 10-35 details allocation of the register fields in the Page Request Control Register; § Table 10-14 provides the respective field definitions.

Figure 10-35 Page Request Control Register §

Table 10-14 Page Request Control Register §

Bit Location	Register Description	Attributes
0	<p>Enable (E) - This field, when set, indicates that the Page Request Interface is allowed to make page requests. If this field is Clear, the Page Request Interface is not allowed to issue page requests. If both this field and the Stopped field are Clear, then the Page Request Interface will not issue new page requests, but has outstanding page requests that have been transmitted or are queued for transmission. When the Page Request Interface is transitioned from not-Enabled to Enabled, its status flags (Stopped, Response Failure, and Unexpected Page Request Group Index (UPRGI) flags) are cleared. Enabling a Page Request Interface that has not successfully Stopped has indeterminate results.</p> <p>Default value is 0b.</p>	RW
1	<p>Reset (R) - When the Enable field is clear, or is being cleared in the same register update that sets this field, writing a 1b to this field, clears the associated implementation dependent page request credit counter and pending request state for the associated Page Request Interface. No action is initiated if this field is written to 0b or if this field is written with any value while the Enable field is Set. Reads of this field return 0b</p>	RW

10.5.2.3 Page Request Status Register (Offset 06h) §

§ Figure 10-36 details allocation of the register fields in the Page Request Error Register; § Table 10-15 provides the respective field definitions.

Figure 10-36 Page Request Status Register §

Table 10-15 Page Request Status Register §

Bit Location	Register Description	Attributes
0	<p>Response Failure (RF) - This field, when Set, indicates that the Function has received a PRG Response Message indicating a Response Failure. The Function expects no further responses from the host (any received are ignored). This field is Set by the Function and Cleared when a one is written to the field.</p> <p>For SR-IOV, this field is Set in the PF if any associated Function (PF or VF) receives a PRG Response Message indicating Response Failure.</p> <p>Default value is 0b.</p>	RW1C
1	<p>Unexpected Page Request Group Index (UPRGI) - This field, when Set, indicates that the Function has received a PRG Response Message containing a PRG index that has no matching request. This field is Set by the Function and cleared when a one is written to the field.</p> <p>For SR-IOV, this field is Set in the PF if any associated Function (PF or VF) receives a PRG Response Message that does has no matching request.</p> <p>Default value is 0b.</p>	RW1C
8	<p>Stopped (S) - When this field is Set, the associated page request interface has stopped issuing additional page requests and that all previously issued Page Requests have completed. When this field is Clear the associated page request interface either has not stopped or has stopped issuing new Page Requests but has outstanding Page Requests. This field is only meaningful if Enable is Clear. If Enable is Set, this field is undefined.</p> <p>When the Enable field is Cleared, after having been previously Set, the interface transitions to the stopping state and Clears this field. After all page requests currently outstanding at the Function(s) have completed, this field is Set and the interface enters the disabled state. If there were no outstanding page requests, this field may be Set immediately when Enable is Cleared. Resetting the interface will cause an immediate transition to the disabled state. While in the stopping state, receipt of a Response Failure message will result in the immediate transition to the disabled state (Setting this field).</p> <p>For SR-IOV, this field is Set only when all associated Functions (PF and VFs) have stopped issuing page requests.</p> <p>Default value is 1b.</p>	RO
15	<p>PRG Response PASID Required - If Set, the Function expects a PASID on PRG Response Messages when the corresponding Page Requests had a PASID. If Clear, the Function does not expect PASID on any PRG Response Message.</p> <p>Function behavior is undefined if this bit is Clear and the Function receives a PRG Response Message with a PASID.</p> <p>Function behavior is undefined if this bit is Set and the Function receives a PRG Response Message with no PASID when the corresponding Page Requests had a PASID.</p> <p>This bit is RsvdZ if the Function does not support PASID.</p>	RO

10.5.2.4 Outstanding Page Request Capacity (Offset 08h) §

This register contains the number of outstanding page request messages the associated Page Request Interface physically supports. This is the upper limit on the number of pages that can be usefully allocated to the Page Request Interface.

This register is Read Only.

10.5.2.5 Outstanding Page Request Allocation (Offset 0Ch) §

This register contains the number of outstanding page request messages the associated Page Request Interface is allowed to issue (have outstanding at any given instance).

The number of PRGs a Page Request Interface has outstanding is less than or equal to the number of request messages it has issued. For example, if system software allocates 1000 messages to a Page Request Interface then a single PRG could use all 1000 of the possible requests. Conversely, at one request per PRG the Page Request Interface would run out of PRG indices (of which there are only 512) before it consumes all its page request credits. A Page Request Interface must pre-allocate its request availability for any given PRG, that is, all the requests required by a given PRG must be available before any of the requests may be issued.

When Shadow functions are enabled, this allocation applies to the Function containing this capability and its enabled Shadow Functions (See Section 7.9.21).

This register is Read/Write. Behavior is undefined if this register is changed while the Enable flag is set. Behavior is undefined if this register is written with a value larger than Outstanding Page Request Capacity. Default value is 0.

When PASID is supported, the Request Allocation remains associated with the Function and is shared across the Function as well as all PASIDs of the Function.

Stopping a PASID does not affect any allocation used by that PASID. The system should continue to respond with PRG Response Messages in order to return Page Request and PRG Index resources to the Function (see § Section 10.4.2.1).

Stop Marker Messages consume buffering but are not included in this allocation (see § Section 10.4.1.2.1). Systems should provide additional buffering for Stop Marker Messages and should limit the number of outstanding Stop Marker Messages to avoid overrunning this additional buffering.

11. TEE Device Interface Security Protocol (TDISP) §

Trusted Execution Environments (TEEs) that include a composition of resources from one or more devices and the host require mechanisms to establish and manage trust relationships. Here we will use the term TEE-I/O to refer to a conceptual framework for performing such operations. This chapter defines a specific architecture for hosts and devices to participate in TEE-I/O (see § Figure 11-1).

TEE-I/O builds upon existing capabilities for the direct assignment of devices to VMs, such as SR-IOV (§ Chapter 9.) and ATS (§ Chapter 10.), to establish Trusted Execution Environment VMs (TVMs). All VMs that are not TVMs are referred to as legacy VMs. In TEE-I/O, the VMM itself may not be trusted by TVMs, and mechanisms are provided to enable the TVM to make trust decisions based on the underlying hardware it is using. Although the VMM is not required to be trusted by TVMs, it continues to perform the resource allocation and system management functions as it does in non-TEE-I/O use models, but in such a way that the results can be tested. The VMM can be blocked from bypassing the security of the affected TVM(s). Legacy VMs that implicitly trust the VMM may co-exist with TVMs in a system.

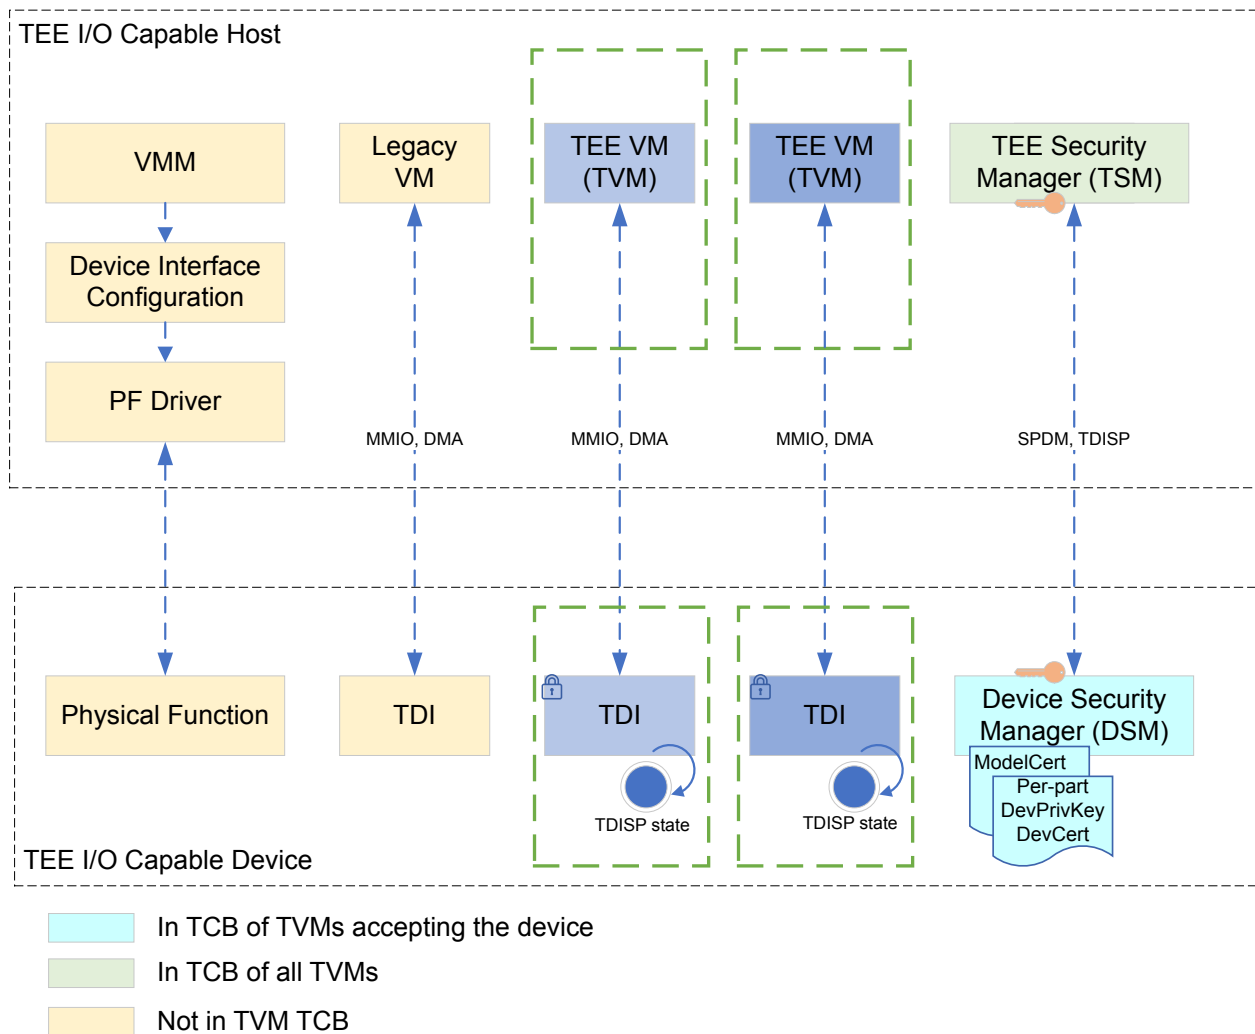

Figure 11-1 Conceptual View with Example Host and Device and Logical Communication Paths §

The **TEE Security Manager (TSM)** is a logical entity in a host that is in the TCB for a TVM and enforces security policies on the host. The Device Security Manager (DSM) is a logical entity in the device that may be admitted into the TCB for a TVM by the TSM and enforces security policies on the device.

The TEE Device Interface (TDI) Security Protocol (TDISP) defines an architecture for devices that support TEE-I/O virtualization, providing the following functions:

1. Establishing a trust relationship between a TVM and a device.
2. Securing the interconnect between the host and device.
3. Attach and detach a TDI to a TVM in a trusted manner.

Although TDISP has been defined in relation to TEE-I/O as describe above, TDISP stands alone as a specification for devices, and such devices may be operated in systems using security architectures other than TEE-I/O, provided that the host functions required by TDISP are supported in an appropriate way by the system.

TDISP defines requirements for TDIs specifically, and also for the entire Device implementing TDIs, where in a specific instance, a TDI may be an entire Device, a non-IOV Function, a PF (and possibly its subordinate VFs), or a VF. Although it is permitted (and generally expected) that TDIs will be implemented such that they can be assigned to Legacy VMs, such use is not the focus of TDISP.

11.1 Overview of the TEE-I/O Security Model as it Relates to Devices §

The TEE-I/O security model is primarily intended to apply to systems using device resources directly assigned to VMs, and this chapter generally assumes this use case. However, devices that are compliant to TDISP can potentially be used in other ways, and such use is not prohibited, although it is outside the scope of this specification.

The TEE-I/O considers all resources, including memory of all types, host processors, TDI's and, in some cases internal state, to be in one of two classes:

- “TEE-assignable” resources have the required trust/security capabilities to be assigned to a TEE. Once assigned to a TEE, these resources become “TEE-Owned.”
- “Non-TEE-assignable” resources either do not possess the required trust/security capabilities to be assigned to a TEE or have been excluded by some implementation-specific mechanism. These resources may, and often do, have a critical role in system function, and therefore it is often desirable to appropriately secure them, although how this is done is outside the scope of this specification.

The TEE-I/O security model does not require the VMM to be trusted by TVMs. Therefore, devices supporting hardware-assisted I/O virtualization (e.g., SR-IOV) require security extensions to ensure that the device's virtualization model does not allow or require intervention by software outside the TVM trust boundary to perform operations that affect the confidentiality and/or integrity of TVM data in-flight or at-rest in the device. The primary focus of TDISP is to define the requirements for TDISP-compliant devices and the necessary elements outside of such devices required to support the TDISP architecture. Additional system capabilities required are outside the scope of TDISP.

TVM data, code, and execution state stored in an assigned device must be protected against:

- Confidentiality breaches: read access by entities (firmware, software, or hardware) not in the TCB of the TVM (such as other TVMs, VMM, etc.).
- Integrity: modification by entities (firmware, software, or hardware) not in the TCB of the TVM (such as other TVMs, VMM, etc.).

This security model does not require protection of TVMs against denial-of-service attacks in general. However, systems may impose a requirement that a TVM not have the ability to cause denial of service to other TVMs, VMM, or other VMs executing on the platform. The TSM by itself may not have all the capabilities needed to defend the platform against denial of service. Enforcing this property is the collective responsibility of the TSM, VMM, device and DSM, and is outside the scope of this specification.

The hardware assisted I/O virtualization schemes for direct I/O from TVMs to devices must address the following to preserve the confidentiality and integrity of the TVMs and the data moved between the TVMs and devices:

1. Authenticating device identity and measurement reporting - Device identities like Vendor ID and Device ID may be spoofed with malicious intent. Firmware executing on devices may have security vulnerabilities, or may have been tampered with. Device debug interfaces may be used to obtain low level access to the device hardware and thereby influence the security property of devices. The TVM must be able to cryptographically check the identity of the device, identity of the firmware components running on the device, and security state of the device (e.g., debug active). CMA/SPDM is used to support these requirements.

2. Device to Host communication Security - Physical access may be used to tamper with the data transferred between the host and the device. Transfers must be cryptographically protected to provide confidentiality, integrity, and replay protection to TVM data, and such schemes must also guard against violations of producer-consumer ordering. IDE is used to support these requirements. In some cases, e.g. for an RCiEP, it may be possible to ensure by construction that communication is not be susceptible to tampering, and therefore may not require the use of IDE. The TSM and DSM are both responsible for ensuring that Device/Host (and, when peer-to-peer is used, Device/Device) communication is secured by IDE, or by other means that satisfy use model requirements.
3. TEE Device Interface (TDI) management - DMA and interrupt remapping tables set up by the VMM may be tampered with by the VMM. The VMM administration of these tables (e.g., IOMMU TLB management, Device TLB management, Page Request handling, etc.) may additionally be tampered with by the VMM to influence the security of the TVM interaction with the device. The device must support locking down configurations of the TDI, reporting the configurations in a trusted manner, securely placing the TDIs into operational state, and subsequently tearing them down when the TDI is detached from a TVM. This chapter defines the mechanisms used to manage the security states of TDIs.
4. Device Security Architecture - Administrative interfaces (e.g., a PF) may be used to influence the security properties of the TDI used by the TVM. The device's security architecture must provide isolation and access control for TVM data in the device for protection against entities that are not in the trust boundary of the TVM. This chapter defines some device security architecture requirements, but additional requirements may exist for specific implementations that are outside the scope of this specification.

This chapter defines the wire protocol and the security objectives that are required to be implemented by the host and the device to be compatible with the TEE-I/O framework and the capabilities that need to be implemented to achieve specified security objectives. The implementation of such capabilities and the physical manifestation of the logical entities are outside the scope of this specification.

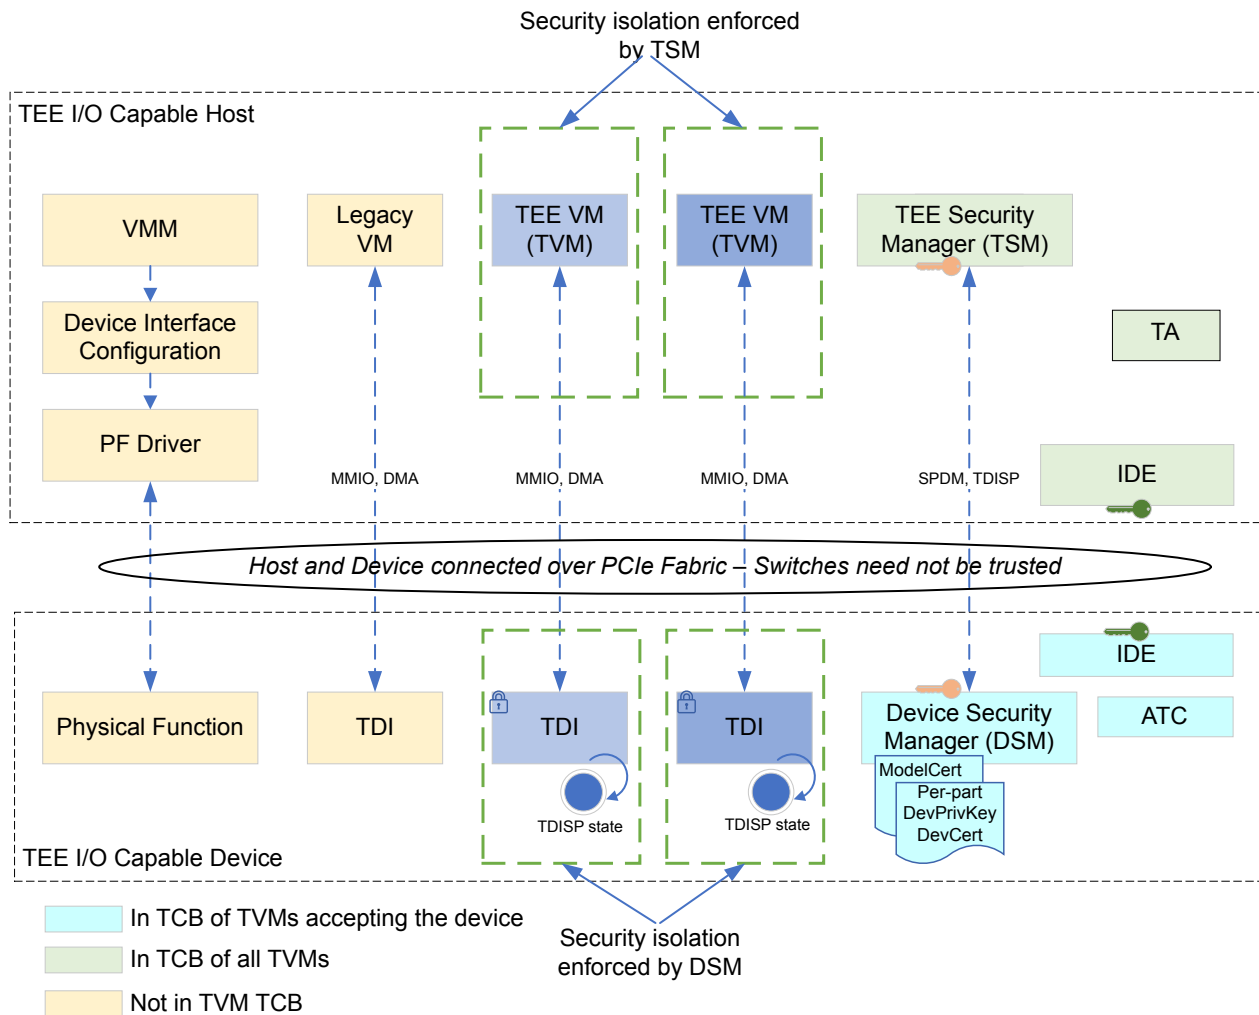

Figure 11-2 TDISP Host/Device Reference Architecture §

§ Figure 11-2 illustrates key elements of the TDISP reference architecture. Typically, a PF is the resource management entity for a TDI and is managed by the PF driver in the VMM. The VMM and the PF driver are not required to be in the TCB of the TVMs. The VMM uses the PF to configure TDIs for assignment to TVMs. TEE-I/O requires the device to organize its hardware/software interfaces such that the PF cannot be used to affect the security of a TDI when it is in use by a TVM. The device must support mechanisms to lockdown the configurations of the TDI, when requested by the TSM, such that any modifications to the TDI configurations, once the TVM has accepted and started using the TDI, are detected as malicious actions. The device is required to implement a security architecture that protects the confidentiality and integrity of TVM data from being tampered with by the PF or other TDIs assigned to other TVMs or VMs. To ensure that error conditions can be appropriately managed, the device should implement Advanced Error Reporting (AER).

There are a variety of additional elements of the reference architecture. Software running on a Host CPU must be associated with a TEE via implementation-specific means. Memory can be a system-level resource or associated with a TDI, and is defined as either TEE memory or non-TEE memory. TEE memory must have mechanisms to ensure the confidentiality of TVM data, and may additionally provide integrity properties on the TVM data. Non-TEE memory is not assumed to have any such mechanisms.

System configuration of Memory Address routing mechanisms must be managed so as to ensure correct system operation, as misrouting of TLPs will in many cases result in conditions indistinguishable from an attack, in turn resulting in an error condition, such as a Misrouted IDE TLP error or an IDE Check Failed error. Except when a peer-to-peer connection has been established between two TDIs, all Requests must be routed to the Root Complex, and in some cases this result is achieved by means of Access Control Services (see § Section 6.12) mechanisms that modify the routing of TLPs.

When Links that could be subject to physical attacks are used, Integrity and Data Encryption (IDE) must be supported and enabled. The use of Selective IDE Streams minimizes the TCB and attack surface by allowing intermediate Switches to be excluded from the TCB. For Endpoint Upstream Ports connected directly to Root Ports, Link IDE meets the stated requirement of minimizing TCB and attack surface, and it is acceptable in such configurations to use Link IDE instead of Selective IDE, provided the TSM and DSM are able to provide acceptable security in this configuration. It is permitted for IDE streams established by the TSM to be used to carry TLPs associated with legacy VMs. Between the same two Ports, separate IDE streams per TDI do not provide additional protection against an adversary employing physical attacks on a Link, so only a single IDE Stream is required. The TLPs once decrypted and authenticated at the device or at the Root Port are in cleartext, and access control mechanisms put in place by the TSM on the host, and the DSM on the device, must provide confidentiality and integrity to the TLP contents against entities not in the TCB of the TVMs. How this is done is outside the scope of this specification.

An RCiEP or other TDI integrated into a Root Complex may not require use of IDE to protect the TLPs, and as such is not required to implement IDE. Such devices may use a Root Complex specific indication that is equivalent to the T bit in the IDE Prefix (NFM) /OHC-C (FM) to indicate that the TLP is associated with a TVM. For simplicity, such Root Complex specific indications are also referred to as the T bit, although this does not imply an implementation requirement. IDE Stream-specific checks and actions defined in later sections are not required for RCiEPs that do not implement IDE. An RCiEP may not require the use of [Secured SPD] for protecting the communication between the TSM and DSM if it is possible to ensure the security of communication by other means.

In general, it is not assumed that system configuration relevant to TEE-I/O operation can be protected against inappropriate modification, and in some cases it may not even be possible to do so. Instead, system elements used with TEE-I/O, including TDISP-compliant devices, detect inappropriate modifications when it is possible to do so, and further protect themselves against security policy violations without depending on other elements of the system for assistance, for example by detecting non-IDE TLPs in cases where IDE is required, and by checking memory addresses in received Requests. The detection by one system element of an error condition results in that element entering a “fail safe” error state, but it may not in all cases be possible for this to be directly communicated to other system elements, for example because an attacker may block attempted notifications, and so in such cases error conditions must be inferred, for example through a TDI’s lack of responsiveness.

This chapter specifies the protocol used by the TSM and DSM to associate an IDE Stream ID to be used by the TDI. The T bit allows the originator of a TLP to indicate that a TLP is associated with a TVM. The T bit is used by the device and the host translation agent (TA) to provide access control to TVM assigned memory and memory mapped I/O registers.

The T bit must be used only as defined for TDISP.

The DSM provides the following functions:

1. Authentication of device identities and measurement reporting.
2. Configuring the IDE encryption keys in the device.
3. Device interface management for locking TDI configuration, reporting TDI configurations, attaching, and detaching TDIs from TVMs.
4. Implementing access control and security mechanisms to isolate TVM provided data from entities not in the TCB of the TVM.

The TSM provides the following functions:

1. Provide interfaces to the VMM to assign memory, CPU, and TDI resources to TVMs.
2. Implements the security mechanisms and access controls (e.g., IOMMU translation tables, etc.) to protect confidentiality and integrity of the TVM data and execution state in the host from entities not in the TCB of the TVM.
3. Use TDISP protocol to manage the security state of the TDIs to be used by TVMs.
4. Establishing/managing IDE encryption keys for the host, and, if needed, scheduling key refreshes.

Secured messages as specified in Section [6.31] are used by TSM and DSM to communicate TDISP messages securely. The secure session establishment is used by the TSM to authenticate the DSM (Optionally, the DSM may be configured to authenticate the TSM, if required by the system design), negotiate cryptographic parameters, and establish shared keying material.

Once the SPDM secure session has been established, the session enters the application phase where all application data between the TSM and DSM are communicated using secured messages within the SPDM secure session. Two types of application data are used by TEE-I/O:

- IDE Key Programming – When IDE is required, the IDE_KM protocol is used for key programming. An IDE stream may also be established between two devices for peer-to-peer communication.
- TDI Management – the TSM uses the TDISP protocol to manage the TDI attach and detach to a TVM. The TSM steps the TDI through the TDISP states as part of the TDI lifecycle management process such as:
 - Locking a TDI configuration for assignment of the TDI to the TVM
 - Making the TDI operational if the TVM approves of the device
 - Detaching a previously assigned TDI from a TVM.

The DSM must track the SPDM session that was used to establish the IDE keys for an IDE stream. For the IDE stream to be usable for carrying TVM data, all the IDE keys for the IDE stream that will be used by the TDI assigned to a TVM must be programmed by the TSM.

Multiple TDIs (e.g., SR-IOV VFs) in a device may generate or receive transactions over the IDE stream established by the TSM and DSM to secure the communication links between the host and the device. One or more of these TDIs may be assigned to TVMs, and one or more of these TDIs may be assigned to legacy VMs. The TSM manages and tracks the TDISP state associated with the TDIs assigned to TVMs.

11.2 TDISP Rules §

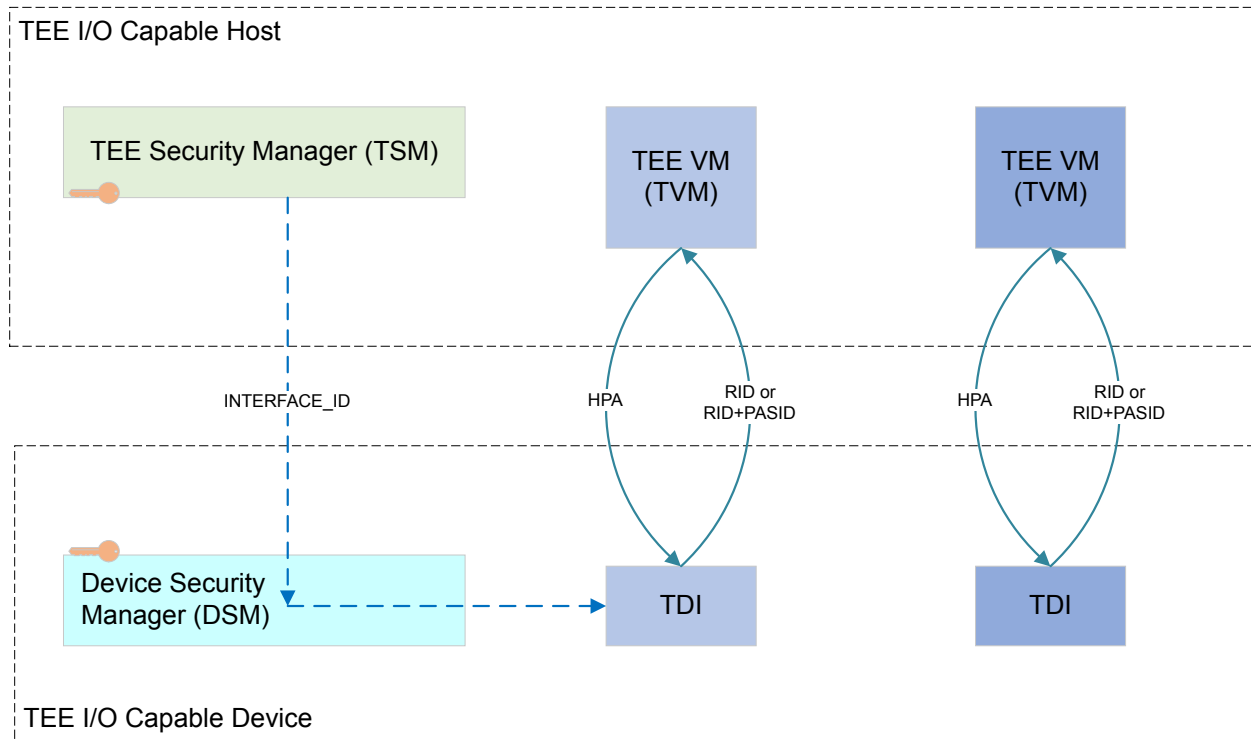

Figure 11-3 Identification of Requests §

As illustrated in § Figure 11-3, a TDI is managed by a specific DSM, and within the domain of that DSM it is necessary for each TDI to have a unique identifier, called an `INTERFACE_ID`, that is used in all TSM/DSM messages to indicate the applicable TDI. MMIO requests originated from the TVM are translated by the host and directed to appropriate TDI based on the HPA. Requests generated by the TDI contain the Requester ID (RID) of the function hosting the TDI, and may also have a PASID.

The `INTERFACE_ID` is composed of a `FUNCTION_ID` field that identifies the function of the device hosting the TDI and a Reserved field provided for future expansion (see § Figure 11-4 and § Table 11-1). Within the `FUNCTION_ID`, the Function Number and Device Number are assigned by the device/DSM. The Bus Number and Segment Number are assigned during system enumeration and must not be changed for a TDI in `CONFIG_LOCKED` and `RUN` (see below). If the Segment Number is known to the device, and Requester Segment Valid is Set, then the Requester Segment value must match the Segment Number for the device. The DSM must ensure that only valid TDIs are addressed.

Figure 11-4 TDI Identifier – INTERFACE_ID §

Table 11-1 INTERFACE_ID Definition §

Offset	Field	Size (Bytes)	Description
0	FUNCTION_ID	4	Identifies the function of the device hosting the TDI: 15:0 Requester ID 23:16 Requester Segment (Reserved if Requester Segment Valid is Clear) 24 Requester Segment Valid 31:25 Reserved
4	Reserved	8	Reserved

Each TDI in the device is associated with a TDISP state machine (see § Figure 11-5).

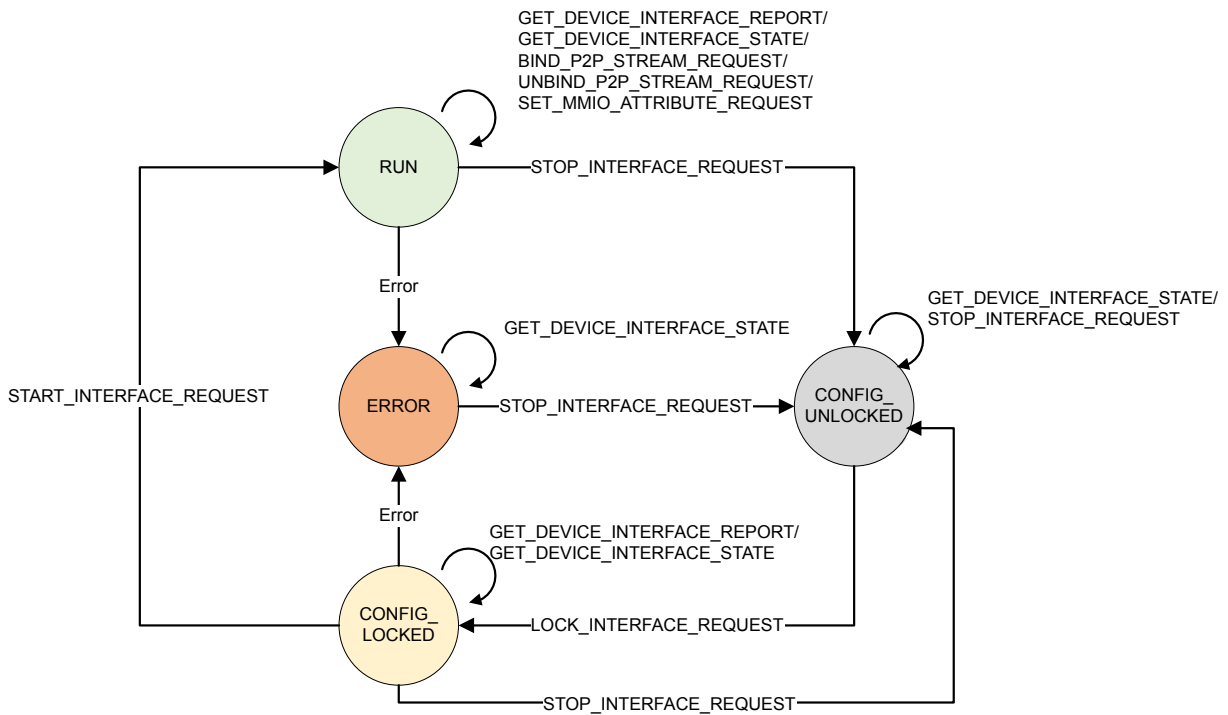

Figure 11-5 TDISP State Machine §

The TSM steps the TDI through these security states as part of the TDI security lifecycle management process, such as locking a TDI configuration in preparation for assignment of the TDI to the TVM, transitioning the TDI to the operational state, and detaching the TDI from a TVM. A TDI is considered “locked” in CONFIG_LOCKED, and RUN. A TDI is considered “unlocked” when in ERROR and CONFIG_UNLOCKED.

For a TDI that supports assignment to Legacy VMs, if a TDI is assigned to a Legacy VM, the VMM assigns the TDI in CONFIG_UNLOCKED, and the TSM must ensure that the TDI remains in that state unless and until the TDI is removed from the Legacy VM and prepared for re-assignment to a TDI.

TDISP requires certain TLPs to be rejected, which means that first the TLP is processed according to the same rules that apply to all other TLPs, and only then are the TDISP-specific rules applied. If the result is a determination that the TLP must be rejected, the associated TDI must transition to ERROR where indicated, but no further error reporting or logging is required to be performed on that TLP, although it is optionally permitted on a case-by-case basis that a Request be handled as an Unsupported Request, and/or a Completion be handled as an Unexpected Completion, or that the TLP be dropped.

IDE Streams that are bound for use with TDISP are permitted to be used for non-TDISP TLPs as well, however:

- for such TLPs the T bit must be Clear in Transmitted TLPs, and must be ignored in Received TLPs (as defined in § Section 6.33.4).
- the DSM must ensure that such TLPs are not allowed to access TVM confidential data.

Security properties for each state and transition rules are as follows:

- **CONFIG_UNLOCKED**
 - This is the default state. In CONFIG_UNLOCKED the VMM configures the TDI to be assigned to a TVM.
 - A TDI is not required to protect confidential data placed into it in this state; TVMs should not place confidential data into a TDI in this state.
 - Memory Requests originating within a TVM (as indicated by the T bit being Set) must be rejected in this state (see § Section 11.2.1)
 - This state must be entered from any other state in response to the STOP_INTERFACE_REQUEST message. When the TDI transitions to CONFIG_UNLOCKED, the DSM must ensure all TVM confidential data held by the device in the context of that TDI cannot be exposed as plaintext outside the device and, to the maximum extent possible, the ciphertext associated with TVM data must not be exposed outside the device.
- **CONFIG_LOCKED**
 - Once the TDI configuration is finalized by the VMM, the VMM requests the TSM to lock the TDI configuration by transitioning the TDI to CONFIG_LOCKED.
 - The DSM must transition a TDI to CONFIG_LOCKED only in response to a LOCK_INTERFACE_REQUEST message.
 - Memory Requests originating within a TVM (as indicated by the T bit being Set) must be rejected in this state (see § Section 11.2.1)
 - The LOCK_INTERFACE_REQUEST must indicate the Stream ID of the IDE stream to bind to the TDI, if IDE is required to secure the transfers to/from the device.
 - On entry to this state, the DSM must perform all necessary actions to lock the TDI configuration, and then must start tracking the TDI for changes that affect the configuration or the security of the TDI. Changes detected must be treated as an error, and the TDI transitioned to ERROR. An example list of architectural configurations registers that should be locked and tracked is shown in § Section 11.2.6. It is typically required for the DSM to track additional device-specific configurations, such as the

configuration of work queues, device specific configurations such as MAC address, storage volume, etc.

- The TVM may obtain the identity and measurements of the device hosting the TDI from the DSM, and also, if applicable, verify that an IDE stream has been established by the TSM between the host and the device. The TVM may request the TSM to obtain the TDI configurations using the GET_DEVICE_INTERFACE_REPORT request from the DSM. The TVM may then evaluate the device identity and measurements, in addition to the TDI report to determine if the device meets the security requirements of the TVM.
- If the TVM approves of the device, the TVM may request the TSM to transition the TDI to RUN.

- **RUN**

- TDI resources are operational and permitted to be accessed and managed by the TVM.
- On entry to this state, the DSM must continue tracking the TDI for changes that affect the configuration or the security of the TDI. Changes detected must be treated as an error, and the TDI transitioned to ERROR.

- **ERROR**

- The TDI must not expose confidential TVM data.
- Memory Requests originating within a TVM (as indicated by the T bit being Set) must be rejected in this state (see § Section 11.2.1).
- The TDI must restrict TLP operations as defined in § Section 11.2.1.
- In ERROR, the TDI may still have confidential TVM data, and it is permitted that clearing this data be deferred until the receipt of a STOP_INTERFACE_REQUEST to transition the TDI to CONFIG_UNLOCKED.
 - It is permitted, but not required, that the TDI transition automatically from ERROR to CONFIG_UNLOCKED, if and only if the TDI first clears all TVM confidential data.

In CONFIG_LOCKED and RUN, the following conditions must be treated as errors, and cause the TDI to move to ERROR:

- Changes to TDI configuration that affect the configuration or the security of the TDI.
 - The Completion Status of Configuration Writes that modify TDI configuration must not be affected.
 - See also § Section 11.2.6.
- Changes to the Requester ID
- Resetting the TDI using a Function Level Reset. A PF reset affects all subordinate VF TDIs, whereas a VF reset affects only that TDI.
- Any IDE stream bound to the TDI transitions to the Insecure state.
- Except when the TDI implements mechanisms to recover from and/or suitably handle, receipt of a poisoned TLP or detecting data integrity errors in the device for data associated with that TDI, where the error is not recoverable.
- Other device specific conditions or changes in configuration that affect trust properties.

The STOP_INTERFACE_REQUEST message may be used to transition the TDI to CONFIG_UNLOCKED. When the TDI transitions back to CONFIG_UNLOCKED, it must ensure that all TVM confidential data held by the device cannot be exposed as plaintext outside the device. To the maximum extent possible the ciphertext associated with TVM confidential data must not be exposed outside the device.

The TSM is permitted to issue a GET_DEVICE_INTERFACE_REPORT in CONFIG_LOCKED and RUN.

The TSM is permitted to issue a GET_DEVICE_INTERFACE_STATE request in all states.

Some TDIs may support peer-to-peer communication with other devices. The Stream ID of the IDE stream(s) used for this communication are configured into the device using the BIND_P2P_STREAM_REQUEST message. This message must only be accepted by the DSM if the TDI is in RUN. The device must be ATS capable, and must have ATS enabled, to support peer-to-peer communication between TVM-assigned TDIs. The TSM and VMM must coordinate the use of ACS mechanisms to redirect device peer-to-peer traffic to the Root Complex, and the TSM must only issue a BIND_P2P_STREAM_REQUEST if the TLPs to be associated with that Selective IDE Stream will, in fact, travel between the two peer devices and not to/from the Root Complex.

Certain configurations require all requests originating from a TDI to be sent to the Root Complex, even if the device is in possession of a Translated Address that appears to refer to a resource within the TDI or elsewhere within the device. Devices are strongly encouraged to implement redirection functionality to send all such requests to the Root Complex. A DSM must advertise the availability of such functionality so that the TSM can establish the correct configuration for the TDI and the rest of the system.

Some TDIs may support updating attributes of one or more MMIO ranges associated with the TDI using the SET_MMIO_ATTRIBUTE_REQUEST.

A TDI must not rely on I/O resources and I/O requests for providing functionality to a TVM. I/O resources must not be able to compromise the confidentiality or integrity of TVM data.

It is not required that Configuration Requests to a TDI be secured.

11.2.1 TDISP TLP Rules §

This section defines the rules for TLPs that are associated with TVMs. In cases where it is possible to ensure communication is not tampered with, it may be possible to avoid the use of IDE, but some equivalent to constructs defined by IDE, particularly the T bit, may still be required, and how this is done is outside the scope of this specification. Under all circumstances, devices must ensure that device memory with the IS_NON_TEE_MEM attribute Clear can only be read/written within the context of an authorized TVM (indicated, when IDE is used, by the T bit being Set).

In all cases, traffic that has no security requirement is not required by TDISP to be secured by IDE or other means, although in specific platforms there may be additional security requirements, for example to apply IDE to all TLPs between the host and a particular device.

