Table of Contents

1.	Introduction.....	127
1.1	An Evolving I/O Interconnect	127
1.2	PCI Express Link.....	128
1.3	PCI Express Fabric Topology	129
1.3.1	Root Complex	130
1.3.2	Endpoints.....	131
1.3.2.1	Legacy Endpoint Rules	131
1.3.2.2	PCI Express Endpoint Rules	132
1.3.2.3	Root Complex Integrated Endpoint Rules	132
1.3.3	Switch	133
1.3.4	Root Complex Event Collector	134
1.3.5	PCI Express to PCI/PCI-X Bridge	134
1.4	Hardware/Software Model for Discovery, Configuration and Operation	134
1.5	PCI Express Layering Overview	135
1.5.1	Transaction Layer	136
1.5.2	Data Link Layer	136
1.5.3	Physical Layer	136
1.5.4	Layer Functions and Services	137
1.5.4.1	Transaction Layer Services	137
1.5.4.2	Data Link Layer Services	138
1.5.4.3	Physical Layer Services	138
1.5.4.4	Inter-Layer Interfaces	139
1.5.4.4.1	Transaction/Data Link Interface.....	139
1.5.4.4.2	Data Link/Physical Interface	139
2.	Transaction Layer Specification.....	141
2.1	Transaction Layer Overview.....	141
2.1.1	Address Spaces, Transaction Types, and Usage.....	141
2.1.1.1	Memory Transactions.....	142
2.1.1.2	I/O Transactions.....	142
2.1.1.3	Configuration Transactions.....	143
2.1.1.4	Message Transactions	143
2.1.2	Packet Format Overview	143
2.2	Transaction Layer Protocol - Packet Definition	145
2.2.1	Common Packet Header Fields.....	145
2.2.1.1	Common Packet Header Fields for Non-Flit Mode.....	145
2.2.1.2	Common Packet Header Fields for Flit Mode	148
2.2.2	TLPs with Data Payloads - Rules	171
2.2.3	TLP Digest Rules - Non-Flit Mode Only	174
2.2.4	Routing and Addressing Rules	175
2.2.4.1	Address-Based Routing Rules	175
2.2.4.2	ID Based Routing Rules	178
2.2.5	First/Last DW Byte Enables Rules	182
2.2.5.1	Byte Enable Rules for Non-Flit Mode	182
2.2.5.2	Byte Enable Rules for Flit Mode	185
2.2.6	Transaction Descriptor	185
2.2.6.1	Overview	185

2.2.6.2	Transaction Descriptor - Transaction ID Field	186
2.2.6.3	Transaction Descriptor - Attributes Field.....	193
2.2.6.4	Relaxed Ordering and ID-Based Ordering Attributes	194
2.2.6.5	No Snoop Attribute.....	194
2.2.6.6	Transaction Descriptor - Traffic Class Field	195
2.2.7	Memory, I/O, and Configuration Request Rules	195
2.2.7.1	Non-Flit Mode	195
2.2.7.1.1	TPH Rules.....	199
2.2.7.2	Flit Mode	202
2.2.8	Message Request Rules	204
2.2.8.1	INTx Interrupt Signaling - Rules	206
2.2.8.2	Power Management Messages.....	210
2.2.8.3	Error Signaling Messages	211
2.2.8.4	Locked Transactions Support	212
2.2.8.5	Slot Power Limit Support.....	213
2.2.8.6	Vendor-Defined Messages.....	214
2.2.8.6.1	PCI-SIG Defined VDMs.....	216
2.2.8.6.2	Device Readiness Status (DRS) Message.....	217
2.2.8.6.3	Function Readiness Status Message (FRS Message)	218
2.2.8.6.4	Hierarchy ID Message	220
2.2.8.7	Ignored Messages	221
2.2.8.8	Latency Tolerance Reporting (LTR) Message	222
2.2.8.9	Optimized Buffer Flush/Fill (OBFF) Message	223
2.2.8.10	Precision Time Measurement (PTM) Messages	224
2.2.8.11	Integrity and Data Encryption (IDE) Messages	227
2.2.9	Completion Rules	230
2.2.9.1	Completion Rules for Non-Flit Mode	231
2.2.9.2	Completion Rules for Flit Mode	233
2.2.10	TLP Prefix Rules	236
2.2.10.1	TLP Prefix General Rules - Non-Flit Mode.....	236
2.2.10.2	Local TLP Prefix Processing	236
2.2.10.2.1	Vendor Defined Local TLP Prefix.....	237
2.2.10.3	Flit Mode Local TLP Prefix	237
2.2.10.4	End-End TLP Prefix Processing - Non-Flit Mode.....	238
2.2.10.4.1	Vendor Defined End-End TLP Prefix	239
2.2.10.4.2	Root Ports with End-End TLP Prefix Supported	240
2.2.11	OHC-E Rules - Flit Mode.....	240
2.3	Handling of Received TLPs.....	241
2.3.1	Request Handling Rules	245
2.3.1.1	Data Return for Non-UIO Read Requests	251
2.3.1.2	UIO Read Completions	256
2.3.1.3	UIO Write Completions.....	257
2.3.2	Completion Handling Rules	257
2.4	Transaction Ordering	259
2.4.1	Transaction Ordering Rules for TLPs not using UIO or Flow-Through IDE Streams.....	259
2.4.2	Ordering Rules for UIO	265
2.4.3	Update Ordering and Granularity Observed by a Read Transaction	266
2.4.3.1	Ordering and Granularity for Non-UIO Reads	266
2.4.3.2	Ordering and Granularity for UIO Reads.....	267
2.4.4	Update Ordering and Granularity Provided by a Write Transaction	267

2.4.4.1	Ordering and Granularity for Non-UIO Writes	267
2.4.4.2	Ordering and Granularity for UIO Writes	268
2.5	Virtual Channel (VC) Mechanism.....	268
2.5.1	Virtual Channel Identification (VC ID)	272
2.5.2	TC to VC Mapping.....	272
2.5.3	VC and TC Rules	274
2.6	Ordering and Receive Buffer Flow Control	275
2.6.1	Flow Control (FC) Rules	276
2.6.1.1	FC Information Tracked by Transmitter.....	284
2.6.1.2	FC Information Tracked by Receiver	290
2.7	End-to-End Data Integrity	297
2.7.1	ECRC Rules.....	297
2.7.2	Error Forwarding (Data Poisoning)	302
2.7.2.1	Rules For Use of Data Poisoning	303
2.8	Completion Timeout Mechanism	304
2.9	Link Status Dependencies.....	305
2.9.1	Transaction Layer Behavior in DL_Down Status	305
2.9.2	Transaction Layer Behavior in DL_Up Status	306
2.9.3	Transaction Layer Behavior During Downstream Port Containment.....	307
3.	Data Link Layer Specification.....	309
3.1	Data Link Layer Overview.....	309
3.2	Data Link Control and Management State Machine.....	310
3.2.1	Data Link Control and Management State Machine Rules.....	311
3.3	Data Link Feature Exchange	314
3.4	Flow Control Initialization Protocol.....	316
3.4.1	Flow Control Initialization State Machine Rules	316
3.4.2	Scaled Flow Control	324
3.5	Data Link Layer Packets (DLLPs)	324
3.5.1	Data Link Layer Packet Rules	325
3.6	Data Integrity Mechanisms.....	334
3.6.1	Introduction.....	334
3.6.2	LCRC, Sequence Number, and Retry Management (TLP Transmitter)	335
3.6.2.1	LCRC and Sequence Number Rules (TLP Transmitter)	335
3.6.2.2	Handling of Received DLLPs (Non-Flit Mode).....	343
3.6.2.3	Handling of Received DLLPs (Flit Mode).....	344
3.6.3	LCRC and Sequence Number (TLP Receiver) (Non-Flit Mode).....	345
3.6.3.1	LCRC and Sequence Number Rules (TLP Receiver).....	345
4.	Physical Layer Logical Block.....	351
4.1	Introduction.....	351
4.2	Logical Sub-block.....	351
4.2.1	8b/10b Encoding for 2.5 GT/s and 5.0 GT/s Data Rates.....	353
4.2.1.1	Symbol Encoding.....	353
4.2.1.1.1	Serialization and De-serialization of Data	354
4.2.1.1.2	Special Symbols for Framing and Link Management (K Codes)	355
4.2.1.1.3	8b/10b Decode Rules.....	356
4.2.1.2	Framing and Application of Symbols to Lanes.....	357
4.2.1.2.1	Framing and Application of Symbols to Lanes for TLPs and DLLPs in Non-Flit Mode.....	357
4.2.1.3	Data Scrambling	360

4.2.2	128b/130b Encoding for 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s Data Rates	361
4.2.2.1	Lane Level Encoding	362
4.2.2.2	Ordered Set Blocks	363
4.2.2.2.1	Block Alignment	363
4.2.2.3	Data Blocks	364
4.2.2.3.1	Framing Tokens in Non-Flit-Mode	364
4.2.2.3.2	Transmitter Framing Requirements in Non-Flit Mode	369
4.2.2.3.3	Receiver Framing Requirements in Non-Flit Mode	370
4.2.2.3.4	Receiver Framing Requirements in Flit Mode	372
4.2.2.3.5	Recovery from Framing Errors in Non-Flit Mode and Flit Mode	373
4.2.2.4	Scrambling in Non-Flit Mode and Flit Mode	373
4.2.2.5	Precoding	379
4.2.2.5.1	Precoding at 32.0 GT/s Data Rate	380
4.2.2.6	Loopback with 128b/130b Code in Non-Flit Mode and Flit Mode	382
4.2.3	Flit Mode Operation	382
4.2.3.1	1b/1b Encoding for 64.0 GT/s and higher Data Rates	382
4.2.3.1.1	PAM4 Signaling	384
4.2.3.1.2	1b/1b Scrambling	385
4.2.3.1.3	Gray Coding at 64.0 GT/s and Higher Data Rates	386
4.2.3.1.4	Precoding at 64.0 GT/s and Higher Data Rates	387
4.2.3.1.5	Ordered Set Blocks at 64.0 GT/s and Higher Data Rates	390
4.2.3.1.6	Alignment at Block/ Flit Level for 1b/1b Encoding	391
4.2.3.2	Processing of Ordered Sets During Flit Mode Data Stream	392
4.2.3.3	Data Stream in Flit Mode	394
4.2.3.4	Bytes in Flit Layout	400
4.2.3.4.1	TLP Bytes in Flit	400
4.2.3.4.2	DLP Bytes in Flit	403
4.2.3.4.2.1	Flit Sequence Number and Retry Mechanism	407
4.2.3.4.2.1.1	IDLE Flit Handshake Phase	413
4.2.3.4.2.1.2	Sequence Number Handshake Phase	413
4.2.3.4.2.1.3	Normal Flit Exchange Phase	415
4.2.3.4.2.1.4	Received Ack and Nak Processing	416
4.2.3.4.2.1.5	Ack, Nak, and Discard Rules	418
4.2.3.4.2.1.6	Flit Replay Scheduling	424
4.2.3.4.2.1.7	Flit Replay Transmit Rules	426
4.2.3.4.3	CRC Bytes in Flit	430
4.2.3.4.4	ECC Bytes in Flit	431
4.2.3.4.5	Ordered Set insertion in Data Stream in Flit Mode	437
4.2.4	Link Equalization Procedure for 8.0 GT/s and Higher Data Rates	438
4.2.4.1	Rules for Transmitter Coefficients	450
4.2.4.2	Encoding of Presets	451
4.2.5	Link Initialization and Training	452
4.2.5.1	Training Sequences	453
4.2.5.2	Alternate Protocol Negotiation	473
4.2.5.3	Electrical Idle Sequences (EIOS and EIEOS)	476
4.2.5.4	Inferring Electrical Idle	481
4.2.5.5	Lane Polarity Inversion	482
4.2.5.6	Fast Training Sequence (FTS)	482
4.2.5.7	Start of Data Stream Ordered Set (SDS Ordered Set)	484
4.2.5.8	Link Error Recovery	484

4.2.5.9	Reset	485
4.2.5.9.1	Fundamental Reset	485
4.2.5.9.2	Hot Reset.....	486
4.2.5.10	Link Data Rate Negotiation	486
4.2.5.11	Link Width and Lane Sequence Negotiation	486
4.2.5.11.1	Required and Optional Port Behavior	486
4.2.5.12	Lane-to-Lane De-skew.....	487
4.2.5.13	Lane vs. Link Training	488
4.2.6	Link Training and Status State Machine (LTSSM) Descriptions	488
4.2.6.1	Detect Overview	489
4.2.6.2	Polling Overview.....	489
4.2.6.3	Configuration Overview	489
4.2.6.4	Recovery Overview.....	489
4.2.6.5	L0 Overview	490
4.2.6.6	L0s Overview.....	490
4.2.6.7	L0p Overview	490
4.2.6.7.1	Link Management DLLP	494
4.2.6.8	L1 Overview	497
4.2.6.9	L2 Overview	497
4.2.6.10	Disabled Overview.....	497
4.2.6.11	Loopback Overview.....	498
4.2.6.12	Hot Reset Overview	498
4.2.7	Link Training and Status State Rules	498
4.2.7.1	Detect.....	501
4.2.7.1.1	Detect.Quiet.....	501
4.2.7.1.2	Detect.Active.....	502
4.2.7.2	Polling	502
4.2.7.2.1	Polling.Active	503
4.2.7.2.2	Polling.Compliance	504
4.2.7.2.3	Polling.Configuration	509
4.2.7.2.4	Polling.Speed.....	509
4.2.7.3	Configuration.....	510
4.2.7.3.1	Configuration.Linkwidth.Start	511
4.2.7.3.1.1	Downstream Lanes.....	511
4.2.7.3.1.2	Upstream Lanes.....	512
4.2.7.3.2	Configuration.Linkwidth.Accept	514
4.2.7.3.2.1	Downstream Lanes.....	514
4.2.7.3.2.2	Upstream Lanes.....	515
4.2.7.3.3	Configuration.Lanenum.Accept.....	517
4.2.7.3.3.1	Downstream Lanes.....	518
4.2.7.3.3.2	Upstream Lanes.....	519
4.2.7.3.4	Configuration.Lanenum.Wait.....	520
4.2.7.3.4.1	Downstream Lanes.....	520
4.2.7.3.4.2	Upstream Lanes.....	520
4.2.7.3.5	Configuration.Complete.....	521
4.2.7.3.5.1	Downstream Lanes.....	521
4.2.7.3.5.2	Upstream Lanes.....	523
4.2.7.3.6	Configuration.Idle	525
4.2.7.4	Recovery	529
4.2.7.4.1	Recovery.RcvrLock	529