The following rules apply to the TDI acting as a Requester:

- In systems where IDE is required, a TDI in CONFIG_LOCKED or RUN must transmit TLPs with T bit Set only on an IDE stream bound to the TDI.
 - All TLPs not associated with a peer-to-peer IDE Stream must use the Default IDE Stream, if one has been configured.
- Memory Reads must only be issued while in RUN and must Set the T bit.
- For Memory Reads issued by the TDI while in RUN, the corresponding Completion(s) must be handled normally if and only if the TDI is still in RUN, and must otherwise be rejected.
 - A TDI in RUN must ignore the value of the T bit in Received Completions.
- Memory Writes other than MSI/MSI-X interrupts must only be issued while in RUN and must Set the T bit.

The MSI capability in the Configuration Space of the function hosting the TDI is not required to have a trusted configuration. With MSI-X, it is possible for the TVM to program the MSI-X table and MSI-X PBA in a trusted manner.

It is permitted for a TDI in CONFIG_LOCKED to issue an MSI/MSI-X interrupt only if the T bit is Clear. TDIs in RUN must observe the following rules:

- An MSI interrupt must be generated with T bit Clear.

- An MSI-X interrupt must be generated with T bit Clear if the MSI-X table is not part of the MMIO ranges that are locked and reported in the DEVICE_INTERFACE_REPORT, else the MSI-X interrupt must be generated with T bit Set.

If a TEE-I/O capable device supports locking and reporting of MSI-X table, it must allocate the MSI-X table and PBA such that the entirety of the MSI-X table and PBA may be mapped onto separate isolated processor pages. The MSI-X Table and the PBA base addresses must each be aligned to the minimum processor page size on supported platforms. 64KB alignment is recommended to provide compatibility across various processor architectures.

TEE-I/O capable devices must locate the ST table, if supported, in the MSI-X table, if ST mode of operation is supported.

The following rules apply to the TDI acting as a Completer:

- Received Memory Requests targeting device memory with the IS_NON_TEE_MEM (see § Section 11.3.22) attribute Clear must be handled normally if and only if all of the following conditions are satisfied:
 - the T bit for the Request is Set
 - the TDI is in RUN
 - if IDE is required, the Request is received on a Stream ID bound to the TDI;

in all other cases, the Request must be rejected.

- The TDI's handling is not modified by TDISP state for Received Memory Requests targeting MMIO with IS_NON_TEE_MEM Set.
- The value of the T bit in the Completion(s) returned by the TDI must match the value of the T bit in the corresponding Request.

There are specific requirements for ATS Invalidation Requests, Invalidation Completions, Page Request Messages and PRG Responses, defined in § Section 11.4.10. VDMs not defined by PCI-SIG must be specified by the Vendor as TDI-specific or not TDI-specific. A TDI is permitted to Transmit and to handle normally Received TDI-Specific Messages while in CONFIG_LOCKED, RUN, and ERROR if and only if the T bit is Set.

11.2.2 TDISP Message Transport §

All TDISP messages must be transported between TSM and DSM using secured messages as specified by Secured CMA/SPDM (see § Section 6.31.4) used within a secure session established between TSM and DSM as specified by [SPDM].

TDISP requires the TSM and the DSM to support AES-256-GCM as the Authenticated Encryption with Associated Data (AEAD) algorithm to protect data transferred using secured messages. The random data field of the secured messages must not be used for TDISP messages or IDE Key Management protocol messages, and this field must have a length of zero.

Function 0 of the device must support the DOE Extended Capability to establish the SPDM session and transport the secured messages.

The [SPDM] Requester role is assumed by the TSM in the host and the Responder role is assumed by the DSM. The TSM is permitted to use an untrusted channel (e.g., proxy through the VMM) to access the transport mechanism.

DOE error conditions only impact TDISP state if the DOE error itself causes an unrecoverable condition, for example by rendering the secure session unusable.

TDISP messages are transported as follows:

- The Requester (TSM) must use the [SPDM] VENDOR_DEFINED_REQUEST format

- The Responder (DSM) must use the [SPDM] VENDOR_DEFINED_RESPONSE format
- The StandardID field of VENDOR_DEFINED_REQUEST and VENDOR_DEFINED_RESPONSE message must contain the value assigned in [SPDM] to identify PCI-SIG.
- The VendorID field of VENDOR_DEFINED_REQUEST and VENDOR_DEFINED_RESPONSE message must contain the value assigned to identify PCI-SIG.
- The first byte of the VendorDefinedReqPayload/VendorDefinedRespPayload is the Protocol ID, and must contain the value 01h to indicate TDISP.
- The TDISP message forms the request or response payload in the VendorDefinedReqPayload or VendorDefinedRespPayload, respectively.
- The VENDOR_DEFINED_REQUEST/VENDOR_DEFINED_RESPONSE must in turn form the Application Data field of a Secured Message per [Secured SPDM].

The encapsulation is as illustrated in § Figure 11-6:

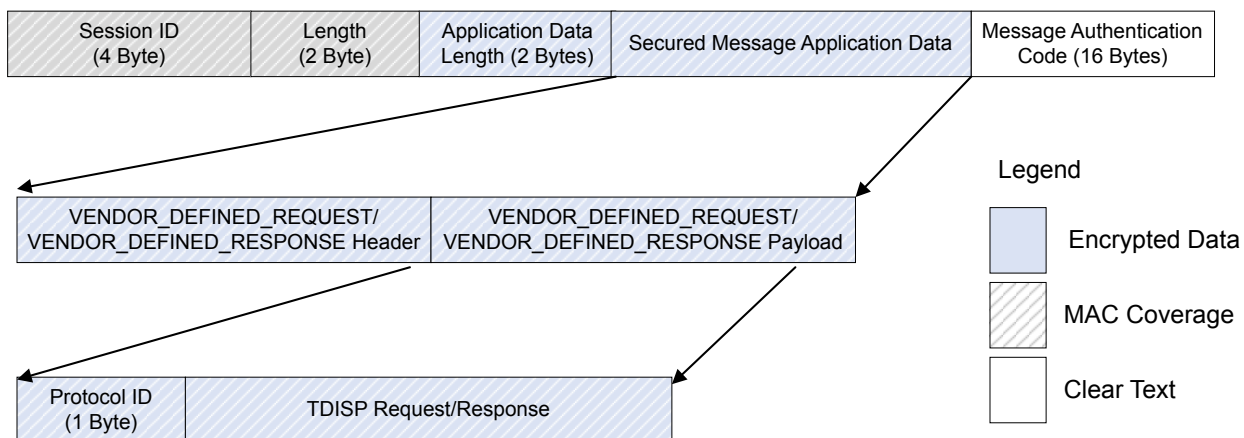

Figure 11-6 TDISP Request/Response Encapsulation §

If a TDISP message is received that has not been transferred securely per [Secured SPDM], the received TDISP message must not be used, and must not result in a response.

11.2.3 Requirements for Requesters (TSM) §

A Requester must not exceed the number of allowed outstanding requests to a specific DSM as indicated by NUM_REQ_ALL, and for a specific TDI as indicated by NUM_REQ_THIS (see § Table 11-9). If the Requester has sent a request to a Responder and wants to send a subsequent request to the same Responder, then the Requester must wait to send the subsequent request until after the Requester completes one of the following actions:

1. Receives the response from the Responder for an outstanding request.
2. Times out waiting for a response.
3. Receives an indication, from the transport layer, that transmission of the request message failed.

A Requester is permitted to send simultaneous request messages to different Responders.

11.2.4 Requirements for Responders (DSM) §

A Responder is not required to process more than NUM_REQ_THIS requests at a time. A Responder that is not ready to accept a new request message must either respond with a TDISP_ERROR response message with ERROR_CODE=BUSY or silently discard the request message.

If a Responder is working on a request message from a Requester, the Responder is permitted to respond with ERROR_CODE=BUSY.

If a Responder enables simultaneous communications with multiple Requesters, the Responder is expected to distinguish the Requesters by using the Session ID in the Secured Message.

11.2.5 TDISP Timing Requirements §

TDISP inherits timing requirements from the SPDM protocol used to encapsulate the messages.

11.2.6 DSM Tracking and Handling of Locked TDI Configurations (Informative) §

The DSM must track attempts to modify registers or other changeable device configuration controls affecting any Physical Function, Virtual Function, or non-IOV Function hosting a TDI in CONFIG_LOCKED or RUN. Precisely what must be tracked is implementation specific, and because the security properties of the device depend on correct implementation of these mechanisms, it is strongly recommended that persons skilled in building and validating secure hardware be deeply involved in the design and validation for all implementations.

§ Table 11-2 provides some general guidance regarding architecturally defined registers. Device-specific registers must be evaluated by the device vendors to determine if modifications to those are allowable. Device vendors must also evaluate additional device specific registers that are mapped into memory space or configuration space of the device to determine if they must be locked and tracked for modifications.

Read-only registers, hardware initialized registers, and registers used as selectors for reading out data (e.g., the Power Budgeting Data Select register) are excluded from this table. The DSM must ensure that attempts to modify those registers cannot affect the security of the TDI.

Table 11-2 Example DSM Tracking and Handling for Architected Registers §

Register / Capability / Extended Capability	Example Response to Register Modification	Description
<u>Cache Line Size, Latency Timer Interrupt Line</u>	Allowed	
<u>Command Register</u>	See description	Clearing any of the following bits causes the TDI hosted by the Function to transition to ERROR: <ul style="list-style-type: none"> • <u>Memory Space Enable</u> • <u>Bus Master Enable</u> Modification of other bits is allowed.
<u>Status Register</u>	Allowed	

Register / Capability / Extended Capability	Example Response to Register Modification	Description
BIST Register, Base Address Registers, Expansion ROM Base Address	Error Register	Transition hosted TDI to ERROR.
<u>PCI Power Management Capability</u>	See description	If a power transition leads to the function losing its state, then the device transitions the TDI hosted by that function to ERROR.
<u>Device Control Register</u> , <u>Device Control 2 Register</u> , <u>Device Control 3 Register</u>	See description	Modifying state of any of the following bits causes the TDI hosted by the function to transition to ERROR: <ul style="list-style-type: none"> • <u>Extended Tag Field Enable</u> • <u>Phantom Functions Enable</u> • <u>Initiate Function Level Reset</u> • <u>Enable No Snoop</u> • <u>10-bit Tag Requester Enable</u> • <u>14-bit Tag Requester Enable</u> Modification of other bits is allowed.
<u>Device Status Register</u> , <u>Device Status 2 Register</u> , <u>Device Status 3 Register</u>	Allowed	
<u>Link Control Register</u> , <u>Link Control 2 Register</u> , <u>Link Control 3 Register</u> , <u>16.0 GT/s Control Register</u> , <u>32.0 GT/s Control Register</u> , <u>64.0 GT/s Control Register</u>	Allowed	If modifications to these registers lead to a Link Down condition, the IDE streams configured in the device transition to the Insecure state, and as a result TDIs bound to those streams transition to ERROR.
<u>Link Status Register</u> , <u>Link Status 2 Register</u> , <u>16.0 GT/s Status Register</u> , <u>32.0 GT/s Status Register</u> , <u>64.0 GT/s Status Register</u>	Allowed	
<u>MSI Capability</u>	Allowed	
<u>MSI-X Capability</u>	See description	If MSI-X table was locked and reported, then any modifications cause transition to ERROR. Modifications are allowed otherwise.
<u>Secondary PCIe Extended Capability</u> , <u>Physical Layer 16.0 GT/s Extended Capability</u> , <u>Physical Layer 32.0 GT/s Extended Capability</u> , <u>Physical Layer 64.0 GT/s Extended Capability</u> , <u>Lane Margining at the Receiver Extended Capability</u> , <u>Flit Error Injection Extended Capability</u>	Allowed	If modifications to these registers lead to a Link Down condition, the IDE streams configured in the device transition to the Insecure state, and as a result TDIs bound to those streams transition to ERROR.
<u>ACS Extended Capability</u> , <u>Latency Tolerance Reporting Extended Capability</u>	Allowed	
<u>L1 PM Substates Extended Capability</u>	Allowed	If modifications to this register lead to a Link Down condition, the IDE streams configured in the device transition to the Insecure state, and as a result TDIs bound to those streams transition to ERROR.

Register / Capability / Extended Capability	Example Response to Register Modification	Description
<u>Advanced Error Reporting Extended Capability</u>	Allowed	As specified in § Section 6.2.3.2.2 , error mask register settings control reporting of detected errors, but do not block error detection.
<u>Enhanced Allocation Capability, Resizable BAR Extended Capability, VF Resizable BAR Extended Capability, ARI Extended Capability, PASID Extended Capability</u>	Error	Transition the TDI to ERROR.
<u>Virtual Channel Extended Capability, Multi-Function Virtual Channel Extended Capability</u>	Allowed – see description	Device must enforce transaction ordering when TC/VC mapping is changed, or arbitration tables are updated.
<u>Vendor Specific Capability, Vendor Specific Extended Capability, Designated Vendor Specific Extended Capability</u>	See description	To be analyzed by the vendor based on the security principles provided by TDISP.
<u>Multicast Extended Capability</u>	Error	Enabling multicast mechanism is not supported for TEE-I/O capable devices. Transition hosted TDIs to ERROR.
<u>Dynamic Power Allocation Extended Capability</u>	Allowed	A device must guard against the part being placed outside of its specification. If the device cannot reliably operate within the power allocation through mechanisms like throttling, frequency control, etc. then the device transitions hosted TDIs to ERROR.
<u>TPH Requester Extended Capability</u>	See description	To be analyzed by the vendor based on the security principles provided by TDISP.
<u>Precision Time Measurement Extended Capability, Hierarchy ID Extended Capability, Native PCIe Enclosure Management Extended Capability, Alternate Protocol Extended Capability</u>	Allowed	
<u>Protocol Multiplexing Extended Capability</u>	Allowed	A TEE-I/O capable device that supports PMUX must not transmit or receive transactions for TDIs in CONFIG_LOCKED or RUN using PMUX packets. If modifications to this register lead to a Link Down condition, the IDE streams configured in the device transition to the Insecure state, and as a result TDIs bound to those streams transition to ERROR.
<u>Shadow Functions Extended Capability</u>	Not Applicable	Use of shadow functions is not permitted for TEE-I/O usages.
<u>Data Object Exchange Extended Capability</u>	Allowed	
<u>Integrity and Data Encryption Extended Capability</u>	See description	Modifying the stream control register, selective IDE RID association registers, or selective IDE address association registers of streams that are bound to locked TDIs is an error, and the device transitions the TDIs bound to such stream to ERROR.

Register / Capability / Extended Capability	Example Response to Register Modification	Description
ATS Extended Capability	Allowed	
Page Request Extended Capability, SR-IOV Extended Capability	Error	Transition hosted TDIs to ERROR.
VPD Capability	Allowed	

11.2.7 TVM Acceptance of a TDI §

A TVM must ask the following questions before it accepts a TDI into its TCB:

1. Is the identity of the device and the measurements reported by the device hosting the TDI acceptable?
2. Is there a SPDM secure session established between the TSM and the DSM, and does the identity authenticated by the TSM to setup the SPDM secure session match the identity reported to the TVM?
3. When IDE is required, were all IDE keys for the IDE stream used by the TDI established or verified by the TSM?
4. Has the VMM configured the TDI and mapped the TDI into the TVM address space as expected?

The TVM queries the TSM using a TSM-provided interface to determine the answers to questions 1, 2 and 3. The TVM then requests a report of the TDI configuration (see § Section 11.3.10) from the DSM and may use it, with support from the TSM to determine the answer to question 4.

If the answer to all of these questions is a yes, then the TVM may accept the TDI into its TCB.

11.3 TDISP Message Formats and processing §

11.3.1 TDISP Request Codes §

§ Table 11-3 defines the TDISP request codes. All TDISP-compatible implementations must use the following TDISP request codes. Unsupported request codes must return a TDISP_ERROR response message with ERROR_CODE=UNSUPPORTED_REQUEST.

Table 11-3 TDISP Request Codes §

Message	Code Value	Required/ Optional for Device	Legal TDISP states	Description
GET_TDISP_VERSION	81h	Required	N/A	This request message must retrieve a device's TDISP version
GET_TDISP_CAPABILITIES	82h	Required	N/A	Retrieve protocol capabilities of the device
LOCK_INTERFACE_REQUEST	83h	Required	CONFIG_UNLOCKED	Move TDI to CONFIG_LOCKED
GET_DEVICE_INTERFACE_REPORT	84h	Required	CONFIG_LOCKED, RUN	Obtain a TDI report

Message	Code Value	Required/ Optional for Device	Legal TDISP states	Description
GET_DEVICE_INTERFACE_STATE	85h	Required	CONFIG_UNLOCKED, CONFIG_LOCKED, RUN, ERROR	Obtain state of a TDI
START_INTERFACE_REQUEST	86h	Required	CONFIG_LOCKED	Start a TDI
STOP_INTERFACE_REQUEST	87h	Required	CONFIG_UNLOCKED, CONFIG_LOCKED, RUN, ERROR	Stop and move TDI to CONFIG_UNLOCKED (if not already in CONFIG_UNLOCKED)
BIND_P2P_STREAM_REQUEST	88h	Optional	RUN	Bind a P2P stream
UNBIND_P2P_STREAM_REQUEST	89h	Optional	RUN	Unbind a P2P stream
SET_MMIO_ATTRIBUTE_REQUEST	8Ah	Optional	RUN	Update attributes of specified MMIO range
VDM_REQUEST	8Bh	Optional	N/A	Vendor defined message request

11.3.2 TDISP Response Codes §

The Request Response Code field in the response message must specify the appropriate response code (see § Table 11-4) for a request. On a successful completion of an operation, the specified response message must be returned. Upon an unsuccessful completion of an operation, the TDISP_ERROR response message must be returned. Undefined/ unsupported response codes must be treated as if they were TDISP_ERROR.

Table 11-4 TDISP Response Codes §

Message	Code Value(h)	Required/ Optional	Description
TDISP_VERSION	01	Required	Version supported by device.
TDISP_CAPABILITIES	02	Required	Protocol capabilities of the device.
LOCK_INTERFACE_RESPONSE	03	Required	Response to LOCK_INTERFACE_REQUEST
DEVICE_INTERFACE_REPORT	04	Required	Report for a TDI
DEVICE_INTERFACE_STATE	05	Required	Returns TDI state
START_INTERFACE_RESPONSE	06	Required	Response to request to move TDI to RUN
STOP_INTERFACE_RESPONSE	07	Required	Response to a STOP_INTERFACE_REQUEST
BIND_P2P_STREAM_RESPONSE	08	Optional	Response to bind P2P stream request
UNBIND_P2P_STREAM_RESPONSE	09	Optional	Response to unbind P2P stream request
SET_MMIO_ATTRIBUTE_RESPONSE	0A	Optional	Response to update MMIO range attributes
VDM_RESPONSE	0B	Optional	Vendor defined message response
TDISP_ERROR	7F	Required	Error in handling a request

11.3.3 TDISP Message Format and Protocol Versioning §

§ Table 11-5 defines the fields that are included in all TDISP messages. Unless otherwise specified, the following rules shall apply to all request and response messages in TDISP:

- Reserved, unspecified, or unassigned values in enumerations or other numeric ranges are reserved for future definition of the TDISP specification. Reserved numeric and bit fields must be written as zero (0) and ignored when read.
- Byte ordering of multi-byte numeric fields or multi-byte bit fields is "Little Endian" (that is, the lowest byte offset holds the least significant byte, and higher offsets hold the more significant bytes).
- All message fields, regardless of size or endianness, map the highest numeric bits to the highest numerically assigned byte in monotonically decreasing order until the least numerically assigned byte of that field.

All TDISP messages include the one Byte TDISPVersion field, which is divided into two sub-fields

- Bits 7:4 - Major Version – The major version of the TDISP Specification. A device must not communicate by using an incompatible TDISP version value. The Major version is incremented when the protocol modification breaks backward compatibility.
- Bits 3:0 - Minor Version – The minor version of the TDISP specification. A specification with a given minor version extends a specification with a lower minor version if they share the major version. The Minor Version is incremented when the protocol modification maintains backward compatibility.

This version of TDISP is V1.0, represented as 10h.

See § Section 11.3.5 for details on compatible version negotiation.

Table 11-5 TDISP Message Format §

Offset	Field	Size (Bytes)	Description
0	TDISPVersion	1	The TDISPVersion field represents the version of the specification encoded as follows: <ul style="list-style-type: none"> • Bits 7:4 – Major Version • Bits 3:0 – Minor Version
1	MessageType	1	The code identifying the type of the message (see § Table 11-3 and § Table 11-4).
2	Reserved	2	Reserved
4	INTERFACE_ID	12	The TDI's ID, as defined in § Section 11.2
16	TDISP message payload	Variable	Zero or more bytes that are specific to the MessageType

The device must fail the request and return the indicated response code if any of the error cases defined in § Table 11-6 are detected:

Table 11-6 Generic Error Response Codes §

Error Code	Description
INVALID_REQUEST	One or more of the fields of the request being invalid

Error Code	Description
VERSION_MISMATCH	Protocol version is unsupported or is not the agreed upon version
BUSY	Device cannot process the request due to being busy
UNSPECIFIED	Error due to an unspecified reason
VENDOR_SPECIFIC_ERROR	Error due to a vendor specific reason
INVALID_INTERFACE	The INTERFACE_ID indicated is not within the domain of the DSM

11.3.4 GET_TDISP_VERSION §

This request message must retrieve the device's TDISP version. In all future TDISP versions, the TDISP_GET_VERSION and TDISP_VERSION response messages will be backward compatible with all previous versions. The Requester must begin the discovery process by sending a TDISP_GET_VERSION request message with major version 1h. All Responders must always support TDISP_GET_VERSION request message with major version 1h and provide a TDISP_VERSION response containing all supported versions, as the TDISP_GET_VERSION request message table describes. The Requester must consult the TDISP_VERSION response to select a common (typically highest) version supported. The Requester must use the selected version in all future communication of other requests. A Requester must not issue other requests until it has received a successful TDISP_VERSION response and has identified a common version supported by both sides. A Responder must not respond to TDISP_GET_VERSION request message with ERROR_CODE=RESPONSE_NOT_READY.

A host system is permitted to use GET_TDISP_VERSION to determine if a device support TDISP.

11.3.5 TDISP_VERSION §

Table 11-7 TDISP_VERSION §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	VERSION_NUM_COUNT (N)	1	Number of version number entries. Minimum permitted value is 1.
17	VERSION_NUM_ENTRY[1-N]	1 x N	8-bit version entry where each entry is formatted as: <ul style="list-style-type: none"> 7:4 – Major Version Number 3:0 – Minor Version Number

11.3.6 GET_TDISP_CAPABILITIES §

Used to retrieve the Responder's TDISP capabilities. TDISP protocol inherits the SPDM timing specifications, including the timing parameter CT used to determine the time the Responder must respond to a message needing cryptographic processing.

Table 11-8 GET_TDISP_CAPABILITIES §

Offset	Field	Size(Bytes)	Description
Payload (All fields in little endian format)			
16	TSM_CAPS	4	TSM Capability Flags Bits 31:0 – Reserved

11.3.7 TDISP_CAPABILITIES §

Capabilities supported by Responder.

Table 11-9 TDISP_CAPABILITIES §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	DSM_CAPS	4	DSM Capability Flags Bits 31:0 – Reserved
20	REQ_MSGS_SUPPORTED	16	Bitmask indicating each type of request message supported by the device, where the bit index corresponds to the message code defined in § Table 11-3 minus 80h.
36	LOCK_INTERFACE_FLAGS_SUPPORTED	2	Bitmask indicating lock interface flags supported by the device, where the bit index corresponds to the FLAGS field definition in § Table 11-10. Lack of support for a specific flag indicates that software must not assume any particular device behavior regarding the related capability, unless it has device-specific knowledge through other means.
38	-	3	Reserved
41	DEV_ADDR_WIDTH	1	Device reports the number of address bits it supports. For example, a value of 52 in this field indicates support for Bits 51:0.
42	NUM_REQ_THIS	1	Number of outstanding Requests permitted by the DSM for this TDI.
43	NUM_REQ_ALL	1	Number of outstanding Requests permitted by the DSM for all TDIs managed by this DSM.

11.3.8 LOCK_INTERFACE_REQUEST §

The LOCK_INTERFACE_REQUEST is used to move the TDI to CONFIG_LOCKED, provided that the DSM confirms that the device, including elements of Function 0 and the TDI itself, is acceptably configured and in an acceptable state.

The device must fail the request if any of the following errors are detected:

- Interface ID specified in the request is not hosted by the device.
- TDI is not in CONFIG_UNLOCKED.

- For TDIs where IDE is required:
 - The default Stream does not match the Stream ID indicated
 - The default stream does not have IDE keys programmed for all sub-streams
 - All IDE keys of the default stream were not configured over the SPDM session on which the LOCK_INTERFACE_REQUEST was received
 - Multiple IDE configuration registers in the device have been configured as the default stream
 - The default Stream is associated with a TC other than TC0
- Phantom Functions Enabled
- Device PF BARs configured with overlapping addresses
- Expansion ROM base address, if supported, configured to overlap with a BAR
- Resizable BAR control registers programmed with an unsupported BAR size
- VF BARs are configured with address overlapping another VF BAR, a PF BAR or Expansion ROM BAR
- Unsupported system page size is configured in the system page size register of SR-IOV capability
- Cache Line Size configured for LN requester capability (deprecated in PCIe Revision 6.0), if supported and enabled, does not match the system cache line size specified in the LOCK_INTERFACE_REQUEST or is configured to a value not supported by the device.
- ST mode selected in TPH Requester Extended Capability, if supported and enabled, does not correspond to a mode supported by the function hosting the TDI.
- Other device determined errors in the device or TDI configurations

The LOCK_INTERFACE_REQUEST binds and configures the following parameters into the TDI:

- MMIO_REPORTING_OFFSET – To avoid leaking physical addresses to a TVM, the TSM specifies a MMIO_REPORTING_OFFSET to be applied to all future DEVICE_INTERFACE_REPORT generated by this TDI. MMIO_REPORTING_OFFSET is a signed (2's complement) 64-bit value that must be added to all MMIO physical addresses reported by the TDI. In order to maintain host-specific page alignment, the TSM is permitted to supply the corresponding lower bits of MMIO_REPORTING_OFFSET as zero. The TSM must supply an offset that does not result in overflow/underflow.
- NO_FW_UPDATE when Set indicates that when this TDI is in CONFIG_LOCKED or RUN, the device must not accept firmware updates. This option allows certain TVM to opt-out of further firmware updates to the device once the TVM starts using the TDI. To perform a firmware update, a VMM must detach from the TEEs all TDI that are locked with NO_FW_UPDATE=1 from the TVM and move them to CONFIG_UNLOCKED.
- System cache line size.
Whether MSI-X table and PBA in the function hosting the TDI must be locked. A TDI is permitted to lock the MSI-X table and PBA even if not directed to do so. If the MSI-X table and PBA are not locked, then they must not be reported in the DEVICE_INTERFACE_REPORT. If the MSI-X table and PBA are locked, transactions to access the MSI-X table and PBA without the T bit Set must be rejected.
- BIND_P2P when Set indicates whether the Direct-P2P (device/device peer-to-peer) support may be enabled later via BIND_P2P_STREAM_REQUEST messages and a valid P2P address mask is specified in the request.
- ALL_REQUEST_REDIRECT when Set indicates that TDI must redirect all ATS Translated Requests upstream to the Root Complex, using the default Selective IDE Stream if one is configured, to perform access checks. This includes TDI accesses to the local resources within TDI or other resources of a device that are based on a Translated Address.

On successful processing of the request, the device responds with a LOCK_INTERFACE_RESPONSE message.

Table 11-10 LOCK_INTERFACE_REQUEST §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	FLAGS	2	<p>Bit 0 NO_FW_UPDATE – When 1, indicates that device firmware updates are not permitted while in CONFIG_LOCKED or RUN. When 0, indicates that firmware updates are allowed while in these states.</p> <p>Bit 1 System Cache Line Size – when 0 indicates the system CLS is 64 bytes and when Set indicates system CLS is 128 bytes.</p> <p>Bit 2 LOCK_MSIX – Lock MSI-X table and PBA.</p> <p>Bit 3 BIND_P2P – When 1, indicates that Direct-P2P support may be enabled later via BIND_P2P_STREAM_REQUEST messages and a valid P2P address mask is specified in this request. When 0, indicates that Direct-P2P is not allowed or enabled for this TDI.</p> <p>Bit 4 ALL_REQUEST_REDIRECT – The TDI must redirect all ATS Translated Requests upstream to the Root Complex to perform access checks.</p> <p>Bits 15:5 Reserved</p>
18	Stream ID for Default Stream	1	Indicates the Stream ID for the Stream configured as the IDE default stream.
19	-	1	Reserved
20	MMIO_REPORTING_OFFSET	8	MMIO ranges reported in all DEVICE_INTERFACE_REPORT is reported with this offset added to the physical address
28	BIND_P2P_ADDRESS_MASK	8	Mask to be applied to target addresses for peer-to-peer transaction issued by the TDI using the BIND_P2P_STREAM_REQUEST stream (to clear-out any metadata information embedded in the address). This mask must be applied prior to using the Selective IDE Address Association mechanism. This mask is not applicable or applied for Requests bound to the Root Complex.

11.3.9 LOCK_INTERFACE_RESPONSE §

LOCK_INTERFACE_RESPONSE is provided on successful handling of the LOCK_INTERFACE_REQUEST and the device having moved the TDI to CONFIG_LOCKED. The response message also provides a START_INTERFACE_NONCE that is generated when the TDI is locked. This nonce should be generated by the device in response to moving the TDI to CONFIG_LOCKED. This nonce must be destroyed when the TDI moves to CONFIG_UNLOCKED or ERROR from CONFIG_LOCKED. See § Section 11.3.14 for additional rules regarding this nonce.

Generating a LOCK_INTERFACE_RESPONSE implies that the device has successfully completed the following operations:

- All in-flight and accepted work for the TDI, before lock request was received, are aborted
- All DMA for the TDI, before the lock request was received, are completed, or aborted
- If function hosting the TDI is capable of Address Translation Service (ATS), all ATS requests for the TDI, generated before the lock request was received, have completed, or aborted. The device must invalidate translations cached in the ATC by the Requester ID of the function hosting the TDI.
- If function hosting the TDI is capable of Page Request Interface Service (PRI), page requests for the TDI, generated before the lock request was received, have received responses or the TDI will discard page responses for outstanding page requests.

- Additional private resources that need to be assigned to the TDI by the DSM at the time of locking the TDI have been successfully allocated and assigned.
- DSM has carried out necessary actions on the device side to lock the TDI configuration and IDE configuration registers for the default stream. DSM has enabled mechanisms to track changes to the configurations of the TDI and the IDE configuration register for the default stream.

It is permitted for a TDI to return INVALID_DEVICE_CONFIGURATION in response to a LOCK_INTERFACE_REQUEST for implementation-specific reasons.

Table 11-11 LOCK_INTERFACE_RESPONSE §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	START_INTERFACE_NONCE	32	Device generated nonce to include in START_INTERFACE_REQUEST message.

§ Table 11-12 defines the error codes and conditions:

Table 11-12 LOCK_INTERFACE_REQUEST Error Codes §

Error Code	Description
INVALID_REQUEST	Device supports IDE capability and <ul style="list-style-type: none"> • Keys have not been configured for all sub-streams of the default stream • Keys for the default stream were not configured using the SPDM session on which the LOCK_INTERFACE_REQUEST was received
INSUFFICIENT_ENTROPY	The device fails to generate nonce.
INVALID_INTERFACE_STATE	If the TDI is not in CONFIG_UNLOCKED.
INVALID_DEVICE_CONFIGURATION	Locking the TDI failed due to invalid/unsupported device configurations.

11.3.10 GET_DEVICE_INTERFACE_REPORT §

The GET_DEVICE_INTERFACE_REPORT is used to request a DEVICE_INTERFACE_REPORT from the device. The DEVICE_INTERFACE_REPORT may, in some cases, be larger than the requester can consume in a single response, so the requester is provided with the means to request a specific portion of the overall DEVICE_INTERFACE_REPORT to be sent with a given response.

The device must fail the request if any of the following errors are detected:

- Interface ID in the request is not hosted by the device
- TDI is not in CONFIG_LOCKED or RUN
- Invalid offset specified

Table 11-13 GET_DEVICE_INTERFACE_REPORT §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			

Offset	Field	Size (Bytes)	Description
16	OFFSET	2	<p>Offset in bytes from the start of the report to where the read request message begins. The responder must send its report starting from this offset.</p> <p>For first GET_DEVICE_INTERFACE_REPORT request, the Requester must set this field to 0.</p> <p>For non-first requests, Offset is the sum of PORTION_LENGTH values in all previous DEVICE_INTERFACE_REPORT responses.</p>
18	LENGTH	2	<p>Length of report, in bytes, to be returned in the corresponding response. Length is an unsigned 16-bit integer.</p> <p>This value is the smaller of the following values:</p> <ul style="list-style-type: none"> Capacity of requester's internal buffer for receiving Responder's report. The REMAINDER_LENGTH of the preceding DEVICE_INTERFACE_REPORT response. <p>For the first GET_DEVICE_INTERFACE_REPORT request, the requester must use the capacity of the requester's receiving buffer. If offset=0 and length=FFFFh, the requester is requesting the entire report.</p> <p>The Responder is permitted to provide less than the requested length if the Responder's buffer length is limited.</p>

11.3.11 DEVICE_INTERFACE_REPORT §

Table 11-14 DEVICE_INTERFACE_REPORT §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	PORTION_LENGTH	2	Number of bytes of this portion of TDI report. This must be less than or equal to LENGTH received as part of the request. For example, the Responder is permitted to set this field to a value less than LENGTH received as part of the request due limitations on the Responder's internal buffer.
18	REMAINDER_LENGTH	2	Number of bytes of the TDI report that have not been sent yet after the current response. For the last response, this field must be 0 as an indication to the Requester that the entire TDI report has been sent.
20	REPORT_BYTES	PORTION_LENGTH	Requested contents of TDI report

The TDI report is structured as follows:

Table 11-15 TDI Report Structure §

Offset	Field	Size (Bytes)	Description
0	INTERFACE_INFO	2	<p>Bit 0 When 1, indicates that device firmware updates are not permitted while in CONFIG_LOCKED or RUN. When 0, indicates that firmware updates are permitted while in these states</p> <p>Bit 1 TDI generates DMA requests without PASID</p> <p>Bit 2 TDI generates DMA requests with PASID</p>

Offset	Field	Size (Bytes)	Description
			Bit 3 ATS supported and enabled for the TDI Bit 4 PRS supported and enabled for the TDI Bit 15:5 Reserved
2	-	2	Reserved for future use.
4	MSI_X_MESSAGE_CONTROL	2	MSI-X capability message control register state. Must be Clear if a) capability is not supported or b) MSI-X table is not locked.
6	LNR_CONTROL	2	LNR control register from LN Requester Extended Capability. Must be Clear if LNR capability is not supported. LN is deprecated in PCIe Revision 6.0.
8	TPH_CONTROL	4	TPH Requester Control Register from the TPH Requester Extended Capability. Must be Clear if a) TPH capability is not support or b) MSI-X table is not locked.
12	MMIO_RANGE_COUNT (N)	4	Number of MMIO Ranges in report
16	MMIO_RANGE	N * 16	<p>Each MMIO Range of the TDI is reported with the MMIO reporting offset added. Base and size in units of 4K pages</p> <ul style="list-style-type: none"> • 8 bytes – First 4K page with offset added • 4 bytes - Number of 4K pages in this range • 4 bytes – Range Attributes <p>Bit 0 Bit 0 – MSI-X Table – if the range maps MSI-X table. This must be reported only if locked by the LOCK_INTERFACE_REQUEST.</p> <p>Bit 1 MSI-X PBA – if the range maps MSI-X PBA. This must be reported only if locked by the LOCK_INTERFACE_REQUEST.</p> <p>Bit 2 IS_NON_TEE_MEM – must be 1b if the range is non-TEE memory. For attribute updatable ranges (see below), this field must indicate attribute of the range when the TDI was locked.</p> <p>Bit 3 IS_MEM_ATTR_UPDATABLE – must be 1b if the attributes of this range is updatable using SET_MMIO_ATTRIBUTE_REQUEST.</p> <p>Bit 15:4 Reserved</p> <p>Bit 31:16 Range ID – a device specific identifier for the specified range. The range ID may be used to logically group one or more MMIO ranges into a larger range.</p>
16 + N * 16	DEVICE_SPECIFIC_INFO_LEN (L)	4	Number of bytes of device specific information
16 + N * 16 + 4	DEVICE_SPECIFIC_INFO	L	Device specific information

A TDI may generate (a) all DMA requests without PASID, (b) all DMA requests with PASID, or (c) some DMA requests with and others without PASID.

The Range ID is used to logically group the ranges reported in the report into logical groups.

MMIO ranges assigned via BAR(s) must be reported in ascending order starting with the lowest numbered BAR such that the first range corresponds to the first BAR and so on. The range ID reports the BAR equivalent Indicator (BEI). Values 0-7 of the Range ID are reserved to indicate the BEI. The device must report the BAR equivalent Indicator (BEI) for ranges associated with a PCIe BAR.

When reporting the MMIO range for a TDI, the MMIO ranges must be reported in the logical order in which the TDI MMIO range is configured such that the first range reported corresponds to first range of pages in the TDI and so on.

The device is permitted to include additional device specific information to the TVM in the report. The device specific information may be used to report configurations of the TDI and/or to enumerate capabilities of the TDI. Example of such device specific information include:

- A network device may include receive-side scaling (RSS) related information such as the RSS hash and mappings to the virtual station interface (VSI) queues, etc.
- A NVMe device may include information about the associated name spaces, mapping of name space to command queue-pair mappings, etc.
- Accelerators may report capabilities such as algorithms supported, queue depths, etc.

The following sequence diagram shows the high-level request-response message flow for Responder response when it cannot return the entire data requested by the Requester in the first response.

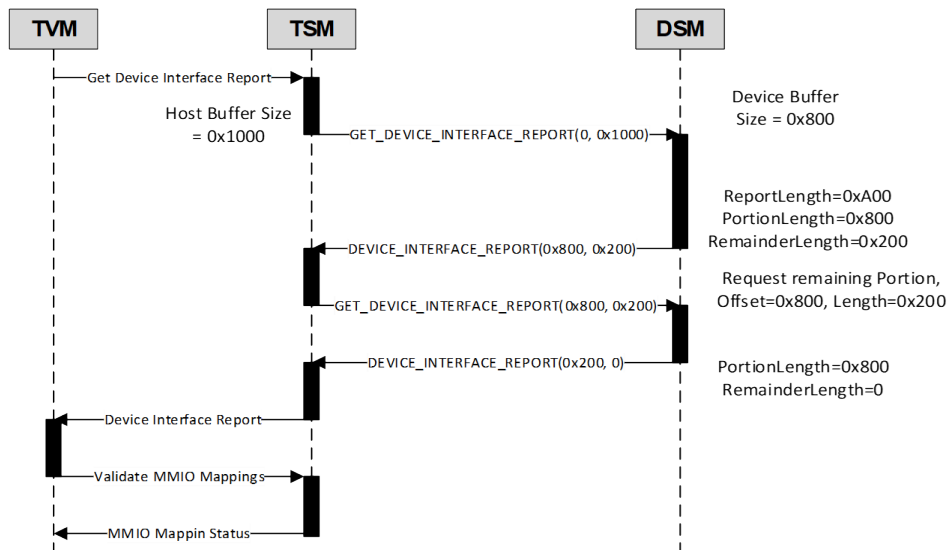

Figure 11-7 Example Flow Where DSM is Unable to Return Full Length Report §

§ Table 11-16 defines the error codes and conditions:

Table 11-16 GET_DEVICE_INTERFACE_REPORT Error Response Codes §

Error Code	Description
INVALID_REQUEST	OFFSET is invalid.
INVALID_INTERFACE_STATE	The TDI is not in CONFIG_LOCKED.

11.3.12 GET_DEVICE_INTERFACE_STATE §

The GET_DEVICE_INTERFACE_STATE is used to request a DEVICE_INTERFACE_STATE from the device.

The device must fail the request if the following error is detected:

- Interface ID in the request is not hosted by the device.

11.3.13 DEVICE_INTERFACE_STATE §

Table 11-17 DEVICE_INTERFACE_STATE §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	TDI_STATE	1	TDI status 0 CONFIG_UNLOCKED 1 CONFIG_LOCKED 2 RUN 3 ERROR Others Reserved

11.3.14 START_INTERFACE_REQUEST §

The START_INTERFACE_REQUEST carries the interface ID of the TDI. This request is used to transition the TDI to RUN, where is managed and operated by the TVM.

This request is expected to be generated by the TSM on request from the TVM.

The device must fail the request if any of the following errors are detected:

- If the interface ID in the request is not hosted by the device.
- START_INTERFACE_NONCE in the request is not valid i.e., does not match the nonce generated by the device in the LOCK_INTERFACE_RESPONSE.
- TDI is not in CONFIG_LOCKED.

If no errors are encountered, the device prepares to transition the referenced TDI to RUN. Moving the TDI to RUN may involve device side actions like enabling device side memory encryption, etc. The TDI must also invalidate the START_INTERFACE_NONCE before moving the TDI to RUN such that this nonce cannot be used again.

Table 11-18 START_INTERFACE_REQUEST §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	START_INTERFACE_NONCE	32	Device generated nonce for message (from LOCK_INTERFACE_RESPONSE)

11.3.15 START_INTERFACE_RESPONSE §

§ Table 11-19 defines the error codes and conditions:

Table 11-19 START_INTERFACE_REQUEST Error Response Codes §

Error Code	Description
INVALID_NONCE	START_INTERFACE_NONCE mismatch.
INVALID_INTERFACE_STATE	The TDI is not in CONFIG_LOCKED.

11.3.16 STOP_INTERFACE_REQUEST §

The STOP_INTERFACE_REQUEST carries the interface ID of the TDI.

The device must fail the request the following error is detected:

- If the interface ID in the request is not hosted by the device.

In response to the STOP_INTERFACE_REQUEST the following actions must be performed:

- Abort all in-flight and accepted operations that are being performed by the TDI
- Wait for outstanding responses for the aborted operations
- All DMA read and write operations by the TDI are aborted or completed
- All interrupts from the TDI have been generated
- If function hosting the TDI is capable of Address Translation Service (ATS), all ATS requests by the TDI have completed or aborted. All translations cached in the device for ATS requests generated by this TDI have been invalidated.
- If function hosting the TDI is capable of Page Request Interface Service (PRI), no more page requests will be generated by the TDI. Additionally, either page responses have been received for all page requests generated by the TDI or the TDI will discard page responses for outstanding page requests.
- Scrub internal state of the device to remove secrets associated with the TDI such that those secrets will not be accessible.
- Reclaim and scrub private resources (e.g., memory encryption keys for device attached memories, etc.) assigned to the TDI.

The Device must generate the STOP_INTERFACE_RESPONSE once these actions are completed.

11.3.17 STOP_INTERFACE_RESPONSE §

No request-specific responses are defined

11.3.18 BIND_P2P_STREAM_REQUEST §

A TDI is permitted to support peer-to-peer transactions secured from end-to-end between two devices. Such devices must support configuring one or more selective IDE Stream(s) such that the selective IDE stream configuration registers

provide the address and Requester ID ranges for the peer device. Such peer-to-peer IDE streams must be used by a device only if the device supports Address Translation Services and the capability is enabled for the device.

The BIND_P2P_STREAM_REQUEST binds such peer-to-peer stream IDs to the TDI. The device must fail the request if any of the following apply:

- Interface ID in the request is not hosted by the device
- TDI does not support binding peer-to-peer streams
- TDI is not in RUN
- Stream ID specified does not have IDE keys programmed for all sub streams
- All IDE keys of the stream identified by the Stream ID were not configured over the SPDM session on which the LOCK_INTERFACE_REQUEST was received
- Multiple IDE configuration registers have been programmed with the same stream ID
- IDE configuration register for this stream is configured as the default stream
- Address and/or RID association registers of this streams IDE configuration registers overlap with other IDE configuration registers

In response to the request, DSM carries out necessary actions on the device side to lock the IDE configurations for the specified stream ID and enables mechanisms to track changes to the IDE configuration registers.

Through a device-specific mechanism the DSM ensures correctness of transaction ordering (i.e., if transactions were previously routed through the default stream ID specified by the LOCK_INTERFACE_REQUEST then the TDI has implemented fences or other mechanism before it starts using the peer-to-peer stream ID specified by this request).

Following processing the request, the device generates the BIND_P2P_STREAM_RESPONSE.

When a TDI generates a transaction, if the transaction's address or Requester ID as applicable matches an IDE configuration register and the stream ID configured is one of the P2P streams bound to the TDI, then the device uses that P2P stream for the transaction. If the transaction does not match one of the P2P IDE streams, then the transaction uses the default stream identified by the stream ID bound using the LOCK_INTERFACE_REQUEST.

All ATS requests and requests with addresses for which translations were not previously obtained from the Translation Agent in the Root Complex must use the default stream identified by the stream ID bound at time of locking the TDI.

Table 11-20 BIND_P2P_STREAM_REQUEST §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	P2P_STREAM_ID	1	ID of the P2P stream to bind to this TDI.

11.3.19 BIND_P2P_STREAM_RESPONSE §

§ Table 11-21 defines the error codes and conditions:

Table 11-21 BIND_P2P_STREAM_REQUEST Error Response Codes §

Error Code	Description
INVALID_REQUEST	TDI does not support binding P2P streams. P2P_STREAM_ID is invalid

Error Code	Description
	<p>Keys have not been configured for all sub-streams of the P2P stream</p> <p>Keys for the stream identified by P2P_STREAM_ID were not configured by the SPDM session on which the LOCK_INTERFACE_REQUEST was received</p> <p>IDE registers with configurations for the P2P_STREAM_ID is marked as the default stream.</p> <p>Multiple IDE registers are configured with the P2P_STREAM_ID</p> <p>The IDE registers configured for this P2P_STREAM_ID have overlaps with other valid IDE registers.</p>
INVALID_INTERFACE_STATE	If the TDI is not in RUN.

11.3.20 UNBIND_P2P_STREAM_REQUEST §

The UNBIND_P2P_STREAM_REQUEST unbinds a previously bound peer-to-peer stream IDs from the TDI. The device must fail the request if any of the following apply:

- Interface ID in the request is not hosted by the device
- TDI does not support binding peer-to-peer streams
- TDI is not in RUN
- Stream ID specified was not previously bound to this TDI

Following processing the request, the device generates the UNBIND_P2P_STREAM_RESPONSE.

An UNBIND_P2P_STREAM_RESPONSE implies that the device has successfully completed the following operations:

- All DMA read and write operations by the TDI using the specified P2P stream are aborted or completed
- Remove locking made active on the IDE configuration registers for this stream such that the IDE register may be reprogrammed without affecting the security of the TDI

If the device supports continuing the peer-to-peer operations following the unbind then through a device-specific mechanism the device ensures correctness of transaction ordering (i.e., if transactions were previously routed through this p2p stream then the TDI has implemented fences or other mechanism before it starts using the default stream ID).

Table 11-22 UNBIND_P2P_STREAM_REQUEST §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	P2P_STREAM_ID	1	ID of the P2P stream to unbind from this TDI.

11.3.21 UNBIND_P2P_STREAM_RESPONSE §

§ Table 11-23 defines the error codes and conditions:

Table 11-23 UNBIND_P2P_STREAM_REQUEST Error Response Codes §

Error Code	Description
INVALID_REQUEST	TDI does not support binding P2P streams. P2P_STREAM_ID is invalid P2P_STREAM_ID was not previously bound to this TDI.
INVALID_INTERFACE_STATE	If the TDI is not in RUN.

11.3.22 SET_MMIO_ATTRIBUTE_REQUEST §

The SET_MMIO_ATTRIBUTE_REQUEST enables a TVM to update attributes of one or more MMIO ranges reported in the DEVICE_INTERFACE_REPORT. The MMIO ranges in a TDI that support updateable attributes are device specific.

The device must fail the request if any of the following apply:

- Interface ID in the request is not hosted by the device
- TDI does not support updateable MMIO attributes
- TDI does not support updateable MMIO attributes for the requested MMIO range
- TDI does not support the specified attribute for the requested MMIO range
- TDI does not support the value specified for the attribute
- TDI is not in RUN
- The MMIO range specified in the request is not associated with TDI

Responding with a failure is not fatal to the TDI and does not lead to a change in the TDI state.

Following processing the request, the device generates the SET_MMIO_ATTRIBUTE_RESPONSE.

IS_NON_TEE_MEM attribute may be updated to 1 to allow sharing the requested MMIO range with an entity not in the TVM trust boundary. Following the successful update of the attribute to 1, the specified MMIO range may be accessed using requests with T bit set to 0 or 1, or using a non-IDE Request. While the processing of the request is outstanding, a device may continue to reject Requests with the T bit Clear that access the MMIO range being updated.

IS_NON_TEE_MEM attribute may be updated to 0 to disallow sharing the MMIO range with an entity not in the TVM trust boundary. Following the successful update of the attribute to 0, the specified MMIO range may only be accessed using Requests with T bit Set, and Requests with T bit Clear must be rejected. While the processing of the request is outstanding, a device is permitted to continue to allow accesses via Requests with the T bit Clear.

A SET_MMIO_ATTRIBUTE_RESPONSE implies that the device has successfully completed updating the attributes for the specified MMIO range and the updated attributes are in affect for all subsequent accesses to this MMIO range.

Table 11-24 SET_MMIO_ATTRIBUTE_REQUEST §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	MMIO_RANGE	16	Base and size of the MMIO range to update attributes. <ul style="list-style-type: none"> • 8 bytes – First 4K page with offset added

Offset	Field	Size (Bytes)	Description
			<ul style="list-style-type: none"> 4 bytes – Number of 4K pages in this range 4 bytes – Range Attributes <ul style="list-style-type: none"> Bits 1:0 Reserved – must be zero. Bit 2 IS_NON_TEE_MEM – set to 1b if the range is non-TEE memory. Bits 15:3 Reserved Bits 31:16 Range ID – a device specific identifier for the specified range.

11.3.23 SET_MMIO_ATTRIBUTE_RESPONSE §

§ Table 11-25 defines the error codes and conditions:

Table 11-25 SET_MMIO_ATTRIBUTE_REQUEST Error Response Codes §

Error Code	Description
INVALID_REQUEST	<p>TDI does not support updateable MMIO attributes</p> <p>TDI does not support updateable attributes for requested MMIO range</p> <p>TDI does not support specified attribute for requested MMIO range</p> <p>TDI does not support the value specified for the attribute</p> <p>The range specified in the request is not associated with TDI</p>
INVALID_INTERFACE_STATE	If the TDI is not in RUN.

11.3.24 TDISP_ERROR §

The TDISP_ERROR is permitted to be used by the device to complete any of the requests issued to the device.

Table 11-26 TDISP_ERROR §

Offset	Field	Size (Bytes)	Description
Payload (All fields in little endian format)			
16	ERROR_CODE	4	Error Code
20	ERROR_DATA	4	Error Data
24	EXTENDED_ERROR_DATA	Variable	Extended Error Data.

Table 11-27 Error Code and Error Data §

Error Code	Value (h)	Description	Error Data	Extended error data
Reserved	0000	Reserved	Reserved	None
INVALID_REQUEST	0001	One or more request field is invalid.	Reserved	None

Error Code	Value (h)	Description	Error Data	Extended error data
BUSY	0003	The Responder received the request message and the Responder decided to ignore the request message, but the Responder may be able to process the request message if the request message is sent again in the future.	Reserved	None
INVALID_INTERFACE_STATE	0004	The Responder received the request while in the wrong state, or received an unexpected request. For example, the GET_DEVICE_INTERFACE_REPORT before LOCK_INTERFACE_REQUEST, or any command between multiple GET_DEVICE_INTERFACE_REPORT	Reserved	None
UNSPECIFIED	0005	Unspecified error occurred.	Reserved	None
UNSUPPORTED_REQUEST	0007	Request code is unsupported	Request code	None
VERSION_MISMATCH	0041	The version in not supported	Reserved	None
VENDOR_SPECIFIC_ERROR	00FF	Vendor defined	Length of extended error data	See required formatting of extended error data for vendor defined errors
INVALID_INTERFACE	0101	INTERFACE_ID does not exist.	Reserved	None
INVALID_NONCE	0102	The received nonce does not match the expected one.	Reserved	None
INSUFFICIENT_ENTROPY	0103	The Responder fails to generate nonce.	Reserved	None
INVALID_DEVICE_CONFIGURATION	0104	Invalid/Unsupported device configurations.	Reserved	None

§ Table 11-28 defines the EXTENDED_ERROR_DATA format for vendor defined TDISP_ERROR response messages:

Table 11-28 EXTENDED_ERROR_DATA §

Offset	Field	Size (Bytes)	Description
0	REGISTRY_ID	1	ID of the registry assigning the VENDOR_ID 00h – PCI-SIG assigned vendor ID 01h – CXL assigned vendor ID
1	VENDOR_ID_LEN	1	Length of VENDOR_ID field.
2	VENDOR_ID	VENDOR_ID_LEN	VENDOR_ID as assigned by the registry identified by REGISTRY_ID
2 + VENDOR_ID_LEN	VENDOR_ERR_DATA	Variable	Vendor defined error data.

11.3.25 VDM_REQUEST §

§ Table 11-29 defines the VDM_REQUEST format:

Table 11-29 VDM_REQUEST §

Offset	Field	Size (Bytes)	Description
0	REGISTRY_ID	1	ID of the registry assigning the VENDOR_ID 00h – PCI-SIG assigned vendor ID 01h – CXL assigned vendor ID
1	VENDOR_ID_LEN	1	Length of VENDOR_ID field.
2	VENDOR_ID	VENDOR_ID_LEN	VENDOR_ID as assigned by the registry identified by REGISTRY_ID
2 + VENDOR_ID_LEN	VENDOR_DATA	Variable	Vendor defined data.

11.3.26 VDM_RESPONSE §

§ Table 11-30 defines the VDM_RESPONSE format:

Table 11-30 VDM_RESPONSE §

Offset	Field	Size (Bytes)	Description
0	REGISTRY_ID	1	ID of the registry assigning the VENDOR_ID 00h – PCI-SIG assigned vendor ID 01h – CXL assigned vendor ID
1	VENDOR_ID_LEN	1	Length of VENDOR_ID field.
2	VENDOR_ID	VENDOR_ID_LEN	VENDOR_ID as assigned by the registry identified by REGISTRY_ID
2 + VENDOR_ID_LEN	VENDOR_DATA	Variable	Vendor defined data.

11.4 Device Security Requirements §

11.4.1 Device Identity and Authentication §

A TEE-I/O capable device must implement the [SPDM] as the device secure communication protocol with the host. The device must use SPDM protocol to report the device identity and support the authentication. The security property defined in SPDM specification must be satisfied.

The device is recommended to implement the Device Identifier Composition Engine (DICE) architecture specified by the Trusted Computing Group (TCG). In this case, a DICE certificate must be returned in SPDM protocol and used to provide device identity and support authentication.

11.4.2 Firmware and Configuration Measurements §

A TEE-I/O capable device must implement [SPDM] to return device measurements to the TSM. The TEE-I/O device may report hash-based measurement(s), and/or secure version number (SVN) to the host.

The device is recommended to implement TCG DICE. In this case, the device hash-based measurement and/or SVN must also be included in the DICE TCB info structure. The information reported in SPDM Measurement response and DICE TCB info must be consistent.

The device is permitted to support mutable firmware update. In this case, the device is recommended to follow established industry firmware resilience guidelines, such as NIST SP 800-193, to ensure the new firmware provides equal or better security.

The device is permitted to support runtime update without reset. Such a capability must be reported via `INTERFACE_INFO`, and can be blocked via `NO_FW_UPDATE`. A runtime update image must be of an equal or higher SVN if active TDIs are to be maintained. The device must report `SPDM_MEAS_FRESH_CAP` to indicate if the device has capability to report fresh measurements or old measurements computed during last device reset. If a DICE device supports runtime update, the security property defined in DICE specification must still be satisfied, such as DICE certificate creation. An attempt to lower the SVN must be rejected by the device if there are active TDIs in `CONFIG_LOCKED` or `RUN`. Alternately, if the device has the capability to secure and clean all TVM data in a trusted manner before such a downgrade, the device is permitted to transition the interfaces in `CONFIG_LOCKED` or `RUN` to `ERROR`, terminate IDE streams used for TEE-I/O, and terminate the SPDM session with `TSM` before a firmware downgrade.

Devices that do not support runtime update when there are TDIs in `CONFIG_LOCKED` or `RUN` must handle a forced update by terminating the IDE streams used for TEE-I/O, and the SPDM session between the `TSM` and `DSM`, and transitioning associated TDI(s) to `ERROR`.

11.4.3 Securing Interconnects §

TEE-I/O capable devices must support Integrity and Data Encryption (IDE) to protect transactions on the interconnect between the device and the Root Complex. Devices must support selective IDE streams between the Root Complex and the device. Use of IDE to protect transactions may not be required for RCiEP.

Peer-to-peer links, between the devices must be protected to avoid loss of confidentiality and integrity. Peer-to-peer must use IDE to secure communications. Other kinds of interconnects must be protected using interconnect specific extensions such that they provide equivalent security to address the threat model outlined in IDE.

The symmetric stream encryption keys and IV of each IDE Sub-Stream are secret and compromising these breaks the security of the solution. The device must implement adequate security measures to prevent leakage of the encryption key at rest and in use. The stream encryption keys must not be revealed in plaintext form outside the device. The device must not allow modifications to the stream encryption keys or the IV through untrusted mechanisms.

TEE-I/O capable devices must transition interfaces `CONFIG_LOCKED`, `RUN` to `ERROR` when the IDE stream(s) bound to those interface transition to Insecure state. The device must implement suitable mechanisms to contain propagation of data past the transition to Insecure state.

Receipt of a Completion with UR/CA or Completion timeout (following recovery retries) for requests initiated by a device on an interface in `CONFIG_LOCKED`, `RUN` indicates occurrence of an uncorrectable error (e.g., IOMMU translation tables corrupted, etc.) in handling the non-posted request. The device must transition the interface for which UR/CA was received to `ERROR` to stop consumption and propagation of errors if the error is not recoverable.

11.4.4 Device Attached Memory §

Certain devices implement device attached memory where such memory is used by logic in the device to host the TVM data. The device must ensure the confidentiality of the TVM data stored in such memory devices such that the TVM data is not revealed as plaintext outside the device or to entities not in the TVM TCB. To the maximum extent possible the ciphertext associated with the TVM data must not be exposed outside the device. The device may additionally provide integrity properties on the TVM data.

IMPLEMENTATION NOTE:

SECURITY OF DEVICE ATTACHED MEMORY §

Certain devices may implement memory encryption as a mechanism to provide confidentiality of TVM data stored into those memory devices. Such devices may additionally provide integrity properties on the memory content. The configurations of memory encryption as well as other configurations related to the device attached memory in such devices is managed by the DSM. The TSM relies on the DSM to secure such configurations. Securing of memory configurations, establishing memory encryption, and all related security checks must be performed no later than in response to the first LOCK_INTERFACE_REQUEST received by the DSM for a device interface hosted by the device. If the memory configurations are not acceptable to meet TVM security requirements, then device interfaces must not be transitioned to CONFIG_LOCKED.

11.4.5 TDI Security §

TEE-I/O capable devices must support [Secure SPDM] to establish a secure communication session between the TSM and DSM. The devices must support the TDI state and the device interface management protocol in TDISP for managing the device security states as they are assigned to TVMs and detached from TVMs.

All sub-streams of the IDE stream bound to the TDI must be programmed over the same SPDM session used to lock the interface. Attempting to configure IDE keys into a sub-stream using different SPDM sessions is an error and must be rejected. IDE key refresh must be accepted only on the SPDM session that was used to establish the initial IDE keys.

TDIs in RUN state may transmit/receive transactions with peer TDIs over peer-to-peer selective IDE streams if the device model supports such communication. The peer-to-peer selective IDE streams may be used for communication if the IDE keys for such streams were also configured with the same SPDM session as that was used to transition the TDI to CONFIG_LOCKED.

When the SPDM session used to program an IDE stream key enters session termination phase, all IDE streams configured with keys over that SPDM session must transition to an Insecure state and all TDI that were transitioned to CONFIG_LOCKED over that SPDM session must transition to ERROR.

When an IDE stream transitions to Insecure state, all TDIs in CONFIG_LOCKED/RUN bound to that IDE stream must transition to ERROR.

TEE-I/O capable devices must ensure that confidentiality and integrity of configurations and data associated with a TVM assigned TDI. Devices must implement suitable mechanisms to prevent leakage and tamper of such configuration and data from other TDIs including from the physical function of the device.

Devices may consider the administration functions provided through the physical function or the administrative queue of the device as untrusted. Typically, such administrative interfaces managed by the VMM are trusted by the TDIs (such as virtual function or TDIs) by virtual machines that include the VMM in the trust boundary. As the TVM may not include the VMM in the trust boundary, the administrative actions performed by the VMM may need to be mediated by the DSM to ensure that the administrative actions do not compromise the confidentiality or integrity of the TVM data, link encryption keys, SPDM session keys, and other secrets that are essential to the security of the solution. Administrative functions (e.g., QOS configurations, etc.) that are benign and could only lead to denial of service if misused may be allowed when the TDI is in CONFIG_LOCKED, RUN state.

TEE-I/O capable device should be designed to avoid or minimize the need for host driver intervention for TDI specific configuration or control operations where such operations if carried out maliciously may lead to confidentiality or integrity of the TVM data being compromised. Certain operations that only affect the quality of service or performance characteristics of the TDI but otherwise are benign to the functional correctness and security of the interface may be

carried out by host driver on behalf of the TVM. The host driver may not be in the trust boundary of the TVM assigned TDIs and may not be trusted to provide software emulation of TVM operations.

Changing the device configurations such as reprogramming the physical function or virtual function BAR, changing configurations of the TDIs, etc. may be used to temporarily drop a transaction originated by the TVM or lead to exposure of TVM confidential data (e.g., redirecting it to registers of a different virtual function than the one to which it is bound, etc.). Such configurations elements may be in the configuration space of the physical function, configuration space of the virtual functions, MMIO registers mapped by the physical function or the virtual function BARs, etc. Such configurations changes should be considered hostile actions and the TDI must be transition from CONFIG_LOCKED/RUN to ERROR.

Errors or failures encountered in the DSM or in other parts of logic in the device where the failures are not recoverable, or lead to the DSM losing state of the TDI, must lead to the device transitioning to a secure failed state where the TDIs in CONFIG_LOCKED/RUN transition to ERROR.

11.4.6 Data Integrity Errors §

Receipt of a poisoned TLP on an interface in RUN indicates occurrence of uncorrectable data integrity errors. Except when the TDI implements mechanisms to recover from and/or suitably handle, receipt of such a TLP must transition the interface from RUN to ERROR to prevent bad data consumption and propagation. The device should implement suitable protection schemes such as parity or ECC on its internal data buffers and caches to detect data integrity errors. If uncorrectable data integrity errors were detected, then the affected interfaces must transition from CONFIG_LOCKED/RUN to ERROR and poison signaled to the requester as appropriate. The device may provide a mechanism to report and log the occurrence of such errors. Devices must scrub and clear information in such logs and reporting registers (e.g., syndrome) that may reveal confidential data.

11.4.7 Debug Modes §

Devices may support multiple debug modes or debug capabilities. Some of the debug capabilities may allow a software debugger to collect statistics, error logs, etc. Such debug capabilities must not affect the security of the device, and must not lead to a compromise of the confidentiality or integrity of the TVM data provided to the device.

Debug configuration may, for example, be reported in SPDM measurements, such as non-invasive debug mode or invasive debug mode. A DICE device may report operation flags in DICE TCB info, such as debug mode.

Other debug modes may allow the debugger to affect the security of the device by providing mechanisms, for example, to bypass signature verification, trace data flowing through the device buses, affect the measurement process itself, etc. The device may support and use debug-mode identity certificates to identify such debug modes being active. This enables the TVM (and remote verifiers) to determine if the TVM may provide secrets to the device. TEE-I/O capable devices may restrict authorization of such debug modes to an early window following cold reset (i.e., the debug authorization occurs before secrets have been provided to the device or secrets in the device itself have been unlocked). When the debug authorization window is active, the device must not participate in SPDM session setup. Alternately, a TEE-I/O capable device may allow debug authorization to always occur but in response to the debug authorization request transition the IDE stream states to Insecure, terminate the SPDM session with the TSM, and transition all TDIs in CONFIG_LOCKED, RUN state to ERROR state prior to enabling the debug interface. Such devices provide the assurance that secrets already provided to the device by the TVM are not accessible to the debugger.

11.4.8 Conventional Reset §

A conventional reset (cold, warm, or hot) leads to the device changing all its Port registers and state machines to their initialization values, and the TDISP state of all TDIs transitions to CONFIG_UNLOCKED.

Device reset architecture must ensure that all TVM data, IDE keys, other encryption keys (e.g., P2P links, intra-device interconnects, etc.) and SPDM session keys are cleared such that they are not exposed in plaintext through any mechanism following exit from the reset.

Devices may authorize debug following a reset and if the stream encryption keys are not scrubbed and cleared, they may become accessible to the debugger using debug tools. In addition to the stream encryption keys, TVM data held in clear text in the device (e.g., in the device's coherent caches, register files, SRAMs, etc.) may become accessible to debuggers using debug tools. The TEE-I/O capable device must implement suitable mechanisms to scrub residual secrets from device internal structures before authorizing debug access following a reset.

Devices may lose power as part of the conventional reset and may not have state coming out of the reset to determine whether the device was in use by a TVM or not. A TEE-I/O capable device should assume that prior to a conventional reset there may have been a TDI associated with a TVM and thus implement suitable mechanisms to ensure that residual data and secrets are not leaked in plaintext following such a reset.

The device measurement registers must be reset to their default values as part of a reset that requires firmware reload. Some devices may reload firmware on a warm reset, whereas others may require a cold reset or a D3 state transition.

11.4.9 Function Level Reset §

A function level reset of a VF or non-IOV function must affect the TDI hosted by that function. A function level reset of the PF must affect all subordinate VF TDIs. A function level reset must transition all affected TDIs from CONFIG_LOCKED, RUN state to ERROR state such that a STOP_INTERFACE_REQUEST request is required to clean up the TDI state and scrub TVM data/secrets prior to the transition of the affected TDIs to CONFIG_UNLOCKED state.

A functional level reset to Functions other than Function 0 does not affect active SPDM sessions or IDE streams.

11.4.10 Address Translation Services (ATS) and Access Control Services (ACS) §

TEE-I/O capable devices that support ATS and have ATS enabled must generate translation requests and page requests for a TDI in RUN state with T bit Set.

If device supports IDE, then these requests must be generated over the IDE stream bound to the TDI by the LOCK_INTERFACE_REQUEST.

ATS requests not sent using the default IDE stream, must not be assumed to accurately reflect the permissions of that TDI, and as such if the device is caching host-memory, must not allow sharing between TEE TDIs and non-TEE TDIs of that cached value.

ATS Translation Requests issued by the TDI while in RUN must have the T bit Set, and the Translation Completion(s) must be received with the T bit Set. Translation Completion(s) received with the T bit Clear must transition the TDI to ERROR.

ATS Translated Read or Write Requests must only be issued by the TDI while in RUN, and must Set the T bit. Completions for ATS Translated Read Requests issued by the TDI while in RUN are permitted to be received with the T bit Set or Clear.

ATS Invalidation Request and Invalidation Completion Messages are permitted to use or not use IDE. If IDE is used, Invalidation Requests applying to translations for a TDI in the RUN state are permitted to have the T bit Set or Clear. If the Invalidation Request uses IDE, then the Invalidation Completion must use the same IDE Stream as the Invalidation Request, and must match the T bit value from the Invalidation Request.

Page Request Messages must only be issued while in RUN, and must Set the T bit. Page requests from multiple interfaces in RUN are permitted to be grouped into a Page Request Group. A PRG Response must use the same IDE Stream as the

corresponding Page Request, and must have the T bit Set. A violation of this rule must result in the TDI transitioning to ERROR.

Untranslated P2P requests generated by a TDI in RUN state must be redirected upstream towards the Root Complex over the default IDE stream bound to the TDI when the interface was transitioned to CONFIG_LOCKED state.

When there are no P2P streams bound to the interface, all translated P2P requests generated by a TDI must be directed upstream towards the Root Complex over the default IDE stream bound to the interface when the TDI was transitioned to CONFIG_LOCKED state. When there are P2P streams bound to the TDI, translated P2P requests generated by a TDI may be sent over a P2P stream bound to the TDI using the BIND_P2P_STREAM_REQUEST.

TEE-I/O capable devices must enforce integrity of the Address Translation Cache (ATC) such that the translations provided by the Root Complex cannot be modified through untrusted accesses.

Requirements on the device's PASID/ATS capabilities:

- Execute Permission Supported must be Clear
- Global Invalidate Supported must be Clear

Devices must, in all Translation Completions, treat the G bit as zero.

The use of Access Control Services (ACS) mechanisms for redirection must be coordinated with the device configuration to ensure that the correct Selective IDE Stream will be used. Specifically:

- ACS Translation Blocking
- ACS P2P Request Redirect
- ACS P2P Completion Redirect
- ACS Upstream Forwarding
- ACS P2P Egress Control
- ACS Direct Translated P2P

11.5 Requirements Placed on Host Security due to TDI Requirements §

11.5.1 Address Translation §

The property of memory being either TEE memory or non-TEE memory, must, as observed by a TVM executing on the host, match the view of memory as observed by a TDI assigned to that TVM. The translation agent (TA) is permitted to use the T bit being 1 to identify requests originated by a TDI in RUN state. The TVM relies on the TSM and TA to translate requests from TVM assigned TDIs such that:

1. An untrusted VMM cannot compromise the integrity of translation of Guest Physical Address or Guest Virtual Address to a physical address.
2. The Translation Agent (TA) ensures that Untranslated Requests transmitted by a TDI are checked against the access permissions for that TDI.
3. An Address Translation Cache (ATC) in the TDI, if enabled, is consistent with the Address Translation and Protection Tables (ATPT) associated with the TVM and changes to the ATPT are observed by both the CPU TLB, IOMMU TLB, as well as the ATC.
4. Identifiers such as Requester ID (and PASID) used for ATPT lookup are verified for integrity such that attempts to forge these identifiers are prevented.

- Identifiers such as Requester ID and ITAGs used to process invalidation completions are verified for integrity such that attempts to forge these identifiers are prevented.

11.5.2 MMIO Access Control §

The TSM must provide the following access controls on TVM assigned MMIO resources:

- Verify that all MMIO resources reported by the device through the `DEVICE_INTERFACE_REPORT` have been made accessible to the TVM and the order in which these resources are mapped into the TVM address space match the expected mapping order.
- Restrict a TVM and TVM assigned TDIs to only access MMIO resources that have been assigned to that TVM.
- TLPs with the T bit Set may be generated to MMIO resources of a TVM only by accesses originated by that TVM or by components in the TCB of that TVM such as other TDIs assigned to that TVM that are in RUN state.

11.5.3 DMA Access Control §

The TSM must provide the following access controls to TVM assigned memory and MMIO resources:

- DMA through untranslated or already-translated requests to TVM memory must be allowed only from TDIs accepted by a TVM in its TCB. Such DMA may be to the confidential memory of the TVM or non-confidential memory accessible to the TVM. When a TVM accepts a TDI in its TCB, it accepts the entirety of the device in its TCB. A device is in the TCB of all TVMs that accept TDIs of that device in their TCBs. The TVM that accepts a device into its TCB trusts the device to not spoof identifiers used for DMA access control such as the source Requester ID (and the PASID). A TVM that does not accept a TDI of a device must not have the device in its TCB and such devices must not have access to TVM memory or MMIO resources using either untranslated or already-translated requests.

11.5.4 Device Binding §

The TVM uses the authentication and measurement reporting protocol specified by [SPDM] to determine if the identity and measurements reported by the device hosting the TDI are acceptable prior to admitting the device into its TCB. The TVM needs to further determine if the authenticated device is presently bound to the host using an IDE stream (if applicable) and a SPDM session established by the TSM.

The TSM must provide a trusted mechanism to determine if:

- A SPDM session is active between the TSM and the DSM in the device authenticated by the TVM.
- IDE keys for the IDE stream used by that TDI have been established by the TSM.

11.5.5 Securing Interconnects §

The symmetric stream encryption keys and IV of each IDE Sub-Stream are secret and compromising these breaks the security of the solution. The host must implement adequate security measures to prevent leakage of the encryption key at rest and in use. The stream encryption keys and IV must not be revealed outside the TSM and the TSM TCB. The host must not allow modifications to the stream encryption keys or the IV through untrusted mechanisms. These protections apply to all host-specific mechanisms that contribute to maintaining confidentiality and integrity of IDE streams, for example Key Set change mechanisms or key refresh timers.

The host must program a unique encryption key for each IDE sub-stream and must not re-use the encryption keys when the IDE sub-stream keys are refreshed.

11.5.6 Data Integrity Errors §

The host must provide data containment mechanisms to prevent consumption and further propagation of data in a poisoned TLP by a TVM or components in the TVM TCB.

It is strongly recommended that the host implement suitable protection schemes such as parity or ECC on its internal data buffers and caches to detect data integrity errors. If uncorrectable data integrity errors were detected, then the host must poison the data to prevent consumption and propagation by TVM, TVM assigned TDIs, or other components in the TVM TCB. The host must scrub registers that log information about the error, such as the syndrome, that could reveal confidential data.

11.5.7 TSM Tracking and Handling of Locked Root Port Configurations (Informative) §

The TSM must track attempts to modify registers or other changeable configuration controls affecting Root Ports connecting to devices in CONFIG_LOCKED or RUN. Precisely what must be tracked is implementation specific, and because the security properties of the device depend on correct implementation of these mechanisms, it is strongly recommended that persons skilled in building and validating secure hardware be deeply involved in the design and validation for all implementations. § Table 11-31 provides some general guidance regarding architecturally defined registers. Root Complex implementation-specific registers must be evaluated to determine if modifications to those are allowable. Read-only registers, hardware initialized registers, and registers used as selectors for reading out data (e.g., the Power Budgeting Data Select register) are excluded from this table. The TSM must ensure that attempts to modify those registers cannot affect the security of associated TDI(s).

Table 11-31 Example TSM Tracking and Handling for Root Port Configurations §

Register / Capability / Extended Capability	Example Response to Register Modification	Description
<u>Cache Line Size</u> , <u>Latency Timer</u> , <u>Interrupt Line</u>	Allowed	
<u>Command Register</u>	See description	Clearing following bits causes the hosted IDE streams to transition to Insecure state: <ul style="list-style-type: none"> <u>Memory Space Enable</u> <u>Bus Master Enable</u> Modification of other bits is allowed.
<u>Status Register</u>	Allowed	
<u>BIST Register</u> , <u>Base Address Registers</u> , <u>Expansion ROM Base Address</u> , <u>Primary Bus Number</u> , <u>Secondary Bus Number</u> , <u>Subordinate Bus Number</u> , <u>Root Port Segment Number</u>	Error	Transitions hosted IDE streams to Insecure State.

Register / Capability / Extended Capability	Example Response to Register Modification	Description
<u>I/O base, I/O Limit</u>	Allowed	
<u>Secondary Status Register</u>	Allowed	
Memory Base, Memory Limit	Error	Transitions hosted IDE streams to Insecure State.
<u>Prefetchable Memory Base, Prefetchable Memory Limit</u>	Error	Transitions hosted IDE streams to Insecure State.
<u>I/O Base Upper 16 Bits I/O Limit Upper 16 Bits</u>	Allowed	
<u>Bridge Control Register</u>	Allowed	
<u>PCI Power Management Capability</u>	Allowed	If a power transition leads to the port losing its state, then the IDE streams hosted by that port transition to Insecure state.
<u>Device Control</u>	See description	Modifying Extended Tag Field Enable must cause streams hosted by the port to transition to Insecure state
<u>Device Status</u>	Allowed	
<u>Link Control</u>	See description	Disabling or retraining the link leads to IDE streams configured in the Root Port to transition to Insecure state
<u>Link Status, Link Status 2</u>	Allowed	
<u>Slot Status</u>	Allowed	
<u>Root Control</u>	Allowed	
<u>Root Status</u>	Allowed	
<u>Device Control 2</u>	See description	Modifying state of 10-bit Tag Requester Enable causes streams hosted by the port to transition to Insecure state. Modification of other bits is allowed.
<u>Device Control 3</u>	See description	Modifying state of 14-bit Tag Requester Enable causes streams hosted by the port to transition to Insecure state. Modification of other bits is allowed.
<u>Link Control 2, Link Control 3</u>	See description	Modifications to these registers are allowed. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.
<u>MSI Capability, MSI-X Capability</u>	Allowed	
Lane Margining at the Receiver	See description	Modifications to these registers are allowed. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.
<u>Secondary PCIe Extended Capability, Physical Layer 16.0 GT/s Extended Capability, Physical Layer 32.0 GT/s</u>	See description	Modifications to these registers are allowed. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.

Register / Capability / Extended Capability	Example Response to Register Modification	Description
<u>Extended Capability, Physical Layer 64.0 GT/s Extended Capability</u>		
<u>ACS Extended Capability</u>	Allowed	
<u>Latency Tolerance Reporting Extended Capability</u>	Allowed	
<u>L1 PM Substates Extended Capability</u>	See description	Modifications to these registers are allowed. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.
<u>Advanced Error Reporting Extended Capability</u>	Allowed	As specified in § Section 6.2.3.2.2 , error mask register settings control reporting of detected errors, but do not block error detection.
<u>Enhanced Allocation Capability</u>	Error	Transitions hosted IDE streams to Insecure State.
<u>Resizable BAR Extended Capability</u>	Error	Transitions hosted IDE streams to Insecure State.
<u>FRS Queueing Extended Capability</u>	Allowed	
<u>Flattening Port Bridge Extended Capability</u>	Error	Transitions hosted IDE streams to Insecure State.
<u>Virtual Channel Extended Capability</u>	Allowed – see description	Root Port enforces transaction ordering when TC/VC mapping is changed, or arbitration tables are updated.
Vendor Specific Capability	See description	To be analyzed by the vendor based on the security principles provided by TDISP.
Vendor Specific Extended Capability	See description	To be analyzed by the vendor based on the security principles provided by TDISP.
Designated Vendor Specific Extended Capability	See description	To be analyzed by the vendor based on the security principles provided by TDISP.
<u>RCRB Header Extended Capability</u>	Allowed	
Root Complex Internal Link Control	See description	Modifications to this register is allowed. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.
<u>Multicast Extended Capability</u>	Error	Enabling multicast mechanism is not supported for TEE-I/O operation. Transitions hosted IDE streams to Insecure State.
<u>Dynamic Power Allocation Extended Capability</u>	Allowed	A Root Port must guard against the part being placed outside of its specification. If the Root Port cannot reliably operate within the power allocation through mechanisms like throttling, frequency control, etc. then the Root Port must transition hosted IDE streams to Insecure state.
<u>TPH Requester Extended Capability</u>	Allowed	
<u>DPC Extended Capability</u>	Allowed	

Register / Capability / Extended Capability	Example Response to Register Modification	Description
<u>Precision Time Measurement Extended Capability</u>	Allowed	
<u>Native PCIe Enclosure Management Extended Capability</u>	Allowed	
<u>Alternate Protocol Extended Capability</u>	Allowed	
<u>System Firmware Intermediary Extended Capability</u>	Allowed	
<u>Protocol Multiplexing Extended Capability</u>	Allowed	A Root Port that supports PMUX must not transmit or receive IDE TLPs using PMUX packets. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.
<u>Data Object Exchange Extended Capability</u>	Allowed	
<u>Integrity and Data Encryption Extended Capability</u>	See description	Modifying the stream control register, selective IDE RID association registers, or selective IDE address association registers of streams that are bound to TVM assigned TDIs is an error, and the stream transitions to the Insecure state.
<u>Flit Error Injection Extended Capability</u>	See description	Modifications to this register is allowed. If the modifications lead to a link failure, the IDE streams configured in the port transition to Insecure state.

11.5.8 IDE Extended Capability registers §

The host must enforce the integrity of IDE Extended Capability registers of the Root Ports used to configure streams used for TEE-I/O in the Root Port. Following mechanisms among others may be used to provide such integrity protection:

1. Restrict write access to such registers to the TSM or components in TSM TCB.
2. Transition the corresponding IDE stream to Insecure state if attempted to be modified by entities other than the TSM or components in TSM TCB.

TSM may provide an interface for the VMM to manage the lifecycle of IDE streams used for TEE-I/O. The VMM may use this TSM provided interface to configure, enable, disable, and reclaim (including non-graceful shutdown/reclaim) stream control registers. The details of such interfaces that may be provided by the TSM to the VMM are outside the scope of TDISP.

11.6 Overview of Threat Model and Mitigations §

This section provides a very brief overview. It is strongly recommended that thorough threat model analysis be conducted by competent security expert(s) for all implementations.

11.6.1 Interconnect Security §

The interconnect used to attach the device to the host needs to be secure against threats from physical attacks on the links. Adversaries are expected to have the ability to use lab equipment, interposers, custom devices, Switch firmware modifications, Switch routing table modifications, debug hooks in the Switches and Retimers, etc. to capture the data, re-order the data, or drop data transiting the links.

The adversary is expected to have the ability to perform reordering of transactions that are not legally allowed by the interconnect protocol.

The adversary may attempt to reprogram the encryption keys and replay protection counters associated with the link protection schemes to violate the confidentiality or integrity of the transactions on the link or to replay transactions on the link.

The adversary is expected to have the ability to craft custom devices or exploit vulnerabilities in authentic devices to attempt to spoof the identities used by the interconnect protocol (e.g., RID, PASID) to bypass access controls based on these identities.

These threats are addressed by use of IDE to secure the TLPs that carry TVM data.

The integrity protection on the TLP headers helps detect tampering of the identities such as RID and PASID. The use of selective IDE streams enables detection of attempts by the requester to use a RID outside the range defined by the RID association registers. The device and host secure the IDE keys and SPDM secure session keys from entities not in the TVM TCB. The device detects modifications to IDE configurations as errors and transitions all associated TDIs to ERROR state. If an SPDM session transitions to session termination phase, then all IDE streams that had keys established over that session transition to insecure state and all TDI that were transitioned to CONFIG_LOCKED state over that SPDM session transition to ERROR. The host may either prevent modifications to IDE configurations or treat them as errors and transition the IDE streams to Insecure state.

A TDI can be associated with an IDE stream only if the IDE stream was keyed using the same SPDM secure session as that used for the LOCK_INTERFACE_REQUEST. A TDI can be associated with a P2P IDE stream only if the P2P IDE stream was keyed using the same SPDM secure session as that used for the BIND_P2P_STREAM_REQUEST. An IDE stream transitioning to Insecure state moves the associated TDIs to ERROR.

The host should guard against the following additional threats, using implementation-specific mechanisms, for security of IDE and TEE-I/O:

- Configurations used by the host to route addresses to Root Ports should be protected to prevent rerouting of transactions to unintended destinations:
 - TVM initiated transactions to device memory
 - P2P requests routed through the host
 - Device initiated transactions to host memory
- Reset of the host Root Ports and other logic blocks to place them in HwInit state
- Debug modes that affect the confidentiality and integrity of IDE keys, IVs, routing configurations, and other functions of the host that affect TEE-I/O security objectives.

11.6.2 Identity and Measurement Reporting §

The adversary is expected to have the ability to build custom devices that mimic a legitimate device but be otherwise maliciously crafted to compromise the confidentiality and/or integrity of the TVM confidential data provided to the device.

The adversary may have control of the version of device firmware that loads even in authentic devices and be able to exploit vulnerabilities that may exist in specific versions of the firmware.

The devices may support debug capabilities that the adversary can invoke to affect the confidentiality and/or integrity data in the device or functional operations of the device.

The adversary is expected to use physical accesses and/or access to local/remote debug interfaces among others to attempt to subvert the root of trust of the device including the services provided by the device root of trust for measurement, reporting, identity, authorization, or update.