4.2.7.4.2	Recovery.Equalization.....	535
4.2.7.4.2.1	Downstream Lanes.....	536
4.2.7.4.2.1.1	Phase 1 of Transmitter Equalization.....	537
4.2.7.4.2.1.2	Phase 2 of Transmitter Equalization.....	539
4.2.7.4.2.1.3	Phase 3 of Transmitter Equalization.....	540
4.2.7.4.2.2	Upstream Lanes.....	542
4.2.7.4.2.2.1	Phase 0 of Transmitter Equalization.....	543
4.2.7.4.2.2.2	Phase 1 of Transmitter Equalization.....	545
4.2.7.4.2.2.3	Phase 2 of Transmitter Equalization.....	546
4.2.7.4.2.2.4	Phase 3 of Transmitter Equalization.....	548
4.2.7.4.3	Recovery.Speed.....	549
4.2.7.4.4	Recovery.RcvrCfg.....	551
4.2.7.4.5	Recovery.Idle.....	558
4.2.7.5	L0.....	561
4.2.7.6	L0s.....	563
4.2.7.6.1	Receiver L0s.....	563
4.2.7.6.1.1	Rx_L0s.Entry.....	563
4.2.7.6.1.2	Rx_L0s.Idle.....	563
4.2.7.6.1.3	Rx_L0s.FTS.....	563
4.2.7.6.2	Transmitter L0s.....	564
4.2.7.6.2.1	Tx_L0s.Entry.....	564
4.2.7.6.2.2	Tx_L0s.Idle.....	564
4.2.7.6.2.3	Tx_L0s.FTS.....	565
4.2.7.7	L1.....	566
4.2.7.7.1	L1.Entry.....	566
4.2.7.7.2	L1.Idle.....	566
4.2.7.8	L2.....	568
4.2.7.8.1	L2.Idle.....	568
4.2.7.8.2	L2.TransmitWake.....	569
4.2.7.9	Disabled.....	569
4.2.7.10	Loopback.....	570
4.2.7.10.1	Loopback.Entry.....	570
4.2.7.10.2	Loopback.Active.....	574
4.2.7.10.3	Loopback.Exit.....	576
4.2.7.11	Hot Reset.....	577
4.2.8	Clock Tolerance Compensation.....	578
4.2.8.1	SKP Ordered Set for 8b/10b Encoding.....	579
4.2.8.2	SKP Ordered Set for 128b/130b Encoding.....	579
4.2.8.3	SKP Ordered Set for 1b/1b Encoding.....	583
4.2.8.4	Rules for Transmitters.....	587
4.2.8.5	Rules for Receivers.....	590
4.2.9	Compliance Pattern in 8b/10b Encoding.....	591
4.2.10	Modified Compliance Pattern in 8b/10b Encoding.....	592
4.2.11	Compliance Pattern in 128b/130b Encoding.....	594
4.2.12	Modified Compliance Pattern in 128b/130b Encoding.....	596
4.2.13	Jitter Measurement Pattern in 128b/130b.....	596
4.2.14	Compliance Pattern in 1b/1b Encoding.....	597
4.2.15	Modified Compliance Pattern in 1b/1b Encoding.....	598
4.2.16	Jitter Measurement Pattern in 1b/1b Encoding.....	598
4.2.17	Toggle Patterns in 1b/1b encoding.....	599

4.2.18	Lane Margining at Receiver	599
4.2.18.1	Receiver Number, Margin Type, Usage Model, and Margin Payload Fields.....	600
4.2.18.1.1	Step Margin Execution Status	605
4.2.18.1.2	Margin Payload for Step Margin Commands	605
4.2.18.2	Margin Command and Response Flow	606
4.2.18.3	Flit Mode 8.0 GT/s Margining Behavior	609
4.2.18.4	Receiver Margin Testing Requirements	609
4.3	Retimers.....	614
4.3.1	Retimer Requirements	615
4.3.2	Supported Retimer Topologies.....	616
4.3.3	Variables	617
4.3.4	Receiver Impedance Propagation Rules.....	618
4.3.5	Switching Between Modes	618
4.3.6	Forwarding Rules.....	618
4.3.6.1	Forwarding Type Rules.....	619
4.3.6.2	Orientation, Lane Numbers, and Data Stream Mode Rules	619
4.3.6.3	Electrical Idle Exit Rules	620
4.3.6.4	Data Rate Change and Determination Rules	623
4.3.6.5	Electrical Idle Entry Rules	623
4.3.6.6	Transmitter Settings Determination Rules.....	625
4.3.6.7	Ordered Set Modification Rules	627
4.3.6.8	DLLP, TLP, Logical Idle, and Flit Modification Rules	629
4.3.6.9	8b/10b Encoding Rules.....	629
4.3.6.10	8b/10b Scrambling Rules	630
4.3.6.11	Hot Reset Rules.....	630
4.3.6.12	Disable Link Rules.....	631
4.3.6.13	Loopback	631
4.3.6.14	Compliance Receive Rules	632
4.3.6.15	Enter Compliance Rules	634
4.3.7	Execution Mode Rules	636
4.3.7.1	CompLoadBoard Rules	636
4.3.7.1.1	CompLoadBoard.Entry	637
4.3.7.1.2	CompLoadBoard.Pattern	637
4.3.7.1.3	CompLoadBoard.Exit	638
4.3.7.2	Link Equalization Rules	638
4.3.7.2.1	Downstream Lanes.....	639
4.3.7.2.1.1	Phase 1.....	639
4.3.7.2.1.2	Phase 2.....	639
4.3.7.2.1.3	Phase 3 Active.....	639
4.3.7.2.1.4	Phase 3 Passive.....	640
4.3.7.2.2	Upstream Lanes.....	640
4.3.7.2.2.1	Phase 0.....	640
4.3.7.2.2.2	Phase 1 Active.....	640
4.3.7.2.2.3	Phase 2 Active.....	640
4.3.7.2.2.4	Phase 2 Passive.....	641
4.3.7.2.2.5	Phase 3.....	641
4.3.7.2.3	Force Timeout.....	641
4.3.7.3	Follower Loopback.....	642
4.3.7.3.1	Follower Loopback.Entry.....	642
4.3.7.3.2	Follower Loopback.Active.....	642

4.3.7.3.3	Follower Loopback.Exit.....	643
4.3.8	Retimer Latency.....	643
4.3.8.1	Measurement.....	643
4.3.8.2	Maximum Limit on Retimer Latency.....	643
4.3.8.3	Impacts on Upstream and Downstream Ports	643
4.3.9	SRIS	644
4.3.10	L1 PM Substates Support	646
4.3.11	Retimer Configuration Parameters.....	647
4.3.11.1	Global Parameters	648
4.3.11.2	Per Physical Pseudo Port Parameters.....	648
4.3.12	In Band Register Access.....	649
5.	Power Management	651
5.1	Overview	651
5.2	Link State Power Management	652
5.3	PCI-PM Software Compatible Mechanisms	656
5.3.1	Device Power Management States (D-States) of a Function	656
5.3.1.1	D0 State.....	657
5.3.1.2	D1 State.....	657
5.3.1.3	D2 State.....	657
5.3.1.4	D3 State.....	658
5.3.1.4.1	D3 _{Hot} State.....	659
5.3.1.4.2	D3 _{Cold} State.....	660
5.3.2	PM Software Control of the Link Power Management State.....	661
5.3.2.1	Entry into the L1 State	662
5.3.2.2	Exit from L1 State.....	664
5.3.2.3	Entry into the L2/L3 Ready State	665
5.3.3	Power Management Event Mechanisms.....	665
5.3.3.1	Motivation.....	665

7.5.3.20	Link Status 2 Register (Offset 32h)	1083

7.5.3.21	Slot Capabilities 2 Register (Offset 34h)	1086
7.5.3.22	Slot Control 2 Register (Offset 38h)	1087
7.5.3.23	Slot Status 2 Register (Offset 3Ah)	1087
7.6	PCI Express Extended Capabilities	1087
7.6.1	Extended Capabilities in Configuration Space	1087
7.6.2	Extended Capabilities in the Root Complex Register Block	1087
7.6.3	PCI Express Extended Capability Header	1088
7.7	PCI and PCIe Capabilities Required by the Base Spec in Some Situations	1088
7.7.1	MSI Capability Structures	1088
7.7.1.1	MSI Capability Header (Offset 00h)	1090
7.7.1.2	Message Control Register for MSI (Offset 02h)	1091
7.7.1.3	Message Address Register for MSI (Offset 04h)	1093
7.7.1.4	Message Upper Address Register for MSI (Offset 08h)	1093
7.7.1.5	Message Data Register for MSI (Offset 08h or 0Ch)	1094
7.7.1.6	Extended Message Data Register for MSI (Optional)	1094
7.7.1.7	Mask Bits Register for MSI (Offset 0Ch or 10h)	1095
7.7.1.8	Pending Bits Register for MSI (Offset 10h or 14h)	1095
7.7.2	MSI-X Capability and Table Structure	1096
7.7.2.1	MSI-X Capability Header (Offset 00h)	1099
7.7.2.2	Message Control Register for MSI-X (Offset 02h)	1100
7.7.2.3	Table Offset/Table BIR Register for MSI-X (Offset 04h)	1101
7.7.2.4	PBA Offset/PBA BIR Register for MSI-X (Offset 08h)	1101
7.7.2.5	Message Address Register for MSI-X Table Entries	1102
7.7.2.6	Message Upper Address Register for MSI-X Table Entries	1103
7.7.2.7	Message Data Register for MSI-X Table Entries	1103
7.7.2.8	Vector Control Register for MSI-X Table Entries	1103
7.7.2.9	Pending Bits Register for MSI-X PBA Entries	1104
7.7.3	Secondary PCI Express Extended Capability	1105
7.7.3.1	Secondary PCI Express Extended Capability Header (Offset 00h)	1107
7.7.3.2	Link Control 3 Register (Offset 04h)	1107
7.7.3.3	Lane Error Status Register (Offset 08h)	1108
7.7.3.4	Lane Equalization Control Register (Offset 0Ch)	1109
7.7.4	Data Link Feature Extended Capability	1111
7.7.4.1	Data Link Feature Extended Capability Header (Offset 00h)	1112
7.7.4.2	Data Link Feature Capabilities Register (Offset 04h)	1113
7.7.4.3	Data Link Feature Status Register (Offset 08h)	1114
7.7.5	Physical Layer 16.0 GT/s Extended Capability	1115
7.7.5.1	Physical Layer 16.0 GT/s Extended Capability Header (Offset 00h)	1117
7.7.5.2	16.0 GT/s Capabilities Register (Offset 04h)	1117
7.7.5.3	16.0 GT/s Control Register (Offset 08h)	1118
7.7.5.4	16.0 GT/s Status Register (Offset 0Ch)	1118
7.7.5.5	16.0 GT/s Local Data Parity Mismatch Status Register (Offset 10h)	1119
7.7.5.6	16.0 GT/s First Retimer Data Parity Mismatch Status Register (Offset 14h)	1120
7.7.5.7	16.0 GT/s Second Retimer Data Parity Mismatch Status Register (Offset 18h)	1120
7.7.5.8	Physical Layer 16.0 GT/s Reserved (Offset 1Ch)	1121
7.7.5.9	16.0 GT/s Lane Equalization Control Register (Offsets 20h to 3Ch)	1121
7.7.6	Physical Layer 32.0 GT/s Extended Capability	1122
7.7.6.1	Physical Layer 32.0 GT/s Extended Capability Header (Offset 00h)	1124
7.7.6.2	32.0 GT/s Capabilities Register (Offset 04h)	1124
7.7.6.3	32.0 GT/s Control Register (Offset 08h)	1125

7.7.6.4	32.0 GT/s Status Register (Offset 0Ch).....	1126
7.7.6.5	Received Modified TS Data 1 Register (Offset 10h).....	1127
7.7.6.6	Received Modified TS Data 2 Register (Offset 14h).....	1128
7.7.6.7	Transmitted Modified TS Data 1 Register (Offset 18h)	1129
7.7.6.8	Transmitted Modified TS Data 2 Register (Offset 1Ch)	1130
7.7.6.9	32.0 GT/s Lane Equalization Control Register (Offset 20h)	1131
7.7.7	Physical Layer 64.0 GT/s Extended Capability	1133
7.7.7.1	Physical Layer 64.0 GT/s Extended Capability Header (Offset 00h)	1134
7.7.7.2	64.0 GT/s Capabilities Register (Offset 04h).....	1134
7.7.7.3	64.0 GT/s Control Register (Offset 08h).....	1135
7.7.7.4	64.0 GT/s Status Register (Offset 0Ch).....	1135
7.7.7.5	64.0 GT/s Lane Equalization Control Register (Offset 10h)	1136
7.7.8	Flit Logging Extended Capability	1138
7.7.8.1	Flit Logging Extended Capability Header (Offset 00h)	1138
7.7.8.2	Flit Error Log 1 Register (Offset 04h)	1139
7.7.8.3	Flit Error Log 2 Register (Offset 08h)	1141
7.7.8.4	Flit Error Counter Control Register (Offset 0Ch)	1142
7.7.8.5	Flit Error Counter Status Register (Offset 0Eh)	1143
7.7.8.6	FBER Measurement Control Register (Offset 10h).....	1144
7.7.8.7	FBER Measurement Status 1 Register (Offset 14h).....	1145
7.7.8.8	FBER Measurement Status 2 Register (Offset 18h).....	1145
7.7.8.9	FBER Measurement Status 3 Register (Offset 1Ch).....	1146
7.7.8.10	FBER Measurement Status 4 Register (Offset 20h).....	1146
7.7.8.11	FBER Measurement Status 5 Register (Offset 24h).....	1147
7.7.8.12	FBER Measurement Status 6 Register (Offset 28h).....	1147
7.7.8.13	FBER Measurement Status 7 Register (Offset 2Ch).....	1147
7.7.8.14	FBER Measurement Status 8 Register (Offset 30h).....	1148
7.7.8.15	FBER Measurement Status 9 Register (Offset 34h).....	1148
7.7.8.16	FBER Measurement Status 10 Register (Offset 38h).....	1149
7.7.9	Device 3 Extended Capability Structure	1149
7.7.9.1	Device 3 Extended Capability Header (Offset 00h).....	1149
7.7.9.2	Device Capabilities 3 Register (Offset 04h)	1150
7.7.9.3	Device Control 3 Register (Offset 08h)	1152
7.7.9.4	Device Status 3 Register (Offset 0Ch)	1154
7.7.10	Lane Margining at the Receiver Extended Capability.....	1155
7.7.10.1	Lane Margining at the Receiver Extended Capability Header (Offset 00h).....	1158
7.7.10.2	Margining Port Capabilities Register (Offset 04h)	1158
7.7.10.3	Margining Port Status Register (Offset 06h)	1159
7.7.10.4	Margining Lane Control Register (Offset 08h)	1159
7.7.10.5	Margining Lane Status Register (Offset 0Ah)	1160
7.7.11	ACS Extended Capability	1161
7.7.11.1	ACS Extended Capability Header (Offset 00h)	1162
7.7.11.2	ACS Capability Register (Offset 04h)	1163
7.7.11.3	ACS Control Register (Offset 06h).....	1164
7.7.11.4	Egress Control Vector Register (Offset 08h).....	1166
7.8	Common PCI and PCIe Capabilities.....	1168
7.8.1	Power Budgeting Extended Capability	1168
7.8.1.1	Power Budgeting Extended Capability Header (Offset 00h)	1168
7.8.1.2	Power Budgeting Data Select Register (Offset 04h)	1169
7.8.1.3	Power Budgeting Control Register (Offset 06h)	1169