The adversary may have controls that allow downgrading a device firmware after the TVM has verified the measurements and may use this ability to exploit vulnerabilities in the downgraded version.

The adversary may have control on the version of firmware/software components that are loaded in the host that are in the TVM trust boundary and be able to exploit vulnerabilities that may exist in specific versions of the firmware/software.

The adversary may have physical access to the host and/or access to local/remote debug interfaces among others to attempt to subvert the TVM root of trust in the host.

These threats are mitigated by use of [SPDM] for identity and measurement reporting.

The devices implement security mechanisms to protect the root of trust in the device. Devices implement secure mechanisms to provision the device root of trust. Devices implement secure root of trust for measurement and protect the integrity of the measurement registers. Devices protect the Root of Trust (RoT) and Root of Trust for Measurement (RTM) from debug modes. TSM provides device binding information to the TVM such that the TVM can answer the questions outlined in § Section 11.2.7 to determine if the device if it is accepting a device in a secure state into its TCB.

11.6.3 TDI Assignment and Detach §

Assigning a TDI to a TVM includes providing access to the MMIO resources of the TDI, and establishing access controls on DMA from the TDI to the TVM memory.

The adversary may be software outside the trust boundary of the TVM, including other TVMs, devices that are not trusted by the TVM, or an adversary using debug interfaces, etc. to influence the correctness and/or integrity of the MMIO resource assignment to a TVM and correctness and/or integrity of the DMA translation tables.

An adversary such as an untrusted VMM, or a TDI controlled by software outside the TVM trust boundary (including an unrelated/untrusted TVM), may attempt to maliciously access the MMIO resources assigned to a TVM to affect the confidentiality and/or integrity of the registers and MMIO mapped resources in the device.

An adversary such as an untrusted VMM may attempt to map the MMIO resources assigned to a TVM in an incorrect order and thereby attempt to trick a TVM to access a wrong set of registers and/or resources in the TDI.

The adversary may attempt to exploit properties like address decode priorities by assigning overlapping MMIO resources to two or more TDIs to redirect the transactions.

The adversary may attempt to reprogram a TDI that is being used by a TVM to affect the functioning of the TDI to influence the confidentiality and/or integrity of the transactions on the link or confidential data in the TDI. Examples of such reprogramming may include modifying the MMIO BAR of the device to attempt to drop transactions.

The adversary may attempt to asynchronously change the device state by issuing resets to the device to cause the device to drop established protections when a TVM is actively using the device.

The adversary may have the ability to launch a maliciously crafted TVM that collaborates with the adversary in violating the confidentiality and integrity of the TVM data.

These threats are mitigated by the use of TDISP.

TDISP provides the protocol and security requirements to lock TDI configurations using a LOCK_INTERFACE_REQUEST, obtain a report of the locked TDIs using a GET_DEVICE_INTERFACE_REPORT, securely enabling the memory space and DMA for TVM access using START_INTERFACE_REQUEST. A nonce generated by the device when the TDI is transitioned to CONFIG_LOCKED and verified on request to transition to RUN provide the property that all transitions through the TDISP state machine occur due to TDISP requests generated in the same SPDM secure session.

The DEVICE_INTERFACE_REPORT provides a trusted report of the TDI configurations, the list of MMIO resources associated with the TDI, and the order in which they must be mapped into the TVM address space. The TVM and TSM use the DEVICE_INTERFACE_REPORT to enforce that all MMIO resources of a TDI are assigned to the TVM to which the TDI is assigned and that the MMIO resources are mapped into the TVM address space in the expected order. § Section 11.5.1 specifies the requirements on the TSM to enforce address translation integrity. § Section 11.5.2 specifies the requirements on the TSM to enforce MMIO access control. The TSM through these access control mechanisms ensures that accesses with T bit Set can be generated to a MMIO register only by the TVM that has been allocated those resources. The device in RUN must only allow a Request to access memory with IS_NON_TEE_MEM Clear when the Request's T bit is Set. If the device supports IDE capability, accesses targeting memory with IS_NON_TEE_MEM Clear must be accepted only on an IDE stream bound to the TDI.

TSM uses host specific mechanisms to enforce DMA access control. The TSM uses the STOP_INTERFACE_REQUEST to ensure that all worked queued into a TDI has been drained and stopped before the resources allocated to a TVM can be reclaimed.

The TSM is expected not to bind any P2P streams using BIND_P2P_STREAM_REQUEST message unless the host supports ATS translation, and the Root Complex performs the correct TEE access checks at the time an ATS Translation Request is issued. Upon receipt of a Translation Completion that resolves to an address described by a P2P stream, the device receiving the Translation Completion is assured that it has full permission to request access to the specified resource. Similarly, any device that has a P2P stream configured and that receives a request on that stream with the T bit Set is assured that the sender has full permission to request access to the specified resource. No additional access checks are required or expected to be performed by the receiver.

TSM allows a TVM to update MMIO attributes of a TDI using SET_MMIO_ATTRIBUTE_REQUEST if the pages in the MMIO range of the request were allocated to the TVM making the request.

Devices track configurations of TDIs in CONFIG_LOCKED to detect attempts to reconfigure the TDI. Function level resets transition the TDI to ERROR. Conventional resets require the device to clear residual TVM secrets, IDE secrets, and SPDM session secrets such that they are not accessible to entities outside TVM trust boundary.

12. Architectural Out-of-Band Management §

12.1 Introduction §

“Sidebands” are physical interfaces other than the high-speed Lanes connecting two Ports, typically used for out-of-band platform management functionality. Out-of-band (OOB) management refers to the ability to communicate with peripheral subsystems, such as adapters and components, without interacting with firmware/software running on the host CPU(s).

This chapter provides a “toolkit” with a variety of potentially applicable technology ingredients, including, for example [SMBus] addressing, discrete signaling consolidation and Flexible I/O signal function negotiation, and how to utilize enhanced interfaces such as [I3C-Basic] and managed USB 2.0. The intent of centralizing this content in this document is to yield major improvements in capability and consistency to the physical, electrical, and logical domains for both systems and existing or new future form factor specifications or revisions.

The following table provides relative comparisons of typical architectural out-of-band interfaces and basic use guidance. *Bandwidth* is shown as the theoretical interface speed and is not indicative of practical throughput. The term *Isolated Control Plane* means that the interface does not involve the Link. For example, PCIe Vendor-Defined Messages (VDMs) are typically used for out-of-band management that does not involve firmware/software running on the host CPU(s) but does traverse Links. Some applications choose to isolate such traffic for reasons including host bandwidth or security.

Table 12-1 Relative Comparisons of Typical Architectural Out-of-Band Interfaces §

General Out-of-Band Interface Usage Guidance	Transfer Rate	Isolated Control Plane	Example Applications
Discrete/Physical Signals	Signal propagation delay	Y	PERST#, PRSNTNT#, PWRBRK#, PWRDIS
Serialized/Virtual Signals (e.g., PESTI)	≈250 Kb/s	Y	Real-time virtual signals, OOB Controls/status
[SMBus] or [I2C]	100, 400, 1000 Kb/s	Y	EEPROM, I/O Expanders, Sensors, MCTP, Security
[I3C-Basic]	12.5 Mb/s SDR mode	Y	Hub Control, MCTP
USB 2.0	480 Mb/s	Y	Serial, Ethernet (NC-SI and TCP/IP), Mass Storage, MCTP, Security, Bridges to SPI, [I2C], and [I3C]
PCIe VDM	Link-specific	N	MCTP

12.2 Framework for Sidebands §

Sideband signals refer to all signals that cross a defined interface, other than those associated with the high-speed Link itself. Sideband signals impact platforms such as through added cost, additional conductors and circuits for optional signals that might be rarely or never used. This negatively impacts cross compatibility and establishes legacy constraints that might impede more efficient solutions. Although sideband signals typically travel in parallel with the Link, sideband signals often interact with components other than the two that implement the Ports at each end of the Link.

The architectural framework defined here provides:

- A partial catalog of sideband signals already in common use for defined form factors.
- Reference physical topologies representing how sideband signals are used at the platform level.
- Extensible mechanisms for sideband capability discovery and control.
- Roles and responsibilities of various platform elements in relation to sideband signals.

The goal of the framework is to simplify the definition and evolution of form factors and platforms by providing form factor agnostic consistency and structure to sideband signal handling.

12.3 Sideband Signaling Mechanisms §

This section describes three methods of sideband handling for form factor and other interface specifications to use as tools. These include fixed function interfaces using discrete sidebands, Flexible I/O (Flex I/O) and Peripheral Sideband Tunneling Interfaces (PESTI). Each of these mechanisms are utilized where appropriate with the following sections providing specific guidance.

12.3.1 Discrete Sidebands §

Discrete sideband signals are physical wires and/or pins that have diverse functions such as those related to platform power up (e.g., **PERST#**), Link control (e.g., **CLKREQ#**), or non-Link functionality (e.g., 2-wire). These physical wires can be transmitted using different methods (e.g., copper, optical). Discrete sideband signals are not limited to digital, two-state or a single functional purpose or direction. Considerations for incorporating discrete sideband signals include architectural needs (e.g., **PERST#**), low latency needs, (e.g., **PWRBRK**), or fault domain minimization control (e.g., **PWRDIS**). Form factor specifications are permitted decide to incorporate such signal types when weighing functionality against interconnect size and cost.

In general, vendor specific platform requirements drive fan-in or fan-out requirements for each signal (e.g., whether **CLKREQ#** is independent for each function).

Examples of discrete signals incorporated in multiple form factors:

- **PERST#** - PCIe Reset (and similar component reset mechanisms) is a signal that causes a component to execute a Fundamental Reset. See § Section 6.6.1 for details.
- **PRSNT#** - Presence (and similar component presence mechanisms) is a class of signal that provides an indication of the presence of the adapter, component, or cable, and optionally the insertion or removal of an adapter, component or cable. See § Section 6.7.1 for details.
- **PWRDIS** - Power Disable (and similar component power disable mechanisms) is a signal that causes an adapter or component to disable use of its own power. See § Section 6.7.3.3 for details.
- **PWRBRK#** - Emergency Power Reduction (and similar adapter or component emergency power reduction mechanisms) is a signal that causes an adapter or component to reduce its own power consumption to a safe level. See § Section 6.24 for details.
- **CLKREQ#** - Clock Request (and similar platform clock request mechanisms) is a signal that causes a platform to provide reference clock to the adapter or component. See § Section 8.6.8 for details.
- **WAKE#** - Wake Up (and similar platform wakeup mechanisms) is a signal that causes a sleeping platform to restore main power to the adapter or component. See § Section 5.3.3.2 for details.

An example of a signal with alternative solutions:

- **SMRST#** – SMBus Reset is a discrete sideband for recovering SMBus hang or stuck busy type conditions without interfering with the form factor's primary workload. This signal is a good candidate for exclusion or serialization, since it is high latency and may be rarely or ever used. It is common practice for applications that do not have a discrete **SMRST#** signal to use bus reset methods such as SMBus clock low reset or by executing SCL pulses followed by a STOP condition.

12.3.2 Flex I/O Sidebands §

Flexible input/output signals/interfaces (Flex I/O) utilize the concept where interface pins are permitted to be flexibly (re)purposed following discovery and determination of mutual capabilities and applying rules that guarantee safe and backward compatibility, where applicable, across the electrical and logical domains. When represented as a signal, form factor specifications should use the **FLEXIO-[N:Ø]** nomenclature.

Flex I/O interfaces provide the following benefits:

- Improved hardware interface utilization compared to fixed function pins.
- Opportunity to continually leverage evolving high-speed management interfaces.
- Flexibility to include, at present or future, value-added out-of-band functionality between platforms and peripheral subsystems, such as adapters or components.

IMPLEMENTATION NOTE:

FLEX I/O PINS ARE NOT CALLED RESERVED §

Flex I/O signals are purposefully not called Reserved (RSVD) pins, which are typically specified to include no defined usage within a specific form factor specification version. RSVD pins typically call out both the platform and adapter sides to not connect any functional circuit, except high frequency filters such as on the CEM connector.

Flex I/O signal/interface engagement requires these steps, with guidelines described below:

1. Default State
2. Discovery
3. Compatibility Check
4. Control Negotiation

12.3.2.1 Flex I/O Default State Guidelines §

A Flex I/O interface pin is permitted to default to:

1. **Unused:** Unconnected (electrical open) or with a specific termination as dictated by a specific form factor or connector/cable specification.
2. **Pre-Wired/Inert:** This is where a pin/interface is wired with a predetermined circuit and connectivity but does not perform the intended functionality until after negotiation is complete. Voltage bias before negotiation is allowed. An example is a form factor specific required Flex I/O signal connected to platform logic that defaults to tristate/high impedance with a platform-side pullup resistor to the platform side's +3.3 V auxiliary power rail. Then after negotiation is complete, the signal is allowed to be used for its intended purpose. Form factor

specifications must ensure that any allowed default circuit conditions are electrically safe and do not impose logical domain constraints. An example is a cross power domain electrical stress or leakage condition.

3. **Switchable Function:** This is where a pin/interface defaults to a pre-defined function (often a legacy function), but then is electrically or logically switchable to an alternate function. An example is a form factor interface that defaults to JTAG functionality, with all the associated requirements such as default terminations and connectivity. Then following a positive discovery and compatibility check (defined below), a control disengages the default functionality and then engages the intended alternate functionality.

12.3.2.2 Flex I/O Discovery Phase Guidelines §

When used, Flex I/O capabilities are required to be described in FRU Information (See § Section 12.6). Form factor specified usages of Flex I/O signal(s) or interface(s) must be provided for discovery purposes via form factor specified FRU Information descriptors. Examples include, but are not limited to, pin number, pin functionality, supported power domain(s), bus topology and any signal integrity attributes deemed necessary to achieve the intended functionality. The [CEM-6.0] provides an example.

12.3.2.3 Flex I/O Compatibility Check Guidelines §

Failure to conform to the following guidance could result in undefined behaviors or effects not limited to electrical damage.

1. The platform must compare the adapter's advertised Flex I/O capabilities with the platform side interface capabilities and policy, if applicable, before attempting to perform any of these actions:
 - a. Change from a pin or circuit default state.
 - b. Communicate new control settings.
 - c. Utilize Flex I/O pin functionality in any way, such as toggling Flex I/O connected GPIO.
2. Mismatch: If a Flex I/O pin or interface functionality mismatch is detected between a platform capability or policy and interposer, adapter, or component, then the above three actions must be avoided.
3. Single-ended Flex I/O functionality on differentially optimized signals is allowed. Implementers must be aware of potential effects between such single ended signals, such as crosstalk being an unintended signal aggressor on a victim, impedance mismatches and other unintended effects along the signaling paths.
4. Differential interfaces utilizing single-ended optimized Flex I/O signals is prohibited due to differences, such as target impedance, improper GND shielding, board routing, connector design, etc.
5. Flex I/O usage and signal engagement may be applicable to one or more specific peripheral supported power states (such as Main power state only versus Auxiliary power and Main power states). If a peripheral advertises more than one supported power state, it is allowed to have a control command (if such a command is advertised as supported) for selecting a subset of power states that the peripheral must adhere in reference to specific Flex I/O interface(s). It is the responsibility of the peripheral to provide the necessary cross power domain isolation to avoid inadvertent behaviors.
6. Flex I/O usages are permitted to be independent of an adapter's or component's Link state.
7. Single-ended signal voltage negotiation for Flex I/O pins is outside the scope of this specification.
8. Using Flex I/O pins as power supply rails is prohibited, due to possible ill effects such as an incorrect or malicious software setting causing electrical stress or damage.

12.3.2.4 Flex I/O Control Negotiation Guidelines §

Failure to conform to the following guidance could result in undefined behaviors or effects not limited to electrical damage. See § Section 12.7 for the control/command protocol detail. Dynamic reconfiguration of Flex I/O is left to the implementer.

There are four scenarios for how Flex I/O controls assume their intended functionality:

1. Pre-wired circuit with configurable direction, purpose, signaling or protocol: This scenario occurs when an interface is pre-wired before any negotiated functionality. The interface must remain inactive until supported uses are discovered, and the requisite compatibility and policy check are complete, and the appropriate negotiations or controls are executed. Upon completing the negotiation, communication is permitted to commence from either side, as applicable.
2. Only platform side control is necessary: Following a successful discovery and compatibility check, engaging an interface might only require platform side control. For example, [CEM] supports legacy JTAG terminations by default. Upon discovery of a Flex I/O USB capability and compatible platform support, the platform must change from the default JTAG pin functions to USB 2.0. Note that this can be done with one control since no special break-before-make is needed to be electrically safe and USB 2.0 specification compliant.
3. Only peripheral or adapter side control is required: Commanding an adapter to perform specific engage or disengage operations must use a to-be-defined MCTP-based control method.
4. Both the platform and adapter side controls are necessary: Commanding a peripheral subsystem to perform specific engage and/or disengage operations must use a to-be-defined MCTP-based control method. Commanding the system side to perform specific engage and/or disengage operations is permitted to use implementation specific controls, such as a multiplexor select. It is important to use the engage and disengage order and other guidelines below.

12.3.2.5 General Flex I/O Control Guidelines §

1. Engagement Order: “Engaging” a Flex I/O is defined as enabling desired interface circuitry, connectivity and/or starting communication. Caution should be taken when electrically engaging an interface. Where applicable, the following order is advised.
 - **First:** Platform side. This is the PCI Express Link downstream facing port side.
 - **Second:** Interposer, adapter, or component side. This is the PCI Express Link upstream facing port side.
2. Disengagement Order: “Disengaging” a Flex I/O is defined as disabling or reverting to default interface circuitry, severing connectivity and/or ceasing communication. Where applicable, the following order is advised.
 - **First:** Interposer, adapter, or component side. This is the PCI Express Link upstream facing port side.
 - **Second:** Platform side. This is the PCI Express Link downstream facing port side.
3. Re-configuration Order: Reconfiguration might be desired between two functions or from an active Flex I/O interface type back to default state. The “break-before-make” paradigm is recommended by using the disengagement, followed by engagement order prescribed above. The duration between the break and the make steps is form factor specific. An example is to ensure that a higher voltage function is sufficiently drained before engaging a lower voltage function that might be intolerant to the higher voltage.
4. Forced Disengagement: Flex I/O functions are required to disengage upon the power state of the platform, interposer, adapter, or component dropping below the minimum negotiated power level or outside of the specified electrical operating conditions.

5. Flex I/O Run-time Reconfiguration: Run-time reconfiguration of Flex I/O is allowed when adhering to the guidelines stated within this specification. The logical domain handling of run-time change in Flex I/O functionality is implementation specific.
6. Reset Flex I/O back to defaults: If a Flex I/O signal changes functionality when main power is enabled, it must go back to its default state upon loss of the main power. If Flex I/O functionality changes when only auxiliary power is applied, it must go back to default upon loss of auxiliary power. Adapter or component use of non-volatile information to automatically revert Flex I/O to a previous state is prohibited.

12.3.3 Peripheral Sideband Tunnelling Interface (PESTI) Sidebands §

12.3.3.1 PESTI Introduction §

Peripheral Sideband Tunnelling Protocol (PESTI) is a single wire, half-duplex, bidirectional Universal Asynchronous Receive Transmit (UART) communication channel with a protocol that enables optional discovery and optional, real-time, virtual wire tunnelling between platform and peripheral agents. PESTI enables the minimization of the number of discrete sidebands signals, while extending functionality via scalable, form factor specific, extensible, and real-time virtual wires. PESTI is point-to-point with fanout support that utilizes a bus snooping and bus switching command method. PESTI provides message integrity detection support. PESTI protocol leverages common UART framing to create a simple, low logic, low cost out-of-band payload and signal tunnel. PESTI communication is based on a command and response method (no interrupt) where the peripheral/target is permitted to only transmit data upon request by the initiator. In some applications, PESTI protocol is permitted to occur on top of a traditionally static presence signal, thereby not incurring any extra signal cost for this interface.

This specification describes the base physical and protocol layers, from which form factor specifications are permitted to customize for specific attributes and virtual wire purposes. § Figure 12-11 shows a typical PESTI example for tunnelling virtual wired through a PCI Express Cable for managing the discrete sidebands on an interposer, adapter, or component.

PESTI is not intended to duplicate or replace what can be done over other non-real time interfaces. PESTI also does not currently support higher level protocols inclusive of message encryption.

NOTE: Open Compute Project Modular-PESTI §

The Open Compute Project also supports the identical “Modular-PESTI” [<https://www.opencompute.org/wiki/Server/DC-MHS>] interface and protocol.

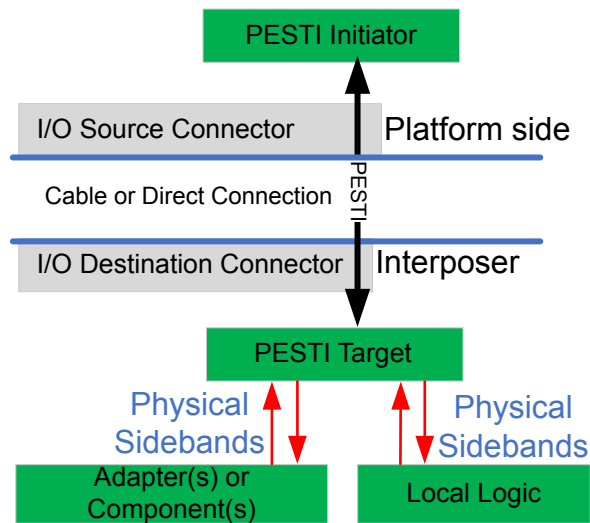

Figure 12-1 Example PESTI Application §

12.3.3.2 PESTI Physical Interface §

PESTI utilizes UART framing, operates directly at 3.3 V logic levels, and is a single, half-duplex signal:

- +3.3 Volt LVCMOS (open drain)
- 250,000 BAUD +/- 2%
- 8-O-1 (8 data bits, Odd Parity, 1 stop bit)
- Half-duplex

Figure 12-2 UART Data Framing §

12.3.3.3 PESTI Electrical Circuit §

The circuit shown in § Figure 12-3 is such that an unpowered ($V_{3P3_Target} = 0$ Volts) component holds the PESTI wire low indicating simple presence. Once the component has power and can respond to a command, the target General Purpose Input/Output (GPIO) sourcing the gate of the P-FET will be driven low. Once V_{3P3_Target} is engaged by turning the P-channel FET on, a rising edge of the PESTI signal is observed at the initiator. For this mechanism to operate as intended, the default state of the target GPIO must be an input (high impedance).

When used as simple presence, the initiator side circuit must remain the same as shown in § Figure 12-3. The adapter or component side circuit can be simplified to a pull-down resistor with a maximum value of 2.27 Kohm +5% tolerance and minimum nominal value of 200 ohm -5% tolerance.

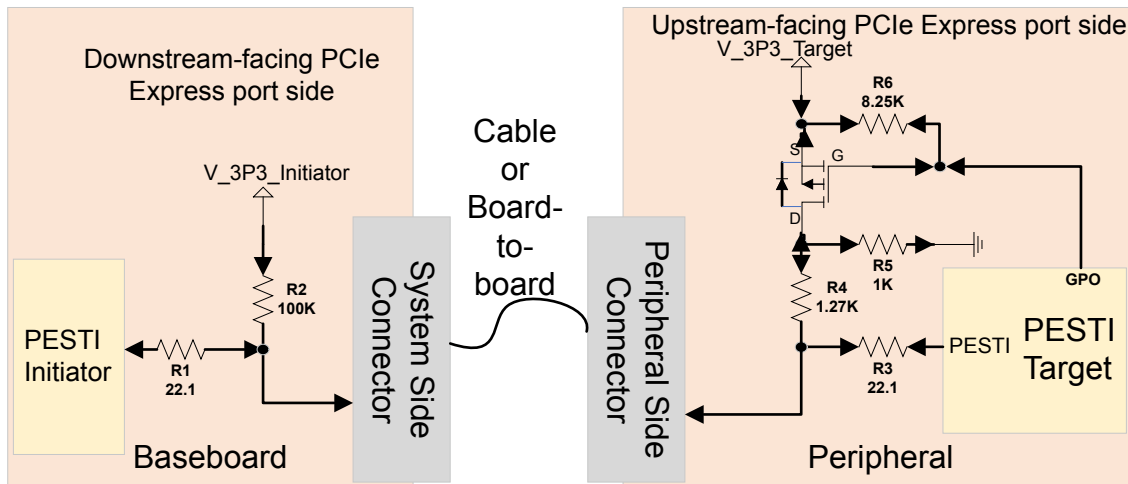

Figure 12-3 PESTI Circuit Diagram §

For non-hot-plug applications, PESTI is permitted to double as the presence signal, thereby incurring no added pin cost. Doing so for hot-plug applications is discouraged due to potential ambiguity or delay in determining a physical presence change versus an unresponsive target. PESTI is permitted to be utilized to indirectly tunnel physical presence status of hot-plug capable downstream targets.

IMPLEMENTATION NOTE: ELECTRICAL COMPONENT SELECTION FACTORS §

Referring to § Figure 12-3 above, **R1** and **R3** are recommended series termination resistor values. The values might require adjustment to the driver and transmission line characteristics.

R2 must be selected considering:

- Select the maximum value to minimize the current sourced into an unpowered target.
- Logic high=1 must be guaranteed to meet the baseboard initiator logic V_{in} High Minimum when cable/PESTI target is not attached/present.

R4/R5 must be selected considering:

- **R4** and **R5** (pull-down) and **R2** (pull-up) must guarantee a logic low=0 at the baseboard initiator logic if detection of an unpowered target is desired.
- **R4** value provides the rise time to a logic high at the initiator or target for an open-drain interface.
- **R5** provides a path to GND for the current sourced by **R2** on the source board to drain or bleed voltage accumulation at an unpowered target.

12.3.3.4 PESTI DC Specifications §

Table 12-2 PESTI DC Specifications §

Symbol	Parameter	Min	Max	Units	Comments
VDD	Bus Voltage	3.135	3.465	V	3.3 +/-5%
VIH	HIGH level input voltage	2.0		V	3.3 V LVCMOS
VIL	LOW level input voltage		0.8	V	3.3 V LVCMOS

12.3.3.5 PESTI Target Detection §

Presence of a PESTI target is characterized by a rising edge of PESTI. The default input state of PESTI at an initiator is HIGH=1 indicating that there is no adapter or component present. If the PESTI signal is observed as static low for more than t_{DBREAK} (See § Table 12-5), that target adapter or component is indicating simple presence. A rising edge of the PESTI signal indicates to the initiator that a target is ready to receive and process commands.

A UART BREAK event is when the wire is being driven/held low for a time greater than the entire frame length. Example: At 250 KBAUD, the PESTI frame length is nominally $4 \mu s * 11\text{-bit positions}$ which is $44 \mu s$. PLD logic is permitted to detect a BREAK condition by starting a timer at the falling edge of the signal. A valid BREAK assertion does not require a falling edge to be detected. In some cases, target UART receiver logic is permitted to not implement a BREAK detect status register. Depending upon the UART implementation, a BREAK event is permitted to present itself in status registers as an abnormal frame with a data value = 00h that has both a Parity Error (PE) and a Framing Error (FE: Stop bit = 0).

A valid PESTI frame is characterized by a Start bit of LOW=0, Stop bit of HIGH=1, and an odd number of ones (including Parity).

Target Detection Rules:

1. An initiator must not attempt communication while PESTI is held low (simple presence) by the target.
2. A PESTI target must not release BREAK until it is ready to respond to the payload request command.
3. Minimum low (BREAK) assertion width required to guarantee detection at the initiator is t_{DBREAK} .
4. An adapter or component is permitted to request a re-start of the discovery process by asserting and releasing BREAK at any time prior to the transition to the active phase (see § Section 12.3.3.6.2).

The PESTI circuit shown in § Figure 12-3 guarantees that BREAK will be asserted from the time that platform input power is applied to the time that the target is powered and ready to respond to a command.

12.3.3.6 PESTI Protocol Commands §

12.3.3.6.1 Discovery Payload Request (DPR) §

PESTI compliant targets must support the following command.

- Discovery Payload Request: Data Byte Value = 00h

Following PESTI target presence detection, the initiator will transmit the payload request command to the target. The target response is to transmit the contents of its discovery payload for capture by the initiator. See See § Table 12-6 for

payload requirements. The command is permitted to be sent autonomously by a PLD or under the direction of Systems Management Firmware (SMFW). See § Section 12.3.3.9 for initiator interface registers accessible to SMFW.

12.3.3.6.2 PESTI Virtual Wire Exchange (VWE) §

PESTI compliant targets must support the following command.

- Virtual Wire Exchange: Data Byte Value = 01h

Once a target's attributes (number, type, and order of virtual wires) have been identified by parsing the payload, an exchange of virtual wires between initiator and target is permitted to commence. This phase of the protocol is known as the active phase. Virtual wires are optional, and a target is not required to support any virtual wire bytes in or out following the VWE command.

If a PESTI target does not support virtual wires, it must respond with an acknowledge data byte (value = 00h) after receiving the VWE command.

The acknowledge feature can be utilized as a health monitor of the target. Alternatively, SMFW is permitted to disable the active phase by clearing $APEN=0$ (see § Section 12.3.3.9) to disable communication to a target after the discovery phase.

12.3.3.6.3 PESTI Fanout MUX Control §

The MUX switch control command must be supported in PESTI fanout control components only.

- MUX/switch control: Data Byte Value = 02h

See § Section 12.3.3.14 for additional details.

12.3.3.7 PESTI Initiator Abort §

A PESTI transaction sequence is defined as a series of data bytes exchanged between an initiator and a target. A sequence begins with the initiator transmitting one or more data bytes to the target. The sequence ends when the initiator receives the expected number of data bytes from the target. During the active phase, a target is required to recognize that a sequence is being terminated prior to its completion. The conditions for requiring termination of a sequence are architecture and implementation specific.

During Initiator Transmission:

In place of a valid data frame, the initiator is permitted to assert a BREAK condition to cancel a sequence that is in progress. The initiator must not interrupt a data frame after the Start bit has been sent. If an event occurs that requires an abort after a Start bit has been transmitted, the initiator must not assert BREAK until t_{TIDLE} (See § Table 12-5) after the previous Stop bit has been transmitted. When this sequence is observed by a target, it must ignore previous data bytes in that sequence and prepare for the start of the next sequence.

During Target Transmission:

The initiator abort assertion is permitted to occur at any point within a target transmitted frame. It is permitted to also occur during the active phase turn around period between initiator transmit and target transmit. In this case, it would be asserted following the Stop bit of the final byte transmitted by the initiator. The assertion width (t_{ABREAK} ; See § Table 12-5) is guaranteed to be detected by a target that samples the PESTI logic state prior to transmitting any Start bit in the

sequence. When an abort is detected, a target must not attempt to transmit any additional bytes and prepare itself for a new sequence start from the initiator.

12.3.3.8 PESTI Broadcast §

To minimize initiator logic, a single UART instance is permitted to be shared (multiplexed) among several targets. Multiplexing requires that targets be serviced in a round-robin rotation. Round-robin servicing has a limitation that responses cannot be captured from multiple targets simultaneously. However, an initiator is permitted to implement logic to transmit a command to several targets in parallel.

A broadcast sequence is characterized by the first byte of the sequence beginning with a data byte value of FFh. The second byte of the sequence is the command. An initiator must not use the broadcast command to request data or an acknowledge from any target. A target must not respond to the broadcast command with data or an acknowledge back to the initiator.

An example application is the Power Brake (e.g., PWRBRK#) sideband signal is permitted to be a virtual wire used to rapidly reduce power consumption of multiple adapters or components. PESTI initiators that implement a shared UART must support broadcast of a Power Brake event.

Figure 12-4 PESTI Broadcast Command §

Round-robin servicing naturally staggers PWR_BRK de-assertion during a virtual wire exchange which is a common platform preference to avoid excessive inrush current from high power loads. Additional delay between PWRBRK# de-assertion to multiple targets is implementation specific and controlled via SMFW and initiator logic that feeds into the appropriate PESTI channel.

An initiator is permitted to issue broadcast commands back-to-back without waiting for a response.

12.3.3.9 PESTI Initiator Control and Status Registers §

§ Table 12-3 defines the initiator register bits enable control and status indicators for each connected PESTI wire.

Table 12-3 PESTI Initiator Control and Status Registers §

Field Name	Description	Attributes
DISCOVERY_STATUS [1:0] (a.k.a. DSTAT)	00b No BREAK detected; PESTI wire is static HIGH=1 (<i>Default</i>)	RO
	01b PESTI wire is static LOW=0 (simple presence).	
	10b Discovery payload has been received with a good checksum.	
	11b BREAK release detected, but payload has not been successfully received.	
	Initiator implementation requires the following behavior:	

Field Name	Description	Attributes																		
	<ul style="list-style-type: none"> Once a BREAK release is detected, the allowable DSTAT values must exclude 00b until the next fundamental PLD reset or cycle of platform input power. If APEN=1b and DSTAT=10b, then the target component is in the active phase and a BREAK condition on the PESTI wire must not transition DSTAT to a value of 01b. If APEN=0b, then a BREAK asserted by the target will result in DSTAT=01b. See § Section 12.3.3.13 for more information. <p style="text-align: center;"><i>Table 12-4 PESTI Discovery Status State Transitions</i> §</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">DSTAT Current State</th> <th style="text-align: center;">DSTAT Future State</th> <th style="text-align: center;">State Input</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">xxb (Any State)</td> <td style="text-align: center;">00b (Absent)</td> <td>Power on Reset (POR)</td> </tr> <tr> <td style="text-align: center;">00b (Absent)</td> <td style="text-align: center;">01b (PRSNT#)</td> <td>BREAK asserted following POR de-assertion or an unpowered adapter or component is present or a static presence</td> </tr> <tr> <td style="text-align: center;">01b (PRSNT#)</td> <td style="text-align: center;">11b (PESTI Presence)</td> <td>BREAK release by the target, simple presence or PESTI component removal prior to target BREAK release while platform power is on.</td> </tr> <tr> <td style="text-align: center;">11b (PESTI Presence)</td> <td style="text-align: center;">10b (Payload Good)</td> <td>Discovery Payload received without any errors</td> </tr> <tr> <td style="text-align: center;">10b (Payload Good)</td> <td style="text-align: center;">11b (PESTI Presence)</td> <td>BREAK assertion and release by target if not in active phase. Figure 12-5 PESTI Protocol Phases §

12.3.3.10 PESTI AC Specifications §

Table 12-5 PESTI AC Specifications §

Symbol	Parameter	Min	Max	Units	Comments
t_{BAUD}	BAUD rate	245000	255000	Hz	250000 +/- 2%
t_{FRAME}	Start +8b Data +Parity +Stop	42.7	45.3	μ s	$1/t_{BAUD} * 11$ bits
t_F	Fall Time	-	120	ns	Same as 1 MHz [SMBus] (VIH,MIN + 0.15 V) to (VIL,MAX - 0.15 V)
t_R	Rise Time	-	120	ns	Same as 1 MHz [SMBus] (VIL,MAX - 0.15 V) to (VIH,MIN + 0.15 V)
t_{SPIKE}	Noise Spike suppression time	0	50	ns	Same as 400 kHz [SMBus]. Noise suppression is recommended.
t_{ABREAK}	Initiator Abort	50	55	μ s	Synchronous to a normal START of frame when the initiator is transmitting. Asynchronous to START when the target is transmitting.

	BREAK assertion time				
t_{DBREAK}	Target Discovery BREAK assertion time	50	-	μs	PESTI target BREAK can persist
t_{BPAUSE}	Broadcast Pause	20	-	μs	Pause to allow fanout snooper completion of channel enables
t_{IIDLE}	Initiator End of STOP to START	0	-	ns	STOP is typically sampled at the midpoint of the bit, so there is approximately 2 μs of time to the next START.
t_{TIDLE}	Target End of STOP to START	-	1000	ns	This is required for the target to sample for initiator abort prior to START of target TX.
t_{MARK}	End of BREAK to START time	3.88	4.12	μs	MARK time is 1 BAUD period between end of initiator abort BREAK and START of new command
t_{DPTAR}	Discovery Phase Turnaround Time	100	-	ns	MAX not specified. It is bound by payload size and <u>t_{DPRT0}</u> .
t_{APTAR}	Active Phase Turnaround Time	0.1	200	μs	Between Target RX and Target TX of a response. MAX reduces time to sample initiator BREAK/Abort signal just before START. Target MCU should not have trouble meeting minimum time required to allow the initiator to prepare for RX following TX.
t_{DPRT0}	Discovery payload receive timeout	-	250	ms	Allows for 150 ms <u>t_{DPTAR}</u> + 2048-byte payload size.
t_{APRT0}	Active Phase receive timeout	-	500	μs	Includes margin beyond <u>t_{APTARMAX}</u> + 8* <u>t_{FRAMEMAX}</u> + 7* <u>t_{TIDLEMAX}</u> = 389 μs
t_{APBI}	Active phase bus IDLE time	10	-	μs	Between initiator RX from target and initiator TX to same target
t_{MSC_WDT}	Mux Switch Control Watchdog Timeout	100	-	ms	Time for a snooper to detect a stuck bus following a downstream channel select operation

12.3.3.11 PESTI Discovery Phase §

A PESTI target is required to support the DPR command when simple presence is not implemented. Payload format requirements enable the initiator implementation to be common and target agnostic. The discovery payload is typically consumed by the initiator logic (e.g., SIZE, CHECKSUM) and SMFW. The payload contents can be scaled to meet vendor requirements.

Discovery Phase Command and Target Response

Figure 12-6 PESTI Discovery Command and Response Format §

Discovery Payload Turnaround Time (t_{DPTAR}): Maximum time allowed between initiator completing transmission of the DPR command and the response beginning to be received at the initiator.

Discovery Rules

Following the BREAK de-assertion by a PESTI target, the initiator must transmit the discovery request command to that target if $DPEN=1$.

- Turnaround time from target command received to start of response transmission has a minimum requirement of t_{DPTAR} .
- A target must complete the discovery payload response within the payload RX timeout of t_{DPRTO} .
- If a target BREAK condition is observed by the initiator with $APEN=0$, $DSTAT[1:0]$ must be transitioned by logic to 11b (Discovery not complete) until a new payload is received successfully.
- The initiator must not transmit the VWE command unless a successful discovery payload is received and $APEN=1$.
 - Success means within the RX timeout period (t_{DPRTO}) with no byte parity or framing errors and a verified checksum.
- While $DPEN=1$, an initiator must continuously attempt to retrieve a discovery payload from a PESTI target that is present.
 - Example: Round-robin servicing by a single initiator UART to multiple targets:
If the discovery payload is not successfully received after an initial attempt plus two retries per target, the next target in the round-robin rotation will be serviced. When servicing returns to the target, the discovery request command is sent again as a set (initial + two retries) until successful.

If a target is unresponsive, the minimum time between successive transmissions of the DPR command from initiator to any target is t_{DPRTO} . Retries described in the example above are applicable to round-robin implementations only and not a requirement of this specification and is left to the initiator implementation.

Discovery Payload

The minimum required payload (8 bytes) is shown in § Table 12-6 for the case when simple presence is not implemented. The payload size must be a multiple of eight bytes including the checksum.

Table 12-6 PESTI Discovery Payload §

Byte/Bit	7	6	5	4	3	2	1	0
00h	**PAYLOAD_FORMAT_VERSION [7:0]**							
01h	**DISCOVERY_PAYLOAD_SIZE [7:0]**							
02h	**VENDOR_ID [15:0]**							
03h	**VENDOR_ID [7:0]**							
04h	**DEVICE_CLASS [7:0]**							
05h	**DEVICE_ID [15:8]**							
06h	**DEVICE_ID [7:0]**							
07h	RSVD	RSVD	RSVD	RSVD	RSVD	RSVD	**PEC_SUPPORT**	**VENDOR_ID_FORMAT**
08h to (N-1)h	Optional Vendor Specific Region (Varies)+ **Padding (0 – 7 Bytes)**							
Nh	**Checksum**							

Notes:

**Required region

***Minimum value of N=1, Maximum value of N=2040

PAYLOAD_FORMAT_VERSION[7:0]

Indicates the payload format version. This field must be 02h. 01h is used by the Open Compute Project.

DISCOVERY_PAYLOAD_SIZE[7:0]

Indicates the total static payload size. The value of this bit field represents (payload total # of bytes / 8) - 1.

VENDOR_ID[15:0]

Utilize the PCI-SIG assigned Vendor ID, when available. If the vendor does not have a PCI-SIG Vendor ID (which applies to PESTI included subsystems such as a power converter board or a cable), then set VENDOR_ID_FORMAT = 1.

DEVICE_CLASS[7:0]

Indicates the device class of the PESTI target peripheral

Note that a given form factor is permitted to define specific module classes.

DEVICE_ID[15:0]

Vendor specific with intent to represent a unique type of device. Not intended for unit specific information such as a serial number.

VENDOR_ID_FORMAT

0 = PCI-SIG assigned Vendor ID of the company delivering the adapter or component with the PESTI target

1 = Non-PCI-SIG assigned Vendor ID. e.g., Open Compute Project assigned.

PEC_SUPPORT

1 means that the target supports packet error byte checking (PEC) on command, write data, and read data returned to the PESTI initiator.

RSVD

Reserved for future use

Vendor Specific Region

Optional, implementation specific and is recommended to contain its own sub-payload version.

CHECKSUM[7:0]

CRC-8 with polynomial=0x07, Seed=0x00 is required in the discovery payload.

12.3.3.12 PESTI Active Phase §

Once a PESTI is transitioned to the active phase, the initiator autonomously exchanges hardware controlled virtual wires with each target component. The HW controlled virtual wire inputs and outputs are target DEVICE CLASS[15:0] specific. The number of bytes in and out and their respective usages are fixed per device class.

If the number of virtual wire bytes out is zero, the initiator will skip transmitting Virtual Wire Output (VWOUT_0) and wait to receive any Virtual Wire Input (VWIN_N) bytes. If the number of virtual wire bytes is zero, then an acknowledge target response of 00h is required from the target, whenever one is expected at the initiator. SMFW is permitted to clear APEN=0 so that the VWE command is not transmitted, and the bus will remain idle until the next power on reset or re-entry to the discovery phase.