7.8.1.4	Power Budgeting Data Register (Offset 08h)	1171
7.8.1.5	Power Budgeting Capability Register (Offset 0Ch)	1176
7.8.1.6	Power Budgeting Sense Detect Register (Offset 0Dh)	1177
7.8.2	Latency Tolerance Reporting (LTR) Extended Capability	1180
7.8.2.1	LTR Extended Capability Header (Offset 00h)	1181
7.8.2.2	Max Snoop Latency Register (Offset 04h)	1181
7.8.2.3	Max No-Snoop Latency Register (Offset 06h)	1182
7.8.3	L1 PM Substates Extended Capability	1182
7.8.3.1	L1 PM Substates Extended Capability Header (Offset 00h)	1183
7.8.3.2	L1 PM Substates Capabilities Register (Offset 04h)	1184
7.8.3.3	L1 PM Substates Control 1 Register (Offset 08h)	1185
7.8.3.4	L1 PM Substates Control 2 Register (Offset 0Ch)	1187
7.8.3.5	L1 PM Substates Status Register (Offset 10h)	1188
7.8.4	Advanced Error Reporting Extended Capability	1188
7.8.4.1	Advanced Error Reporting Extended Capability Header (Offset 00h)	1191
7.8.4.2	Uncorrectable Error Status Register (Offset 04h)	1191
7.8.4.3	Uncorrectable Error Mask Register (Offset 08h)	1194
7.8.4.4	Uncorrectable Error Severity Register (Offset 0Ch)	1196
7.8.4.5	Correctable Error Status Register (Offset 10h)	1199
7.8.4.6	Correctable Error Mask Register (Offset 14h)	1200
7.8.4.7	Advanced Error Capabilities and Control Register (Offset 18h)	1201
7.8.4.8	Header Log Register (Offset 1Ch)	1203
7.8.4.9	Root Error Command Register (Offset 2Ch)	1204
7.8.4.10	Root Error Status Register (Offset 30h)	1205
7.8.4.11	Error Source Identification Register (Offset 34h)	1207
7.8.4.12	TLP Prefix Log Register (Offset 38h)	1208
7.8.5	Enhanced Allocation Capability Structure (EA)	1209
7.8.5.1	Enhanced Allocation Capability First DW (Offset 00h)	1209
7.8.5.2	Enhanced Allocation Capability Second DW (Offset 04h) [Type 1 Functions Only]	1210
7.8.5.3	Enhanced Allocation Per-Entry Format (Offset 04h or 08h)	1210
7.8.6	Resizable BAR Extended Capability	1215
7.8.6.1	Resizable BAR Extended Capability Header (Offset 00h)	1218
7.8.6.2	Resizable BAR Capability Register	1218
7.8.6.3	Resizable BAR Control Register	1221
7.8.7	VF Resizable BAR Extended Capability	1223
7.8.7.1	VF Resizable BAR Extended Capability Header (Offset 00h)	1225
7.8.7.2	VF Resizable BAR Capability Register (Offset 04h)	1225
7.8.7.3	VF Resizable BAR Control Register (Offset 08h)	1225
7.8.8	ARI Extended Capability	1227
7.8.8.1	ARI Extended Capability Header (Offset 00h)	1227
7.8.8.2	ARI Capability Register (Offset 04h)	1228
7.8.8.3	ARI Control Register (Offset 06h)	1229
7.8.9	PASID Extended Capability Structure	1229
7.8.9.1	PASID Extended Capability Header (Offset 00h)	1230
7.8.9.2	PASID Capability Register (Offset 04h)	1231
7.8.9.3	PASID Control Register (Offset 06h)	1231
7.8.10	FRS Queueing Extended Capability	1233
7.8.10.1	FRS Queueing Extended Capability Header (Offset 00h)	1233
7.8.10.2	FRS Queueing Capability Register (Offset 04h)	1234

7.8.10.3	FRS Queueing Status Register (Offset 08h)	1234
7.8.10.4	FRS Queueing Control Register (Offset 0Ah)	1235
7.8.10.5	FRS Message Queue Register (Offset 0Ch)	1235
7.8.11	Flattening Portal Bridge (FPB) Capability	1236
7.8.11.1	FPB Capability Header (Offset 00h)	1237
7.8.11.2	FPB Capabilities Register (Offset 04h)	1237
7.8.11.3	FPB RID Vector Control 1 Register (Offset 08h)	1239
7.8.11.4	FPB RID Vector Control 2 Register (Offset 0Ch)	1240
7.8.11.5	FPB MEM Low Vector Control Register (Offset 10h)	1241
7.8.11.6	FPB MEM High Vector Control 1 Register (Offset 14h)	1242
7.8.11.7	FPB MEM High Vector Control 2 Register (Offset 18h)	1244
7.8.11.8	FPB Vector Access Control Register (Offset 1Ch)	1245
7.8.11.9	FPB Vector Access Data Register (Offset 20h)	1246
7.8.12	Flit Performance Measurement Extended Capability	1247
7.8.12.1	Flit Performance Measurement Extended Capability Header (Offset 00h)	1247
7.8.12.2	Flit Performance Measurement Capability Register (Offset 04h)	1248
7.8.12.3	Flit Performance Measurement Control Register (Offset 08h)	1249
7.8.12.4	Flit Performance Measurement Status Register (Offset 0Ch)	1251
7.8.12.5	LTSSM Performance Measurement Status Register (Offsets 10h to 20h)	1252
7.8.13	Flit Error Injection Extended Capability	1253
7.8.13.1	Flit Error Injection Extended Capability Header (Offset 00h)	1254
7.8.13.2	Flit Error Injection Capability Register (Offset 04h)	1255
7.8.13.3	Flit Error Injection Control 1 Register (Offset 08h)	1255
7.8.13.4	Flit Error Injection Control 2 Register (Offset 0Ch)	1257
7.8.13.5	Flit Error Injection Status Register (Offset 10h)	1258
7.8.13.6	Ordered Set Error Injection Control 1 Register (Offset 14h)	1259
7.8.13.7	Ordered Set Error Injection Control 2 Register (Offset 18h)	1260
7.8.13.8	Ordered Set Error Tx Injection Status Register (Offset 1Ch)	1261
7.8.13.9	Ordered Set Error Rx Injection Status Register (Offset 20h)	1262
7.9	Additional PCI and PCIe Capabilities	1263
7.9.1	Virtual Channel Extended Capability	1263
7.9.1.1	Virtual Channel Extended Capability Header (Offset 00h)	1264
7.9.1.2	Port VC Capability Register 1 (Offset 04h)	1265

Status of this Document

This section describes the status of this document at the time of its publication. Other documents may supersede this document. A list of current PCISIG publications and the latest revision of this specification can be found at pcisig.com

This is the *PCI Express Base 6.2 Specification*. This consists of Base 6.1 plus approved ECNs, errata, and editorial corrections. See [Critical Errata](#) and [Important Errata and Approved ECNs](#).

- The [NCB-PCI_Express_Base_6.2.pdf](#) is normative (i.e., the official specification). It contains no changebars.
- The [CB-PCI_Express_Base_6.2-vs-6.1.pdf](#) is informative. It contains changebars relative to the *PCI Express Base 6.1 Specification* [[PCIe-6.1](#)].

NOTE: Background on the new Document Process §

The new PCISIG document system is a variant of the w3c Respec tool (see <https://github.com/w3c/respec/wiki>). Respec is a widely used tool written to support the World Wide Web specifications. The PCISIG variant is <https://github.com/sglaser/respec>. Both Respec and the PCISIG variant are open source (MIT License) Javascript libraries. They operate in the author's browser and provide a rapid edit / review cycle without requiring any special tools be installed.

Respec is built on top of HTML5, the document format for the World Wide Web <http://www.w3.org/TR/html5/>. HTML is a text-based document format that allows us to deploy tools commonly used for software development (git, continuous integration, build scripts, etc.) to better manage and control the spec development process.

PCISIG enhancements to Respec support document formatting closer to existing PCISIG practice as well as automatic creation of register figures (eliminating about half of the manually drawn figures).

NOTE: Navigating in changebar documents §

The Base 6.0.1 version introduces a new errata delivery process. Instead of having a separate “change this to that” document, a new version of the specification is produced with the changes integrated into the document. This makes it easier to consume and less likely that errata will be overlooked.

All changes are annotated with the **↔** character. Searching for this character in a PDF reader will step through all changes. There is a **↔** character in the upper right of page 1 that can be copied into the search string.

Inserted text is yellow and underlined. It contains the **↑** character.

Deleted text is red and struck through. It contains the **↓** character.

All errata are identified by a “red box” near the first change in a chunk of changes. This box contains one or more triangle characters that can navigate through the changes for the associated errata.

The upward pointing triangle is a link to the associated errata table entry.

The right pointing triangle is a link to the next change associated with this errata. If this is the last change, this triangle is not present.

The left pointing triangle is a link to the previous change associated with this errata. If this is the first change, this triangle is not present.

Changes that are not marked with a red box are considered editorial in nature and are not associated with an errata.

Where the automated process can't correctly identify changes (e.g., figures and equations), the errata table contains the change description.

Revision History

Revision	Revision History	Date
1.0	Initial release.	07/22/2002
1.0a	Incorporated Errata C1-C66 and E1-E4.17.	04/15/2003
1.1	Incorporated approved Errata and ECNs.	03/28/2005
2.0	Added 5.0 GT/s data rate and incorporated approved Errata and ECNs.	12/20/2006
2.1	<p>Incorporated <i>Errata for the PCI Express Base Specification, Rev. 2.0</i> (February 27, 2009), and added the following ECNs:</p> <ul style="list-style-type: none"> • Internal Error Reporting ECN (April 24, 2008) • Multicast ECN (December 14, 2007, approved by PWG May 8, 2008) • Atomic Operations ECN (January 15, 2008, approved by PWG April 17, 2008) • Resizable BAR Capability ECN (January 22, 2008, updated and approved by PWG April 24, 2008) • Dynamic Power Allocation ECN (May 24, 2008) • ID-Based Ordering ECN (January 16, 2008, updated 29 May 2008) • Latency Tolerance Reporting ECN (22 January 2008, updated 14 August 2008) • Alternative Routing-ID Interpretation (ARI) ECN (August 7, 2006, last updated June 4, 2007) • Extended Tag Enable Default ECN (September 5, 2008) • TLP Processing Hints ECN (September 11, 2008) • TLP Prefix ECN (December 15, 2008) 	03/04/2009
3.0	<p>Added 8.0 GT/s data rate, latest approved Errata, and the following ECNs:</p> <ul style="list-style-type: none"> • Optimized Buffer Flush/Fill ECN (8 February 2008, updated 30 April 2009) • ASPM Optionality ECN (June 19, 2009, approved by the PWG August 20, 2009) • Incorporated End-End TLP Changes for RCs ECN (26 May 2010) and Protocol Multiplexing ECN (17 June 2010) 	11/10/2010
3.1	<p>Incorporated feedback from Member Review</p> <p>Incorporated Errata for the PCI Express® Base Specification Revision 3.0</p> <p>Incorporated M-PCIe Errata (3p1_active_errata_list_mpcie_28Aug2014.doc and 3p1_active_errata_list_mpcie_part2_11Sept2014.doc)</p> <p>Incorporated the following ECNs:</p> <ul style="list-style-type: none"> • ECN: Downstream Port containment (DPC) • ECN: Separate Refclk Independent SSC (SRIS) Architecture • ECN: Process Address Space ID (PASID) • ECN: Lightweight Notification (LN) Protocol 	10/8/2014

Revision	Revision History	Date
	<ul style="list-style-type: none"> • ECN: Precision Time Measurement • ECN: Enhanced DPC (eDPC) • ECN: 8.0 GT/s Receiver Impedance • ECN: L1 PM Substates with CLKREQ • ECN: Change Root Complex Event Collector Class Code • ECN: M-PCIe • ECN: Readiness Notifications (RN) • ECN: Separate Refclk Independent SSC Architecture (SRIS) JTOL and SSC Profile Requirements 	
3.1a	<p>Minor update:</p> <p>Corrected: Equation 4.3.9 in Section 4.3.8.5., Separate Refclk With Independent SSC (SRIS) Architecture. Added missing square (exponent=2) in the definition of B.</p> <p>$B = 2.2 \times 10^{12} \times (2.\pi)^2$ where ^= exponent.</p>	12/5/2015
4.0	<p>Version 0.3: Based on PCI Express® Base Specification Revision 3.1 (October 8, 2014) with some editorial feedback received in December 2013.</p> <ul style="list-style-type: none"> • Added § Chapter 9. , Electrical Sub-block: Added § Chapter 9. (Rev0.3-11-30-13_final.docx) • Changes related to Revision 0.3 release • Incorporated PCIe-relevant material from PCI Bus Power Management Interface Specification (Revision 1.2, dated March 3, 2004). This initial integration of the material will be updated as necessary and will supersede the standalone Power Management Interface specification. <p>Version 0.5 (12/22/14, minor revisions on 1/26/15, minor corrections 2/6/15)</p> <ul style="list-style-type: none"> • Added front matter with notes on expected discussions and changes. • Added ECN:Retimer (dated October 6, 2014) • Corrected § Chapter 4. title to, “Physical Layer Logical Block”. • Added Encoding subteam feedback on § Chapter 4. • Added Electrical work group changes from PCIe Electrical Specification Rev 0.5 RC1 into § Chapter 9. 	2/6/2015
	<p>Version 0.7: Based on PCI Express® Base Specification Version 4.0 Revision 0.5 (11/23/2015)</p> <ul style="list-style-type: none"> • Added ECN_DVSEC-2015-08-04 • Applied ECN PASID-ATS dated 2011-03-31 • Applied PCIe Base Spec Errata: PCIe_Base_r3 1_Errata_2015-09-18 except: <ul style="list-style-type: none"> ◦ B216; RCIE ◦ B256; grammar is not clear • Changes to Chapter 7. Critical Errata

Revision	Errata	Description
6.0.1	A20	<p>Partial Header Encryption Corrections:</p> <ul style="list-style-type: none"> Define Partial Header Encryption Mode field for Like IDE Correct Partial Header Encryption Algorithm to correct functional issues and to use Byte level granularity instead of bit granularity as required in AES-GCM. Update § Figure L-1 to include Attr[2] (a.k.a. A2 or IDO). Add § Section L.2 .
6.0.1	A27	Clarify Flit Mode Receiver parsing requirements regarding of the Length field.
6.0.1	A35	<p>Shared Flow Control Corrections:</p> <ul style="list-style-type: none"> Split Table 3-2 into § Table 3-2 and § Table 3-3 Correct encoding of Symbol +0 bit 3 in § Figure 3-9, § Figure 3-10, and § Figure 3-11 to match § Table 3-3 Remove obsolete “Shared Flow Control Flit_Marker” text from the Recommended Priority of Scheduled Transmissions Implementation Note.
6.0.1	A35a	Shared Flow Control Usage Limit is <u>RsvdP</u> for Non-Flit Mode components.