Virtual Wire Exchange Example (1 Byte Out/In)

Figure 12-7 Single Byte PESTI Virtual Wire Exchange §

Virtual Wire Exchange Example (N Byte Out/ M Byte In)

Figure 12-8 Multi-byte PESTI Virtual Wire Exchange §

Active Phase Rules

1. Minimum PESTI idle period between initiator RX of the previous target response & TX of the next target command is t_{APBI}
2. While $ASTAT=1$, $DSTAT$ must remain 10b (Discovery Complete)
3. A target assertion of BREAK while $ASTAT=1$ must result in $APERR=1$.
4. A target must wait a minimum of t_{APTAR} before transmitting a VWE response.
5. A target must complete a response to the initiator within the RX timeout of t_{APRTO} .
6. The maximum period between commands sent from an initiator to that same target is not bound by this specification. The active phase of any component is under the control of SMFW and can be disabled.
7. If target supports virtual wire OUTs only, the target must respond with 00h back to the initiator as confirmation of receiving the OUTs.
8. SMFW is permitted to clear $APEN$ to disable the active phase for a component.
9. Asymmetrical number of out and in bytes is permitted.

The method to route virtual wires to/from internal platform logic or other entities and the PESTI is outside the scope of this document. The usage of the virtual wires (internal commands/policies or connections to local physical signals) by the target is also outside the scope of this document.

Example VWIRE Bit Mapping Definition

Below is an example of how a form factor, such as an interposer to a [CEM] slot, is permitted to map legacy wires onto virtual wires over PESTI.

Table 12-7 Example VWIRE_OUT_0 (Initiator to Target) §

7	6	5	4	3	2	1	0
RSVD	RSVD	RSVD	RSVD	RSVD	RSVD	S0_RUN	PWR_BRK
PWR_BRK		Active high (1=Assert, 0=De-assert) virtual wire					
S0_RUN		Active high (1=True, 0=False) virtual wire indicating platform power state is in ACPI S0.					
RSVD		Reserved for Future Use					

Table 12-8 Example VWIRE_IN_0 (Target to Initiator) §

7	6	5	4	3	2	1	0
RSVD	RSVD	RSVD	RSVD	RSVD	RSVD	RSVD	WAKE
WAKE		Active high (1=Assert, 0=De-assert) virtual wire indicating the target component request to enter the ACPI S0_RUN state.					
RSVD		Reserved for Future Use					

Packet Error Checking

Packet Error Checking (PEC) is optional in the initiator and target. PEC is recommended in the active phase when information integrity is critical to the application (e.g., an errant control may cause more ill effects than a bit flip on an analog read that gets averaged out over time). A target's PEC support is described in a discovery payload bit. PEC utilizes CRC-8. Enabling PEC adds to active phase latency.

When supported by the target and set by the initiator, the one-byte command (CMD) bit 7 indicates to the target that the PEC byte is being delivered following with the command byte.

Example: CMD=81h, VWOUT_0, PEC, Turnaround, VWIN_0, PEC

If the target indicates no PEC support in the discovery payload, then the initiator must not set bit 7 in the CMD nor deliver an extra PEC byte following the command. This is because following the turnaround, the target may drive contention on against the incoming PEC byte.

If the CMD to target has bit 7 set indicating PEC:

1. The initiator must supply the PEC byte.
2. If the PEC check at the target fails, then the target must drop the command and, if applicable, receive payload. A method to indicate from target to initiator that a PEC failure occurred is out of scope of this specification.
3. The target must append a PEC byte to the end of the active phase payload response (just as it does for the discovery payload).
4. If the initiator calculates a bad PEC on the target response message, the initiator must drop the response. Further handling, such as retries, is implementation specific.

For commands such as CMD=00h for get discovery payload, PEC is optional, since the 1-byte command has parity.

Example Supported Commands with and without PEC

01h = Put 1 Virtual Wire Byte, Get 1 Virtual Wire Byte

81h = Put 1 Virtual Wire Byte with PEC, Get 1 Virtual Wire Byte with PEC

12.3.3.13 PESTI Target Reset and Fault Handling §

If the target resets during the discovery phase prior to the entry to the active phase (e.g., APEN=0), the DSTAT value would revert to 11b (Payload not received.) The initiator would autonomously send the payload request command if DPEN=1. The target component would not be transitioned to the active phase until DSTAT=10b. If discovery had not previously completed or DPEN=0, the component would not be discovered and would not transition to the active phase.

If the target resets during the active phase, it must be observed as temporary unresponsiveness at the initiator. This would be reflected in the ACTIVE_PHASE_ERROR (APERR) register bit if any RX timeout or parity error occurred. Following target reset, a BREAK assertion and release would be observed by the initiator. During the active phase (DSTAT[1:0]=10b & APEN=1), DSTAT must be locked. Locking the discovery status and payload data is required so that FW can safely consume the contents at any warm or cold reset. Since discovery has already occurred, the initiator would resume sending the virtual wire exchange command and the target would not observe a discovery request command. Once a component has transitioned to the active phase, the only method to unlock the discovery payload and status is by SMFW clearing, then setting DPEN.

12.3.3.14 PESTI Fan-Out §

Applications where the ability to fan-out a PESTI bus to multiple targets exist. Since the number N is not a priori known by the motherboard, and pre-plumbing for a maximum quantity requires additional interconnects, PESTI fan-out support helps scale the ability to support PESTI type features.

This specification version includes the scope of fanout from between 2 to 8 downstream buses. Although out of scope, nesting of multiple tiers of fan-out within a single hierarchy is possible with additional command codes and circuitry. In all fanout cases, it is left to the designer to understand the latency effects of fanout width (and depth). Two methods are shown where the MUX method is for typical fanout needs and the Switch method is targeted for applications that require the ability to broadcast commands simultaneously with all targets.

Two fanout methods of operation include the MUX and Switch methods (see circuits below):

- MUX method: Typical 1-to-many fanout. Broadcast commands are not supported.
- Switch method: For applications requiring broadcast commands to all attached targets.

Two modes of operation for a fanout controller include Target Mode and Snoop Mode:

- Target Mode (Default):
 - Controller acts as a target supporting discovery and active phases.
 - Only the fanout controller is permitted to be attached to the initiator bus.
 - MUX Method: No channels are selected.
 - Switch Method: Fanout controller on Ch0 is always enabled; all others default disabled.
 - Must support =1 status command for the initiator reading information from the fanout controlling PESTI target such as:
 - The current MUX/switch settings
 - If an issue was observed such as a closed switch bus hang watchdog timeout
 - Live status of downstream subsegments (when the MUX or switch is open for a particular subsegment)
- Snoop Mode:
 - Fanout controller must enter snoop mode any time any other target(s) are attached to a bus.
 - Is permitted to process broadcast commands if application relevant.
 - Listen/Process only special fanout control commands (MUX Select or Switch channel enable), thereby ignoring discovery and target mode active phase commands intended for other targets.

Example MUX Select commands are permitted to include:

- Go to Target Mode and de-select all subsegments.
- Select specific subsegment(s) as connected, which can be comprised of 1, all or select groups.

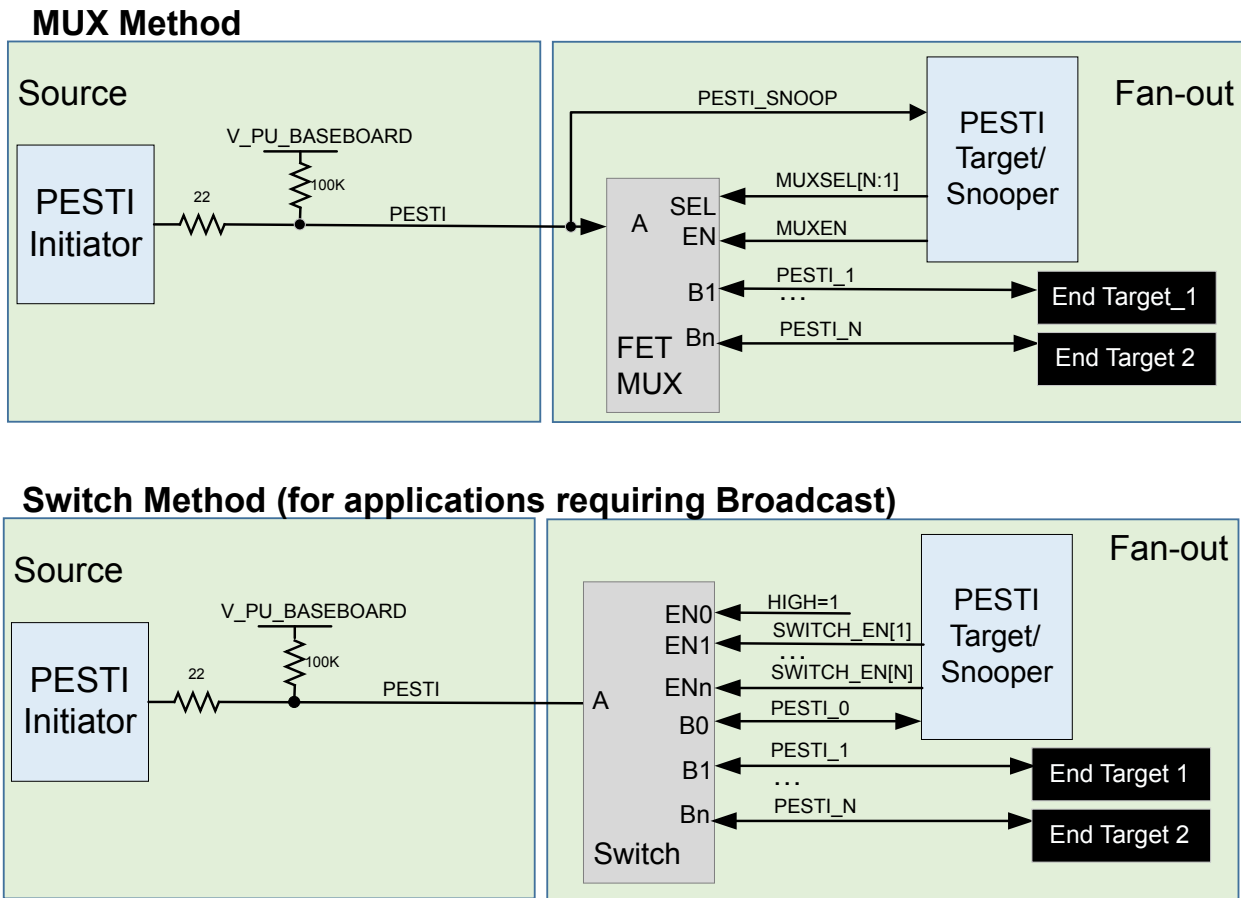

Figure 12-9 PESTI Fan-out Methods §

Buffer(s) might be necessary if the Target/Snooper and the FET MUX or Switch have significant layout stubs. The designer is permitted to choose a switch with active buffers versus a FET switch to avoid reflection effects.

Since any downstream interface is permitted to have a strap (such as a strong presence pulldown resistor) or be in a stuck state driving high or low, it is imperative to not create a deadlock condition where the Fanout controller cannot observe new commands to change the MUX or switch settings. Therefore, it is required to have the fanout controller implement a watchdog timer of at least t_{MSC_WDT} after closing one or more channels to oversee any signaling activity. If no such activity (rising or falling edges), the PESTI snooper must open the selected channel(s) after the timeout.

An alternative option is for the fanout controller to always be able to observe and report upstream the state of any downstream sub-channel so that the PESTI initiator can choose to not close a suspect channel.

MUX Switch Control (MSC) Command Structure

Table 12-9 MSC_CTRL_VAL (Initiator to PESTI Snooper Target) Data Byte Value = 02h §

7	6	5	4	3	2	1	0
RSVD	RSVD	RSVD	DS_ALL_CH_SEL	DS_CH_SEL[2:0]		ENABLE	
ENABLE		Active high (1=Enable, 0=Disable)					

7	6	5	4	3	2	1	0
When the mux or switch is disabled, only the snoopers target can receive communication from the initiator. All downstream MUX or switch channels must be disabled.							
DS_CH_SEL[2:0]		Hex representation of downstream channel select (0...7 decimal). This bitfield is only used if ENABLE = 1b and DS_ALL_CH_SEL = 0b.					
DS_ALL_CH_SEL		When set to 1b, then all downstream channels are connected. Used for broadcast commands only. This bitfield is only valid if ENABLE = 1b. When this bitfield is set to 1b then DS_CH_SEL bitfield must be set to 000b.					
RSVD		Reserved for Future Use.					

Table 12-10 MSC_STAT_VAL (PESTI Snooper Target to Initiator) §

7	6	5	4	3	2	1	0
RSVD						NOT_ACK	
NOT_ACK		Not Acknowledge					
0b		Success					
1b		Error					
RSVD		Reserved for Future Use.					

Figure 12-10 PESTI Mux Switch Control Format §

Fanout Rules:

1. PESTI snoopers must not be nested. Only a single fanout level is supported.
2. A PESTI snooper fanout target must default to all downstream PESTI channels disabled during the discovery phase.
3. A PESTI snooper must not respond to a discovery payload request command = 00h when any downstream channel is selected.
4. A PESTI snooper must not respond to any virtual wire exchange using command 01h when any downstream channel is selected.
5. Except for when broadcast commands are supported and transmitted, only a single downstream channel of a Switch can be selected at any given time.
6. Non-snooper targets must ignore argument(s) following the MSCMSC command = 02h.
7. On any PESTI that a fanout switch is present, the initiator must begin any broadcast with the following sequence:

- Broadcast start value = FFh
 - Wait for t_{BPAUSE} (Broadcast Pause)
 - Resume with typical broadcast sequence of FFh (repeated) followed by the broadcasted command value(s).
8. A fanout switch snooper must enable all downstream channels at any start of a broadcast indicated by 0xFF as the first, or repeated, data byte of a sequence.
 9. Once the broadcast sequence is complete, the initiator must utilize the MSC command to select a single downstream channel of any switch or MUX prior to resuming typical communication.

12.3.3.15 PESTI Security Considerations §

Although PESTI is a basic, low-level data communication channel the following threats are identified with possible mitigations, although the specific mitigations are implementation specific.

Threats

1. Physical implant/signal re-routing: Assurance, where applicable, that the PESTI target is on the same HW (or same target) as other management interfaces. Security Protocols and Data Model (SPDM) types of security capabilities are the likely current method used to address this treat.
2. Physical implant, man-in-the-middle snooping or alteration of payloads or virtual wires in flight. Potentially mitigated with encrypted payloads most likely using SPDM defined methods.

12.4 Managed USB 2.0 §

Numerous use cases exist for USB 2.0 as a plug-and-play, out of band management interface, such as:

- Adapter or component firmware update, telemetry, debug, and security operations such as attestation, recovery, and measurement.
- MCTP direct to an adapter or component.
- TCP/IP or Network Controller-Sideband Interface (NC-SI) traffic.
- Bridge to common low-level interfaces such as GPIOs, UARTs, SPI, I3C and JTAG.

USB Rules:

1. The USB Host must be on the platform side of the form factor interface.
2. USB 2.0 high speed and full speed modes are supported.
3. USB 2.0 low speed and USB 1.1 mode devices are prohibited when directly connected to the form factor interface but are allowed when attached to a downstream port of a device side USB hub.
4. USB 2.0 low speed is prohibited due to USB 2.0's support of larger packet sizes as well as common handling of Flex I/O default terminations and D+ pullup-based attach detection (e.g., CEM JTAG vs USB Flex I/O alternate function rules).
5. USB 2.0 voltage through form factor interfaces must be 3.3 V to support standard discrete components such as bridges and hubs and to provide maximum signaling margin for long busses. Voltage translation when connecting USB 2.0 to components that do not support 3.3 V is implementation specific.

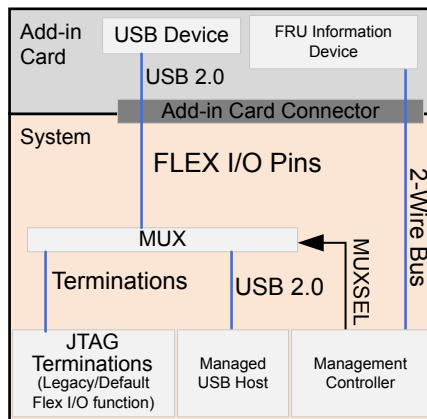

Figure 12-11 [CEM] form factor example circuit for repurposing legacy JTAG to USB 2.0 mode §

12.5 2-Wire Interface §

[I2C] and [SMBus] are long standing and useful bus interfaces that are expected to be fully supported for the foreseeable future. Form factor specifications dictate the electrical particulars, such as the reference voltage, power domain, peripheral capacitive loading and define such an interface as being required, optional or unsupported. Although the SMBUS specification is stable in terms of revisions, especially at the electrical level, it is always encouraged that form factor specifications attempt to reference the latest versions of the [SMBus] specification when possible. [SMBus-3.2] version 3.2 is the preferred minimum version at the time of this writing due to support for the Default Target Address feature, while using inclusive terminology. The remainder of this specification refers to [SMBus] and not [I2C]. However, [I2C] compliant components that are not [SMBus] compliant, such as an EEPROM or MUX, are permitted at the designer's discretion.

MIPI [I3C-Basic] is an additional protocol option that shares the same physical 2-wire interface as the [SMBus] interface. This specification defines a backward-compatible method of discovering and enabling the optional [I3C-Basic] mode on the existing 2-wire interface. The [I3C-Basic] architecture includes an optional intermediary component known as 2-wire Hub (see § Section 12.5.3.3) to addresses specific [SMBus] challenges related to asynchronous communications. [I3C-Basic] defines the protocol, including its electrical characteristics. The recommended PCI Architecture to allow interoperability with legacy adapters is for the platform to use the 2-wire Hub which provides a method for a transition between [I2C] / [SMBus] and I3C. Legacy [SMBus] and [I3C-Basic] have different electrical requirements which needs to be considered in the platform design. The [I3C-Basic] provides a common electrical requirement definition across all PCIe form-factor connectors (interfaces).

Common Interface and Signal Names

Historically, the [SMBus] interface and signal names were used in various form factor specifications. With the addition of optional I3C interface on the same pins, the following generic terms should be utilized, when referring to either [SMBus] or I3C:

1. "2-wire interface"
2. Signal names "SCL" for the serial clock wire and "SDA" for the serial data wire

12.5.1 2-Wire Interface Use Cases §

Throughout this section, the generic term 2-wire interface references either [SMBus], [I2C], or [I3C-Basic].

Table 12-11 2-wire Interface Example Usages §

Functionality	Typical Applications
Field Replaceable Unit (FRU) Information	Discovery of Hardware inventory, capabilities such as bus topologies, features supported, etc.
Security	Attestation of HW/FW, Root of Trust for Measurement, Root of Trust for Update, Root of Trust for Recovery, Data Encryption
Configuration / Controls	Flex I/O, Link subdivision
Update	Peripheral Subsystem Firmware
Health	Error Causes, Crash Dump Logs, Temperature, External Link States
Telemetry	Power, Throughput

12.5.2 2-Wire Addressing §

To ease topology and component discovery operations, § Table 12-12 lists common SMBus default target addresses recommended to be used by all PCI Express-based form factors, when such component exist. Components supporting both SMBus and I3C modes must stop responding to their original SMBus address(es) upon transitioning to I3C mode, as described in § Section 12.5.4.2.

§ Table 12-12 identifies the recommended addresses for specific SMBus usages. Note that a card carrier is defined as one with a connector edge based on a form factor that includes connector slots based on one or more instances of the same or different form factor, sometimes referred to as passenger slots. An example is a [CEM] card carrier containing one or more M.2 form factor slots.

IMPLEMENTATION NOTE: RECOMMENDED 2-WIRE INTERFACE ADDRESSES §

All implementations are recommended to use the addresses in § Table 12-12 for the listed usages to ease discovery. For all usages, any address other than the ones listed in § Table 12-12 are permitted.

Platform makers should avoid these listed addresses on the same subsegments.

For maximum backward compatibility, platform makers should not include any component addresses on the same (sub)-segment that connects to the form factor.

The addresses shown have synergy with other industry standards such as [NVM-Express].

Table 12-12 Baseline SMBus Recommended Default Target Addresses [§]

Default Target Address: Binary with x indicating R/W (Hex 8-bit/Hex 7-bit)	Recommended Usages
1010 010xb (A4h/52h)	Recommended for FRU Information Device on a card carrier ¹
1010 011xb (A6h/53h)	Recommended for FRU Information Device on a PCI Express-based adapter or component ¹ .
0011 101xb (3Ah/1Dh)	Recommended for Primary MCTP-compliant Management Target ²
1101 010xb (D4h/6Ah)	Recommended for Secondary MCTP-compliant Management Target ³
1110 100xb (E8h/74h)	Recommended for Addressable SMBus MUX, if applicable
1110 000xb (E0h/70h)	Recommended for 2-wire Hub ⁴

Notes:

1. The FRU Information Device is a typically an optional element. Form factor specified features that need out-of-band discovery descriptors must make the FRU Information Device required and available in the appropriate earliest discoverable power state (auxiliary and/or main power).
2. Primary MCTP target: This target must operate when main power is applied. This interface is permitted to operate when only auxiliary power is applied.
3. Secondary MCTP target: This target is permitted to operate when auxiliary and/or main power is applied.
4. 2-wire⁴ Hubs must default to the static address listed and are then permitted to be changed via register programming or via [I3C-Basic] Dynamic Addressing.

Interposer discovery details are left to the implementer, with designer care needed to avoid address conflicts if the 2-wire interface extends into standard form factors.

End Form Factors on a Carrier in SMBus mode

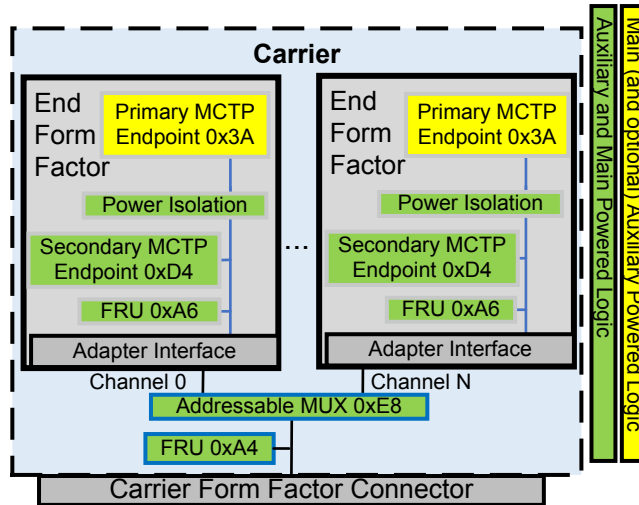

Figure 12-12 Example of 2-wire, 8-bit addressing for a card carrier with N end form factors in SMBus mode §

12.5.3 2-wire Bus Sharing §

The subsections describe 2-wire interface sharing options for fanout on an adapter or component or between form factor instances.

12.5.3.1 2-wire Multi-Drop Topology §

A multi-drop topology with a 2-wire interface is permitted. In platform topologies utilizing a multi-drop 2-wire interface, unique addresses must be assigned:

- Either statically (e.g., using a unique slot identifier control method) or
- Dynamically using SMBus Address Resolution Protocol (ARP) or [I3C-Basic]'s Dynamic Addressing.

Caution should be taken as the use of multi-drop 2-wire topology exposes the potential for malicious adapters or components to initiate traffic to other adapters or components on the same subsegment.

12.5.3.2 SMBus MUX Use §

An addressable SMBus MUX is defined as a bidirectional fan-out multiplexer with one upstream channel and one or more downstream channels configured by a 2-wire interface command (not discrete mux select signals) from a Management Controller to select zero or exactly one downstream channel to the upstream channel.

The use of addressable switches, which allow for connecting multiple downstream subsegments to the upstream segment at one time is not recommended, for reasons that include signal integrity, security and addressing complexities.

IMPLEMENTATION NOTE: SECURITY CONCERNS WITH SMBUS MUXES §

Platform implementations utilizing 2-wire switches/MUXes are recommended to mitigate against security risks of errant or malicious adapters or components that could initiate peer-to-peer traffic to other adapters, components, or other platform adapters or components on the same 2-wire segment.

Platform designers are recommended to consider that switches/MUXes interrupt the continuity of the shared bus breaking the arbitration and acknowledgment mechanisms of SMBus. This creates major challenges for implementations utilizing multi-initiator protocols, such as MCTP, especially when:

- MCTP messages initiated by downstream components are spread over long periods of time (e.g., as per [PLDM-Firmware-Update]), or
- asynchronous communication happens (e.g., asynchronous event or alert reporting as [PLDM-Platform-Monitoring-Control]), or
- response times may be difficult to predict, or response messages delayed (e.g., due to complex computations, such as cryptographic ones required for the SPDM attestation flows defined in [SPDM]).

Additional challenges in the above scenarios exist when switches/MUXes interrupt the continuity of the shared bus and:

1. the platform uses MCTP bridging (management controller is not the source of the MCTP communication and thus has more difficulty to predict the MCTP request/response patterns) or
2. downstream port enabling/disabling is not synchronized with SMBus transactions (e.g., truncating the MCTP packets).

Platforms utilizing MCTP protocol in such scenarios are recommended to use a 2-wire Hub component instead (see the next section). Switching to [I3C-Basic] mode may be another alternative to address such challenges but only possible if all downstream components support [I3C-Basic] (I3C is a single-initiator protocol even when running MCTP and it also allows explicit control of I3C in-band interrupts).

12.5.3.3 2-wire Hub Use §

It may be beneficial to use a 2-wire Hub component for reasons including:

- a. Bus capacitance isolation.
- b. Fanout of I3C and SMBus components with I3C in-band interrupt aggregation across all downstream channels.
- c. Voltage translation and power domain isolation.
- d. Using offload capabilities such as SMBus agents to send and receive asynchronous SMBus messages, such as those utilized by MCTP.

An example use of such a 2-wire Hub is presented in § Figure 12-13. This architecture is recommended to address the interoperability challenges existing with simple MUX components, as described in § Section 12.5.3.2 . SMBus endpoints can initiate asynchronous messages even if they do not support I3C mode of operation. I3C mode, which is typically available with such 2-wire Hubs, allows protocol and voltage transition to enable coexistence of SMBus and I3C components.

Figure 12-13 Example of 2-wire Hub Use §

2-wire Hub components should be discovered using the I3C DCR value of 0xC2. See the allocation at [\[I3C-DCR\]](#).

It should be recognized by implementers and form factor specifications that the high signaling rates drive for subsegment capacitance that is significantly lower than the SMBUS specification. This can limit the achievable bus speed or require utilizing intermediary logic such as I3C hubs when considering entire channel characteristics.

12.5.4 [\[I3C-Basic\]](#) Support on Existing SMBus Signals §

Most PCI Express-based platforms have supported [\[SMBus\]](#) as an optional 2-wire interface (i.e., Serial Clock and Serial Data) for adapter or component management purposes. This section defines [\[I3C-Basic\]](#) as an additional option where the [\[I3C-Basic\]](#) interface shares the same 2 wires as the [\[SMBus\]](#) interface.

While [\[SMBus\]](#) was defined with different electrical requirements for different form-factors, [\[I3C-Basic\]](#) is defined with one interoperable set of behaviors for PCI Express. This section defines the behaviors that:

- Determine which interface is active
- Define the electrical requirements for PCI Express [\[I3C-Basic\]](#)

12.5.4.1 [I3C Basic Overview](#) §

Key attributes of [\[I3C-Basic\]](#) support on existing [\[SMBus\]](#) signals are the following:

- Supports the *MIPI™ Alliance Specification for I3C Basic, Version 1.0* available at [\[I3C-Basic\]](#) (See Implementation Note [Optional I3C Features](#)).
- Sideband 2-wire bus reliant use cases should be defined using either [\[SMBus\]](#) only or both [\[SMBus\]](#) and [\[I3C-Basic\]](#).
- If optional I3C Basic is supported, then I3C Data shares the same signal as SMBus Data, and I3C Clock share the same signal as SMBus Clock.
- If optional I3C Basic is supported, SMBus voltage levels must also be tolerated for backwards compatibility.
- I3C operating voltage must utilize 1.8 V signaling as defined in [\[I3C-Basic\]](#). The rationale is for maximum bus length and allowed capacitance which eases implementations in large platforms.

IMPLEMENTATION NOTE: OPTIONAL I3C FEATURES §

The following I3C features from [I3C-Basic-1.1.1] should be supported if I3C is supported:

- The Target Reset pattern (RSTACT) with Common Command Code 0x2A (Broadcast) and 0x9A (Direct).
 - This allows the host to perform a I3C peripheral reset without having to go back to SMBus mode.
- Asynchronous Timing Control (Mode 0) (support determined if GETXTIME CCC is acknowledged)
 - This aids in scenarios needing real time communication by providing a timestamp.
- Grouped addressing (support determined through GETCAPS CCC)
 - This allows broadcast request to multiple I3C Basic components using a single message.
- SETBUSCON CCC

[I3C-Basic] recommends using SETBUSCON to inform I3C Targets of the specific use of the Bus, and that vendor specific CCCs will be used. Can also inform I3C Targets of the version of the specification that the Controller supports.

IMPLEMENTATION NOTE: POTENTIAL ELECTRICAL CONTENTION §

Due to the nature of [I3C-Basic] utilizing push-pull active drivers, implementers should be cautious about possible corner case scenarios where electrical contention could occur (e.g., an I3C component is actively driving data high while the initiator goes through a reset and drives data open drain low as part of a new command). Actions such as the initiator beginning a recovery sequence with an SMBus clock low timeout to reset the target is advised.

12.5.4.2 I3C Basic Discovery and Mode Changing §

The goal of the I3C Basic adapter or component discovery flow as shown in § Figure 12-14 is to enable an I3C Basic capable host and I3C Basic capable components to establish I3C Basic communication while allowing backward compatibility with legacy [SMBus] components. If one side of communication supports both [SMBus] and I3C Basic and the other side supports SMBus only, then SMBus protocol and voltage is used. If there is a mix of I3C Basic and SMBus components that are active on the same bus, then only [SMBus] protocol and voltage is used. Mixed Fast Mode is prohibited. This flow should be initiated after any power rail state change.

The discovery flow uses reserved address 1111 110xb (FCh 8-bit/7Eh 7-bit) to determine if there are components that support I3C Basic on the bus. Address 7Eh (7-bit) is reserved in the [SMBus] specification and cannot be assigned to any SMBus component. Address 7Eh (7-bit) is defined for I3C Basic and every I3C Basic component will respond as per the I3C Basic Specification. Any time a component that supports both SMBus and I3C Basic receives a cycle for address 7Eh (7-bit), it should disable SMBus (not drive or stretch the clock, nor ACK SMBus addresses) until reset to help the host determine if there are SMBus only components on the bus. If only I3C Basic components are detected and the host chooses to use I3C Basic, then the component requires a transition time from 3.3 V to the I3C Basic voltage within the time $T_{smb2i3c}$ (see § Table 12-14). A reset by driving a system management hardware mechanism (e.g., a hardware reset or power removal) if supported by a given formfactor or driving the clock low for a specified period reverts the interface

to SMBus at 3.3 V signaling within the time $T_{i3c2smb}$ (see § Table 12-14). An I3C Basic Target Reset issued by the host resets the I3C Basic interface but does not impact the signaling voltage. See § [Figure 12-14](#) for more details of this flow.

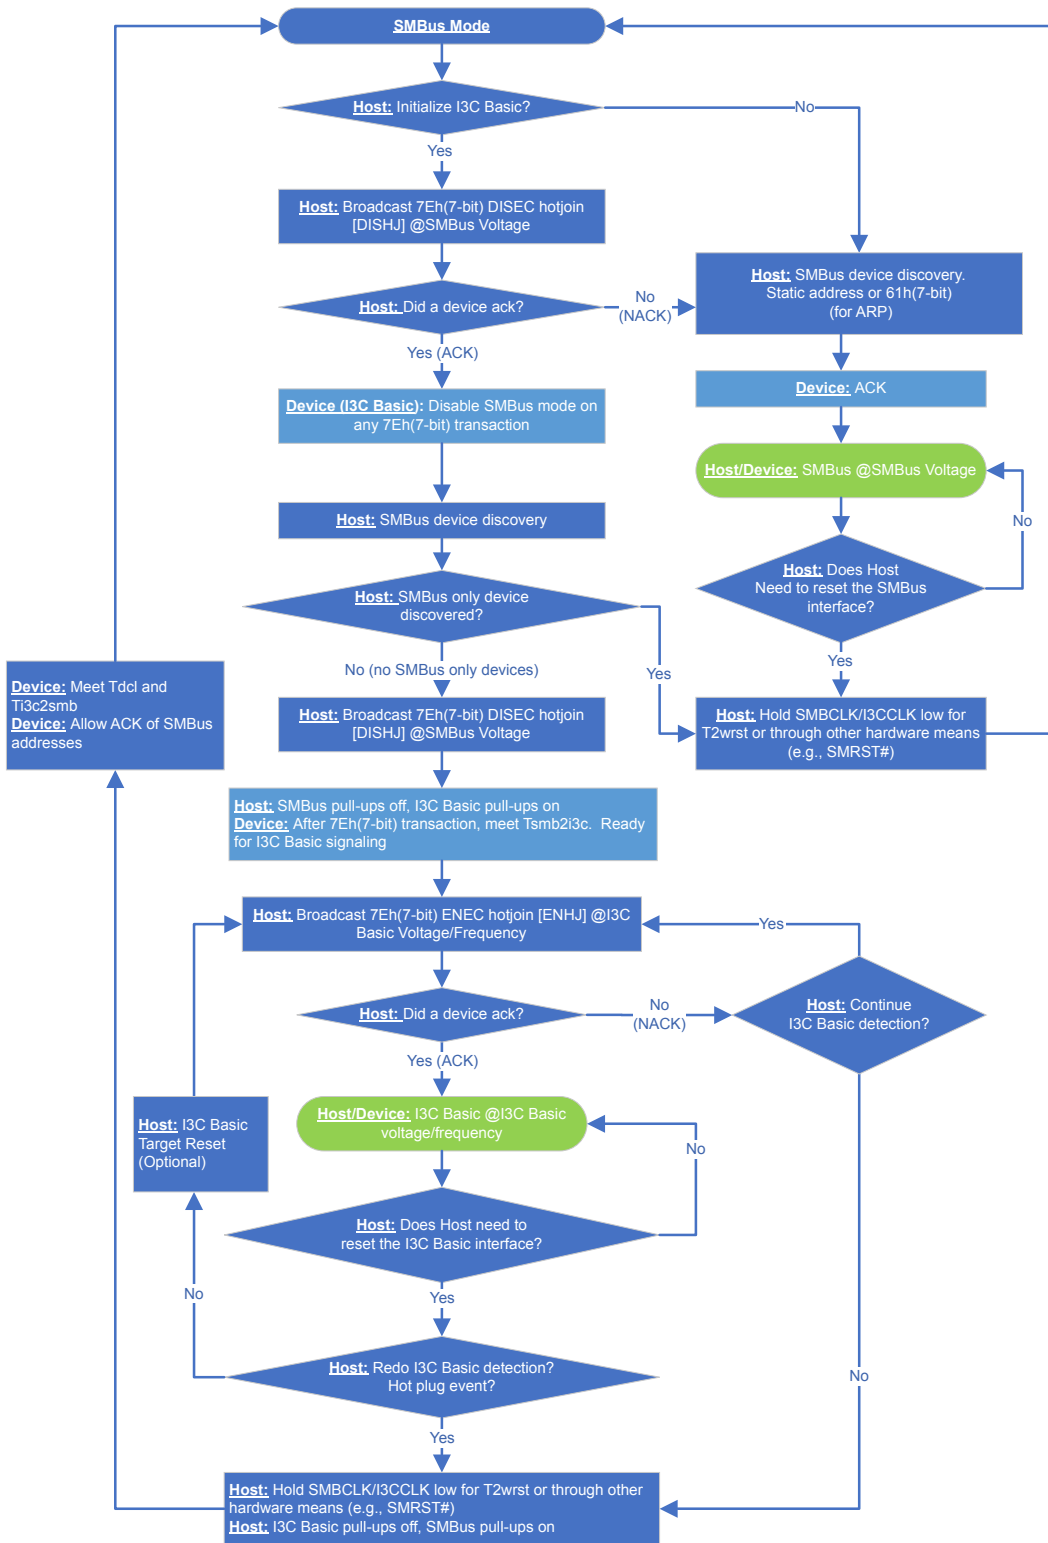

Figure 12-14 SMBus to I3C Transition Flow §

12.5.4.3 I3C Basic DC and AC Signal Requirements §

The I3C Basic operating voltage and capacitance for SCL and SDA is defined in § Table 12-13.

For more information on logic levels or bus timings, refer to [I3C-Basic].

Table 12-13 I3C Basic Logic Signaling DC Specification §

Symbol	Parameter	Min	Nominal	Max	Unit	Notes
V_{ddi3c}	I3C Basic Operating Voltage	1.65	1.80	1.95	V	
C_{i3c}	Total adapter and component capacitance for I3C support			20	pF	1

Notes:

1. Total capacitance the platform board will see from the adapter including all connector, board routing, component package wires, and component on die parasitic effects when the target component(s) is/are in I3C Basic mode. The capacitance of SMBus components on the I3C Basic interface even if not operational is also included.

§ Table 12-14 defines the component maximum transition times between [SMBus] and I3C. During $T_{smb2i3c}$, the host will transition the pull-ups from V_{ddsmb} to V_{ddi3c} and the component will transition to V_{ddi3c} based signaling. During $T_{i3c2smb}$, the host will transition the pull-ups from V_{ddi3c} to V_{ddsmb} and the component will transition to V_{ddsmb} based signaling.

Table 12-14 I3C Timing Requirements §

Symbol	Parameter	Min	Max	Unit	Notes
$T_{smb2i3c}$	Component transition time from SMBus to I3C Basic		20	ms	1, 2
T_{dcl}	Component Clock low reset time	25	35	ms	2, 3
$T_{i3c2smb}$	Component transition time from I3C Basic to SMBus		20	ms	2, 3
T_{2wrst}	Host clock low timeout	50		ms	

Notes:

1. The host must wait a minimum of $T_{smb2i3c}$ before sending I3C commands.
2. No SMBus or I3C transmissions must occur during $T_{smb2i3c}$, T_{dcl} , and $T_{i3c2smb}$.
3. The host must wait a minimum of $T_{dcl}+T_{i3c2smb}$ before sending SMBus commands.

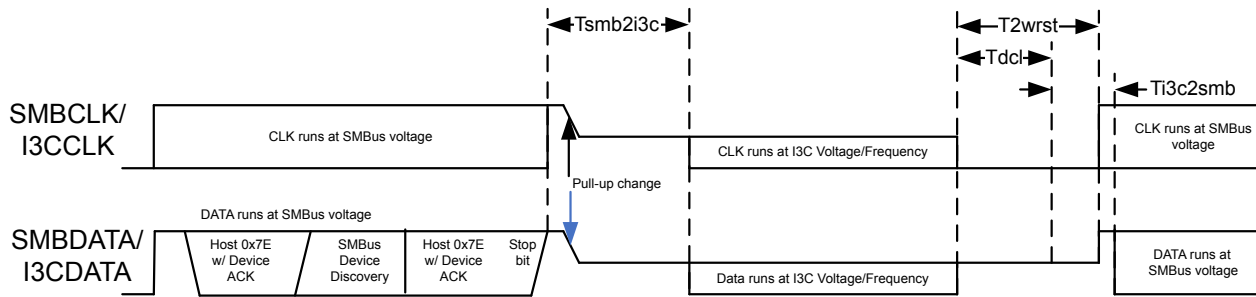

Figure 12-15 Component Timing Diagram for Transition to I3C Signaling Voltage §

12.6 Field Replacement Unit (FRU) Information §

FRU Information is data that describes an adapter or component. FRU Information includes data about the adapter or component such as:

- Inventory information (e.g., serial number, model number, etc.).
- Capability information (e.g., power consumption, performance, etc.).
- Information required by the host to configure the adapter or component (e.g., supported connector subdivision combinations, clocking modes supported, etc.).

FRU Information may be made available to a Baseboard Management Controller or service processor using the following mechanisms:

- Over the 2-wire interface with use of the protocol defined in § Section 12.6.1 .
- Over 2-wire interface, USB, or PCIe VDMs with use of the MCTP protocol.

In-band access of FRU Information via a method such as Management Message Passthrough (MMPT) or Memory-Mapped BMC Interface (MMBI) [MMBI] is outside the scope of this chapter.

12.6.1 FRU Information Device Requirements §

FRU Information is contained in a FRU Information Device. The following list contains requirements and recommendations for FRU Information Devices regardless of the operating mode being [SMBus]/[I2C] or [I3C]:

1. A 2-wire discoverable Field Replaceable Unit (FRU) Information Device must be implemented as a required element when dictated by form-factor specifications such as to support specific features.
2. The FRU Information Device is permitted to be any implementation that meets the requirements in this specification (e.g., a physical integrated circuit or virtually emulated by firmware).
3. The FRU Information Device is recommended to be protected from write operations that may corrupt or replace FRU Information. The exception is when the FRU Information is accessed via MCTP or while in a manufacturing mode. An adapter or component is permitted to update the FRU Information in conjunction with a firmware update.
4. The FRU Information Device must support at least 8 full writes.

5. The FRU Information Device must be accessible in any of the following power states:
 - a. Main power only.
 - b. Main power and auxiliary power if auxiliary power is supported.
 - c. Auxiliary power only if auxiliary power is supported.
6. If auxiliary power is supplied, then the availability and transitions of main power must not disrupt FRU Information Device access.
7. The FRU Information Device must be accessible on the 2-wire interface within 1 second after power becomes valid and must remain accessible while power is valid unless otherwise specified.
8. Clock-low timeout-based reset recovery must be supported per the [SMBus] Specification or [I3C-Basic] section of this specification. The FRU Information Device must be accessible on the 2-wire bus within 1 second after the de-assertion of clock-low timeout-based reset. It is recommended to reset the current address pointer due to clock-low reset.

12.6.1.1 FRU Information Device Requirements Specific to SMBus/I2C Mode §

This section describes the FRU Information Device requirements and recommendations when using SMBus/I2C read and write transactions.