Revision	Errata	Description
6.0.1	A37	Corrections to the Flit Sequence Number and Retry Mechanism (see § Section 4.2.3.4.2.1)
6.0.1	A38	L0p Corrections: <ul style="list-style-type: none"> • Preserve LFSR relationship between Lanes on width increase • Update scrambler behavior during L0p width increase • Update Link Management DLLP Behavior • Update LFSR advancement rules for L0p
6.0.1	A53	Define the <u>Flit Error Counter Interrupt Enable bit</u> in the <u>Flit Error Counter Control Register</u> .
6.0.1	A62	Clarify OHC rules.
6.0.1	A67	Training Set Corrections: <ul style="list-style-type: none"> • Clarify equalization fields in <u>TS0 Ordered Sets</u> (see § Table 4-29).
6.0.1	A73	Modified TS1/TS2 corrections
6.1	A392	Clarify End-to-End TLP Prefix Support indications to software.
6.1	A393	Corrections to Flow Control rules <ul style="list-style-type: none"> • To clarify that when [Merged] is used, distinct UpdateFCs are sent for Posted and Completion credits. This provides buffer consumption visibility to the transmitter allowing a vendor-specific Quality of Service (QoS) mechanism to be implemented. • Clarify definition of <u>FC Unit Size</u> • Require consistency across VCs for shared credits – for example, if one VC advertises [<u>Infinite.3</u>], all VCs must also advertise it • Update minimum flow control credit rules. • Clarify scale factor rules when [<u>Zero</u>] or [<u>Merged</u>] are used. • Update § <u>Equation 2-8</u> • Add § <u>Equation 2-9</u> • Update § <u>Equation 2-10</u> • Add § <u>Equation 2-11</u> • Update § <u>Equation 2-16</u> • Add § <u>Equation 2-17</u> and § <u>Equation 2-18</u>
6.2	A531	Correct § <u>Figure 6-64 “IDE TLP Prefix (NFM)”</u> and clarify text.
6.2	A540	Corrections to Equalization Phase 1 rules.
6.2	A544	Corrections to Flit Ack and Nak rules.
6.2	A577	Define EIE pattern for Retimers for 1b/1b encoding.
6.2	A578	Required modifications for Retimer timeouts for 64.0 GT/s.
6.2	A587	Correct inconsistencies between decimal and binary values listed in § <u>Table 2-5 “Flit Mode TLP Header Type Encodings”</u> .

Important Errata and Approved ECNs

Revision	Errata / ECN	Description
6.0.1	B5	Clarify value of the Alternate Protocol Count field in the <u>Alternate Protocol Capabilities Register</u> .
6.0.1	B7	Incorrect capability name used in the description of the Capability ID field of <u>Lane Margining at the Receiver Extended Capability Header</u> .
6.0.1	B8	Clarify that behavior is undefined when <u>Message Data Register for MSI low bits</u> conflict with the MME setting.
6.0.1	B10	A single PCI Express Function is permitted to contain multiple VSEC structures.
6.0.1	B11	Clarify Retimer Loopback behavior.
6.0.1	B12	Recommend that parity errors in Control SKP OS be checked only when immediately preceded by a Data Block.
6.0.1	B13	Clarify <u>Alternate Protocol Negotiation Status</u> error values.
6.0.1	B14	Define what it means for Scaled Flow Control to be “activated”.
6.0.1	B15	<u>Margining Ready</u> applies to speeds above 16.0 GT/s.
6.0.1	B16	Update Link Number encoding in § <u>Table 4-28</u> .
6.0.1	B17	Add Implementation Note: <u>Implementation Note: Delays in Data Link Layer Link Active Reflecting Link Control Operations</u>
6.0.1	B18	Clarify Receiver Impedance Propagation Rules.
6.0.1	B21	Update recommended behavior on transitions from Hot Reset to <u>Detect.Active</u> .
6.0.1	B22	Clarify Flit Mode poison rules.
6.0.1	B23	<ul style="list-style-type: none"> Shrink figures § <u>Figure 3-9</u> and § <u>Figure 3-10</u> so they're not cut off. Redraw § <u>Figure 4-27</u> so it's readable. <p>Figure 1 Old Figure: Flit Mode and Non-Flit Mode processing with 8b/10b and 128b/130b encoding on the Transmit side §</p>

Revision	Errata / ECN	Description
----------	--------------	-------------

Figure 2 New Figure: Flit Mode and Non-Flit Mode processing with 8b/10b and 128b/130b encoding on the Transmit side §

- Redraw § Figure 4-28 so it's readable.

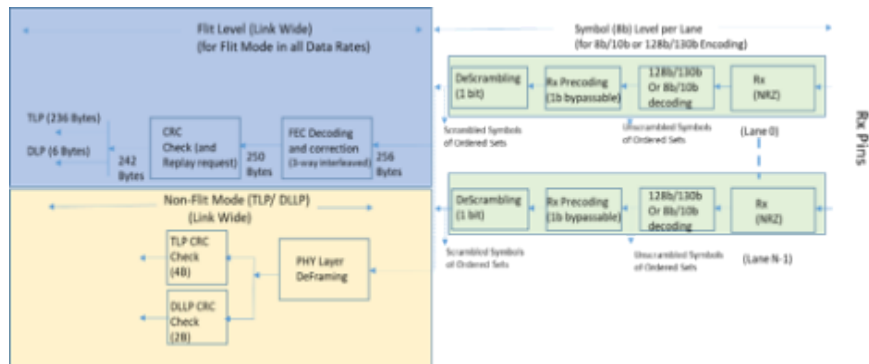

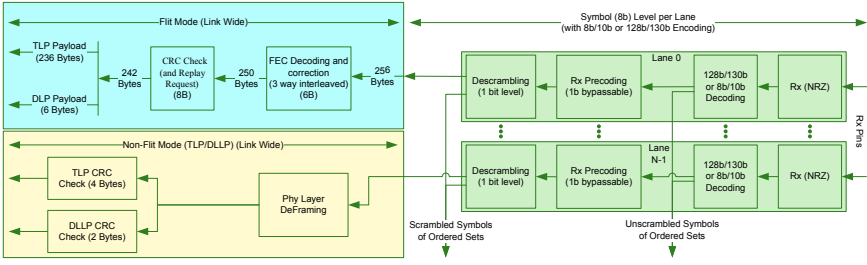

Figure 3 Old Figure: Flit Mode and Non-Flit Mode processing with 8b/10b and 128b/130b encoding on the Receive side §

6.0.1	B44	Extended Synch is not used for L0s in Flit Mode, but is still relevant for other purposes.																																																															
6.0.1	B45	Add 64.0 GT/s encoding to Enable SKP OS Generation Vector.																																																															
6.0.1	B48	Clarify 1b/1b encoding <u>EIOSQ</u> terminology in Compliance and Modified Compliance Patterns.																																																															
6.0.1	B49	<u>Execute Requested</u> is reserved in all Memory Requests other than Untranslated Memory Read Requests.																																																															
6.0.1	B50	Typo in units column of § Table 8-16, Parameter T _{TX-CH-UPW-RJ-64G}																																																															

Revision	Errata / ECN	Description
6.0.1	B51	<ul style="list-style-type: none"> • Typo in units column of § Table 8-18, Parameter <u>Z_{C-DC}</u> • Locate artwork for § Figure 8-84
6.0.1	B54	Don't send Selective IDE Stream IDE Sync and IDE Fail messages unless the V bit is Set for that <u>RID Base</u> .
6.0.1	B55	The “subsequent IDE TLPs” error reporting language applies regardless of how Insecure was reached.
6.0.1	B56	<u>Selective IDE Stream Enable</u> and <u>Link IDE Stream Enable</u> are edge triggered.
6.0.1	B58	The <u>Selective IDE Stream Control Register</u> , <u>Default Stream</u> field only applied to Selective IDE Streams.
6.0.1	B59	Routed to Root Complex is permitted only when the Partner Port is a Root Port, as indicated by the Default Stream bit being Set.
6.0.1	B60	Clarify rules for selecting the Selective IDE Stream for a given TLP.
6.0.1	B64	Clarify Segment number processing rules in Flit Mode Completer Transaction ID processing.
6.0.1	B66	<p>The <u>Data Link Feature Exchange Enable</u> field was renamed to <u>Data Link Feature Exchange Is Enabled</u>.</p> <p>This errata also applies to <u>[PCIE-5.0]</u>.</p>
6.0.1	B68	Correct Type field value in § Figure 10-13 (was 0000 0000b should be 0000 0011b).
6.0.1	B69	In Shared Flow Control Usage Limit Enable, clarify wording to indicate which Shared Flow Control Usage Limit is affected (duplicate field names in <u>VC Resource Control Register</u> and <u>MFVC VC Resource Control Register</u>).
6.0.1	B70	DC Balance correction in 1b/1b encoding of <u>TS0</u> , <u>TS1</u> , and <u>TS2</u>
6.0.1	B71	Consolidate description of 1b/1b behavior for <u>SKP Ordered Sets</u>
6.0.1	B72	TS2 Symbol 6, operating at 2.5 or 5.0 GT/s and Requesting equalization 32.0 GT/s encoding is only for 32.0 GT/s (was “32.0 GT/s or higher ”)
6.0.1	B75	Clarify behavior in CMA-SPDM Rules.
6.0.1	B77	Update artwork for § Figure 6-79.
6.0.1	B79	In Flit Mode, the 16.0 GT/s Local Data Parity Mismatch Status Register, 16.0 GT/s First Retimer Data Parity Mismatch Status Register, and 16.0 GT/s Second Retimer Data Parity Mismatch Status Register are used at all 128b/130b and 1b/1b data rates.
6.0.1	B81	Clarify 128b/130b Control and Standard SKP Alternation Rule interactions with <u>L0p</u>
6.0.1	B82	Editorial: <u>SRIS_Mode_Enabled</u> is a variable, not a bit.
6.0.1	B83	Define CXL Src bit in ATS Translation Requests. This is bit 3 in byte 15 in § Figure 10-10, § Figure 10-11, § Figure 10-12, and § Figure 10-13. Editorial change in § Table 10-3.
6.0.1	B85	Loopback Follower changes

Revision	Errata / ECN	Description
6.0.1	B86	<ul style="list-style-type: none"> • § Table 4-28 Equalization Byte 0 correction (Symbols 1,9) • § Table 4-26 Symbol 6 8.0 GT/s should be 8.0 GT/s or higher • § Section 4.2.7.4.4 , Width change rule change, change “128b/138b” to “128b/130b or 1b/1b” (3 places)
6.0.1	B87	Update <u>Recovery.RcvrLock</u> behavior when hardware autonomous equalization is not adopted
6.0.1	B88	Define 1b/1b Phy Payload type Alternation Rule
6.0.1	B89	<ul style="list-style-type: none"> • Change name of <u>L0p Supported</u> capability bit (was Receiver L0p Supported) • Clarify <u>Target Link Width</u> behavior • Clarify <u>L0p.Priority</u> behavior
6.0.1	B90	Clarify Receiver Framing Requirements (including <u>L0p</u> in Flit Mode)
6.0.1	B92	Clarify that the LTSSM must not advertise speeds above 32.0 GT/s in <u>Polling.Active</u> and <u>Polling.Configuration</u> . During those states, negotiation for greater than 32.0 GT/s is occurring.
6.0.1	B93	Add implementation note “Reject Coefficient Values with TS0 Ordered Sets” in § Section 4.2.7.4.2.2.1 .
6.0.1	B94	<u>Attr[2]</u> was incorrectly shown as Reserved in § Figure 10-6, § Figure 10-7, § Figure 10-10, and § Figure 10-11.
6.0.1	B95	Clarify historical timestam invalidation behavior in § Section 6.21.3.2 .
6.0.1	B96	Correct the register width of the <u>Root Capabilities Register</u> , § Table 7-31. Was 32 bits, but the register is actually 16 bits wide.
6.0.1	B98	Update § Figure 7-222 and § Table 7-201 to better reflect that the Virtual Channel Extended Capability uses Capability ID 0002h or 0009h.
6.0.1	B99	Clarify that intermediate receivers should not check crossing 4 KB boundaries. Implementing this check could invalidate such silicon changes for future TLP Type definitions (e.g., such future TLP Types could be similar to the existing Atomic CAS where the relationship between the TLP Length field and the affected memory range is not 1:1).
6.0.1	B100	Clarify that <u>L0p</u> is supported at all data rates.
6.0.1	B102	Segment was erroneously left out of IDE RID Association mechanism
6.0.1	B103	Clarify IDE TLP Aggregation rules. See § Section 6.33.6 .
6.0.1	B104	Add implementation note <u>SKP Ordered Sets in a Data Stream in Flit Mode</u> to § Section 4.2.8.5 .
6.0.1	B106	Clarify the FM/NFM rules for PCRC.
6.0.1	B107	Clarify that IDE TLPs in FM always have OHC-C.
6.0.1	B108	CMA-SPDM state should not be affected by FLR.
6.0.1	B111	Clarify Retimer response for Access Retimer Register command.
6.0.1	B112	Add implementation note <u>Security Issues Associated with Non-Enabled Bytes</u> .

Revision	Errata / ECN	Description
6.0.1	B113	<p>The following figures incorrectly described reserved bits as RsvdP that should be RsvdZ. some of these were also incorrect in [PCIe-5.0] but were correct in [PCIe-4.0].</p> <ul style="list-style-type: none"> • § Figure 7-32 – Slot Status Register • § Figure 7-124 – Device Status 3 Register • § Figure 7-375 – Link IDE Stream Status Register • § Figure 7-378 – Selective IDE Stream Status Register
6.0.1	B114	Add new § Section 4.2.18.3 describing Lane Margining contents for Flit Mode <u>Control SKP Ordered Sets at 8.0 GT/s.</u>
6.0.1	B115	Clarify the Variant bit rules in § Section 2.7.1 .
6.0.1	B116	OHC-A1 is also used for Route to Root Complex Messages (e.g., Page Request Messages) and for Translation Requests that Set NW
6.0.1	B117	Clarify that "overflow" for the PR Received Counters (NPR/CPL) means the 64b counter itself overflows.
6.0.1	B118	Clarify that, with system support for DRS, Devices are permitted to take longer than 1 second to become Configuration-Ready.
6.0.1	B119	Clarify text in Segment Captured bit description.
6.0.1	B120	When the length of an ATS Request is improper, the result should be undefined, not a Malformed TLP.
6.0.1	B121	Clarify TLP Prefix Processing rules for Flit Mode.
6.0.1	B122	Clarify completion rules for TLPs with Reserved Type field values.
6.0.1	B123	Deprecate Flit Mode TLP Suffixes. They were unused and have latency concerns.
6.0.1	B124	Clarify that Equalization Bypass to Highest NRZ Rate Disable is optional.
6.0.1	B127	Clarify L0p Framing Error rule. Clarify L0p retimer behavior.
6.0.1	B128	Update the Compliance Pattern for 1b/1b operation.
6.0.1	B130	Clarify <u>Loopback.Active</u> language.
6.0.1	B131	<ul style="list-style-type: none"> • Deprecate <u>Report Longest Burst vs First Burst</u> • <u>Flit Error Counter</u> does not roll over • Introductory text in § Section 7.7.8.7 describes all FBER Measurement Status Registers (i.e., <u>FBER Measurement Status 1 Register</u> through <u>FBER Measurement Status 10 Register</u>) • Remove Pseudo Port wording in <u>Lane #0 Correctable Counter</u> (also applies to the rest of the Lane counters).
6.0.1	B132	<p>Correct Tag field usage in Messages and Vendor-Defined Messages.</p> <ul style="list-style-type: none"> • Message byte 6 is Reserved unless specifically defined. • Reserved bits must be copied intact during translation to/from Flit Mode and Non-Flit Mode.

Revision	Errata / ECN	Description
6.1	B429	Scaled Flow Control updates
6.1	B430	Data Link Feature is required in Flit Mode
6.1	B431	Errata against UIO ECN: Remove the sentence “Because UIO can only be enabled when end-to-end UIO support exists, it is never necessary for the Root Complex to take ownership of UIO Requests.” from the <u>Implementation Note Root Complex Support for peer-to-peer Non-Posted Memory Transactions that Traverse Hierarchies.</u>
6.1	B432	Mandate capacitor placement on the Transmit end of a Link.
6.1	B433	Clarify valid tag values for 14-bit tags.
6.1	B434	Clarify rules for Switch FM to NFM translation.
6.1	B435	Address Routed Message corrections in Flit Mode.
6.1	B436	Clarification of Tag keep-out ranges.
6.2	B500	Clarify rules for PASID application.
6.2	B501	Clarify rules for Address Routed Messages.
6.2	B502	Clarify <u>OHC-A5</u> requirements for Selective IDE Completions.
6.2	B503	Remove needless indirection regarding requirement that VFs must not implement PASID Extended Capability.
6.2	B506	Clarify rules for TDI regarding MSI/MSI-X.
6.2	B507	Errata B507: Remove Implementation Note “FUTURE TEE EXTENSIONS”: TEE extensions for sub-function I/O-virtualization techniques will be covered in a future revision of this specification.
6.2	B508	Remove unnecessary restriction on VC1 in <u>SVC</u> .
6.2	B510	Correct typo in <u>Recovery.RcwrCfg</u> .
6.2	B512	Clarify application of IDE Default Stream to Translation Requests and Untranslated Memory Requests.
6.2	B513	Clarify application of ordering rules for Flow-Through Selective IDE.
6.2	B515	Clarify Flit Performance Measurement mechanisms.
6.2	B515a	Clarify Segment rules for Flit Mode Requesters/Completers within an RC.
6.2	B517	Correct § <u>Figure 6-46</u> “CMA-SPDM as Part of a Layered Architecture”.
6.2	B518	Correct use of “Precision Time Measurement”.
6.2	B520	Clarify Phase 1 of Transmitter Equalization text.
6.2	B522	Correct paragraph alignment.
6.2	B524	Clarify rules for <u>EQ TS2</u> Ordered Set use.
6.2	B525	Add <u>L0p</u> register cross-references.

Revision	Errata / ECN	Description
6.2	B529	Clarify earmarked TLP handling.
6.2	B535	FLIT_REPLAY_NUM clarifications.
6.2	B536	Clarify Segment Base programming for certain scenarios.
6.2	B537	Clarify rules for Selective IDE for Configuration Requests.
6.2	B538	Clarify Privileged Mode Requested and Execute Requested/Execute Permitted rules corrupted during Revision 6.0 development.
6.2	B541	Clarify <u>L0p</u> request handling rules.
6.2	B546	<p>Clarify figures and text regarding TLP Header Byte 6 for Message Requests.</p> <p>The following NFM Message Request Header figures in § Section 2.2.8 have byte 6 labeled as “Tag”. Change the label to “R” or “Reserved” (based on what fits). 6.2	B547	Clarify <u>AT</u> field requirements for Messages Routed by Address.
6.2	B548	Clarify <u>MMB Capabilities Register</u> language.
6.2	B549	Clarify handling of received DMWr Requests.
6.2	B550	Clarify and cross-reference existing rules regarding Segment exceptions for Root Ports.
6.2	B551	Clarify <u>SKP Ordered Set</u> rules with <u>L0p</u> .
6.2	B552	Correct omission of <u>TS0</u> in rules for Phase 1 of Transmitter Equalization.
6.2	B553	Clarify text regarding Electrical Idle Sequences on entry to <u>Recovery.RcvrLock</u> .
6.2	B554	Clarify Autonomous Change / Selectable De-emphasis for <u>TS1/TS2 Ordered Set</u> with 1b/1b Encoding.
6.2	B555	Clarify content of <u>TS2 Ordered Set</u> with 1b/1b Encoding.
6.2	B556	Clarify handling of <u>NOP2 DLLP</u> during equalization.
6.2	B557	Clarify Flit Replay Transmit rules.
6.2	B559	UIO clarifications.
6.2	B561	Clarify and cross-reference DMWr capability reporting.
6.2	B562	<u>OHC-E</u> clarifications.
6.2	B564	Clarify <u>L0p</u> Link width rules.

Revision	Errata / ECN	Description
6.2	B565	Clarify rules for handling an invalid Flit Sequence Number in a received Ack Flit or Nak Flit.
6.2	B566	Clarify Retimer data rate change and determination rules.
6.2	B568	Correct Bad DLLP entry in § Table 6-4 “Data Link Layer Error List”.
6.2	B569	Clarify handling of ID Routed Messages targeting a Function that is not implemented.
6.2	B571	<p>Correct figures to reduce the Key Sub-Stream field width to 3 bits. This affects:</p> <ul style="list-style-type: none"> • § Figure 6-57 • § Figure 6-58 • § Figure 6-59 • § Figure 6-60 • § Figure 6-61
6.2	B572	Clarify rules for implementing <u>PTM Extended Capability</u> .
6.2	B573	Clarify Data Stream, and rules for choosing Flit Mode vs. Non-Flit Mode.
6.2	B575	Clarify <u>Half Scrambling</u>
6.2	B576	Add Implementation Note: Forwarding D21.3 Symbol with Incorrect Disparity.
6.2	B580	Clarify rules to detect an <u>SDS</u> .
6.2	B581	Add Implementation Note <u>Orthogonality of L0p and L1/L2</u>
6.2	B583	Clarify definition of UIO TLPs.
6.2	B583a	Clarify that Translation Requests are not defined for UIO Memory Reads.
6.2	B585	Correct section references.
6.2	B586	Clarify definition of Idle Flit, Nop Flit, and Payload Flit.
6.2	B588	DPC doesn't invent Completions for UIO Requests.
6.2	B595	Clarify Larger Tags rules.
6.2	B599	Clarify Precoding negotiaion.
6.1	ECN: TDISP	<p>Incorporate <u>TEE Device Interface Security Protocol (TDISP)</u>, Approved July 22, 2022</p> <p>Minor issues corrected during TDISP incorporation (not individually marked):</p> <ul style="list-style-type: none"> • Update reserved field width in § Table 11-24 to account for IS_NON_TEE_MEM Range Attribute. • In § Section 11.5.7 , table reference corrected to § Table 11-31. • In § Section 11.2 “An example list of architectural configurations registers that should be locked and tracked are specified <u>is shown</u> in § Section 11.2.6 .”

Revision	Errata / ECN	Description
		Section references in Note 3 of § Figure 3-5 were corrected from the published ECN.
6.1	ECN: DOE 1.1	Incorporate <i>Data Object Exchange (DOE)</i> , Revision 1.1 Approved September 29, 2022
6.2	ECN: 12V-2x6	Incorporate 12V-2x6 Connector Updates to PCIe Base 6.0 (12V-2x6), Approved August 9, 2023
6.2	ECN: MMPT	<p>Incorporate Management Message Passthrough via MMIO Mailbox (MMPT), Approved 2023-09-21</p> <p>Errata to the ECN since publication are also incorporated:</p> <ul style="list-style-type: none"> • Added a note that <u>MMB Registers</u> offset 018h-019h are reserved for CXL compatibility. • Added reserved bit definitions to the <u>MMB Capabilities Register</u>, the <u>MMB Control Register</u>, and the <u>MMB Status Register</u> where fields are reserved for CXL compatibility. • Updated the section numbers to align with PCIe Base Spec v6.1. • Updated CXL to <u>[CXL]</u> for notes about legacy compatibility.
6.2	ECN: Architectural Out-of-Band Management	Incorporate Architectural Out-of-Band Management, Approved 2023-12-12
6.2	ECN: Revised CMA-SPDM	Incorporate Component Measurement and Authentication (CMA-SPDM), Revised December 2022

Objective of the PCI Express® Architecture

This document defines the “base” specification for the PCI Express architecture, including the electrical, protocol, platform architecture and programming interface elements required to design and build devices and systems. A key goal of the PCI Express architecture is to enable devices from different vendors to inter-operate in an open architecture, spanning multiple market segments including clients, servers, embedded, and communication devices. The architecture provides a flexible framework for product versatility and market differentiation.

This specification describes the PCI Express® architecture, interconnect attributes, fabric management, and the programming interface required to design and build systems and peripherals that are compliant with the PCI Express Specification.

The goal is to enable such devices from different vendors to inter-operate in an open architecture. The specification is intended as an enhancement to the PCI™ architecture spanning multiple market segments; clients (desktops and mobile), servers (standard and enterprise), and embedded and communication devices. The specification allows system OEMs and peripheral developers adequate room for product versatility and market differentiation without the burden of carrying obsolete interfaces or losing compatibility.

PCI Express Architecture Specification Organization

The PCI Express specifications are organized as a base specification and a set of companion documents.

The *PCI Express Base Specification* contains the technical details of the architecture, protocol, Data Link Layer, Physical Layer, and software interface. The *PCI Express Base Specification* (this document) is applicable to all variants of PCI Express.

The companion specifications define a variety of form factors, including mechanical and electrical chapters covering topics including auxiliary signals, power delivery, and the Adapter interconnect electrical budget.

Documentation Conventions

Capitalization

Some terms are capitalized to distinguish their definition in the context of this document from their common English meaning. Words not capitalized have their common English meaning. When terms such as “memory write” or “memory read” appear completely in lower case, they include all transactions of that type.

Register names and the names of fields and bits in registers and headers are presented with the first letter capitalized and a mixture of capitalization for the remainder.

Numbers and Number Bases

Hexadecimal numbers are written with a lower case “h” suffix, e.g., FFFh and 80h. Hexadecimal numbers larger than four digits are represented with a space dividing each group of four digits, as in 1E FFFF FFFFh. Binary numbers are written with a lower case “b” suffix, e.g., 1001b and 10b. Binary numbers larger than four digits are written with a space dividing each group of four digits, as in 1000 0101 0010b.

All other numbers are decimal.

Implementation Notes

IMPLEMENTATION NOTE:

Implementation Notes should not be considered to be part of this specification. They are included for clarification and illustration only.

Notes

NOTE §

Notes pertain to the specification itself as opposed to implementations of the specification. For example, they are used to describe the document process. They are also used for forward looking information describing anticipated changes for a future version of this specification.

Issues

ISSUE 1

Issues are outstanding items in the specification. They indicate things like missing, outdated, or lower quality artwork, anticipated changes that are being deferred to a subsequent version of the specification, potential errata items noticed during the editing process, etc.

PCI-SIG's goal is to resolve all notes before the 1.0 published release of the specification (where “resolving” includes deferring an item to later, or determining that the item is not needed or is incorrect).

Implementation Notes, Notes, and Issues can also be inline.

Terms and Acronyms

8b/10b

The data encoding scheme ¹ used in the PCI Express Physical Layer for 5.0 GT/s and below.

10-Bit Tags

A Tag's capability that provides a total of 10 bits for the Tag field. See Tag.

14-Bit Tags

A Tag's capability that provides a total of 14 bits for the Tag field. See Tag.

Access Control Services, ACS

A set of capabilities and control registers used to implement access control over routing within a PCI Express component.

ACS Violation

An error that applies to a Posted or Non-Posted Request when the Completer detects an access control violation.