1. The FRU Information Device must use a 7-bit target address.
2. FRU Information Device capacity must be an even power of 2 in the range of 256 Bytes up to 64 KB.
3. The FRU Information Device must support at least 400 kHz operation in SMBus/I2C mode. The adapter or component should limit bus capacitance. The appropriately tuned pullup resistors are the platform's responsibility. The adapter or component should have no or weak pullup resistors only.
4. FRU Information Device accesses must use 2-byte addresses for read or write offsets. One-byte offsets supplied by the platform during random reads should be zero extended to two-byte offsets. See § Figure 12-17.
5. The FRU Information Device must maintain a current address pointer. The current address pointer must auto increment to the next byte after each byte that is read. Refer to the “Current Address Read” and “Current Sequential Read” in § Figure 12-17. A read of the last byte of the last memory page of the FRU Information Device must cause the current read pointer to roll over to the first byte of the first memory page of the FRU Information Device. For example, for a 256-byte FRU Information Device, a read of the last byte of the FRU Information Device at offset FFh causes the current address pointer to roll over to 00h. The current address pointer must be cleared to 0h upon a power cycle of the FRU Information Device.
6. Any controller on the adapter or component must not initiate traffic to the FRU Information Device on the same adapter or component unless the FRU Information Device is hidden from host view (e.g., by detaching the FRU Information Device from the system-facing 2-wire interface). For example, the FRU Information Device must be hidden from host view during a firmware update that includes new FRU Information. While the FRU Information Device is disconnected from the form-factor connector, accesses to the FRU Information Device via the 2-wire bus must be Not Acknowledged.
7. If the FRU Information over the 2-wire interface is initially provided using a discrete SMBus/I2C FRU Information Device (e.g., a physical EEPROM), the component must be detached from the 2-wire interface when entering I3C mode. If the FRU Information Device is being emulated by a programmable component, such as a microcontroller, then when switching to I3C mode, the virtual FRU Information Device SMBus address must be logically disabled. As mixed fast mode is not supported, designs must not assume that the I3C bus frequency and short SCL high time allows for SMBus/I2C devices with 50 ns glitch filters to coexist.
8. Placing the FRU Information Device behind a 2-wire MUX or hub is prohibited due to possible variability in discovery method.

12.6.1.2 [SMBus]/[I2C] Access Protocol §

The following figures describe the proper logical sequence of supported FRU Information Device read and write commands when in SMBus/I2C mode. Note that the address example is specific to 4 KB component.

Byte Write

Page Write

Current Sequential Read

Figure 12-17 FRU Information Device Reads with Two-Byte Addressing §

12.6.2 FRU Information Format §

This section defines the format of the FRU Information stored in the FRU Information Device. The FRU Information format must comply with the requirements defined in the IPMI Platform Management FRU Information Storage Definition ([IPMI-FRU]).

In addition to CRC-based data integrity, assurance of data authenticity is permitted to support an optional cryptographic signature of the FRU Information Device. It is recommended that the FRU Information be covered by a digital signature of the adapter's or component's firmware and validated when the firmware is updated. If the content is validated during adapter or component firmware initialization, care must be taken to ensure the component and information are available to system management firmware as needed, such as when only auxiliary power is supplied.

The IPMI Platform Management FRU Information Storage Definition ([IPMI-FRU]) allows more than 1 MultiRecord to be in a single FRU Information Device. The follow table describes the specific MultiRecord format that applies to all PCI Express adapters or components.

Table 12-15 PCI-SIG MultiRecord §

Bytes	Factory Default	Description						
PCI-SIG MultiRecord Header								
0h	0C0h	PCI-SIG Record Type ID: This field indicates the IPMI Record Type ID of the PCI-SIG MultiRecord. This field must be set to a value of C0h.						
1h	2h or 82h	Record Format: This field indicates the format of this MultiRecord.						
		<table border="1"> <thead> <tr> <th>Bits</th> <th>Definition</th> </tr> </thead> <tbody> <tr> <td>7</td> <td>When Set, this bit indicates that this is the last MultiRecord in the list.</td> </tr> <tr> <td>6:0</td> <td>This field indicates the MultiRecord format version. This field must be set to a value of 2h.</td> </tr> </tbody> </table>	Bits	Definition	7	When Set, this bit indicates that this is the last MultiRecord in the list.	6:0	This field indicates the MultiRecord format version. This field must be set to a value of 2h.
		Bits	Definition					
7	When Set, this bit indicates that this is the last MultiRecord in the list.							
6:0	This field indicates the MultiRecord format version. This field must be set to a value of 2h.							
2h	Implementation Specific	Record Length (RLEN): This field indicates the length of the PCI-SIG MultiRecord Body in bytes (i.e., the bytes of the MultiRecord excluding the 5-byte MultiRecord header that is common to all MultiRecords).						
3h	Implementation Specific	Record Checksum: This field is used to give the PCI-SIG MultiRecord Body a zero checksum (i.e., the modulo 256 sum of bytes from byte offset 5h to the end of this MultiRecord plus this checksum byte equals 0h).						
4h	Implementation Specific	Header Checksum: This field is used to give the PCI-SIG MultiRecord Header a zero checksum (i.e., the modulo 256 sum of offset 0h of the PCI-SIG MultiRecord Header through this checksum byte equals 0h).						
PCI-SIG MultiRecord Body								
7h:5h	E8FFh	[PCI-SIG IANA Private Enterprise Number]: This field indicates the PCI-SIG's IANA Private Enterprise Number. This field must be set to a value of E8FFh (i.e., 59,647).						
8h	0h	Version Number: This field indicates the version number of this MultiRecord. This field must be 0h in this version of the specification.						
9h	Implementation Specific	Number of Descriptors: This field indicates the number of descriptors in this MultiRecord. The value of 0h is reserved.						
Implementation Specific	Implementation Specific	Descriptor 0: This field contains the first descriptor in this MultiRecord.						
Implementation Specific	Implementation Specific	Descriptor 1: This field contains the second descriptor in this MultiRecord if Number of Descriptors is greater than one; otherwise, this field is not present.						
...						

Table 12-17 PCI-SIG MultiRecord Descriptor §

Bytes	Factory Default	Description
1h:0h	Implementation Specific	Descriptor Type: This field indicates the type of this descriptor. Bits:

Bytes	Factory Default	Description
		15:13 Reserved 11:8 Group ID 0h PCI Express Base Specification 1h PCI Express CEM Specification 2h PCI Express M.2 Specification 3h PCI Express SFF-8639 Module 4h PCI Firmware 5h PCI Express OcuLink 6h PCI Express External Cabling 7h PCI Express CopprLink Internal Cable 8h PCI Express CopprLink External Cable Others Reserved 7:0 Sub-Type (Defined by Group ID owner)
2h	Implementation Specific	Descriptor Version Number: This field indicates the version number of this descriptor. This field must be 0h.
3h	Implementation Specific	Descriptor Length: This field indicates the number of bytes in this descriptor.
Length N-1: 4h	Implementation Specific	Descriptor Data: This field contains the type-specific data associated with this descriptor where N is the total length in bytes of this descriptor.

Each Group ID owner can define a list of sub-types with associated Descriptor Data. The Sub-Type field in the PCI-SIG MultiRecord Descriptor is 8 bits allowing for 256 sub-types.

Descriptor Data can be anything defined by the Group ID owner but should follow IPMI FRU conventions and should be kept as small as possible.

Types of FRU Information that are common across many form factors are defined in PCI-SIG MultiRecord Descriptors in this specification as part of Group ID 0h. Types of FRU Information that are not common across many form factors are defined in PCI-SIG MultiRecord Descriptors in other specifications as part of Group IDs other than 0h.

12.6.3 Common PCI-SIG MultiRecord Descriptors §

This section defines the PCI-SIG MultiRecord Descriptor sub-types for the PCI Express Base Specification group (i.e., Group ID 0h). These descriptors are common across many PCI Express-based adapters and components.

Table 12-18 Descriptor Sub-Types for Group ID 0h §

Descriptor Sub-Type	Description
00h	Connector Subdivision
All other encodings	Reserved

12.6.3.1 Connector Subdivision (Group ID 0h, Sub-Type 0h) §

In some use cases, the host requires the ability to discover connector subdivision combinations of an adapter's or component's upstream-facing connector so that the host can configure the subdivision of the Downstream Port connected to the adapter or component. A couple of examples include:

- a. Two x8 Ports on an adapter with a x16 upstream-facing connector.
- b. Four M.2 x4 connectors on a CEM card carrier with a x16 upstream-facing connector.

This section defines the FRU descriptors that describe the adapter's or component's supported connector subdivision combination(s). If only one connector subdivision combination is supported, then no Connector Subdivision Combinations Descriptor (refer to § Table 12-19) is required. If more than one connector subdivision combination is supported and the implementation supports the PCI-SIG MultiRecord, then a Connector Subdivision Combinations Descriptor with an instance of the Connector Subdivision Descriptor (refer to § Table 12-20) for each supported connector subdivision combination must be present.

The Connector Subdivision Descriptor at the lowest offset in the Connector Subdivision Combinations Descriptor should include the most common expected usage and must be the default Connector Subdivision Descriptor. This is unless a form factor specific method is applied (e.g., the **DUALPORTEN#** sideband signal defined by the [SFF-8639]) or the host commands the form factor to select an alternate Connector Subdivision Descriptor using a mechanism outside the scope of this specification. The default Connector Subdivision Descriptor is defined as the adapter configuration if no control function is sent to select an alternate mode of operation. The adapter or component must revert to the default Connector Subdivision Descriptor only on a Cold Reset.

Each Lane on the upstream-facing connector within each connector subdivision combination that is connected to a Port or another connector on the adapter or component must be described within a single Connector Subdivision Descriptor. Lanes on the upstream-facing connector that are not connected to a Port or another connector on the adapter or component must not be included in the Connector Subdivision Combinations Descriptor. The Lanes associated with a Connector Subdivision Descriptor may be organized as a single subdivision or multiple subdivisions. Each subdivision within each Connector Subdivision Descriptor must be listed in ascending order starting from the adapter's or component's lowest-numbered Lane.

The lowest-numbered Lane must always be with respect to the adapter or component's designated lane 0 without lane reversal. The starting lane number of any subdivision within a Connector Subdivision Descriptor must be less than or equal (if the subdivision width is x1) to the ending lane number of the respective subdivision.

The details of how connector subdivision information is passed from an out-of-band agent (e.g., a Baseboard Management Controller) responsible for reading this information to the platform entity (e.g., the platform BIOS) responsible for configuring the appropriate Downstream Port(s) is implementation specific.

It is recommended that adapters include the Connector Subdivision Combinations Descriptor, even if only a single width configuration is supported, because it enables system firmware to determine degraded link width conditions in situations where an adapter advertises a value in the Maximum Link Width field in the Link Capabilities Register that is less than or greater than the physical adapter connector edge connectivity (e.g., a x8 capable component on an adapter that only connects x4 to the adapter card edge).

Table 12-19 Connector Subdivision Combinations Descriptor §

Byte Offset(s)	Factory Default	Description
1h:0h	0001h	Descriptor Type: This field indicates the type of this descriptor. Bits:

Byte Offset(s)	Factory Default	Description
		15:12 Reserved 11:8 Group ID = 0h (PCI Express Base Specification) 7:0 Sub-Type = 00h (Connector Subdivision)
2h	01h	Descriptor Version Number: This field indicates the version number of this descriptor. This field must be 0h.
3h	04h	Header Length: This field indicates the length of the header portion of this descriptor (meaning from offset 0h until but not including the Connector Subdivision 0 field). This serves the purpose of being able to insert future bytes after the Descriptor Length and before the Connector Subdivision list if new useful attributes arise.
4h	Implementation Specific	Descriptor Length: This field indicates the length of this descriptor in bytes.
Implementation Specific	Implementation Specific	Connector Subdivision 0: This field contains the first connector subdivision.
Implementation Specific	Implementation Specific	Connector Subdivision 1: This field contains the second connector subdivision, if applicable. If there is only one connector subdivision, then this field is not present.
...

The Connector Subdivision Descriptor is shown in § Table 12-20. An upstream PCIe connector is made up of one or more subdivisions. Each subdivision is routed to a Port or another connector on the adapter or component. The Connector Subdivision Descriptor indicates the number of subdivisions and the starting and ending Lane numbers for each subdivision that make up each supported connector subdivision combination.

Table 12-20 Connector Subdivision Descriptor §

Byte Offset(s)	Factory Default	Description
0h	Implementation Specific	Descriptor Length: This field indicates the length of this descriptor in bytes.
1h	Implementation Specific	Number of Subdivisions: This field indicates the number of subdivisions in this descriptor. The permitted range of values is from 1 (e.g., 1 subdivision of maximum supported width) to the number of individual lanes used at the maximum supported width. All other values are Reserved. As an example, a x16 capable adapter can have values from 1 (e.g., one subdivision of x16 width) to 16 (e.g., 16 subdivisions of x1 width).
2h	Implementation Specific	Subdivision 0: This field indicates the starting and ending lanes of the first subdivision of this descriptor. Bits: 7:4 Starting Lane is the lowest-numbered Lane of the first subdivision of this descriptor. 3:0 Ending Lane is the highest numbered Lane of the first subdivision of this descriptor.
3h	Implementation Specific	Subdivision 1: This field indicates the starting and ending lanes of the second subdivision of this descriptor. Bits: 7:4 Starting Lane is the lowest-numbered Lane of the second subdivision of this descriptor.

Byte Offset(s)	Factory Default	Description
		3:0 Ending Lane is the highest numbered Lane of the second subdivision of this descriptor.
...

Example Connector Subdivision Combinations Descriptor for an Adapter Supporting 3 Connector Subdivision Descriptors:

1 Port of x16 Lanes, 2 Ports of x8 Lanes each, 4 Ports of x4 Lanes each

Connector Subdivision Descriptor: 0 (the default)

Number of Subdivisions: 1

Starting Lane of the first subdivision: 0; Ending Lane of the first subdivision: 15

Connector Subdivision Descriptor: 1

Number of Subdivisions: 2

Starting Lane of the first subdivision: 0; Ending Lane of the first subdivision: 7

Starting Lane of second subdivision: 8; Ending Lane of second subdivision: 15

Connector Subdivision Descriptor: 2

Number of Subdivisions: 4

Starting Lane of the first subdivision: 0; Ending Lane of the first subdivision: 3

Starting Lane of second subdivision: 4; Ending Lane of second subdivision: 7

Starting Lane of third subdivision: 8; Ending Lane of third subdivision: 11

Starting Lane of fourth subdivision: 12; Ending Lane of fourth subdivision: 15

12.7 Out-of-Band Control Mechanism §

After inventory and discovery of the features of an interposer, adapter or component, control function(s) may be required. Control commands are recommended to utilize the Management Control Transport Protocol (MCTP). The rationale is to move control functions into a well-supported higher-level protocol versus low level register-based solutions, fixed components like I2C I/O expanders or discrete wires.

IMPLEMENTATION NOTE:

MCTP-BASED CONTROL MECHANISM §

A future revision of this specification will define the MCTP-based control mechanism.

Additional out-of-band control methods are allowed, such as a USB to UART or Ethernet bridges, but should be described within the FRU attributes.

Definition of specific targeted control functions are the responsibility of form factor specifications. There are two types of control targets, where an adapter or component is permitted to include a primary and/or secondary target. In this context, target refers to the physical address and not MCTP Endpoint IDs (EIDs).

1. Primary MCTP Target – The primary MCTP target is for control functions of the adapter or major component, primarily when the component or adapter has main power supplied (i.e., it is not typically supported when only auxiliary power is supplied).
2. Secondary MCTP Target –The secondary target is for control functions when the primary target is offline (such as when only auxiliary power is supplied) or for control functions that do not involve the primary target. Examples include controlling Flex I/O functions or setting a desired connector subdivision mode before the primary target is powered or out of reset. Although a primary target might be typical for most peripheral subsystems, a secondary target might exist if such out-of-band control functions are necessary. The FRU information is recommended to convey the presence and address of the secondary MCTP target.

Forcing control functions to revert to default are implementation specific in terms of when main power is lost, Fundamental Reset, auxiliary power removal or when explicitly changed by the platform (e.g., control settings are permitted to persist via non-volatile storage).

12.8 Retimer Management §

With increasing interface speeds and varied PCIe topologies, Retimers are expected to be more prevalent. Retimer configuration typically utilizes an SMBus-based dedicated configuration EEPROM with non-standard addressing or required out of band connectivity for in-system updates. Thus, Retimer management is left to the implementer.

12.9 Internal Cable Management §

Internal Cable Management guidance is defined for usage with [\[CoprLink\]](#).

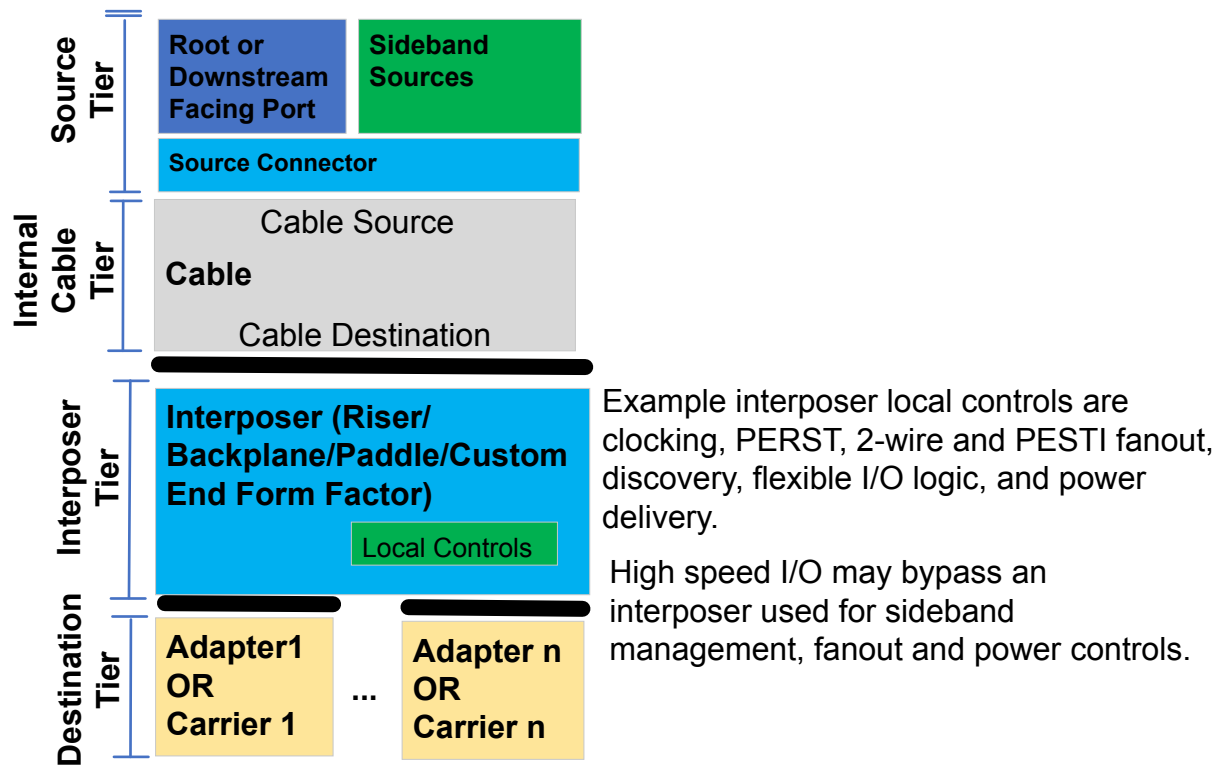

Figure 12-18 Example Tiers Involving Sidebands §

A. Isochronous Applications §

A.1 Introduction §

The design goal of isochronous mechanisms in PCI Express is to ensure that isochronous traffic receives its allocated bandwidth over a relevant time period while also preventing starvation of other non-isochronous traffic.

Furthermore, there may exist data traffic that requires a level of service falling in between what is required for bulk data traffic and isochronous data traffic. This type of traffic can be supported through the use of Port arbitration within Switches, the use of TC labels [1:7], and optional additional VC resources. Policies for assignment of TC labels and VC resources that are not isochronous-focused are outside the scope of the PCI Express specification.

Two paradigms of PCI Express communication are supported by the PCI Express isochronous mechanisms: Endpoint-to-Root-Complex communication model and peer-to-peer (Endpoint-to-Endpoint) communication model. In the Endpoint-to-Root-Complex communication model, the primary isochronous traffic is memory read and write requests to the Root Complex and read completions from the Root Complex. § Figure A-1 shows an example of a simple system with both communication models. In the figure, devices A, B, called Requesters, are PCI Express Endpoints capable of issuing isochronous request transactions, while device C and Root Complex, called Completers, are capable of being the targets of isochronous request transactions. An Endpoint-to-Root-Complex communication is established between device A and the Root Complex, and a peer-to-peer communication is established between device B and device C. In the rest of this section, Requester and Completer will be used to make reference to PCI Express elements involved in transactions. The specific aspects of each communication model will be called out explicitly.

Figure A-1 An Example Showing Endpoint-to-Root-Complex and Peer-to-Peer Communication Models §

Guaranteed bandwidth and deterministic latency require end-to-end configuration of fabric resources. If isochronous traffic is intermixed with non-isochronous traffic, it may not be possible to provide any guarantees/determinism as required by the application usage model. It is recommended that system software configure and assign fabric resources such that traffic intermix either does not occur or is such that the application usage model guarantees can be met. This can be accomplished by assigning dedicated VC resources and corresponding TC labels to the isochronous traffic flow(s) on a given path within the fabric.

Note that there may be one or more isochronous traffic flows per VC/TC label and it is up to system software to insure that the aggregation of these flows does not exceed the requisite bandwidth and latency requirements.

It is also possible for a fabric to support multiple isochronous traffic flows separated across multiple VC (a given flow cannot span multiple VC/TC labels).

In general, as long as the device can meet the isochronous bandwidth and latency requirements, there is nothing to preclude a single VC device from supporting isochronous traffic if multiple TC labels are supported to delineate such traffic from non-isochronous traffic within the fabric.

A.2 Isochronous Contract and Contract Parameters §

In order to support isochronous data transfer with guaranteed bandwidth and deterministic latency, an isochronous contract must be established between a Requester/Completer pair and the PCI Express fabric. This contract must enforce both resource reservation and traffic regulation. Without such a contract, two basic problems, over-subscription and congestion, may occur as illustrated in § Figure A-2. When interconnect bandwidth resources are over-subscribed, the increased latency may cause failure of isochronous service and starvation of non-isochronous services. Traffic congestion occurs when flow control credits are not returned possibly due to a higher than expected/provisioned packet injection rate. This may cause excessive service latencies for both isochronous traffic and non-isochronous traffic.

Figure A-2 Two Basic Bandwidth Resourcing Problems: Over-Subscription and Congestion §

The isochronous transfer mechanism in this specification addresses these problems with traffic regulation including admission control and service discipline. Under a software managed admission control, a Requester must not issue isochronous transactions unless the required isochronous bandwidth and resource have been allocated. Specifically, the isochronous bandwidth is given by the following formula:

$$BW = \frac{N * Y}{T}$$

Equation A-1 Isochronous Bandwidth §

The formula defines allocated bandwidth (BW) as a function of specified number (N) of transactions of a specified payload size (Y) within a specified time period (T). Another important parameter in the isochronous contract is latency. Based on the contract, isochronous transactions are completed within a specified latency (L). Once a Requester/Completer pair is admitted for isochronous communication, the bandwidth and latency are guaranteed to the Requester (a PCI Express Endpoint) by the Completer (Root Complex for Endpoint-to-Root-Complex communication and another PCI Express Endpoint for peer-to-peer communication) and by the PCI Express fabric components (Switches).

Specific service disciplines must be implemented by isochronous-capable PCI Express components. The service disciplines are imposed to PCI Express Switches and Completers in such a manner that the service of isochronous requests is subject to a specific service interval (t). This mechanism is used to provide the method of controlling when an isochronous packet injected by a Requester is serviced. Consequently, isochronous traffic is policed in such manner that only packets that can be injected into the fabric in compliance with the isochronous contract are allowed to make immediate progress and start being serviced by the PCI Express fabric. A non-compliant Requester that tries to inject more isochronous transactions than what was being allowed by the contract is prevented from doing so by the

flow-control mechanism thereby allowing compliant Requesters to correctly operate independent of non-compliant Requesters.

In the Endpoint-to-Root-Complex model, since the aggregated isochronous traffic is eventually limited by the host memory subsystem's bandwidth capabilities, isochronous read requests, and write requests (and Messages) are budgeted together. A Requester may divide the isochronous bandwidth between read requests and write requests as appropriate.

A.2.1 Isochronous Time Period and Isochronous Virtual Timeslot §

The PCI Express isochronous time period (T) is uniformly divided into units of virtual timeslots (t). To provide precise isochronous bandwidth distribution only one isochronous request packet is allowed per virtual timeslot. The virtual timeslot supported by a PCI Express component is reported through the Reference Clock field in the Virtual Channel Capability structure or the Multi-Function Virtual Channel Capability structure. When Reference Clock = 00b, duration of a virtual timeslot t is 100 ns. Duration of isochronous time period T depends on the number of phases of the supported time-based WRR Port arbitration table size. When the time-based WRR Port Arbitration Table size equals to 128, there are 128 virtual timeslots (t) in an isochronous time period (i.e., $T = 12.8 \mu\text{s}$).

Note that isochronous period T as well as virtual timeslots t do not need to be aligned and synchronized among different PCI Express isochronous devices, i.e., the notion of $\{T, t\}$ is local to each individual isochronous device.

A.2.2 Isochronous Payload Size §

The payload size (Y) for isochronous transactions must not exceed Max_Payload_Size (see § Section 7.5.3.4). After configuration, the Max_Payload_Size is set and fixed for each path that supports isochronous service with a value required to meet isochronous latency. The fixed Max_Payload_Size value is used for isochronous bandwidth budgeting regardless of the actual size of data payload associated with isochronous transactions. For isochronous bandwidth budgeting, we have

$$Y = \text{Max_Payload_Size}$$

Equation A-2 Isochronous Payload Size §

A transaction with partial writes is treated as a normally accounted transaction. A Completer must account for partial writes as part of bandwidth assignment (for worst case servicing time).

A.2.3 Isochronous Bandwidth Allocation §

Given T , t and Y , the maximum virtual timeslots within a time period is

$$N_{\max} = \frac{T}{t}$$

Equation A-3 N_{\max} §

and the maximum specifiable isochronous bandwidth is

$$BW_{\max} = \frac{Y}{t}$$

Equation A-4 BW_{\max} §

The granularity with which isochronous bandwidth can be allocated is defined as:

$$BW_{\text{granularity}} = \frac{Y}{T}$$

Equation A-5 $BW_{\text{granularity}}$ §

Given T and t at 12.8 μs and 100 ns, respectively, N_{\max} is 128. As shown in § Table A-1, BW_{\max} and $BW_{\text{granularity}}$ are functions of the isochronous payload size Y .

Table A-1 Isochronous Bandwidth Ranges and Granularities §

Y (bytes)	128	256	512	1024
BW_{\max} (MB/s)	1289	2560	5120	10240
$BW_{\text{granularity}}$ (MB/s)	10	20	40	80

Similar to bandwidth budgeting, isochronous service disciplines including arbitration schemes are based on counting requests (not the sizes of those requests). Therefore, assigning isochronous bandwidth BW_{link} to a PCI Express Link is equivalent to assigning N_{link} virtual timeslots per isochronous period, where N_{link} is given by

$$N_{\text{link}} = \frac{BW_{\text{link}}}{BW_{\text{granularity}}}$$

Equation A-6 N_{link} §

A Switch Port serving as an Egress Port (or an RCRB serving as a “virtual” Egress Port) for an isochronous traffic, the N_{\max} virtual timeslots within T are represented by the time-based WRR Port Arbitration Table in the PCI Express Virtual Channel Capability structure detailed in § Section 7.9.1. The table consists of N_{\max} entries. An entry in the table represents one virtual timeslot in the isochronous time period. When a table entry is given a value of PN, it means that the timeslot is assigned to an Ingress Port (in respect to the isochronous traffic targeting the Egress Port) designated by a Port Number of PN. Therefore, N_{link} virtual timeslots are assigned to the Ingress Port when there are N_{link} entries in the table with value of PN. The Egress Port may admit one isochronous request transaction from the Ingress Port for further service only when the table entry reached by the Egress Port's isochronous time ticker (that increments by 1 every t time and wraps around when reaching T) is set to PN. Even if there are outstanding isochronous requests ready in the Ingress Port, they will not be served until next round of time-based WRR arbitration. In this manner, the time-based Port Arbitration Table serves for both isochronous bandwidth assignment and isochronous traffic regulation.

For an Endpoint serving as a Requester or a Completer, isochronous bandwidth allocation is accomplished through negotiation between system software and device driver, which is outside of the scope of this specification.

A.2.4 Isochronous Transaction Latency §

Transaction latency is composed of the latency through the PCI Express fabric and the latency contributed by the Completer. Isochronous transaction latency is defined for each transaction and measured in units of virtual timeslot t .

- The *read latency* is defined as the round-trip latency. This is the delay from the time when the device submits a memory read request packet to its Transaction Layer (Transmit side) to the time when the corresponding read completion arrives at the device's Transaction Layer (Receive side).
- The *write latency* is defined as the delay from the time when the Requester posts a memory write request to its PCI Express Transaction Layer (Transmit side) to the time when the data write becomes globally visible within the memory subsystem of the Completer. A write to memory reaches the point of global visibility when all agents accessing that memory address get the updated data.

When the upper bound and the lower bound of isochronous transaction latency are provided, the size of isochronous data buffers in a Requester can be determined. For most of common platforms, the minimum isochronous transaction latency is much smaller than the maximum. As a conservative measure, the minimum isochronous transaction latency is assumed to be zero; only guidelines on measuring the maximum isochronous transaction latency are provided here.

For a Requester, the maximum isochronous (read or write) transaction latency (L) can be accounted as the following:

$$L = L_{Fabric} + L_{Completer}$$

Equation A-7 Max Isochronous Transaction Latency §

where L_{Fabric} is the maximum latency of the PCI Express fabric and $L_{Completer}$ is the maximum latency of the Completer.

L_{Fabric} which applies to both read and write transactions, depends on the topology, latency across each PCI Express Link, and the arbitration point in the path between the Requester to the Completer. The latency on a PCI Express Link depends on pipeline delays, width and operational frequency of the Link, transmission of electrical signals across the medium, wake up latency from low power states, and delays caused by Data Link Layer Retry.

A restriction on the PCI Express topology may be imposed for each targeted platform in order to provide a practically meaningful guideline for L_{Fabric} . The values of L_{Fabric} should be reasonable and serve as practical upper limits under normal operating conditions.

The value of $L_{Completer}$ depends on the memory technology, memory configuration, and the arbitration policies in the Completer that comprehend PCI Express isochronous traffic. The target value for $L_{Completer}$ should provide enough headroom to allow for implementation tradeoffs.

Definitions of read and write transaction latencies for a Completer are different:

- Read transaction latency for the Completer is defined as the delay from the time a memory read transaction is available at the Receiver end of a PCI Express Port in the Completer to the time the corresponding read completion transaction is posted to the transmission end of the PCI Express Port.
- Write transaction latency is defined as the delay from the time a memory write transaction is available at the Receiver end of a PCI Express Port in the Completer to the time that the transmitted data is globally visible.

All of the isochronous transaction latencies defined above are based on the assumption that the Requester injects isochronous transactions uniformly. According to an isochronous contract of $\{N, T, t\}$, the uniform traffic injection is defined such that up to N transactions are evenly distributed over the isochronous period T based on a ticker granularity

of virtual timeslot t . For a Requester with non-uniform isochronous transaction injection, the Requester is responsible of accounting for any additional delay due to the deviation of its injection pattern from a uniform injection pattern.

A.2.5 An Example Illustrating Isochronous Parameters §

§ Figure A-3 illustrates the key isochronous parameters using a simplified example with $T = 20t$ and $L = 22t$. A Requester has reserved isochronous bandwidth of four transactions per T . The device shares the allocated isochronous bandwidths for both read requests and write requests. As shown, during one isochronous time period, the Requester issues two read requests and two write requests. All requests are completed within the designated transaction latency L . Also shown in the figure, there is no time dependency between the service time of write requests and the arrival time of read completions.

Figure A-3 A Simplified Example Illustrating PCI Express Isochronous Parameters §

A.3 Isochronous Transaction Rules §

Isochronous transactions follow the same rules as described in § Chapter 2. . In order to assist the Completer to meet latency requirements, the following additional rules further illustrate and clarify the proper behavior of isochronous transactions:

- The value in the Length field of requests must never exceed Max_Payload_Size.

A.4 Transaction Ordering §

In general, isochronous transactions follow the ordering rules described in § Section 2.4 . The following ordering rule further illustrates and clarifies the proper behavior of isochronous transactions:

- There are no ordering guarantees between any isochronous and non-isochronous transactions because the traffic has been segregated into distinct VC resources.
- Isochronous write requests are serviced on any PCI Express Link in strictly the same order as isochronous write requests are posted.
- Switches must allow isochronous posted requests to pass isochronous read completions.

A.5 Isochronous Data Coherency §

Cache coherency for isochronous transactions is an operating system software and Root Complex hardware issue. PCI Express provides the necessary mechanism to control Root Complex behavior in terms of enforcing hardware cache coherency on a per transaction basis.

For platforms where snoop latency in a Root Complex is either unbounded or can be excessively large, in order to meet tight maximum isochronous transaction latency $L_{Completer}$, or more precisely $L_{Root_Complex}$, all isochronous transactions should have the No Snoop Attribute bit set.

A Root Complex must report the Root Complex's capability to the system software by setting the Reject Snoop Transactions field in the VC Resource Capability register (for any VC resource capable of supporting isochronous traffic) in its RCRB. Based on whether or not a Root Complex is capable of providing hardware enforced cache coherency for isochronous traffic while still meeting isochronous latency target, system software can then inform the device driver of Endpoints to set or unset the No Snoop Attribute bit for isochronous transactions.

Note that cache coherency considerations for isochronous traffic do not apply to peer-to-peer communication.

A.6 Flow Control §

Completers and PCI Express fabric components should implement proper sizing of buffers such that under normal operating conditions, no backpressure due to flow control should be applied to isochronous traffic injected uniformly by a Requester. For Requesters that are compliant to the isochronous contract, but have bursty injection behavior, Switches and Completers may apply flow control backpressure as long as the admitted isochronous traffic is uniform and compliant to the isochronous contract. Under abnormal conditions when isochronous traffic jitter becomes significant or when isochronous traffic is oversubscribed due to excessive Data Link Layer Retry, flow control provides a natural mechanism to ensure functional correctness.

A.7 Considerations for Bandwidth Allocation §

A.7.1 Isochronous Bandwidth of PCI Express Links §

Isochronous bandwidth budgeting for PCI Express Links can be derived based on Link parameters such as isochronous payload size and the speed and width of the Link.

Isochronous bandwidth allocation for a PCI Express Link should be limited to certain percentage of the maximum effective Link bandwidth in order to leave sufficient bandwidth for non-isochronous traffic and to account for temporary Link bandwidth reduction due to retries. Link utilization is counted based on the actual cycles consumed on the physical PCI Express Link. The maximum number of virtual slots allowed per Link (N_{link}) depends on the isochronous packet payload size and the speed and width of the Link.

As isochronous bandwidth allocation on a PCI Express Link is based on number of requests N_{link} per isochronous period. There is no distinction between read requests and write requests in budgeting isochronous bandwidth on a PCI Express Link.

A.7.2 Isochronous Bandwidth of Endpoints §

For peer-to-peer communication, the device driver is responsible for reporting to system software if the device is capable of being a Completer for isochronous transactions. In addition, the driver must report the device's isochronous bandwidth capability. The specifics of the report mechanism are outside the scope of this specification.

A.7.3 Isochronous Bandwidth of Switches §

Allocation of isochronous bandwidth for a Switch must consider the capacity and utilization of PCI Express Links associated with the Ingress Port and the Egress Port of the Switch that connect the Requester and the Completer, respectively. The lowest common denominator of the two determines if a requested isochronous bandwidth can be supported.

A.7.4 Isochronous Bandwidth of Root Complex §

Isochronous bandwidth of Root Complex is reported to the software through its RCRB structure. Specifically, the Maximum Time Slots field of the VC Resource Capability register in VC Extended Capability structure indicates the total isochronous bandwidth shared by the Root Ports associated with the RCRB. Details of the platform budgeting for available isochronous bandwidth within a Root Complex are outside of the scope of this specification.

A.8 Considerations for PCI Express Components §

A.8.1 An Endpoint as a Requester §

Before an Endpoint as a Requester can start issuing isochronous request transactions, the following configuration steps must be performed by software:

- Configuration of at least one VC resource capable of supporting isochronous communication and assignment of at least one TC label.
- Enablement of this VC resource.

When the Requester uniformly injects isochronous requests, the Receive Port, either a Switch Port or a Root Port, should issue Flow Control credits back promptly such that no backpressure should be applied to the associated VC. This type of Requester may size its buffer based on the PCI Express fabric latency L_{Fabric} plus the Completer's latency $L_{Completer}$.

When isochronous transactions are injected non-uniformly, either some transactions experience longer PCI Express fabric delay or the Requester gets back-pressured on the associated VC. This type of Requester must size its buffer to account for the deviation of its injection pattern from uniformity.

A.8.2 An Endpoint as a Completer §

An Endpoint may serve as a Completer for isochronous peer-to-peer communication. Before an Endpoint starts serving isochronous transactions, system software must identify/configure a VC resource capable of supporting isochronous traffic and assigned a corresponding TC label.

An Endpoint Completer must observe the maximum isochronous transaction latency ($L_{Completer}$). An Endpoint Completer does not have to regulate isochronous request traffic if attached to a Switch since Switches implement traffic regulation. However, an Endpoint Completer must size its internal buffer such that no backpressure should be applied to the corresponding VC.

A.8.3 Switches §

A Switch may have multiple ports capable of supporting isochronous transactions. Before a Switch starts serving isochronous transactions for a Port, the software must perform the following configuration steps:

- Configuration/enablement of at least one VC resource capable of supporting isochronous communication.
- Configuration of the Port as an Ingress Port:

- Configuration (or reconfiguration if the associated VC of the Egress Port is already enabled) of the time-based WRR Port Arbitration Table of the targeting Egress Port to include N_{link} entries set to the Ingress Port's Port Number. Here N_{link} is the isochronous allocation for the Ingress Port.
- Enabling the targeting Egress Port to load newly programmed Port Arbitration Table.
- Configuration of the Port as an Egress Port:
 - Configuration of each VC's Port Arbitration Table with number of entries set according to the assigned isochronous bandwidth for all Ingress Ports.
 - Select proper VC Arbitration, e.g., as strict-priority based VC Arbitration.
 - If required, configuration of the Port's VC Arbitration Table with large weights assigned accordingly to each associated VC.

Each VC associated with isochronous traffic may be served as the highest priority in arbitrating for the shared PCI Express Link resource at an Egress Port. This is comprehended by a Switch's internal arbitration scheme.

In addition, a Switch Port may use “just in time” scheduling mechanism to reduce VC arbitration latency. Instead of pipelining non-isochronous Transport Layer packets to the Data Link Layer of the Egress Port in a manner that Data Link Layer transmit buffer becomes saturated, the Switch Port may hold off scheduling of a new non-isochronous packet to the Data Link Layer as long as it is possible without incurring unnecessary Link idle time.

When a VC configured to support isochronous traffic is enabled for a Switch Port (ingress) that is connected to a Requester, the Switch must enforce proper traffic regulation to ensure that isochronous traffic from the Port conforms to this specification. With such enforcement, normal isochronous transactions from compliant Requesters will not be impacted by ill behavior of any non-compliant Requester.

The above isochronous traffic regulation mechanism only applies to request transactions but not to completion transactions. When Endpoint-to-Root-Complex and peer-to-peer communications co-exist in a Switch, an Egress Port may mix isochronous write requests and read completions in the same direction. In the case of contention, the Egress Port must allow write requests to pass read completions to ensure the Switch meets latency requirement for isochronous requests.

A.8.4 Root Complex §

A Root Complex may have multiple Root Ports capable of supporting isochronous transactions. Before a Root Complex starts serving isochronous transactions for a Root Port, the Port must be configured by software to enable VC to support isochronous traffic using the following configuration steps:

- Configuration of at least one VC resource capable of supporting isochronous communication and assignment of at least one TC label.
- Configuration of the Root Port as an Ingress Port:
 - Configuration (or reconfiguration if the associated VC in RCRB is already enabled) of the time-based WRR Port Arbitration Table of the targeting RCRB to include N_{link} entries set to the Ingress Port's Port Number. Here N_{link} is the isochronous allocation for the Port.
 - Enabling the targeting RCRB to load newly programmed Port Arbitration Table.
- Configuration of the Root Port as an Egress Port:
 - If supported, configuration of the Root Port's VC Arbitration Table with large weights assigned to the associated VC.

- If the Root Complex supports peer-to-peer traffic between Root Ports, configuration of the Root Port's Port Arbitration Table number of entries is set according to the assigned isochronous bandwidth for all Ingress Ports.

A Root Complex must observe the maximum isochronous transaction latency ($L_{Completer}$ or more precisely $L_{Root_Complex}$) that applies to all the Root Ports in the Root Complex. How a Root Complex schedules memory cycles for PCI Express isochronous transactions and other memory transactions is outside of the scope of this specification as long as $L_{Root_Complex}$ is met for PCI Express isochronous transactions.

When a VC is enabled to support isochronous traffic for a Root Port, the Root Complex must enforce proper traffic regulation to ensure that isochronous traffic from the Root Port conforms to this specification. With such enforcement, normal isochronous transactions from compliant Requesters will not be impacted by ill behavior of any non-compliant Requesters. Isochronous traffic regulation is implemented using the time-based Port Arbitration Table in RCRB.

Root Complex may perform the following operations for invalid isochronous transactions:

- Return partial completions for read requests with the value in the Length field exceeding Max_Payload_Size.

B. Symbol Encoding §

§ Table B-1 shows the byte-to-Symbol encodings for data characters. § Table B-2 shows the Symbol encodings for the Special Symbols used for TLP/DLLP Framing and for interface management. RD- and RD+ refer to the Running Disparity of the Symbol sequence on a per-Lane basis.