Adapter

Used generically to refer to an add-in card or module.

Advanced Error Reporting, AER

Advanced Error Reporting (see § [Section 7.8.4](#)).

Alternative Routing-ID, ARI

Alternative Routing-ID Interpretation. Applicable to Requester IDs and Completer IDs as well as Routing IDs.

ARI Device

A Device associated with an Upstream Port, whose Functions each contain an [ARI Extended Capability](#) structure.

ARI Downstream Port

A Switch Downstream Port or Root Port that supports ARI Forwarding.

ARI Forwarding

Functionality that enables the Downstream Port immediately above an ARI Device to access the Devices extended Functions. Enabling ARI Forwarding ensures the logic that determines when to turn a Type 1 Configuration Request into a Type 0 Configuration Request no longer enforces a restriction on the traditional Device Number field being 0.

Asserted

The active logical state of a conceptual or actual signal.

Async Removal

Removal of an adapter or cable from a slot without lock-step synchronization with the operating system (e.g., in an asynchronous manner without button presses).

Atomic Operation, AtomicOp

One of three architected Atomic Operations where a single PCI Express transaction targeting a location in Memory Space reads the location's value, potentially writes a new value to the location, and returns the original value. This read-modify-write sequence to the location is performed atomically. AtomicOps include [FetchAdd](#), [Swap](#), and [CAS](#).

1. IBM Journal of Research and Development, Vol. 27, #5, September 1983 "A DC-Balanced, Partitioned-Block 8B/10B Transmission Code" by Widmer and Franaszek.

Attribute

Transaction handling preferences indicated by specified Packet header bits and fields (e.g., non-snoop).

Authentication

A process for determining that an entity is what it appears to be (its identity) using defined data objects and digital signatures.

Base Address Register, BAR

Base Address Registers exist within Configuration Space and are used to determine the amount of system memory space needed by a Function and to provide the base address for a mapping to Function memory space. A Base Address Register may map to memory space or I/O space.

Beacon

An optional 30 kHz to 500 MHz in-band signal used to exit the L2 Link Power Management state. One of two defined mechanisms for waking up a Link in L2 (see Wakeup).

Bridge

One of several defined System Elements. A Function that virtually or actually connects a PCI/PCI-X segment or PCI Express Port with an internal component interconnect or with another PCI/PCI-X bus segment or PCI Express Port. A virtual Bridge in a Root Complex or Switch must use the software configuration interface described in this specification.

by-1, x1

A Link or Port with one Physical Lane.

by-8, x8

A Link or Port with eight Physical Lanes.

by-N, xN

A Link or Port with “N” Physical Lanes.

Compare and Swap, CAS

An AtomicOp where the value of a target location is compared to a specified value and, if they match, another specified value is written back to the location. Regardless, the original value of the location is returned.

Character

An 8-bit quantity treated as an atomic entity; a byte.

Clear

A bit is Clear when its value is 0b.

Cold Reset

A Fundamental Reset following the application of main power.

Completer

The Function that terminates or “completes” a given Request, and generates a Completion if appropriate. Generally, the Function targeted by the Request serves as the Completer. For cases when an uncorrectable error prevents the Request from reaching its targeted Function, the Function that detects and handles the error serves as the Completer.

Completer Abort, CA

1. A status that applies to a posted or non-posted Request that the Completer is permanently unable to complete successfully, due to a violation of the Completer’s programming model or to an unrecoverable error associated with the Completer.
2. A status indication returned with a Completion for a non-posted Request that suffered a Completer Abort at the Completer.

Completer ID

The combination of a Completer's Bus Number, Device Number, and Function Number that uniquely identifies the Completer of the Request within a Hierarchy. With an ARI Completer ID, bits traditionally used for the Device Number field are used instead to expand the Function Number field, and the Device Number is implied to be 0.

Completion

A Packet used to terminate, or to partially terminate, a transaction sequence. A Completion always corresponds to a preceding Request, and, in some cases, includes data.

component

A physical device (a single package).

Configuration Software

The component of system software responsible for accessing Configuration Space and configuring the PCI/PCIe bus.

Configuration Space

One of the four address spaces within the PCI Express architecture. Packets with a Configuration Space address are used to configure Functions.

Configuration-Ready

A Function is Configuration-Ready when it is guaranteed that the Function will respond to a valid Configuration Request targeting the Function with a Completion indicating Successful Completion status.

Containment Error Recovery, CER

A general error containment and recovery approach supported by Downstream Port Containment (DPC), where with suitable software/firmware support, many uncorrectable errors can be handled without disrupting applications.

Conventional PCI

Behaviors or features originally defined in the PCI Local Bus Specification. The PCI Express Base 4.0 and subsequent specifications incorporate the relevant requirements from the PCI Local Bus Specification.

Conventional Reset

A Hot, Warm, or Cold Reset. Distinct from Function Level Reset (FLR).

Data Link Layer

The intermediate Layer that is between the Transaction Layer and the Physical Layer.

Data Link Layer Packet, DLLP

A Packet generated in the Data Link Layer to support Link management functions.

data payload

Information following the header in some packets that is destined for consumption by the targeted Function receiving the Packet (for example, Write Requests or Read Completions).

deasserted

The inactive logical state of a conceptual or actual signal.

Deferrable Memory Write, DMWr

A Memory Write where the Requester attempts to write to a given location in Memory Space using the non-posted DMWr TLP Type. A Completer that supports this TLP Type can accept or decline the Request, indicating this by means of the Completion status returned. See § Section 6.32.

Design for Testability, DFT

Design for Testability.

Device (uppercase 'D')

A collection of one or more Functions within a single hierarchy identified by common Bus Number and Device Number. An SR-IOV Device may have additional Functions accessed via additional Bus Numbers and/or Device Numbers configured through one or more SR-IOV Extended Capability structures.

device (lowercase 'd')

1. A physical or logical entity that performs a specific type of I/O.
2. A component on either end of a PCI Express Link.
3. A common imprecise synonym for Function, particularly when a device has a single Function.

Device Readiness Status, DRS

A mechanism for indicating that a Device is Configuration-Ready (see § Section 6.22.1).

DLP

In Flit Mode, the Data Link Layer Payload within a Flit.

Downstream

1. The relative position of an interconnect/System Element (Port/component) that is farther from the Root Complex. The Ports on a Switch that are not the Upstream Port are Downstream Ports. All Ports on a Root Complex are Downstream Ports. The Downstream component on a Link is the component farther from the Root Complex.
2. A direction of information flow where the information is flowing away from the Root Complex.

Downstream Path

The flow of data through a Retimer from the Upstream Pseudo Port Receiver to the Downstream Pseudo Port Transmitter.

Downstream Port Containment, DPC

The automatic disabling of the Link below a Downstream Port following an uncorrectable error, which prevents TLPs subsequent to the error from propagating Upstream or Downstream.

DWORD, DW

Four bytes. Used in the context of a data payload, the 4 bytes of data must be on a naturally aligned 4-byte boundary (the least significant 2 bits of the byte address are 00b).

Egress Port

The transmitting Port; that is, the Port that sends outgoing traffic.

Electrical Idle

A Link state used in a variety of defined cases, with specific requirements defined for the Transmitter and Receiver.

End-End TLP Prefix

A TLP Prefix that is carried along with a TLP from source to destination. See § Section 2.2.10.4.

Endpoint

One of several defined System Elements. A Function that has a Type 00h Configuration Space header.

Endpoint Upstream Port

An Upstream Port that contains Endpoint Functions exclusively.

error detection

Mechanisms that determine that an error exists, either by the first agent to discover the error (e.g., Malformed TLP) or by the recipient of a signaled error (e.g., receiver of a poisoned TLP).

error logging

A detector setting one or more bits in architected registers based on the detection of an error. The detector might be the original discoverer of an error or a recipient of a signaled error.

error reporting

In a broad context, the general notification of errors. In the context of the Device Control register, sending an error Message. In the context of the Root Error Command register, signaling an interrupt as a result of receiving an error Message.

error signaling

One agent notifying another agent of an error either by (1) sending an error Message, (2) sending a Completion with UR/CA Status, or (3) poisoning a TLP.

Extension Device

A component whose purpose is to extend the physical length of a Link.

Extended Function

Within an ARI Device, a Function whose Function Number is greater than 7. Extended Functions are accessible only after ARI-aware software has enabled ARI Forwarding in the Downstream Port immediately above the ARI Device.

FetchAdd, Fetch and Add

An AtomicOp where the value of a target location is incremented by a specified value using two's complement arithmetic ignoring any carry or overflow, and the result is written back to the location. The original value of the location is returned.

Flit

Flow Control Unit

Flow Control

The method for communicating receive buffer status from a Receiver to a Transmitter to prevent receive buffer overflow and allow Transmitter compliance with ordering rules.

Flow Control Packet, FCP

A DLLP used to send Flow Control information from the Transaction Layer in one component to the Transaction Layer in another component.

Flow-Through

Refers to the behavior, by a Switch or Root Complex supporting peer-to-peer, of passing an IDE TLP associated with a Selective IDE Stream from Ingress Port to Egress Port without modification.

FRU Information

Information used to provide inventory and capability information about a board on which the FRU Information Device is located.

FRU Information Device

A storage component such as a real or firmware emulated EEPROM, compatible with components such as the AT 24C256 that stores FRU Information.

Function

Within a Device, an addressable entity in Configuration Space associated with a single Function Number. Used to refer to one Function of a Multi-Function Device, or to the only Function in a Single-Function Device. Specifically included are special types of Functions defined in § Chapter 9. , notably Physical Functions and Virtual Functions.

Function Group

Within an ARI Device, a configurable set of Functions that are associated with a single Function Group Number. Function Groups can optionally serve as the basis for VC arbitration or access control between multiple Functions within the ARI Device.

Function Level Reset, FLR

A mechanism for resetting a specific Endpoint Function (see § Section 6.6.2).

Function Readiness Status, FRS

A mechanism for indicating that a Function is Configuration-Ready (see § Section 6.22.2)

Fundamental Reset

A hardware mechanism for setting or returning all Port states to the initial conditions specified in this document (see § Section 6.6).

GT/s

The number of encoded bits transferred in a second on a direction of a Lane. Short for Giga Transfers per Second.

header

A set of fields that appear at or near the front of a Packet that contain the information required to determine the characteristics and purpose of the Packet.

Hierarchy

A PCI Express I/O interconnect topology, wherein the Configuration Space addresses, referred to as the tuple of Bus/Device/Function Numbers (or just Bus/Function Numbers, for ARI cases), are unique. These addresses are used for Configuration Request routing, Completion routing, some Message routing, and for other purposes. In some contexts a Hierarchy is also called a Segment, and in Flit Mode, the Segment number is sometimes also included in the ID of a Function.

hierarchy domain

The part of a Hierarchy originating from a single Root Port.

Host Bridge

Part of a Root Complex that connects a host CPU or CPUs to a Hierarchy.

Hot Reset

A reset propagated in-band across a Link using a Physical Layer mechanism.

IDE Partner Port

The remote IDE Terminus for an IDE Stream.

IDE Stream

A Port to Port connection established using the mechanisms defined by Integrity and Data Encryption (IDE) to secure TLP traffic between the two Ports. The connection may be in the form of a Selective IDE Stream, in which case it is possible for IDE TLPs to flow through Switches without affecting their security, or in the form of a Link IDE Stream, in which case the two Ports must be connected without intervening Switches.

IDE Terminus

A Port acting as the originator or ultimate destination for IDE TLPs associated with one or more IDE Streams.

IDE TLP

A TLP associated with an IDE Stream and secured using Integrity and Data Encryption (IDE).

in-band signaling

A method for signaling events and conditions using the Link between two components, as opposed to the use of separate physical (sideband) signals. All mechanisms defined in this document can be implemented using in-band signaling, although in some form factors sideband signaling may be used instead.

Ingress Port

Receiving Port; that is, the Port that accepts incoming traffic.

Internal Error

An error associated with a PCI Express interface that occurs within a component and which may not be attributable to a packet or event on the PCI Express interface itself or on behalf of transactions initiated on PCI Express.

I/O Space

One of the four address spaces of the PCI Express architecture.

isochronous

Data associated with time-sensitive applications, such as audio or video applications.

invariant

A field of a TLP header or TLP Prefix that contains a value that cannot legally be modified as the TLP flows through the PCI Express fabric.

Lane

A set of differential signal pairs, one pair for transmission and one pair for reception. A by-N Link is composed of N Lanes.

Layer

A unit of distinction applied to this specification to help clarify the behavior of key elements. The use of the term Layer does not imply a specific implementation.

Link

The collection of two Ports and their interconnecting Lanes. A Link is a dual-simplex communications path between two components.

Link IDE Stream

An IDE Stream applied to all TLPs, except those associated with Selective IDE Stream(s), where the two Ports are connected without intervening Switches, although extension devices may be present on the Link.

Link Segment

The collection of a Port and a Pseudo Port or two Pseudo Ports and their interconnecting Lanes. A Link Segment is a dual simplex communications path between a Component and a Retimer or between two Retimers (two Pseudo Ports).

Lightweight Notification, LN

This protocol is now deprecated. It was a lightweight protocol that supported notifications to Endpoints via a hardware mechanism when cachelines of interest were updated.

Local TLP Prefix

A TLP Prefix that is carried along with a TLP on a single Link. See [§ Section 2.2.10.2](#).

Logical Bus

The logical connection among a collection of Devices that have the same Bus Number in Configuration Space.

Logical Idle

A period of one or more Symbol Times when no information (TLPs, PMUX Packets, DLLPs, or any special Symbol) is being transmitted or received. Unlike Electrical Idle, during Logical Idle the Idle data Symbol is being transmitted and received.

LTR

Abbreviation for Latency Tolerance Reporting

Malformed Packet

A TLP that violates specific TLP formation rules as defined in this specification.

Measurement

A process for calculating a cryptographic hash value of firmware or other configuration state, applying a digital signature, and returning this information.

Memory Space

One of the four address spaces of the PCI Express architecture.

Message

A TLP used to communicate information outside of the Memory, I/O, and Configuration Spaces.

Message Signaled Interrupt, MSI/MSI-X

Two similar but separate mechanisms that enable a Function to request service by writing a system-specified DWORD of data to a system-specified address using a Memory Write Request. Compared to MSI, MSI-X supports a larger maximum number of vectors and independent message address and data for each vector.

Message Space

One of the four address spaces of the PCI Express architecture.

MMIO

Memory-mapped I/O space. Synonymous with the term Memory Space.

MPS

Abbreviation for Max_Payload_Size.

Multicast, MC

A feature and associated mechanisms that enable a single Posted Request TLP sent by a source to be distributed to multiple targets.

Multicast Group, MCG

A set of Endpoints that are the target of Multicast TLPs in a particular address range.

Multicast Hit

The determination by a Receiver that a TLP will be handled as a Multicast TLP.

Multicast TLP

A TLP that is potentially distributed to multiple targets, as controlled by Multicast Capability structures in the components through which the TLP travels.

Multicast Window

A region of Memory Space where Posted Request TLPs that target it will be handled as Multicast TLPs.

Multi-Function Device, MFD

A Device that has multiple Functions.

Multi-Root I/O Virtualization, MR-IOV

A Function that supports the MR-IOV capability. See [MR-IOV] for additional information.

MUST@FLIT

MUST@FLIT features are mandatory for components that support Flit Mode (Flit Mode Supported is Set). *MUST@FLIT* features are strongly recommended for all other components.

naturally aligned

A data payload with a starting address equal to an integer multiple of a power of two, usually a specific power of two. For example, 64-byte naturally aligned means the least significant 6 bits of the byte address are 00 0000b.

NPEM

Native PCIe Enclosure Management

OBFF

Optimized Buffer Flush/Fill

Operating System

Throughout this specification, the terms operating system and system software refer to the combination of power management services, device drivers, user-mode services, and/or kernel mode services.

orderly removal

A hot-plug removal model where the OS is notified when a user/operator wishes to remove an adapter, and the OS has the opportunity to prepare for the event (e.g., quiescing adapter activity) before granting permission for removal.

P2P

Peer-to-peer.

Path

The flow of data through a Retimer, in either the Upstream Path or the Downstream Path.

Packet

A fundamental unit of information transfer consisting of an optional TLP Prefix, followed by a header and, in some cases, followed by a data payload.

Parts per Million, ppm

Applied to frequency, the difference, in millionths of a Hertz, between a stated ideal frequency, and the measured long-term average of a frequency.

PCIe®

PCI Express®

PCI Bridge

See Type 1 Function.

PCI Software Model

The software model necessary to initialize, discover, configure, and use a PCI-compatible device, as specified in [PCI-3.0], [PCI-X], and [Firmware].

Phantom Function Number, PFN

An unclaimed Function Number that may be used to expand the number of outstanding transaction identifiers by logically combining the PFN with the Tag identifier to create a unique transaction identifier.

Physical Function, PF

A PCI Function that contains an SR-IOV Extended Capability structure and supports the SR-IOV capabilities defined in § Chapter 9. .

Physical Lane

See Lane.

Physical Layer

The Layer that directly interacts with the communication medium between two components.

Port

1. Logically, an interface between a component and a PCI Express Link.
2. Physically, a group of Transmitters and Receivers located on the same chip that define a Link.

Power Management

Software or Hardware mechanisms used to minimize system power consumption, manage system thermal limits, and maximize system battery life. Power management involves tradeoffs among system speed, noise, battery life, and AC power consumption.

PMUX Channel

A multiplexed channel on a PMUX Link that is configured to transport a specific multiplexed protocol. See § Appendix G. .

PMUX Link

A Link where Protocol Multiplexing is supported and enabled. See § Appendix G. .

PMUX Packet

A non-PCI Express Packet transported over a PCI Express Link. See § Appendix G. .

Precision Time Measurement, PTM

An optional capability for communicating precise timing information between components.

Process Address Space ID, PASID

The Process Address Space ID, in conjunction with the Requester ID, uniquely identifies the address space associated with a transaction.

Programmed I/O, PIO

A transaction sequence that's initiated by a host processor, often as the result of executing a single load or store instruction that targets a special address range, but can be generated by other mechanisms such as the PCI-Compatible Configuration Mechanism. Notably, host processor loads or stores targeting an ECAM address range generate Configuration Space transactions. Other memory-mapped ranges typically exist to generate Memory Space and I/O Space transactions.

Pseudo Port

1. Logically, an interface between a Retimer and a PCI Express Link Segment.
2. Physically, a group of Transmitters and Receivers located on the same Retimer chip that define a Link Segment.

Quality of Service, QoS

Attributes affecting the bandwidth, latency, jitter, relative priority, etc., for differentiated classes of traffic.

QWORD, QW

Eight bytes. Used in the context of a data payload, the 8 bytes of data must be on a naturally aligned 8-byte boundary (the least significant 3 bits of the address are 000b).

RCiEP

Root Complex Integrated Endpoint.

Receiver, Rx

The component that receives Packet information across a Link.

Receiving Port

In the context of a specific TLP, PMUX Packet, or DLLP, the Port that receives the Packet on a given Link.

Re-driver

A non-protocol aware, software transparent, Extension Device.

repeater

An imprecise term for Extension Device.

Reported Error

An error subject to the logging and signaling requirements architecturally defined in this document.

Request

A Packet used to initiate a transaction sequence. A *Request* includes operation code and, in some cases, address and length, data, or other information.

Requester

The Function that first introduces a transaction sequence into the PCI Express domain.

Requester ID

The combination of a Requester's Bus Number, Device Number, and Function Number that uniquely identifies the Requester within a Hierarchy. With an ARI Requester ID, bits traditionally used for the Device Number field are used instead to expand the Function Number field, and the Device Number is implied to be 0.

Reserved

The contents, states, or information are not defined at this time. Using any Reserved area (for example, packet header bit-fields, configuration register bits) is not permitted. Reserved register fields must be read only and must return 0 (all 0's for multi-bit fields) when read. Reserved encodings for register and packet fields must not be used. Any implementation dependence on a Reserved field value or encoding will result in an implementation that is not PCI Express-compliant. The functionality of such an implementation cannot be guaranteed in this or any future revision of this specification.

Refclk

An abbreviation for Reference Clock.

Retimer

A Physical Layer protocol aware, software transparent, Extension Device that forms two separate electrical Link Segments.

Root Complex, RC

A defined System Element that includes at least one Host Bridge, Root Port, or Root Complex Integrated Endpoint.

Root Complex Component

A logical aggregation of Root Ports, Root Complex Register Blocks, Root Complex Integrated Endpoints, and Root Complex Event Collectors.

Root Port, RP

A PCI Express Port on a Root Complex that maps a portion of a Hierarchy through an associated virtual PCI-PCI Bridge.

Routing Element

A term referring to a Root Complex, Switch, or Bridge in regard to its ability to route, multicast, or block TLPs.

Routing ID, RID

Either the Requester ID or Completer ID that identifies a PCI Express Function.

RP PIO

Root Port Programmed I/O. See § Section 6.2.11.3 .

Rx_MPS_Limit

The computed data payload size limit for a Function receiving a TLP, which is determined by the Rx_MPS_Fixed bit value and Max_Payload_Size setting in one or more Functions. See § Section 2.2.2 for details.

Segment

See Hierarchy

Selective IDE Stream

An IDE Stream applied selectively to TLPs based on ranges of Memory Addresses and RIDs, and where it is possible for secured TLPs to flow through Switches without affecting their security.

Set

A bit is Set when its value is 1b.

Shadow Function

An otherwise unimplemented Function, where its Transaction ID space is used by a Function that implements the Shadow Functions Extended Capability structure.

sideband signaling

A method for signaling events and conditions using physical signals separate from the signals forming the Link between two components. All mechanisms defined in this document can be implemented using in-band signaling, although in some form factors sideband signaling may be used instead.

Single-Function Device, SFD

A device that has a single Function.

Single Root I/O Virtualization, SR-IOV

A Function that supports the SR-IOV Extended Capability defined in this specification.

Single Root PCI Manager, SR-PCIM

Software responsible for configuration and management of the SR-IOV Extended Capability and PF/VF as well as dealing with associated error handling. Multiple implementation options exist; therefore, SR-PCIM implementation is outside the scope of this specification.

SR-IOV Device

A Device containing one or more Functions that have an SR-IOV Extended Capability structure.

SSD

Solid State Drive

Swap, Unconditional Swap

An AtomicOp where a specified value is written to a target location, and the original value of the location is returned.

Switch

A defined System Element that connects two or more Ports to allow Packets to be routed from one Port to another. To configuration software, a Switch appears as a collection of virtual PCI-to-PCI Bridges [PCI-to-PCI-Bridge].

Switch Port

A Port that contains a Switch Downstream Port Function or at least one Switch Upstream Port Function.

Symbol

A 10-bit quantity when using 8b/10b encoding. An 8-bit quantity when using 128b/130b encoding.

Symbol Time

The period of time required to place a Symbol on a Lane (10 times the Unit Interval when using 8b/10b encoding, 8 times the Unit Interval when using 128b/130b encoding, and 4 times the Unit Interval when using 1b/1b encoding).

System Element

A defined Device or collection of Devices that operate according to distinct sets of rules. The following System Elements are defined: Root Complex, Endpoint, Switch, and Bridge.

System Image, SI

A software component running on a virtual system to which specific Functions, PFs, and VFs can be assigned. Specification of the behavior and architecture of an SI is outside the scope of this specification. Examples of SIs include guest operating systems and shared/non-shared protected domain device drivers.

System Software

Includes System Firmware (BIOS, UEFI), Operating System, VMM, management software, platform vendor's add-on to the Operating System.

Tag

A number assigned to a given Non-Posted Request to distinguish Completions for that Request from other Requests.

TEE Device Interface (TDI)

The unit of assignment for an IO-virtualization capable device. For example, a TDI may be an entire Device, a non-IOV Function, a PF (and possibly its subordinate VFs), or a VF.

TEE-I/O

A conceptual framework for establishing and managing Trusted Execution Environments (TEEs) that include a composition of resources from one or more devices (see § Chapter 11.).

TLP Prefix

Additional information that may be optionally prepended to a TLP. TLP Prefixes are either Local or End-End. A TLP can have multiple TLP Prefixes. See § Section 2.2.10.

TPH

Abbreviation for TLP Processing Hints

Transaction Descriptor

An element of a Packet header that, in addition to Address, Length, and Type, describes the properties of the Transaction.

Transaction ID

A component of the Transaction Descriptor including Requester ID and Tag.

Transaction Layer

The Layer that operates at the level of transactions (for example, read, write).

Transaction Layer Packet, TLP

A Packet generated in the Transaction Layer to convey a Request or Completion.

transaction sequence

A single Request and zero or more Completions associated with carrying out a single logical transfer by a Requester.

Transceiver

The physical Transmitter and Receiver pair on a single chip.

Translated Request

A Request using a Translated Memory Address, as indicated by the AT field.

Transmitter, Tx

The component sending Packet information across a Link.

Transmitting Port

In the context of a specific TLP, PMUX Packet, or DLLP, the Port that transmits the Packet on a given Link.

Trusted Computing Base (TCB)

A combination of hardware, firmware, and software, responsible for enforcing a security policy. Bugs or vulnerabilities occurring inside the TCB might jeopardize the security properties of the entire system. By contrast, parts of a computer system outside the TCB shall not be able to create a condition that would allow any more privileges than are granted to them in accordance with the security policy.

Trusted Execution Environment, TEE

Refers to an environment, which may include only a portion of a device, the whole of a device, or a composition of multiple devices, within which some level of “trust” is established, such that operations (including code execution) that occur within this environment are considered “trustworthy”. It is generally the case that one TEE is isolated from other TEEs that are intended to be distinct, and that all TEEs are isolated from untrusted environments.

Trusted Execution Environment Virtual Machine (Trusted Execution Environment VM, TVM)

A Trusted Execution Environment Virtual Machine as defined in the TEE Device Interface Security Protocol (TDISP) reference architecture (see § Chapter 11.).

Tx_MPS_Limit

The computed data payload size limit for a Function transmitting a TLP, which is determined by the Max_Payload_Size setting in one or more Functions. See § Section 2.2.2 for details.

Type 0 Function

Function with a Type 0 Configuration Space Header (see § Section 7.5.1.2).

Type 1 Function

Function with a Type 1 Configuration Space Header (see § Section 7.5.1.3).

Unconditional Swap, Swap

An AtomicOp where a specified value is written to a target location, and the original value of the location is returned.

Unit Interval, UI

Given a data stream of a repeating pattern of alternating 1 and 0 values, the Unit Interval is the value measured by averaging the time interval between voltage transitions, over a time interval long enough to make all intentional frequency modulation of the source clock negligible (see RX: UI and TX: UI).

Unordered I/O, UIO

A set of Request/Completion Types used with supporting Virtual Channel(s) to support a Requester-managed ordering model. See § Section 6.34 .

Unsupported Request, UR

1. A status that applies to a posted or non-posted Request that specifies some action or access to some space that is not supported by the Completer.
2. A status indication returned with a Completion for a non-posted Request that suffered an Unsupported Request at the Completer.

Upstream

1. The relative position of an interconnect/System Element (Port/component) that is closer to the Root Complex. The Port on a Switch that is closest topologically to the Root Complex is the Upstream Port. The Port on a component that contains only Endpoint or Bridge Functions is an Upstream Port. The Upstream component on a Link is the component closer to the Root Complex.
2. A direction of information flow where the information is flowing towards the Root Complex.

Upstream Path

The flow of data through a Retimer from the Downstream Pseudo Port Receiver to the Upstream Pseudo Port Transmitter.

variant

A field of a TLP header that contains a value that is subject to possible modification according to the rules of this specification as the TLP flows through the PCI Express fabric.

Virtual Function, VF

A Function that is associated with a Physical Function. A VF shares one or more physical resources, such as a Link, with the Physical Function and other VFs that are associated with the same PF.

Virtualization Intermediary, VI

A software component supporting one or more SIs—colloquially known as a hypervisor or virtual machine monitor. Specification of the behavior and architecture of the VI is outside the scope of this specification.

wakeup

An optional mechanism used by a component to request the reapplication of main power when in the L2 Link state. Two such mechanisms are defined: Beacon (using in-band signaling) and WAKE# (using sideband signaling).

Warm Reset

A Fundamental Reset without cycling main power.

Zero

The numerical value of zero in a bit, field, or register, of appropriate width for that bit, field, or register.

1. Introduction §

This chapter presents an overview of the PCI Express architecture and key concepts. PCI Express is a high-performance, general purpose I/O interconnect defined for a wide variety of future computing and communication platforms. Key attributes, such as usage model, load-store architecture, and software interfaces, are maintained from PCI Local Bus, whereas PCI Local Bus's parallel bus implementation is replaced by a highly scalable, fully serial interface. PCI Express takes advantage of advances in point-to-point interconnects, Switch-based technology, and packetized protocol to deliver new levels of performance and features. Power Management, Quality of Service (QoS), Hot-Plug/hot-swap support, data integrity, and error handling are among some of the advanced features supported by PCI Express.