C. Physical Layer Appendix §

C.1 8b/10b Data Scrambling Example §

The following subroutines encode and decode an 8-bit value contained in “inbyte” with the LFSR. This is presented as one example only; there are many ways to obtain the proper output. This example demonstrates how to advance the LFSR eight times in one operation and how to XOR the data in one operation. Many other implementations are possible but they must all produce the same output as that shown here.

The following algorithm uses the “C” programming language conventions, where “<<” and “>>” represent the shift left and shift right operators, “>” is the compare greater than operator, and “^” is the exclusive or operator, and “&” is the logical “AND” operator.

```

/*
  this routine implements the serial descrambling algorithm in parallel form
  for the LSFR polynomial:  $x^{16}+x^5+x^4+x^3+1$ 
  this advances the LSFR 8 bits every time it is called
  this requires fewer than 25 xor gates to implement (with a static register)
  The XOR required to advance 8 bits/clock is:
bit 0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15
      8  9 10 11 12 13 14 15 0  1  2  3  4  5  6  7
          8  9 10 11 12 13 14 15
              8  9 10 11 12 13 14 15
                  8  9 10 11 12 13 14 15
  The serial data is just the reverse of the upper byte:
bit 0  1  2  3  4  5  6  7
      15 14 13 12 11 10 9  8
*/

```

```

int scramble_byte(int inbyte)
{
    static int scrambit[16];
    static int bit[16];
    static int bit_out[16];
    static unsigned short lfsr = 0xffff; // 16 bit short for polynomial
    int i, outbyte;

    if (inbyte == COMMA)           // if this is a comma
    {
        lfsr = 0xffff;           // reset the LFSR
        return (COMMA);         // and return the same data
    }

    if (inbyte == SKIP)           // don't advance or encode on skip
        return (SKIP);

    for (i=0; i<16;i++)          // convert LFSR to bit array for legibility
        bit[i] = (lfsr >> i) & 1;

        for (i=0; i<8; i++)      // convert byte to be scrambled for legibility
            scrambit[i] = (inbyte >> i) & 1;

        // apply the xor to the data
    if (!(inbyte & 0x100) &&      // if not a KCODE, scramble the data
        !(TrainingSequence == TRUE)) // and if not in the middle of
    {                               // a training sequence
        scrambit[0] ^= bit[15];
        scrambit[1] ^= bit[14];
        scrambit[2] ^= bit[13];
        scrambit[3] ^= bit[12];

At 2.5 GT/s, scrambling produces the power spectrum (in the 10-bit domain) shown in § Figure C-1.

Figure C-1 Scrambling Spectrum at 2.5 GT/s for Data Value of 0 §

C.2 128b/130b Data Scrambling Example §

The following subroutines illustrate how calculate the next value of the 128b/130b scrambling LFSR and how to scramble (or descramble) an 8-bit value, both given the current value of the LFSR.

This is presented as one example only; there are many ways to obtain the proper output. This example demonstrates how to advance the LFSR eight times in one operation and how to XOR the data in one operation. Many other implementations are possible but they must all produce the same output as that shown here.

The following algorithm uses the “C” programming language conventions, where “<<” and “>>” represent the shift left and shift right operators, “^” is the exclusive or operator, and “|=” is the assignment by bitwise or operator.

```

#include <stdio.h>

// "Set Bit" – Sets bit number "bit" of "var" to the value "val". Bit "bit" of "var" must start cleared.
#define SB(var,bit,val) var |= (val & 1) << bit

// "Get Bit" – Returns the value of bit number "bit" of "var".
#define GB(var,bit) ((var >> bit) & 1)

// Function to advance the LFSR value by 8 bits, given the current LFSR value
unsigned long int calc_next_lfsr(unsigned long int lfsr) {
    unsigned long int next_lfsr = 0;
    SB(next_lfsr,22, GB(lfsr,14) ^ GB(lfsr,16) ^ GB(lfsr,18) ^ GB(lfsr,20) ^ GB(lfsr,21) ^ GB(lfsr,22));
    SB(next_lfsr,21, GB(lfsr,13) ^ GB(lfsr,15) ^ GB(lfsr,17) ^ GB(lfsr,19) ^ GB(lfsr,20) ^ GB(lfsr,21));
    SB(next_lfsr,20, GB(lfsr,12) ^ GB(lfsr,19) ^ GB(lfsr,21));
    SB(next_lfsr,19, GB(lfsr,11) ^ GB(lfsr,18) ^ GB(lfsr,20) ^ GB(lfsr,22));
    SB(next_lfsr,18, GB(lfsr,10) ^ GB(lfsr,17) ^ GB(lfsr,19) ^ GB(lfsr,21));
    SB(next_lfsr,17, GB(lfsr, 9) ^ GB(lfsr,16) ^ GB(lfsr,18) ^ GB(lfsr,20) ^ GB(lfsr,22));
    SB(next_lfsr,16, GB(lfsr, 8) ^ GB(lfsr,15) ^ GB(lfsr,17) ^ GB(lfsr,19) ^ GB(lfsr,21) ^ GB(lfsr,22));
    SB(next_lfsr,15, GB(lfsr, 7) ^ GB(lfsr,22));
    SB(next_lfsr,14, GB(lfsr, 6) ^ GB(lfsr,21));
    SB(next_lfsr,13, GB(lfsr, 5) ^ GB(lfsr,20) ^ GB(lfsr,22));
    SB(next_lfsr,12, GB(lfsr, 4) ^ GB(lfsr,19) ^ GB(lfsr,21) ^ GB(lfsr,22));

D. Request Dependencies §

This specification does not specify the rules governing the creation of resource dependencies between TLPs using different Traffic Classes. Dependencies between packets in different Traffic Classes can create potential deadlock if devices make different assumptions about what is allowed and what is not. Dependencies can be created when a packet is forwarded (transmitted verbatim) or translated (transmitted with modification) from an input Port to an output Port.

Resource dependencies are created when received packets are forwarded/translated on the same or a different Link. Due to the fact that the forwarding/translating device has finite buffer resources this behavior creates a dependency between the ability to receive a packet and the ability to transmit a packet (in potentially a different VC or sub-channel).

The following notation is used to create a framework to enumerate the possibilities:

$$X(m) \rightarrow Y(n)$$

This means:

- a request in sub-channel $X(TC = m)$ is forwarded/translated in sub-channel $Y(TC = n)$.
- n and m are between 0-7.
- X and Y are either **P** (Posted Request), **N** (Non-Posted Request), or **C** (Completion).

The list of possible dependencies is:

$$\begin{aligned} &P(m) \rightarrow P(n) \\ &P(m) \rightarrow N(n) \\ &P(m) \rightarrow C(n) \\ &N(m) \rightarrow P(n) \\ &N(m) \rightarrow N(n) \\ &N(m) \rightarrow C(n) \\ &C(m) \rightarrow P(n) \\ &C(m) \rightarrow N(n) \\ &C(m) \rightarrow C(n) \end{aligned}$$

For a given system, each of these dependencies needs to be classified as legal or illegal for each of the following cases:

- Root Port forwarding to own Link.
- Root Port forwarding to different Root Port's Link.
- Endpoint or Bridge forwarding to own Link.

A Switch is not allowed to modify the TLPs that flow through it, but must ensure complete independence of resources assigned to separate VCs. System software must comprehend the system dependency rules when configuring TC/VC mapping throughout the system.

One possible legal mapping is:

	RC (Same Port)	RC (Different Port)	Endpoint
$P(m) \rightarrow P(n)$	$m \leq n$	$m \leq n$	$m < n$
$P(m) \rightarrow N(n)$	$m < n$	$m < n$	$m < n$
$P(m) \rightarrow C(n)$	illegal	illegal	illegal

	RC (Same Port)	RC (Different Port)	Endpoint
$N(m) \rightarrow P(n)$	$m < n$	$m < n$	$m < n$
$N(m) \rightarrow N(n)$	$m \leq n$	$m \leq n$	$m < n$
$N(m) \rightarrow C(n)$	$m = n$	$m = n$	$m = n$
$C(m) \rightarrow P(n)$	illegal	illegal	illegal
$C(m) \rightarrow N(n)$	illegal	illegal	illegal
$C(m) \rightarrow C(n)$	$m \geq n$	$m \geq n$	$m > n$

Note that this discussion only deals with avoiding the deadlock caused by the creation of resource dependencies. It does not deal with the additional livelock issues (or lack of forward progress) caused by the system's Virtual Channel arbitration policies.

Some of these potential dependencies are illegal or unreachable:

- $P(m) \rightarrow P(n), N(m) \rightarrow N(n)$
 - $m = n$ - This case is illegal and will lead to deadlock, except when a Request is being forwarded from one Port to another of a Switch or Root Complex.
 - $m \neq n$ - See discussion below.
- $P(m) \rightarrow N(n)$
 - $m = n$ - This case is illegal and will lead to deadlock.
 - $m \neq n$ - See discussion below.
- $N(m) \rightarrow P(n)$ - See discussion below.
- $P(m) \rightarrow C(n)$ - This case is illegal and will lead to deadlock.
- $N(m) \rightarrow C(n)$
 - $m = n$ - This case occurs during the normal servicing of a non-posted request by either a root complex or an endpoint.
 - $m \neq n$ - This case is unreachable and should never happen. Completions always use the same TC as the corresponding request.
- $C(m) \rightarrow P(n), C(m) \rightarrow N(n)$ - These cases are unreachable and should never happen due to the fact that completion buffers must be preallocated.
- $C(m) \rightarrow C(n)$
 - $m = n$ - This case is illegal and will lead to deadlock, except when a Completion is being forwarded from one Port to another of a Switch or Root Complex.
 - $m \neq n$ - This case will occur if $N(n) \rightarrow N(m)$ dependencies are allowed.

Other potential dependencies may be legal when comprehended as part of a specific usage model. For example, these cases:

$$P(m) \rightarrow P(n), N(m) \rightarrow N(n), P(m) \rightarrow N(n), N(m) \rightarrow P(n) \quad \text{where } m \neq n$$

might exist where a device services incoming requests by issuing modified versions of those requests using a different Traffic Class (for example, remapping the first requests address and generating the new request with the resulting address). In these cases, suitable rules must be applied to prevent circular dependencies that would lead to deadlock or livelock.

Examples of devices that may find the above mappings useful:

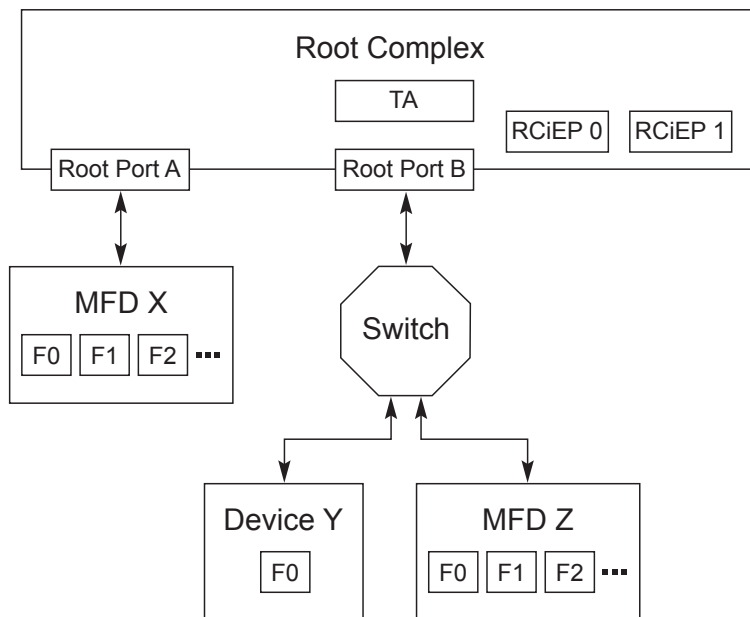

- Bridges to complex protocols that require state to be save/restored to/from host memory, i.e., PCI Express to Infiniband bridges.
- Messaging engines that must do address translation based upon page tables stored in host memory.
- UMA graphics devices that store their frame buffer in host memory.

E. ID-Based Ordering Usage §

E.1 Introduction §

ID-Based Ordering (IDO) is a mechanism that permits certain ordering restrictions to be relaxed as a means to improve performance. IDO permits certain TLPs to pass other TLPs in cases where otherwise such passing would be forbidden. The passing permitted by IDO is not required for proper operation (e.g., deadlock avoidance); it is only a means of improving performance.

For discussing IDO, it's useful to introduce the concept of a “TLP stream”, which is a set of TLPs that all have the same originator.²⁰⁴ For several important cases where TLP passing is normally forbidden, IDO permits such passing to occur if the TLPs belong to different TLP streams.

A-0757A

Figure E-1 Reference Topology for IDO Use §

§ Figure E-1 shows a reference topology. The reference topology is not intended to discourage the use of IDO with other topologies, but rather to provide specific examples for discussion.

Devices X and Z are Multi-Function Devices (MFDs); device Y is a single-Function device. The RCiEPs are Root Complex Integrated Endpoint Functions, and might or might not be part of the same Device. We will assume that one or more Functions are using the Translation Agent (TA) in the Root Complex (RC).

Referring to the ordering table and descriptions in § Section 2.4.1, having the IDO bit set in a Posted Request, Non-Posted Request, or Completion TLP permits that TLP to pass a Posted Request TLP if the two TLPs belong to different TLP streams. In the following examples, DMAR and DMAW stand for Direct Memory Access Read and Write; PIOR and PIOW stand for Programmed I/O Read and Write.

204. That is, the Requester IDs of Requests and the Completer IDs of Completions are all the same.

E.2 Potential Benefits with IDO Use §

Here are some example potential benefits that are envisioned with IDO use. Generally, IDO provides the most benefit when multiple TLP streams share a common Link and that Link becomes congested, either due to high utilization or due to temporary lack of Flow Control (FC) credit.

E.2.1 Benefits for MFD/RP Direct Connect §

Here are some examples in the context of traffic between MFD X and the RC in § Figure E-1.

- Posted Request passing another Posted Request: when a DMAW from F0 is stalled due to an TA miss, if IDO is set for a DMAW from F1, it is permitted within the RC for this DMAW to pass the stalled DMAW from F0.
- Non-Posted Request passing a Posted Request: when a DMAW from F0 is stalled due to an TA miss, if IDO is set for a DMAR Request from F1, it is permitted within the RC for this DMAR Request to pass the stalled DMAW from F0.
- Completion passing a Posted Request: when a DMAW from F0 is stalled due to an TA miss, if IDO is set for a PIOR Completion from F1, it is permitted within the RC for this PIOR Completion to pass the stalled DMAW from F0.

E.2.2 Benefits for Switched Environments §

Here are some examples in the context of traffic within the Switch in § Figure E-1.

- Non-Posted Request passing a Posted Request: when a DMAW from Device Y is stalled within the Switch due to a lack of FC credit from Root Port B, if IDO is set for a DMAR Request from MFD Z, it is permitted within the Switch for this DMAR Request to pass the stalled DMAW from Device Y. The same also holds for a DMAR Request from one Function in MFD Z passing a stalled DMAW from a different Function in MFD Z.
- Completion passing a Posted Request: when a DMAW from Device Y is stalled within the Switch due to a lack of FC credit from Root Port B, if IDO is set for a PIOR Completion from MFD Z, it is permitted within the Switch for this PIOR Completion to pass the stalled DMAW from Device Y. The same also holds for a PIOR Completion from one Function in MFD Z passing a stalled DMAW from a different Function in MFD Z.
- Posted Request passing another Posted Request: within a Switch, there is little or no envisioned benefit from having a DMAW from one TLP stream passing a DMAW from a different TLP stream. However, it is not prohibited for Switches to implement such passing as permitted by IDO.

E.2.3 Benefits for Integrated Endpoints §

Here are some examples for the Root Complex Integrated Endpoints (RCiEPs) in § Figure E-1. The benefits are basically the same as for the MFD/RP Direct Connect case.

- Posted Request passing another Posted Request: when a DMAW from RCiEP 0 is stalled due to an TA miss, if IDO is set for a DMAW from RCiEP 1, it is permitted for this DMAW to pass the stalled DMAW from RCiEP 0.
- Non-Posted Request passing a Posted Request: when a DMAW from RCiEP 0 is stalled due to an TA miss, if IDO is set for a DMAR Request from RCiEP 1, it is permitted for this DMAR Request to pass the stalled DMAW from RCiEP 0.

- Completion passing a Posted Request: when a DMAW from RCiEP 0 is stalled due to an TA miss, if IDO is set for a PIOR Completion from RCiEP 1, it is permitted for this PIOR Completion to pass the stalled DMAW from RCiEP 0.

E.2.4 IDO Use in Conjunction with RO §

IDO and RO²⁰⁵ are orthogonal. Certain instances of passing; for example, a Posted Request passing another Posted Request, might be permitted by IDO, RO, or both at the same time. While IDO and RO have significant overlap for some cases, it is strongly recommended that both be used whenever safely possible. RO permits certain TLP passing within the same TLP stream, which is never permitted by IDO. For traffic in different TLP streams, IDO permits control traffic to pass any other traffic, and generally it is not safe to Set RO with control traffic.

E.3 When to Use IDO §

With Endpoint Functions²⁰⁶, it is safe to Set IDO in all applicable TLPs originated by the Endpoint when the Endpoint is directly communicating with only one other entity, most commonly the RC. For the RC case, “directly communicating” specifically includes DMA traffic, PIO traffic, and interrupt traffic; communicating with RCiEPs or communicating using P2P Root Port traffic constitutes communicating with multiple entities.

With a Root Port, there are no envisioned high-benefit use models where it is safe to Set IDO in all applicable TLPs that it originates. Use models where a Root Port Sets IDO in a subset of the applicable TLPs it originates are outside the scope of this specification.

E.4 When Not to Use IDO §

E.4.1 When Not to Use IDO with Endpoints §

With Endpoint Functions, it is not always safe to Set IDO in applicable TLPs it originates if the Endpoint directly communicates with multiple entities. It may be safe to Set IDO in some TLPs and not others, but such use models are outside the scope of this specification.

For example, in § Figure E-1 if Device Y and MFD Z are communicating with P2P traffic and also communicating via host memory, it is not always safe for them to Set IDO in the TLPs they originate. As an example failure case, let’s assume that Device Y does a DMAW (to host memory) followed by a P2P Write to MFD Z. Upon observing the P2P Write, let’s assume that MFD Z then does a DMAW to the same location earlier targeted by the DMAW from Device Y. Normal ordering rules would guarantee that the DMAW from Device Y would be observed by host memory before the DMAW from MFD Z. However, if IDO is set in the DMAW from MFD Z, the RC would be permitted to have the second DMAW pass the first, causing a different end result in host memory contents.

Synchronization techniques like performing zero-length Reads might be used to avoid such communication failures when IDO is used, but specific use models are outside the scope of this specification.

205. In this Appendix, “RO” is an abbreviation for the Relaxed Ordering Attribute field.

206. Endpoint Functions include PCI Express Endpoints, Legacy PCI Express Endpoints, and Root Complex Integrated Endpoints.

E.4.2 When Not to Use IDO with Root Ports §

With Root Ports, it is not always safe to Set IDO in applicable TLPs it originates if Endpoint Functions in the hierarchy do any P2P traffic. It may be safe to Set IDO in some TLPs and not others, but such use models are outside the scope of this specification.

As an example, in § Figure E-1 if Device Y and MFD Z are communicating with P2P traffic and also communicating with host software, it is not always safe for Root Port B to Set IDO in the TLPs it originates. For example, let's assume that Device Y does a P2P Write to MFD Z followed by a DMAW (to host memory). Upon observing the DMAW, let's assume that the host does a PIO to MFD Z. Normal ordering rules would guarantee that the P2P Write from Device Y would be observed by MFD Z before the PIO from the host. However, if IDO is set in the PIO from the host, the Switch would be permitted to have the PIO pass the P2P Write, ultimately having the two Writes arrive at MFD Z out of order.

IMPLEMENTATION NOTE:

REQUESTER AND COMPLETER IDS FOR RC-ORIGINATED TLPs §

With RC implementations where the Requester ID in a PIO Request does not match the Completer ID in a DMAR Completion, this enables another potential communication failure case if IDO is Set in the Completion. For this case, if a PIO is followed by a DMAR Completion with IDO Set, a Switch below the Root Port could permit the DMAR Completion to pass the PIO, violating the normal ordering rule that a non-RO Read Completion must not pass Posted Requests. The PIO and DMAR Completion would appear to belong to different TLP streams, though logically they belong to the same TLP stream. Special caution is advised in setting IDO with TLPs originating from such RCs.

E.5 Software Control of IDO Use §

E.5.1 Software Control of Endpoint IDO Use §

By default, Endpoints are not enabled to Set IDO in any TLPs they originate.

IMPLEMENTATION NOTE:

THE “SIMPLE” POLICY FOR IDO USE §

It is envisioned that Endpoints designed primarily to communicate directly with only one other entity (e.g., the RC) may find a “simple” policy for setting IDO to be adequate. Here's the envisioned “simple” policy. If the IDO Request Enable bit is Set, the Endpoint Sets IDO in all applicable Request TLPs that it originates. If the IDO Completion Enable bit is Set, the Endpoint Sets IDO in all Completion TLPs that it originates.

It is envisioned that a software driver associated with each Endpoint will determine when it is safe for the Endpoint to set IDO in applicable TLPs it originates. A driver should be able to determine if the Endpoint is communicating with multiple other entities, and should know the Endpoint's capabilities as far as setting IDO with all applicable TLPs when enabled, versus setting IDO selectively. If a driver determines that it is safe to enable the setting of IDO, the driver can set the IDO Request Enable and/or IDO Completion Enable bits either indirectly via OS services or directly, subject to OS policy.

If an Endpoint is designed for communication models where it is not safe to utilize the “simple” policy for IDO use, the Endpoint can implement more complex policies for determining when the Endpoint sets the IDO bit. Such implementations might utilize device-specific controls that are managed by the device driver. Such policies and device-specific control mechanisms are outside the scope of this specification.

E.5.2 Software Control of Root Port IDO Use §

Since there are no envisioned high-benefit “simple” use models for Root Ports setting the IDO bit with TLPs they originate, and there are known communication failure cases if Root Ports set the IDO bit with all applicable TLPs they originate, it is anticipated that Root Ports will rarely be enabled to set IDO in TLPs they originate. Such use models and policies for Root Ports setting IDO are outside the scope of this specification.

F. Message Code Usage §

§ Table F-1 contains a list of currently defined PCI Express Message Codes. Message codes are defined in this specification and in other specifications. This table will be updated as Messages are defined in other specifications but due to document release schedules, this table might not contain recently defined Messages.

Table F-1 Message Code Usage §

Message Code	Routing r[2:0]	Type	Description
0000 0000	011	Msg	Unlock, see § Section 2.2.8.4
0000 0001	010	MsgD	Invalidate Request Message, see § Section 10.3.1
0000 0010	010	Msg	Invalidate Completion Message, see § Section 10.3.2
0000 0100	000	Msg	Page Request Message, see § Section 10.4.1
0000 0101	010	Msg	PRG Response Message, see § Section 10.4.2
0001 0000	100	Msg	Latency Tolerance Reporting (LTR) Message, see § Section 2.2.8.8
0001 0010	100	Msg	Optimized Buffer Flush/Fill (OBFF) Message, see § Section 2.2.8.9
0001 0100	100	Msg	PM_Active_State_Nak, see § Section 2.2.8.2
0001 1000	000	Msg	PM_PME, see § Section 2.2.8.2
0001 1001	011	Msg	PME_Turn_Off, see § Section 2.2.8.2
0001 1011	101	Msg	PME_TO_Ack, see § Section 2.2.8.2
0010 0000	100	Msg	Assert_INTA, see § Section 2.2.8.1
0010 0001	100	Msg	Assert_INTB, see § Section 2.2.8.1
0010 0010	100	Msg	Assert_INTC, see § Section 2.2.8.1
0010 0011	100	Msg	Assert_INTD, see § Section 2.2.8.1
0010 0100	100	Msg	Deassert_INTA, see § Section 2.2.8.1
0010 0101	100	Msg	Deassert_INTB, see § Section 2.2.8.1
0010 0110	100	Msg	Deassert_INTC, see § Section 2.2.8.1
0010 0111	100	Msg	Deassert_INTD, see § Section 2.2.8.1
0011 0000	000	Msg	ERR_COR, see § Section 2.2.8.3
0011 0001	000	Msg	ERR_NONFATAL, see § Section 2.2.8.3
0011 0011	000	Msg	ERR_FATAL, see § Section 2.2.8.3
0100 0000	100	Msg	Ignored Message, see § Section 2.2.8.7

§ Table F-2 contains a list of currently defined Subtype codes for PCI-SIG-Defined VDMs (see § Section 2.2.8.6.1). Subtype codes are defined in this specification and in other specifications. This table will be updated as Subtype codes are defined in other specifications but due to document release schedules, this table might not contain recently defined Subtypes.

Table F-2 PCI-SIG-Defined VDM Subtype Usage §

Subtype	Routing r[2:0]	Type	Description
0000 0000	010 or 011	MsgD	Deprecated; formerly used for LN Message (Lightweight Notification)
0000 0001	011	MsgD	Hierarchy ID Message, See § Section 2.2.8.6.4 and § Section 6.25
0000 1000	100	Msg	Device Readiness Status, see § Section 2.2.8.6.2
0000 1001	000	Msg	Function Readiness Status, see § Section 2.2.8.6.3

G. Protocol Multiplexing §

The Protocol Multiplexing mechanism provides a standard mechanism to transport non-PCI Express protocols across a PCI Express Link. The mechanism supports the multiplexing of PMUX Packets and TLPs onto a single PCI Express Link.

An example system topology using Protocol Multiplexing is shown in § Figure G-1. In this example, the Link may operate in two modes:

- PCI Express Link. Protocol Multiplexing is disabled.
- PMUX Link. Protocol Multiplexing is enabled. Both TLPs and PMUX Packets are used in a coordinated fashion. PMUX Packets may be used to support additional protocols efficiently.

Figure G-1 Device and Processor Connected Using a PMUX Link §

A PMUX Link is shown in § Figure G-2. Arbitration and encapsulation occurs between the transmit queues and the Link. Demultiplexing and decapsulation occurs between the Link and the various receive queues. Packets are sent from transmit queues to the corresponding receive queues. Packets are identified as either PMUX Packets or TLPs.

Figure G-2 PMUX Link §

Important attributes of the Protocol Multiplexing mechanism are:

- Protocol Multiplexing support is optional normative.
- Protocol Multiplexing has no impact on PCI Express components that do not support it.
- Protocol Multiplexing has no impact on PCI Express TLPs and DLLPs, even when it is enabled.
- A Link may be used for both TLPs and PMUX Packets at the same time.

- Protocol Multiplexing does not consume or interfere with PCI Express resources (sequence numbers, credits, etc.). PMUX Packets use distinct resources associated with the specific multiplexed protocol.
- Protocol Multiplexing is disabled by default and is enabled by software. PMUX Packets must not be sent unless enabled by software. PMUX Packets received at Ports that support Protocol Multiplexing are ignored until Protocol Multiplexing is enabled by software.
- Protocol Multiplexing is selectable on a per-Link basis. Protocol Multiplexing may be used on any collection of Links in a system.
- A PMUX Link may support up to four simultaneously active PMUX Channels. Software configures the protocol used on each PMUX Channel.
- PMUX Packets contain an LCRC. This is used to provide data resiliency in a similar fashion as PCI Express TLPs.
- PMUX Packets do not use the ACK/NAK mechanism of PCI Express. Multiplexed protocol specific acknowledgement mechanisms can be used to provide reliable delivery when needed.
- PMUX Packets do not contain a TLP Sequence Number. Instead, they contain a 12 bit PMUX Packet Metadata field that is available for multiplexed protocol specific use.
- PMUX Packet transmitters must contain some arbitration/QoS mechanism for scheduling sending of PMUX Packets, TLPs and DLLPs; however, the mechanism used is outside the scope of this specification.
- The Protocol Multiplexing mechanism does not define any addressing or routing mechanism for PMUX Packets.

PMUX Packets are similar to PCI Express TLPs. The PMUX Packet Flow Through is shown in § Figure G-3. The PCI Express Packet flow through the layers is shown in § Figure 1-5. Changes from PCI Express Packet Flow Through are:

- PMUX Packets use a protocol specific PMUX Protocol Layer instead of the PCI Express Transaction Layer.
- PMUX Packets use a simplified Data Link Layer. The packet integrity portion of the Data Link Layer is mostly unchanged (LCRC computation uses a different seed value). The reliability and flow control aspects of the Data Link Layer are removed (the TLP Sequence Number field is repurposed as PMUX Packet Metadata).
- The Physical Layer is slightly modified to provide a mechanism to identify PMUX Packets.

Figure G-3 PMUX Packet Flow Through the Layers §

G.1 Protocol Multiplexing Interactions with PCI Express §

§ Table G-1 and § Table G-2 describe interactions between Protocol Multiplexing and PCI Express. § Table G-1 describes how PCI Express attributes affect Protocol Multiplexing. § Table G-2 describes how Protocol Multiplexing features affect PCI Express attributes.

Table G-1 PCI Express Attribute Impact on Protocol Multiplexing §

PCI Express Attribute	Impact on Protocol Multiplexing
Link Speed	<p>All PMUX Channels are disabled when the Current Link Speed corresponds to a speed that is not supported by Protocol Multiplexing (see § Section G.5.4). A PMUX Channel may be disabled when the Current Link Speed corresponds to a speed that is not supported by the associated protocol.²⁰⁷</p> <p>Link speed can change either explicitly due to a change in the Target Link Speed field or automatically due to an autonomous Link speed change (see § Section 6.11).</p> <p>The PMUX Protocol Layer is permitted to influence the mechanism used by a component to determine when it requests an autonomous Link speed change. In addition, setting Hardware Autonomous Speed Disable at each end of the Link will prevent certain autonomous Link speed changes (see § Section 7.5.3.18).</p> <p>The PMUX Protocol Layer may be notified of the change.</p>
Link Width	<p>A PMUX Channel may be disabled when the Link Width corresponds to a width that is not supported by the associated protocol.²⁰⁸</p> <p>The PMUX Protocol Layer is permitted to influence the mechanism used by a component to determine when it requests a Link Width change.</p> <p>The PMUX Protocol Layer may be notified of the change.</p>
FLR initiated	All PMUX Channels on a Link are disabled if an FLR is directed to the Upstream Port's Function 0. No PMUX Channels are affected if an FLR is directed to any other Function.
DL_Down	All PMUX Channels on a Link are disabled.
Hot Reset	All PMUX Channels on a Link are disabled.
PERST#	All PMUX Channels on a Link are disabled.
TLP Replay	No effect on Protocol Multiplexing.
DLLP Lost	No effect on Protocol Multiplexing.
TLP Prefix	No effect on Protocol Multiplexing.
Locked Transactions	No effect on Protocol Multiplexing (including no effect on any protocol specific forwarding of PMUX Packets).
AtomicOp Transactions	No effect on Protocol Multiplexing.
Multicast Transactions	No effect on Protocol Multiplexing.
Access Control Services (ACS)	No effect on Protocol Multiplexing.
Alternative Routing ID-Interpretation (ARI)	No effect on Protocol Multiplexing.
TPH Requester	No effect on Protocol Multiplexing.
Virtual Channels	No effect on Protocol Multiplexing. PCI Express Links remain capable of supporting a full complement of VCs.

207. The mechanism software uses to determine what Link Speeds are supported by a protocol is outside the scope of this specification.

208. The mechanism software uses to determine what Link Widths are supported by a protocol is outside the scope of this specification.

PCI Express Attribute	Impact on Protocol Multiplexing
Internal Error	Corrected or Uncorrectable Internal Errors in the PMUX Protocol Layer may be reported as PCI Express Internal Errors.
<u>L0s</u> Link Power State	Protocol Multiplexing tracks the Link state. The PMUX Protocol Layer may request the Link transition back to L0.
<u>L1</u> Link Power State	Protocol Multiplexing tracks the Link state. The PMUX Protocol Layer may request the Link transition back to L0.
Disabled LTSSM State	Disabling a Link also disables all PMUX Channels on the Link.
Loopback LTSSM State	Entering Loopback state disables all PMUX Channels on the Link.
Recovery LTSSM State	No effect on Protocol Multiplexing. The PMUX Protocol Layer may be notified.
Receiver or Framing Error	The error is reported to the PMUX Protocol Layer to indicate that data might have been lost. This can be used to initiate protocol specific error recovery mechanisms. The Error is reported to software using PCI Express Mechanisms.
Lane Reversal	No effect on Protocol Multiplexing. Support for Lane Reversal remains optional.
Polarity Inversion	No effect on Protocol Multiplexing.
Crosslink	No effect on Protocol Multiplexing. Support for Crosslink remains optional. If supported, the PMUX Protocol Layer may be notified of the outcome of the Crosslink Upstream / Downstream negotiation.
Lane assignment rules	Placement and frequency rules for STP Symbols and STP Tokens are not changed (see § Section 4.2.1.2 and § Section 4.2.2.3.2). These rules apply identically to PCI Express TLPs and PMUX Packets.
PCI Power Management Power State	All PMUX Channels on a Link are disabled if the Upstream Port's Function 0 is sent to non-D0 state.
Dynamic Power Allocation (DPA)	No effect on Protocol Multiplexing. The PMUX Protocol Layer is notified of the change and may participate in the power reduction. PCI Express power management includes any power used by the PMUX Protocol Layer.
PCI Power Management Power Consumed / Power Dissipated / Aux_Current	Power required by the PMUX Protocol Layer is included in the PCI structures.
Power Budgeting	Power required by the PMUX Protocol Layer is included in the PCI Express structures.
Slot Power Limit	Slot Power Limit includes power available to PMUX Protocol Layer.
ASPM L0s Entry Condition	The definition of Idle is extended to include: <ul style="list-style-type: none"> No pending PMUX Packets to transmit over the Link. For PMUX Channels that use protocol specific Flow Control, no credits are available to send PMUX Packets in that PMUX Channel.
ASPM L1 Entry Condition	A Link may not enter <u>L1</u> if PMUX Packets are pending or scheduled to be transmitted.
ASPM L0s/L1 Exit Conditions	A Link may be directed to exit L0s or L1 if a component needs to transmit a PMUX Packet. Routing of PMUX Packets through routing elements is outside the scope of this specification; the associated <u>L0s/L1</u> exit rules are also unspecified.

PCI Express Attribute	Impact on Protocol Multiplexing
Bus Renumbering	No effect on Protocol Multiplexing.
Hot Plug	No direct effect on Protocol Multiplexing. Note Hot Plug events indirectly affect Data Link State which, in turn affects Protocol Multiplexing.
TLP Sequence Number	No effect on Protocol Multiplexing. PMUX Packets do not consume TLP Sequence Numbers.
PCI Express Flow Control	No effect on Protocol Multiplexing. PMUX Packets do not consume PCI Express Flow Control credits. Flow Control Update DLLPs must be sent as required by PCI Express.
Error Reporting	No direct effect on Protocol Multiplexing. The PMUX Protocol Layer may be notified when an error is signaled or when an error message is received.
LCRC Errors in TLPs	No effect on Protocol Multiplexing.
Nullified TLPs	No effect on Protocol Multiplexing.
VC Arbitration	No effect on Protocol Multiplexing. Arbitration within PCI Express is unaffected by Protocol Multiplexing.
Port Arbitration	No effect on Protocol Multiplexing. Arbitration within PCI Express is unaffected by Protocol Multiplexing.
Electrical Idle Inference	PMUX Packets count as TLPs for the purpose of inferring Electrical Idle.
MR-IOV	Protocol Multiplexing may co-exist with MR-IOV. PMUX Packets are not part of any MR-IOV Virtual Hierarchy. Protocol Multiplexing is controlled using configuration space in the Management VH(s).

Table G-2 PMUX Attribute Impact on PCI Express §

PMUX Attribute	Impact on PCI Express
PMUX Protocol Error	No effect on PCI Express.
LCRC Errors in PMUX Packets	No effect on PCI Express. PMUX Packets with LCRC errors are discarded without triggering PCI Express replay. This error is reported to the PMUX Protocol Layer and can be used to initiate protocol specific error recovery and/or error reporting mechanisms.
Link Unreliability	The PMUX Protocol Layer is permitted to influence the mechanism used by a component to determine if it requests an autonomous link speed change.
Nullified PMUX Packets	No effect on PCI Express. It is protocol specific whether PMUX Packets within a specific PMUX Channel may be nullified. If supported, PMUX Packets are nullified in the same manner as TLPs (e.g., inverting the LCRC and signaling nullification at the Physical Layer). Receiving a nullified PMUX Packet may be reported to the PMUX Protocol Layer.
Electrical Idle Inference	PMUX Packets count as TLPs for the purpose of inferring Electrical Idle.
PMUX Protocol Layer directs LTSSM to enter Recovery	Both PCI Express and the PMUX Protocol Layer are permitted to direct a transition from L0 to Recovery.
PMUX Channel Enabled / Disabled	No effect on PCI Express
PMUX Packet Receiver Buffer Overflow	No effect on PCI Express. This is a protocol problem within the PMUX Channel. The PMUX Transport Layer must continue to accept such packets dispose of them using protocol specific mechanisms.
Received PMUX Packet larger or smaller than supported by the associated protocol	No effect on PCI Express. These are protocol problems within the PMUX Channel. The PMUX Transport Layer must accept such packets and dispose of them using protocol specific mechanisms.

PMUX Attribute	Impact on PCI Express
Received PMUX Packet that contains more than 125 DWORDs of PMUX Packet Data	<p>No effect on PCI Express. This is an invalid PMUX Packet. The PMUX Transport Layer must accept such a packet and dispose of it. A protocol specific mechanism may be used to report the error.</p> <p>Note: This situation only exists for a packet encoded using 8b/10b. The TLP Length field of a packet encoded using 128b/130b cannot contain values that cause this situation.</p>
PMUX Packet Received on disabled PMUX Channel	<p>No effect on PCI Express. No effect on any other PMUX Channel. Receivers must silently ignore such packets regardless of packet length and regardless of whether or not the packet is nullified.</p> <p>PMUX Packets arriving on a disabled PMUX Channel may occur normally when software is in the process of initializing Protocol Multiplexing.</p>
PMUX Packet Received at component that does not support Protocol Multiplexing	<p>Software should not enable PMUX Packets unless both ends of a Link support Protocol Multiplexing.</p> <p>In the 128b/130b encoding, receiving a PMUX Packet by a component that does not support Protocol Multiplexing is a Framing Error (see § Section 4.2.2.3.1).</p> <p>In the 8b/10b encoding, the PMUX Packet LCRC is computed differently than the TLP LCRC. Receivers that do not support Protocol Multiplexing will interpret PMUX Packets as TLPs with LCRC errors and will not process them.</p>
Large PMUX Packets when PCI Express Max_Payload_Size is small	<p>Under certain conditions, it is possible for a large PMUX Packet to trigger a premature PCI Express replay. For example, this can occur when the time needed to transmit a PMUX Packet is larger than the REPLAY_TIMER (see § Section 3.6.2.1).</p> <p>To avoid this issue, implementations are permitted to not advance (hold) their REPLAY_TIMER during the reception of PMUX Packets.</p> <p>Note: The PCI Express REPLAY_TIMER mechanism has adequate headroom for most cases. This issue exists when (1) Max_Payload_Size is 000b, (2) PMUX Packets are larger than about 80 DWORDs, and (3) the REPLAY_TIMER is at the low end of the -0%/+100% tolerance.</p>

G.2 PMUX Packets §

A PMUX Packet contains the information shown in § Figure G-4.

Figure G-4 PMUX Packet §

PMUX Channel ID is a 2 bit field that identifies which protocol is associated with a PMUX Packet. PMUX Channel ID values are between 0 and 3 (inclusive).

PMUX Packet Metadata is a 12 bit field that provides information about the PMUX Packet. Definition of this field is protocol specific and is outside the scope of this specification.

A PMUX Packet consists of between 0 and 125 DWORDs of PMUX Packet Data. Layout and usage of these DWORDs is protocol specific and is outside the scope of this specification. A PMUX Packet need not have any PMUX Packet Data and may consist only of PMUX Channel ID and PMUX Packet Metadata.

G.3 PMUX Packet Layout §

There are two layouts defined for PMUX Packets. One layout is used for 2.5 and 5.0 GT/s data rates and another layout is used for 8.0 GT/s and higher data rates. These layouts are discussed in the following sections.

G.3.1 PMUX Packet Layout for 8b/10b Encoding §

§ Figure G-5 and § Table G-3 show the layout of PMUX Packets when using 8b/10b encoding. For reference, the 8b/10b encoding of a TLP is also shown (see § Section 4.2.1.2 for the official definition).

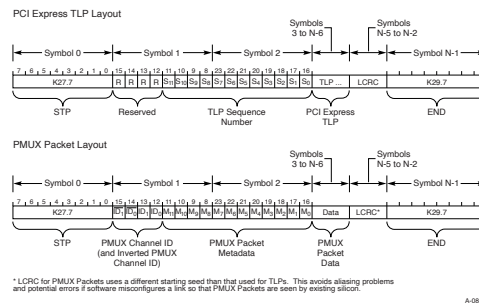

Figure G-5 TLP and PMUX Packet Framing (8b/10b Encoding) §

Table G-3 PMUX Packet Layout (8b/10b Encoding) §

Symbol	Field	Bit Position(s)	PMUX Packet Usage	TLP Usage
0	Start TLP Indicator	7:0	K27.7	
1	Inverted PMUX Channel ID[1:0]	7:6	Inverted (1s complement) of Symbol 1 bits 6:4	Reserved
	PMUX Channel ID[1:0]	5:4	PMUX Channel ID	Reserved
	PMUX Packet Metadata[11:8]	3:0	PMUX Packet Metadata[11:8]	TLP Sequence Number[11:8]
2	PMUX Packet Metadata[7:0]	7:0	PMUX Packet Metadata[7:0]	TLP Sequence Number[7:0]
3 to N-6	Packet	7:0	PMUX Packet	TLP
N-5 to N-2	LCRC	7:0	PMUX LCRC	PCI Express LCRC
N-1	END	7:0	K29.7	

For PMUX Packets, symbols 1 and 2 contain PMUX Packet Metadata in the same bit positions that TLPs use for TLP Sequence Number.

The PMUX LCRC algorithm is identical to the TLP LCRC algorithm as described in [§ Section 3.6.2](#) with the following modifications:

- The seed value is FB3E E248h (TLP LCRC uses FFFF FFFFh).
- The PMUX Channel ID field in Symbol 1 bits 7:4 is included in the PMUX LCRC in the same manner as the 4 reserved bits in the TLP LCRC.
- The PMUX Packet Metadata field is included in the PMUX LCRC in the same manner as the TLP Sequence Number field is included in the TLP LCRC.

IMPLEMENTATION NOTE: PMUX PACKETS AT RECEIVERS THAT DO NOT SUPPORT PROTOCOL MULTIPLEXING §

The bits used for PMUX Channel ID are reserved unless Protocol Multiplexing is supported. As such, Receivers that do not support Protocol Multiplexing must ignore the PMUX Channel ID bits. If software misconfigures Protocol Multiplexing, a component that does not support Protocol Multiplexing could receive a PMUX Packet. To prevent that component from misinterpreting such a PMUX Packet as a valid TLP, the LCRC computation is changed for PMUX Packets. The result is that a valid PMUX Packet will never be misinterpreted as a valid TLP. These LCRC “errors” may trigger PCI Express replay and may result in REPLAY_NUM Rollover correctable errors being reported.

IMPLEMENTATION NOTE: PMUX PACKET LCRC §

The PMUX Channel ID field is covered by the LCRC. As such, when using 8b/10b encoding, receivers must wait until the LCRC is checked to make firm decisions based on the PMUX Channel ID value. The Inverted PMUX Channel ID can be compared against the PMUX Channel ID to make tentative decisions.

Note: The value of the LCRC associated with a given PMUX Packet is independent of the encoding used to transmit the packet.

G.3.2 PMUX Packet Layout at 128b/130b Encoding §

§ Figure G-6 and § Table G-4 show the layout of PMUX Packets when using 128b/130b encoding. For reference, the 128b/130b encoding of a TLP is also shown (see [§ Section 4.2.2.2](#) for the official definition).

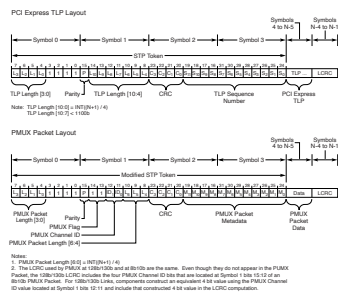

Figure G-6 TLP and PMUX Packet Framing (128b/130b Encoding) §

Table G-4 PMUX Packet Layout (128b/130b Encoding) §

Symbol	Field	Bit Position(s)	PMUX Packet Usage	TLP Usage
0	Start TLP Indicator	3:0	Value of 1111b	
	PMUX Packet Length[3:0]	7:4	Bits [3:0] of the PMUX Packet Length. Bit 0 is the least significant PMUX Packet Length bit.	Bits [3:0] of the TLP Length field. Bit 0 is the least significant TLP Length bit.
1	Frame Parity (P)	7	Even parity of Symbol 0 bits [7:4], Symbol 1 bits [6:0] and Symbol 2 bits [7:4]	
	PMUX Packet Indicator	6:5	Value of 11b	
	PMUX Channel ID[1:0]	4:3	PMUX Channel ID	Bits [10:4] of the TLP Length field. Bit 10 is the most significant TLP Length bit.
	PMUX Packet Length[6:4]	2:0	Bits [6:4] of PMUX Packet Length. Bit 6 is the most significant PMUX Packet Length bit.	
2	PMUX Packet Metadata[11:8]	3:0	PMUX Packet Metadata[11:8]	TLP Sequence Number[11:8]
	Frame CRC (C[3:0])	7:4	CRC of Symbol 0, bits [7:4] and Symbol 1 bits [6:0]	
3	PMUX Packet Metadata[7:0]	7:0	PMUX Packet Metadata[7:0]	TLP Sequence Number[7:0]
4 to N-5	Packet	7:0	PMUX Packet	TLP
N-4 to N-1	LCRC	7:0	PMUX LCRC	PCI Express LCRC

§ Table G-5 describes the encodings of Symbol 1 bits [6:3] in more detail. If these bits contain a value less than 1001b, the packet is a TLP and is processed as described in § Section 4.2.2.²⁰⁹ If these bits contain 1001b, 1010b, or 1011b, the encoding is reserved for future standardization and is processed as described in § Section 4.2.2.3.3. If these bits contain a value greater than or equal to 1100b, the packet is a PMUX Packet is defined as specified in this appendix.²¹⁰

209. The value 1001b supports a maximum TLP Length [10:0] value of 1151 DWORDs (decimal). This will accommodate a TLP consisting of 4096 bytes of payload, 16 bytes of TLP Header, 4 bytes of TLP digest, and 480 bytes of TLP Prefix.

Table G-5 Symbol 1 Bits [6:3] §

Symbol 1 bits [6:3]	Meaning
0xxx _b or 1000 _b	Packet is a TLP. Bits [6:3] are TLP Length [10:7].
1001 _b , 1010 _b , or 1011 _b	Encoding reserved for future standardization. Receivers detecting these encodings shall process them as described in § Section 4.2.2.3.3 .
1100 _b	Packet is a PMUX Packet. PMUX Channel ID is 0.
1101 _b	Packet is a PMUX Packet. PMUX Channel ID is 1.
1110 _b	Packet is a PMUX Packet. PMUX Channel ID is 2.
1111 _b	Packet is a PMUX Packet. PMUX Channel ID is 3.

For PMUX Packets, the packet length in DWORDs is contained in PMUX Packet Length [6:0]. Other than being a smaller field, PMUX Packet Length is interpreted in the same manner as TLP Length. Specifically, PMUX Packet Length also includes the framing and PMUX LCRC DWORDs (see § Section 4.2.2.2).

For PMUX Packets, symbols 2 and 3 contain PMUX Packet Metadata in the same bit positions that TLPs use for TLP Sequence Number.

The PMUX LCRC algorithm is identical to the TLP LCRC algorithm as described in § Section 3.6.2 with the following modifications:

- The seed value is FB3E E248h (TLP LCRC uses FFFF FFFFh).
- The PMUX Channel ID field in Symbol 1 bits 4:3 is used to compute a 4 bit value that is included in the PMUX LCRC in the same manner as the 4 reserved bits in the TLP LCRC. This 4 bit value contains the value that would be used, by the 8b/10b encoding, for Symbol 1 bits 7:4. Specifically, the lower 2 bits of this 4 bit value contain the PMUX Channel ID and the upper 2 bits contain the inverse (1s complement) of the PMUX Channel ID.
- The PMUX Packet Metadata field is included in the PMUX LCRC in the same manner as the TLP Sequence Number field is included in the TLP LCRC.

The Frame CRC and Frame Parity fields are computed as shown below. This is the same algorithm computed over the same bit positions as defined in § Section 4.2.2.2 .

$$\begin{aligned}
 C[0] &= 1b \wedge \text{PMUX_Channel_ID}[0] \\
 &\quad \wedge L[6] \wedge L[4] \wedge L[2] \wedge L[1] \wedge L[0] \\
 C[1] &= 1b \wedge 1b \wedge \text{PMUX_Channel_ID}[0] \\
 &\quad \wedge L[5] \wedge L[4] \wedge L[3] \wedge L[2] \\
 C[2] &= 1b \wedge \text{PMUX_Channel_ID}[1] \\
 &\quad \wedge L[6] \wedge L[4] \wedge L[3] \wedge L[2] \wedge L[1] \\
 C[3] &= \text{PMUX_Channel_ID}[1] \\
 &\quad \wedge \text{PMUX_Channel_ID}[0] \\
 &\quad \wedge L[5] \wedge L[3] \wedge L[2] \wedge L[1] \wedge L[0] \\
 P &= 1b \wedge 1b \wedge \text{PMUX_Channel_ID}[1] \\
 &\quad \wedge \text{PMUX_Channel_ID}[0] \\
 &\quad \wedge L[6] \wedge L[5] \wedge L[4] \wedge L[3] \wedge L[2] \wedge L[1] \wedge L[0] \\
 &\quad \wedge C[3] \wedge C[2] \wedge C[1] \wedge C[0]
 \end{aligned}$$

210. The value 1100_b was chosen to simplify distinguishing PMUX Packets from TLPs and from the reserved encodings.

IMPLEMENTATION NOTE:

PMUX CHANNEL ID AND FRAME CRC §

When using 128b/130b encoding, the PMUX Channel ID field is covered by the Frame CRC and Frame Parity fields. As such, receivers may make decisions based on the PMUX Channel ID value as soon as the Frame CRC and Frame Parity is checked and need not wait until the PMUX LCRC is checked.

Note: The PMUX Channel ID is also covered by the LCRC. The value of the LCRC associated with a given PMUX Packet is independent of the encoding used to transmit the packet.

G.4 PMUX Control §

Protocol Multiplexing is disabled by default. Each PMUX Channel must be explicitly enabled by software at each end of the associated Link. Protocol Multiplexing is disabled whenever the link drops (Data Link Layer indicates DL_Down).

A component that supports Protocol Multiplexing indicates such by the presence of the PMUX Extended Capability.

The following rules apply to components that support Protocol Multiplexing:

- PMUX Packets received in a PMUX Channel that is not enabled are silently ignored.
- PMUX Packets may not be transmitted unless the associated PMUX Channel is enabled. A PMUX Channel may also require additional, protocol specific, initialization mechanisms before PMUX Packets may be transmitted.

G.5 PMUX Extended Capability §

§ Figure G-7 shows the PMUX Extended Capability structure. The presence of this capability indicates that the Port supports the optional Protocol Multiplexing mechanism. This capability is optional and may be present in any Downstream Port and in Function 0 of any Upstream Port. It must not be present in non-zero Functions of Upstream Ports or in RCRBs.

The length of the PMUX Extended Capability is determined by the PMUX Protocol Array Size field (see § Section G.5.2).

This capability contains a list of the protocols supported by the Link (the PMUX Protocol Array). It also contains the mechanism software uses to enable and configure PMUX Channels. This capability must be present in both the Upstream and Downstream Ports of a Link in order for Protocol Multiplexing to be successfully enabled.

Software may enable the Upstream and Downstream Ports of a Link in either order. Software may enable multiple PMUX Channels using a single write to the PMUX Control Register.

Behavior is undefined if software enables Protocol Multiplexing in one Port and the other Port of the Link does not support Protocol Multiplexing. Behavior is also undefined if software configures a PMUX Channel inconsistently (the same PMUX Channel in the Ports on each end of a Link configured with incompatible protocols).

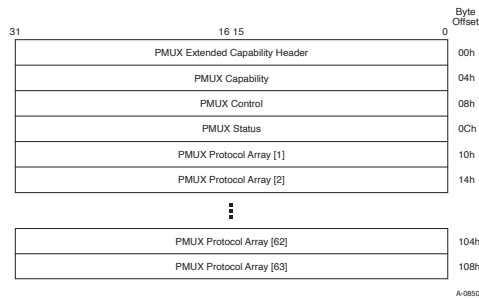

Figure G-7 PMUX Extended Capability §

G.5.1 PMUX Extended Capability Header (Offset 00h) §

§ Figure G-8 details the allocation of fields in the PMUX Extended Capability header; § Table G-6 provides the respective bit definitions.

Figure G-8 PMUX Extended Capability Header §

Table G-6 PMUX Extended Capability Header §

Bit Location	Register Description	Attributes
15:0	PCI Express Extended Capability ID - This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the PMUX Extended Capability is 001Ah.	RO
19:16	Capability Version - This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Must be 1h for this version of the specification.	RO
31:20	Next Capability Offset - This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of capabilities. This offset is relative to the beginning of PCI compatible Configuration Space and thus must always be either 000h (for terminating the list of Capabilities) or greater than 0FFh.	RO

G.5.2 PMUX Capability Register (Offset 04h) §

§ Figure G-9 details the allocation of fields in the PMUX Capability Register. § Table G-7 provides the respective bit definitions.

Figure G-9 PMUX Capability Register §

Table G-7 PMUX Capability Register §

Bit Location	Register Description	Attributes												
5:0	PMUX Protocol Array Size - Indicates the size of this Function's PMUX Protocol Array. This field may be 0 to indicate that even though no protocols are supported, the Port will ignore all received PMUX Packets.	RO												
15:8	<p>PMUX Supported Link Speeds - This field indicates the Link speed(s) where Protocol Multiplexing is supported. Each bit corresponds to a Link speed. If a bit is Set, Protocol Multiplexing is supported at that Link speed. If a bit is Clear, Protocol Multiplexing is not supported at that Link speed.</p> <p>Bit definitions are:</p> <table border="0"> <tr> <td>Bit 8</td> <td>2.5 GT/s</td> </tr> <tr> <td>Bit 9</td> <td>5.0 GT/s</td> </tr> <tr> <td>Bit 10</td> <td>8.0 GT/s</td> </tr> <tr> <td>Bit 11</td> <td>16.0 GT/s</td> </tr> <tr> <td>Bit 12</td> <td>32.0 GT/s</td> </tr> <tr> <td>Bits 15:13</td> <td>RsvdP</td> </tr> </table> <p>At least one Link speed must be supported (i.e., the field must be non-zero). A Port may support any combination of Link speeds. For example, this field could contain the value 0000 0100b indicating that Protocol Multiplexing is only supported at 8.0 GT/s.</p> <p>This field must not indicate support for Link speeds that are not supported by the Link (see § Section 7.5.3.18).</p> <p>Note that this field indicates the Link speeds supported by Protocol Multiplexing for the Link. The Link speeds that a particular protocol supports and the mechanism used to report that information are protocol specific.</p>	Bit 8	2.5 GT/s	Bit 9	5.0 GT/s	Bit 10	8.0 GT/s	Bit 11	16.0 GT/s	Bit 12	32.0 GT/s	Bits 15:13	RsvdP	RO / RsvdP
Bit 8	2.5 GT/s													
Bit 9	5.0 GT/s													
Bit 10	8.0 GT/s													
Bit 11	16.0 GT/s													
Bit 12	32.0 GT/s													
Bits 15:13	RsvdP													

G.5.3 PMUX Control Register (Offset 08h) §

§ Figure G-10 details the allocation of fields in the PMUX Control Register. § Table G-8 provides the respective bit definitions.

Channel *n* is enabled and available for use by the PMUX Protocol Layer when all of the following are true:

- The Channel *n* Assignment field is non-zero.
- The Channel *n* Assignment field is less than or equal to PMUX Protocol Array Size.
- The Channel *n* Assignment field indicates an implemented entry in the PMUX Protocol Array (see § Section G.5.5).
- All of the PMUX Channel *n* Disabled bits are Clear (see § Section G.5.4).

Otherwise, Channel n is disabled.

Figure G-10 PMUX Control Register §

Table G-8 PMUX Control Register §

Bit Location	Register Description	Attributes
5:0	<p>PMUX Channel 0 Assignment - This field indicates the protocol assigned to PMUX Channel 0. If the field is 0h, no protocol is assigned. If the field is non-zero, it is the index in the PMUX Protocol Array of the protocol assigned to PMUX Channel 0.</p> <p>If <u>PMUX Protocol Array Size</u> is less than 63 (see § Section G.5.2), unused upper bits of this field may be hardwired to 0b. If <u>PMUX Protocol Array Size</u> is 0, this entire field may be hardwired to 0.</p> <p>This field defaults to 0h.</p>	<u>RW</u>
13:8	<p>PMUX Channel 1 Assignment - This field indicates the protocol assigned to PMUX Channel 1. If the field is 0h, no protocol is assigned. If the field is non-zero, it is the index in the PMUX Protocol Array of the protocol assigned to PMUX Channel 1.</p> <p>If <u>PMUX Protocol Array Size</u> is less than 63 (see § Section G.5.2), unused upper bits of this field may be hardwired to 0b. If <u>PMUX Protocol Array Size</u> is 0, this entire field may be hardwired to 0.</p> <p>This field defaults to 0h.</p>	<u>RW</u>
21:16	<p>PMUX Channel 2 Assignment - This field indicates the protocol assigned to PMUX Channel 2. If the field is 0h, no protocol is assigned. If the field is non-zero, it is the index in the PMUX Protocol Array of the protocol assigned to PMUX Channel 2.</p> <p>If <u>PMUX Protocol Array Size</u> is less than 63 (see § Section G.5.2), unused upper bits of this field may be hardwired to 0b. If <u>PMUX Protocol Array Size</u> is 0, this entire field may be hardwired to 0.</p> <p>This field defaults to 0h.</p>	<u>RW</u>
29:24	<p>PMUX Channel 3 Assignment - This field indicates the protocol assigned to PMUX Channel 3. If the field is 0h, no protocol is assigned. If the field is non-zero, it is the index in the PMUX Protocol Array of the protocol assigned to PMUX Channel 3.</p> <p>If <u>PMUX Protocol Array Size</u> is less than 63 (see § Section G.5.2), unused upper bits of this field may be hardwired to 0b. If <u>PMUX Protocol Array Size</u> is 0, this entire field may be hardwired to 0.</p> <p>This field defaults to 0h.</p>	<u>RW</u>

G.5.4 PMUX Status Register (Offset 0Ch) §

§ Figure G-11 details the allocation of fields in the PMUX Status Register. § Table G-9 provides the respective bit definitions.

Each channel has a set of Disabled bits. When Channel n Assignment field is non-zero, the Channel n Disabled bits reflect the error status of the channel. The following Disabled bits are defined:

- PMUX Channel n Disabled: Link Speed
- PMUX Channel n Disabled: Link Width
- PMUX Channel n Disabled: Protocol Specific

When there are multiple reasons for disabling a channel, an implementation may choose which reason(s) to report. For example, if a protocol needs bandwidth equivalent to x1 8.0 GT/s, when there is inadequate bandwidth (e.g., the Link is operating at x1 5.0 GT/s, x1 2.5 GT/s, or x2 2.5 GT/s), it could disable the PMUX Channel by indicating any or all of Disabled: Link Width, Disabled: Link Speed, or Disabled: Protocol Specific.

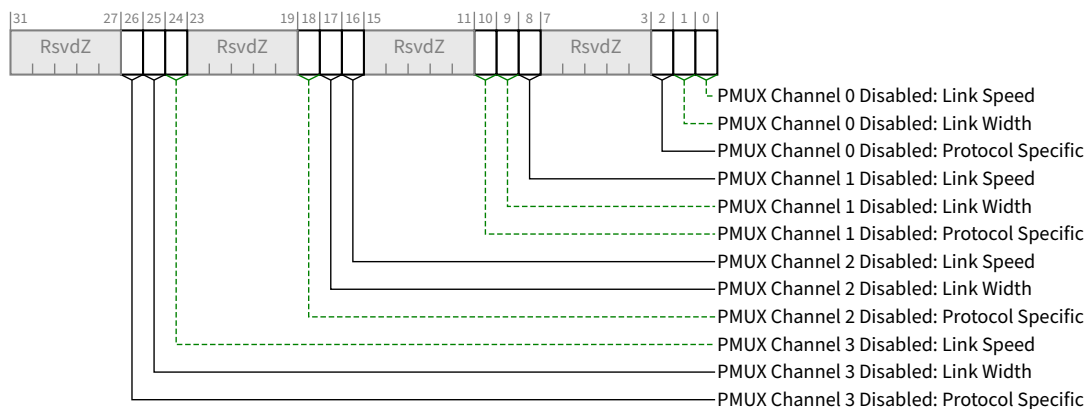

Figure G-11 PMUX Status Register §

Table G-9 PMUX Status Register §

Bit Location	Register Description	Attributes
0	PMUX Channel 0 Disabled: Link Speed - If Set, Channel 0 is disabled because the Current Link Speed (§ Section 7.8.9) is not supported by Protocol Multiplexing or by the protocol assigned to Channel 0. This bit is 0 when no protocol is assigned to Channel 0 (i.e., Channel 0 Control field is 0h).	RO
1	PMUX Channel 0 Disabled: Link Width - If Set, Channel 0 is disabled because the current Link Width is not supported by the protocol assigned to Channel 0. This bit is 0 when no protocol is assigned to Channel 0 (i.e., PMUX Channel 0 Assignment field is 0h).	RO
2	PMUX Channel 0 Disabled: Protocol Specific - If Set, Channel 0 is disabled for protocol specific reasons. This bit is 0 when no protocol is assigned to Channel 0 (i.e., PMUX Channel 0 Assignment field is 0h).	RO
8	PMUX Channel 1 Disabled: Link Speed - If Set, Channel 1 is disabled because the Current Link Speed (§ Section 7.8.9) is not supported by Protocol Multiplexing or by the protocol assigned to Channel 1.	RO

Bit Location	Register Description	Attributes
	This bit is 0 when no protocol is assigned to Channel 1 (i.e., <u>PMUX Channel 1 Assignment</u> field is 0h).	
9	PMUX Channel 1 Disabled: Link Width - If Set, Channel 1 is disabled because the current Link Width is not supported by the protocol assigned to Channel 1. This bit is 0 when no protocol is assigned to Channel 1 (i.e., <u>PMUX Channel 1 Assignment</u> field is 0h).	RO
10	PMUX Channel 1 Disabled: Protocol Specific - If Set, Channel 1 is disabled for protocol specific reasons. This bit is 0 when no protocol is assigned to Channel 1 (i.e., <u>PMUX Channel 1 Assignment</u> field is 0h).	RO
16	PMUX Channel 2 Disabled: Link Speed - If Set, Channel 2 is disabled because the Current Link Speed (§ Section 7.8.9) is not supported by Protocol Multiplexing or by the assigned protocol. This bit is 0 when no protocol is assigned to Channel 2 (i.e., <u>PMUX Channel 2 Assignment</u> field is 0h).	RO
17	PMUX Channel 2 Disabled: Link Width - If Set, Channel 2 is disabled because the current Link Width is not supported by the assigned protocol. This bit is 0 when no protocol is assigned to Channel 2 (i.e., <u>PMUX Channel 2 Assignment</u> field is 0h).	RO
18	PMUX Channel 2 Disabled: Protocol Specific - If Set, Channel 2 is disabled for protocol specific reasons. This bit is 0 when no protocol is assigned to Channel 2 (i.e., <u>PMUX Channel 2 Assignment</u> field is 0h).	RO
24	PMUX Channel 3 Disabled: Link Speed - If Set, Channel 3 is disabled because the Current Link Speed (§ Section 7.8.9) is not supported by Protocol Multiplexing or by the assigned protocol. This bit is 0 when no protocol is assigned to Channel 3 (i.e., <u>PMUX Channel 3 Assignment</u> field is 0h).	RO
25	PMUX Channel 3 Disabled: Link Width - If Set, Channel 3 is disabled because the current Link Width is not supported by the assigned protocol. This bit is 0 when no protocol is assigned to Channel 3 (i.e., <u>PMUX Channel 3 Assignment</u> field is 0h).	RO
26	PMUX Channel 3 Disabled: Protocol Specific - If Set, Channel 3 is disabled for protocol specific reasons. This bit is 0 when no protocol is assigned to Channel 3 (i.e., <u>PMUX Channel 3 Assignment</u> field is 0h).	RO

G.5.5 PMUX Protocol Array (Offsets 10h through 48h) §

The PMUX Protocol Array consists of up to 63 entries. The size of the PMUX Protocol Array is indicated by the PMUX Protocol Array Size field (see § Section G.5.2).

§ Figure G-12 details the allocation of fields in each PMUX Protocol Array Entry. § Table G-10 provides the respective bit definitions.

Figure G-12 PMUX Protocol Array Entry §

Table G-10 PMUX Protocol Array Entry §

Bit Location	Register Description	Attributes
15:0	<p>Protocol ID - In conjunction with Authority ID designates a specific protocol and the mechanism by which that protocol is mapped onto Protocol Multiplexing.</p> <p>This value is assigned by the Vendor associated with the <u>Authority ID</u> field.</p>	RO
31:16	<p>Authority ID - Designates the authority controlling the values used in the <u>Protocol ID</u> field.</p> <p>The Authority ID field contains a Vendor ID as assigned by the PCI-SIG.</p>	RO

The value 0000 0000h indicates an unimplemented PMUX Protocol Array Entry. The PMUX Protocol Array is indexed starting at 1.

PMUX Channel n is enabled and configured to support the protocol associated with PMUX Protocol Array Entry at index m when the PMUX Channel n Assignment field contains the value m (see § Section G.5.3).

Entries in the PMUX Protocol Array with the Authority ID value 1 (0001h) represent protocols that are defined by the PCI-SIG.

Duplicate Entries in the PMUX Protocol Array may be used to represent multiple instances of a particular protocol. This permits software control of the mapping between PMUX Channel ID and a specific instance of a protocol.

IMPLEMENTATION NOTE: MULTIPLE PROTOCOL INSTANCES §

A Link may have a single PMUX Protocol assigned to multiple PMUX Channels. Each PMUX Channel is assigned to a different instance of the protocol. Each instance of a protocol corresponds to an entry in the PMUX Protocol Array.

Consider a Port that supports two instances of protocol X. Two entries in the PMUX Protocol Array would indicate protocol X (indexes A and B for example). To assign instance A to PMUX Channel 0 and instance B to PMUX Channel 2, place the value A in the PMUX Channel 0 Assignment field and the value B in the PMUX Channel 2 Assignment field.

H. Flow Control Update Latency and ACK Update Latency Calculations §

This appendix is informational only and should not be considered normative. Earlier revisions of this specification outlined the method used to calculate the Flow Control Update Latency and Ack Update Latency. This appendix describes the method used to derive the values and preserves the UpdateFactor and AckFactor values.

H.1 Flow Control Update Latency §

Recommended Flow Control Update Latency is described in the Implementation Note in § Section 2.6.1.2 entitled, Non-Flit Mode Flow Control Update Latency.

Flow Control Update Latency tables were simplified in the 4.0 Revision of this specification. At that time, the original tables were moved to this appendix. Note that in the 4.0 Revision of this specification, Tables 2-47 and 2-48 were distinct, but identical tables. The 5.0 Revision contains a single table that applies to 8.0 GT/s or higher.

Original Tables		Simplified Tables	
Base 3.1	Base 4.0 or later	Base 4.0	Base 5.0 or later
Table 2-42	§ Table H-1	Table 2-45	§ Table 2-52
Table 2-43	§ Table H-2	Table 2-46	§ Table 2-53
Table 2-44	§ Table H-3	Table 2-47	§ Table 2-54
n/a	n/a	Table 2-48	

The values in the Tables are measured starting from when the Receiver Transaction Layer makes additional receive buffer space available by processing a received TLP, to when the first Symbol of the corresponding UpdateFC DLLP is transmitted. The values are calculated as a function of the largest TLP payload size and Link width using the formula:

$$\frac{(\text{Rx_MPS_Limit} + \text{TLPOverhead}) \times \text{UpdateFactor}}{\text{LinkWidth}} + \text{InternalDelay}$$

Equation H-1 Max UpdateFC Latency §

where:

Rx_MPS_Limit

The Rx_MPS_Limit value as determined in § Section 2.2.2 . For a Multi-Function Device where different Functions have different Rx_MPS_Limit values, using the smallest Rx_MPS_Limit value across all Functions is strongly recommended.

TLPOverhead

Represents the additional TLP components which consume Link bandwidth (TLP Prefix, header, LCRC, framing Symbols) and is treated here as a constant value of 28 Symbols.

UpdateFactor

Represents the number of maximum size TLPs sent during the time between UpdateFC receptions, and is used to balance Link bandwidth efficiency and receive buffer sizes - the value varies according to Rx_MPS_Limit and Link width. § Table H-1, § Table H-2, and § Table H-3 below include the UpdateFactor(UF).

LinkWidth

The operating width of the Link

InternalDelay

Represents the internal processing delays for received TLPs and transmitted DLLPs, and is treated here as a constant value of 19 Symbol Times for 2.5 GT/s mode operation, 70 Symbol Times for 5.0 GT/s mode operation, and 115 Symbol Times for 8.0 GT/s and 16.0 GT/s modes of operation.

*Table H-1 Maximum UpdateFC Transmission Latency Guidelines for 2.5 GT/s Mode
Operation by Link Width and Max Payload (Symbol Times) §*

H.2 Ack Latency §

Ack Latency tables were simplified in the 4.0 Revision of this specification. At that time, the original tables were moved to this appendix. Note that in the 4.0 Revision of this specification, Tables 3-9 and 3-10 were distinct, but identical tables. The 5.0 Revision contains a single table that applies to 8.0 GT/s or higher.

Original Tables		Simplified Tables	
Base 3.1	Base 4.0 or later	Base 4.0	Base 5.0 or later
Table 3-7	§ Table H-5	Table 3-7	§ Table 3-10
Table 3-8	§ Table H-6	Table 3-8	§ Table 3-11
Table 3-9	§ Table H-7	Table 3-9	§ Table 3-12
n/a	n/a	Table 3-10	

The Maximum Ack Latency limits are calculated using the formula:

$$\frac{(\text{Rx_MPS_Limit} + \text{TLPOverhead}) \times \text{UpdateFactor}}{\text{LinkWidth}} + \text{InternalDelay}$$

Equation H-2 Max Ack Latency §

where:

Rx_MPS_Limit

The Rx_MPS_Limit value as determined in § Section 2.2.2 . For a Multi-Function Device where different Functions have different Rx_MPS_Limit values, using the smallest Rx_MPS_Limit value across all Functions is strongly recommended.

TLPOverhead

represents the additional TLP components which consume Link bandwidth (TLP Prefix, header, LCRC, framing Symbols) and is treated here as a constant value of 28 Symbols.

AckFactor

represents the number of maximum size TLPs which can be received before an Ack is sent, and is used to balance Link bandwidth efficiency and retry buffer size - the value varies according to Rx_MPS_Limit and Link width. Table H-4, Table H-5, and Table H-6 below include the AckFactor(AF).

LinkWidth

is the operating width of the Link.

InternalDelay

represents the internal processing delays for received TLPs and transmitted DLLPs, and is treated here as a constant value of 19 Symbol Times for 2.5 GT/s mode operation, 70 Symbol Times for 5.0 GT/s operation, and 115 Symbol Times for 8.0 GT/s and 16.0 GT/s operation.

Table H-5 Maximum Ack Latency Limit and AckFactor for 2.5 GT/s (Symbol Times) §

		Link Operating Width						
		x1	x2	x4	x8	x12	x16	x32
Rx_MPS_Limit (bytes)	128	237 AF = 1.4	128 AF = 1.4	73 AF = 1.4	67 AF = 2.5	58 AF = 3.0	48 AF = 3.0	33 AF = 3.0
	256	416 AF = 1.4	217 AF = 1.4	118 AF = 1.4	107 AF = 2.5	90 AF = 3.0	72 AF = 3.0	45 AF = 3.0
	512	559 AF = 1.0	289 AF = 1.0	154 AF = 1.0	86 AF = 1.0	109 AF = 2.0	86 AF = 2.0	52 AF = 2.0
	1024	1071 AF = 1.0	545 AF = 1.0	282 AF = 1.0	150 AF = 1.0	194 AF = 2.0	150 AF = 2.0	84 AF = 2.0
	2048	2095 AF = 1.0	1057 AF = 1.0	538 AF = 1.0	278 AF = 1.0	365 AF = 2.0	278 AF = 2.0	148 AF = 2.0
	4096	4143 AF = 1.0	2081 AF = 1.0	1050 AF = 1.0	534 AF = 1.0	706 AF = 2.0	534 AF = 2.0	276 AF = 2.0

I. Async Hot-Plug Reference Model §

This appendix presents a recommended reference model for async hot-plug. The reference model covers three areas:

- Async hot-plug initial configuration
- Async removal configuration and interrupt handling
- Async hot-add configuration and interrupt handling

There are no normative requirements in this section. The entire reference model is contained in a series of implementation notes. The reference model documents how the various hot-plug mechanisms are envisioned be used to implement a robust asynchronous hot-plug model, but does not mandate that they be used that way.

For brevity and readability, this section uses the following acronyms:

DLL

Data Link Layer

DSP

Downstream Port

FWF

firmware first

HPS

Hot-Plug Surprise

OOB

out-of-band

OS

operating system

PD

presence detect

SFW

system firmware

The reference model covers both the HPS and DPC mechanisms. DPC is the recommended mechanism. The reference model covers FWF for DPC but not for HPS.

The reference model provides a recommended framework for DPC software to support Containment Error Recovery (CER) along with async hot-plug. The reference model does not explicitly cover CER outside of async hot-plug, but certain aspects can be leveraged for DPC support of CER when async hot-plug is not being used.

SFW may use the System Firmware Intermediary (SFI) Capability for async hot-plug, orderly removal hot-plug, or other operations. This reference model does not rely on its functionality nor cover its use.

The reference model refers to various bits or fields outlined in § Section 6.7.2 . For brevity, pointers to the associated registers are not replicated in this section.

IMPLEMENTATION NOTE: IN-BAND PRESENCE DETECT MECHANISM DEPRECATED FOR ASYNC HOT-PLUG §

Due to architectural issues, the in-band (Physical-Layer-based) portion of the PD mechanism is deprecated for use with async hot-plug. One issue is that in-band PD as architected does not detect adapter removal during certain LTSSM states, notably the L1 and Disabled States. Another issue is that when both in-band and OOB PD are being used together, the Presence Detect State bit and its associated interrupt mechanism always reflect the logical OR of the inband and OOB PD states, and with some hot-plug hardware configurations, it is important for software to detect and respond to in-band and OOB PD events independently.

If OOB PD is being used and the associated DSP supports In-Band PD Disable, it is recommended that the In-Band PD Disable bit be Set, and the Presence Detect State bit and its associated interrupt mechanism be used exclusively for OOB PD.

As a substitute for in-band PD with async hot-plug, the reference model uses either the DPC or the DLL Link Active mechanism.

The reference model assumes and covers the configurations listed below. While these cover the bulk of the envisioned use cases, many minor variations are not explicitly covered. For example, there are multiple ways to determine if a slot supports OOB PD, and the reference model does not cover them. As another example, the reference model refers to adding or removing an adapter, but some hot-pluggable modules may include a Switch and multiple Endpoint components.

- Reference model assumptions:
 - DSPs support DLL Link Active Reporting
 - DSPs support In-Band PD Disable
 - Operating systems support both HPS and DPC, using DPC if available
- Reference model covers:
 - Slots that support HPS and/or DPC (SW never enables both at same time)
 - Slots with or without OOB PD
 - RPs with or without RP Extensions for DPC

I.1 Async Hot-Plug Initial Configuration §

IMPLEMENTATION NOTE: ASYNC HOT-PLUG INITIAL CONFIGURATION §

Basic Steps	HPS	DPC
Determine capability control entity	<ul style="list-style-type: none"> OS requests, and is granted control of PCIe Native Hot-Plug If FWF, SFW retains control of AER and DPC Else OS requests and is granted control of AER and DPC 	
OS and SFW determine which async hot-plug mechanism to use; OS/SFW interactions here are outside scope of this specification	<ul style="list-style-type: none"> If DPC capability then <ul style="list-style-type: none"> If HPS bit not Set, use DPC Else attempt to Clear HPS bit (§ Section 6.7.4.4) <ul style="list-style-type: none"> If successful, use DPC Else use HPS Else if HPS bit Set, use HPS Else async hot-plug cannot be supported by this slot Configure DSP for selected mechanism 	
OS determines if adapter present	<ul style="list-style-type: none"> If OOB PD supported, use it to determine if adapter is present <ul style="list-style-type: none"> Set In-band PD Disable bit (SFW may have it Set by default) Read PD State bit Else allow Link to attempt to train; use DLL Link Active to determine if adapter is present (and at least minimally functional) 	
If adapter is present, OS waits for adapter to become ready for configuration	<ul style="list-style-type: none"> If using Device Readiness Status (DRS), begin configuration if/after DSP receives a DRS Message If using Configuration RRS Software Visibility, can attempt first Configuration Read (of Vendor ID field) after 100 ms Otherwise, must wait at least 1000 ms before attempting first Configuration Read 	
OS configures for appropriate case	<ul style="list-style-type: none"> If adapter is present, configure system for handling async removal Else configure system for handling async hot-add 	

I.2 Async Removal Configuration and Interrupt Handling §

IMPLEMENTATION NOTE: ASYNC REMOVAL CONFIGURATION §

Basic Steps	HPS	DPC
OS/SFW configure appropriate error handling	<ul style="list-style-type: none"> If OS and driver support a non-CER error recovery approach, its policies may influence some of these error settings Configure the error handling supported by HPS 	<ul style="list-style-type: none"> If OS and driver support CER, its policies may influence some of these error settings Enable uncorrectable AER errors to trigger DPC, including <u>Surprise Down</u> If using RP Extensions for DPC, configure RP PIO error handling Configure RP Completion Timeout handling per platform and OS policies
OS/SFW configure async removal interrupts	<ul style="list-style-type: none"> OS enables DLL State Changed interrupt 	<ul style="list-style-type: none"> If FWF, configure DPC for ERR_COR signaling to enable SFW handling Else configure DPC for interrupt to enable OS handling
	<ul style="list-style-type: none"> If OOB PD supported, OS enables PD Changed interrupt 	

IMPLEMENTATION NOTE:

ASYNC REMOVAL INTERRUPT HANDLING §

Basic Steps	HPS	DPC
Service routine entry	<ul style="list-style-type: none"> If PD Changed or DLL State Change, OS is interrupted 	<ul style="list-style-type: none"> If PD Changed, OS is interrupted <ul style="list-style-type: none"> If FWF, OS invokes SFW; preferably via OS Setting DPC Software Trigger bit (if implemented)
		<ul style="list-style-type: none"> If DPC triggered <ul style="list-style-type: none"> If FWF, DPC sends <u>ERR_COR</u> to signal SFW Else DPC interrupts OS
Prevent further Link activity	<ul style="list-style-type: none"> OS Sets Disable Link; Link goes down and stays down OS polls DLL Link Active until Clear 	<ul style="list-style-type: none"> DPC automatically keeps Link down
Log errors from DSP's AER/DPC		<ul style="list-style-type: none"> If FWF, SFW logs DSP errors <ul style="list-style-type: none"> SFW invokes OS and exits
	<ul style="list-style-type: none"> OS logs and then clears DSP errors 	
OS notifies impacted software/driver, which cease accessing the adapter		
OS determines if adapter is still present	<ul style="list-style-type: none"> Some FFs with OOB PD automatically power off slot and/or disable switched signals If OOB PD supported, use it to determine if adapter is physically present If adapter not determined to be absent, re-enable the Link and slot <ul style="list-style-type: none"> As applicable, Clear Disable Link or release DPC Wait until Link trains or adapter is deemed absent or non-functional If non-functional, optionally perform a slot reset (if supported) If still non-functional, optionally power-cycle the slot (if supported) 	
If OS determined adapter to be present	<ul style="list-style-type: none"> OS waits for adapter to become ready for configuration OS enumerates and configures the adapter If DPC and FWF, OS invokes SFW to log adapter AER errors 	

Basic Steps	HPS	DPC
	<ul style="list-style-type: none"> • OS logs adapter AER errors and then clears them • If OS determines the adapter is suitable for continued operation <ul style="list-style-type: none"> ◦ OS configures for async removal handling ◦ OS resumes driver • Else OS takes OS-specific action 	
Else (adapter not present)	<ul style="list-style-type: none"> • OS ensures DSP is in a clean state ready for a new/different adapter • OS configures for async hot-add handling 	

I.3 Async Hot-Add Configuration and Interrupt Handling §

IMPLEMENTATION NOTE: ASYNC HOT-ADD CONFIGURATION §

Basic Steps	HPS	DPC
OS configures for async hot-add handling		
<ul style="list-style-type: none"> • Enable Link to train if/when an adapter is inserted <ul style="list-style-type: none"> ◦ E.g., Clear Disable Link or release DPC if needed • If appropriate for form factor, enable power controller prior to adapter insertion • If OOB PD supported, enable OS interrupt on PD Changed • Else enable OS interrupt on DLL State Changed 		

IMPLEMENTATION NOTE: ASYNC HOT-ADD INTERRUPT HANDLING §

Basic Steps	HPS	DPC
OS is interrupted due to PD Changed or DLL State Changed		
OS waits for the adapter to become ready for configuration <ul style="list-style-type: none"> • If appropriate for form factor, enable power controller now (following adapter insertion) • Wait for DLL Link Active • Wait for adapter to become ready for configuration 		
OS configures adapter per standard OS conventions		
OS configures for async removal handling		
OS calls driver to complete adapter configuration and begin normal operation

L. Example IDE TLPs and Test Keys §

This appendix includes several example IDE TLPs, intended to be used to verify correct implementation of IDE. Also included are a set of keys to be used for testing, to simplify IDE validation.

L.1 Example NFM IDE TLP Without Partial Header Encryption §

The TLP shown in § Figure L-1, when processed using the Key and IV shown in § Table L-1, which also includes other relevant inputs and outputs, yields the IDE TLP shown in § Figure L-2.

Figure L-8 Example Memory Write IDE TLP with Partial Header Encryption (FM) §

L.5 IDE Test Keys §

The keys defined in this section are intended to be used to simplify IDE validation, for example, by making it easier for verification tools to decrypt and MAC-check TLPs. As illustrated in § Table L-5, the defined test keys consist of a constant value in the more significant bytes of the key, and an incrementing value contained in the two least significant bytes of the key, where the test key number corresponds to the value of the incrementing portion.

These keys are intended for use in validation and test environments only - it is essential these keys are not used in production environments. It is recommended that verification tools check for the inadvertent use of test keys in production settings, and provide an appropriate warning to the user. It is also recommended to check for the use of other key values that have been published as test keys, and for trivial keys such as all 0's.

Table L-5 IDE Test Keys §

Key Number	Key Value – Byte0 [7:0] byte 1[15:8].....Byte N Key, IV, MAC: Follows AES-GCM Specification with Most significant leftmost
0	0B AD 0B AD 0B AD 0B AD 0B AD 0B AD 0B AD 0B AD 0B AD 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00

Key Number	Key Value – Byte0 [7:0] byte 1[15:8].....Byte N Key, IV, MAC: Follows AES-GCM Specification with Most significant leftmost