1.1 An Evolving I/O Interconnect §

The high-level requirements for this evolving I/O interconnect are as follows:

- **Supports multiple market segments and emerging applications:**
 - Unifying I/O architecture for desktop, mobile, workstation, server, communications platforms, and embedded devices
- **Ability to deliver low cost, high volume solutions:**
 - Cost at or below PCI cost structure at the system level
- **Support multiple platform interconnect usages:**
 - Chip-to-chip, board-to-board via connector or cabling
- **A variety of mechanical form factors:**
 - [\[M.2\]](#), [\[CEM\]](#) (Card Electro-Mechanical), [\[U.2\]](#), [\[OCuLink\]](#)
- **PCI-compatible software model:**
 - Ability to enumerate and configure PCI Express hardware using PCI system configuration software implementations with no modifications
 - Ability to boot existing operating systems with no modifications
 - Ability to support existing I/O device drivers with no modifications
 - Ability to configure/enable new PCI Express functionality by adopting the PCI configuration paradigm
- **Performance:**
 - Low-overhead, low-latency communications to maximize application payload bandwidth and Link efficiency
 - High-bandwidth per pin to minimize pin count per device and connector interface
 - Scalable performance via aggregated Lanes and signaling frequency
- **Advanced features:**
 - Comprehend different data types and ordering rules
 - Power management and budgeting
 - Ability to identify power management capabilities of a Device of a specific Function
 - Ability to transition a Device or Function into a specific power state
 - Ability to receive notification of the current power state of a Device of Function
 - Ability to generate a request to wakeup from a power-off state of the main power supply

- Ability to sequence Device power-up to allow graceful platform policy in power budgeting
- Ability to support differentiated services, i.e., different (QoS)
 - Ability to have dedicated Link resources per QoS data flow to improve fabric efficiency and effective application-level performance in the face of head-of-line blocking
 - Ability to configure fabric QoS arbitration policies within every component
 - Ability to tag end-to-end QoS with each packet
 - Ability to create end-to-end isochronous (time-based, injection rate control) solutions
- Hot-Plug support
 - Ability to support existing PCI Hot-Plug solutions
 - Ability to support native Hot-Plug solutions (no sideband signals required)
 - Ability to support async removal
 - Ability to support a unified software model for all form factors
- Data Integrity
 - Ability to support Link-level data integrity for all types of transaction and Data Link packets
 - Ability to support end-to-end data integrity for high availability solutions
- Error handling
 - Ability to support PCI-Compatible error handling
 - Ability to support advanced error reporting and handling to improve fault isolation and recovery solutions
- Process Technology Independence
 - Ability to support different DC common mode voltages at Transmitter and Receiver
- Ease of Testing
 - Ability to test electrical compliance via simple connection to test equipment

1.2 PCI Express Link §

A Link represents a dual-simplex communications channel between two components. The fundamental PCI Express Link consists of two, low-voltage, differentially driven signal pairs: a Transmit pair and a Receive pair as shown in § Figure 1-1. A PCI Express Link consists of a PCIe PHY as defined in § Chapter 4. .

Figure 1-1 PCI Express Link §

The primary Link attributes for PCI Express Link are:

- The basic Link - PCI Express Link consists of dual unidirectional differential Links, implemented as a Transmit pair and a Receive pair. A data clock is embedded using an encoding scheme (see § Chapter 4.) to achieve very high data rates.
- The Signaling method – Each major revision of PCI Express signaling has evolved one (or more) characteristics to increase bandwidth. Throughout this specification, the term **GT/s** is used to refer to the number of encoded bits transferred in a second on a direction of a Lane. The actual effective data rate is dependent on a combination of modulation method, encoding method, and data rate. § Table 1-1 provides a summary of Max Data Rate, Modulation Scheme, Encoding Method, and Effective Max Data Rate with the accounting of only encoding overhead for all the six major revisions of PCI Express.² See § Chapter 4. for more information about the combined signaling method and § Chapter 8. for electrical specification details for each major PCI Express revision.

Table 1-1 PCIe Signaling Characteristics §

Data Rate	Modulation	Encoding	Effective Data Rate (after removing Encoding overhead)	Base Specification Revision					
				6.x	5.x	4.x	3.0	2.0	1.0
2.5 GT/s	NRZ	8b/10b	2 Gbit/s	✓	✓	✓	✓	✓	✓
5.0 GT/s	NRZ	8b/10b	4 Gbit/s	✓	✓	✓	✓	✓	
8.0 GT/s	NRZ	128b/130b	~8 Gbit/s	✓	✓	✓	✓		
16.0 GT/s	NRZ	128b/130b	~16 Gbit/s	✓	✓	✓			
32.0 GT/s	NRZ	128b/130b	~32 Gbit/s	✓	✓				
64.0 GT/s	PAM4	1b/1b	64 Gbit/s	✓					

- Lanes - A Link must support at least one Lane - each Lane represents a set of differential signal pairs (one pair for transmission, one pair for reception). To scale bandwidth, a Link may aggregate multiple Lanes denoted by xN where N may be any of the supported Link widths. A x8 Link operating at the 2.5 GT/s data rate represents an aggregate bandwidth of 20 Gigabits/second of raw bandwidth in each direction. This specification describes operations for x1, x2, x4, x8, and x16 Lane widths.
- Data Stream – PCI Express uses Data Stream in Flit Mode and Data Stream in Non-Flit Mode (see § Section 4.2 , including § Table 4-1 and § Table 4-2). Support of Data Stream in Non-Flit Mode is mandatory, while support of Data Stream in Flit Mode is mandatory only if a data rate that exceeds 32.0 GT/s is supported.
- Initialization - During hardware initialization, each PCI Express Link is set up following a negotiation of Link width, data rate, and Flit mode by the two agents at each end of the Link. No firmware or operating system software is involved.
- Symmetry - Each Link must support a symmetric number of Lanes in each direction, i.e., a x16 Link indicates there are 16 differential signal pairs in each direction.

1.3 PCI Express Fabric Topology §

A fabric is composed of point-to-point Links that interconnect a set of components - an example fabric topology is shown in § Figure 1-2. This figure illustrates a single fabric instance with two Hierarchies composed of a Root Complex (RC), multiple Endpoints, and multiple Switches, interconnected via PCI Express Links.

2. Terms like “PCIe Gen3” are ambiguous and should be avoided. For example, “gen3” could mean (1) compliant with Base 3.0, (2) compliant with Base 3.1 (last revision of 3.x), (3) compliant with Base 3.0 and supporting 8.0 GT/s, (4) compliant with Base 3.0 or later and supporting 8.0 GT/s, ...

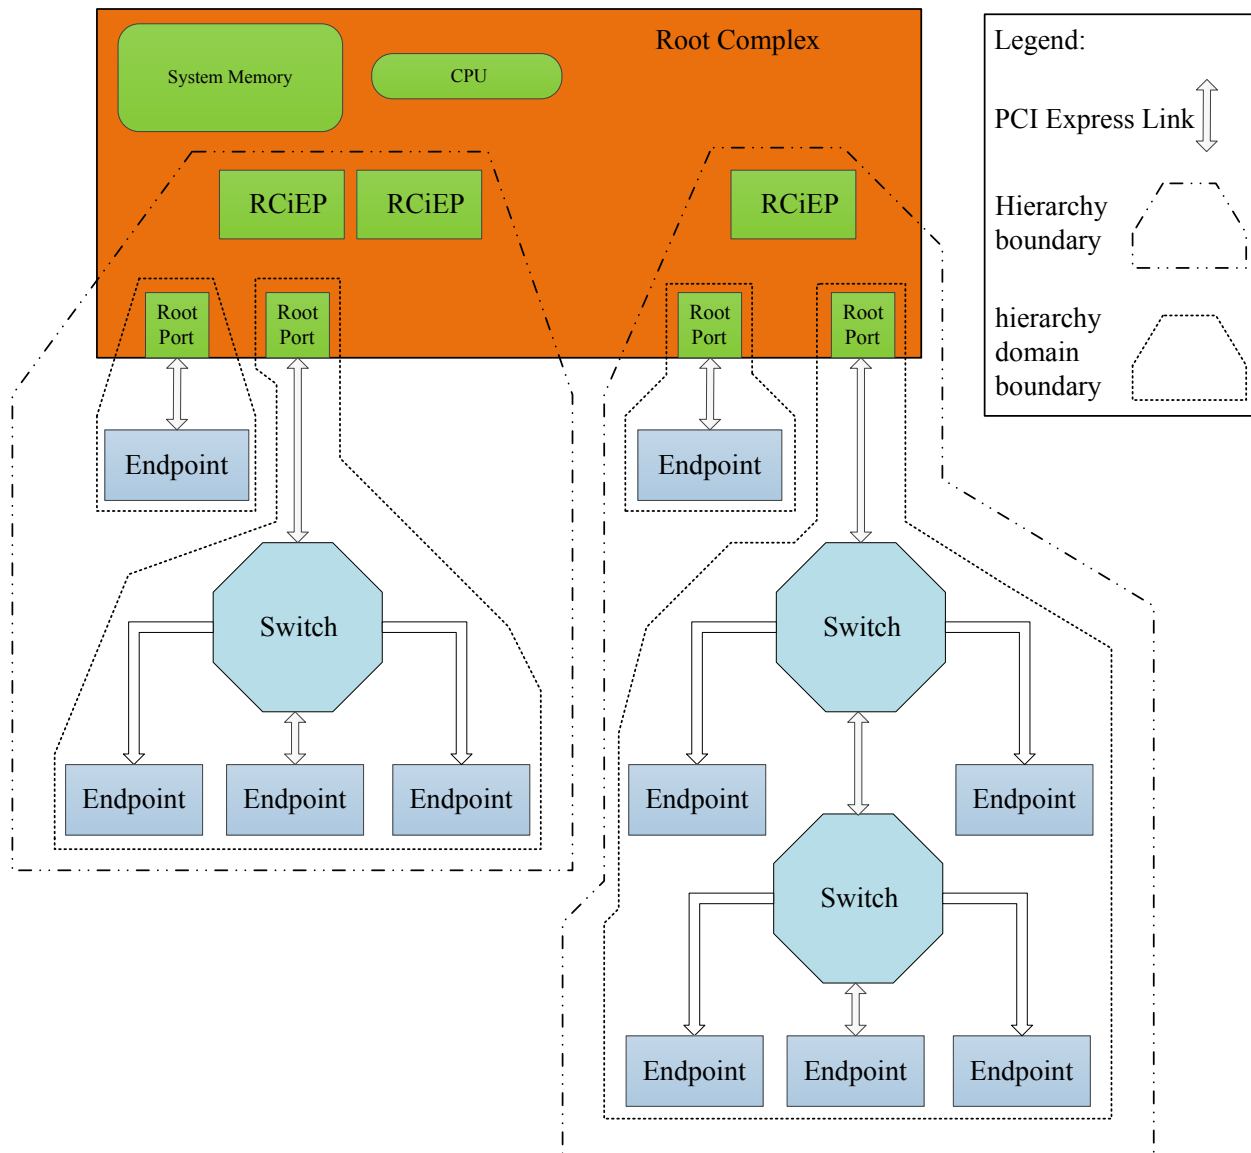

Figure 1-2 Example PCI Express Topology §

1.3.1 Root Complex §

- An RC denotes the root of an I/O hierarchy that connects the CPU/memory subsystem to the I/O.
- As illustrated in § Figure 1-2, an RC may support one or more PCI Express Ports. Each interface defines a separate hierarchy domain. Each hierarchy domain may be composed of a single Endpoint or a sub-hierarchy containing one or more Switch components and Endpoints.
- The capability to route peer-to-peer transactions between hierarchy domains through an RC is optional and implementation dependent. An RC is permitted to "take ownership" of Requests that pass peer-to-peer between Root Ports, reforming and potentially splitting a Request such that it may appear to the ultimate Completer that the RC was the origin of the Request, and subsequently the RC must reform the Completion(s)

being returned to the original Requester. Alternately, an RC implementation may incorporate a real or virtual Switch internally within the Root Complex to enable full peer-to-peer support in a software transparent way. Unlike the rules for a Switch, an RC is generally permitted to split a packet into smaller packets when routing transactions peer-to-peer between hierarchy domains (except as noted below), e.g., split a single packet with a 256-byte payload into two packets of 128 bytes payload each. The resulting packets are subject to the normal packet formation rules contained in this specification (e.g., `Max_Payload_Size`, `Read Completion Boundary (RCB)`, etc.). Component designers should note that splitting a packet into smaller packets may have negative performance consequences, especially for a transaction addressing a device behind a PCI Express to PCI/PCI-X bridge.

Exception: An RC that supports UIO peer-to-peer routing is permitted to split UIO Memory Write Requests only at naturally aligned 64B boundaries.

Exception: An RC that supports peer-to-peer routing of Deferrable Memory Write Requests is not permitted to split a Deferrable Memory Write Request packet into smaller packets (see § Section 6.32).

Exception: An RC that supports peer-to-peer routing of Vendor-Defined Messages is not permitted to split a Vendor-Defined Message packet into smaller packets except at 128-byte boundaries (i.e., all resulting packets except the last must be an integral multiple of 128 bytes in length) in order to retain the ability to forward the Message across a PCI Express to PCI/PCI-X Bridge.

- An RC must support generation of Configuration Requests as a Requester.
- An RC is permitted to support the generation of I/O Requests as a Requester.
 - An RC is permitted to generate I/O Requests to either or both of locations 80h and 84h to a selected Root Port, without regard to that Root Port's PCI Bridge I/O decode configuration; it is recommended that this mechanism only be enabled when specifically needed.
- An RC must not support Lock semantics as a Completer.
- An RC is permitted to support generation of Locked Requests as a Requester.

1.3.2 Endpoints §

Endpoint refers to a type of Function that can be the Requester or Completer of a PCI Express transaction either on its own behalf or on behalf of a distinct non-PCI Express device (other than a PCI device or host CPU), e.g., a PCI Express attached graphics controller or a PCI Express-USB host controller. Endpoints are classified as either legacy, PCI Express, or Root Complex Integrated Endpoints (RCiEPs).

1.3.2.1 Legacy Endpoint Rules §

- A Legacy Endpoint must be a Function with a Type 00h Configuration Space header.
- A Legacy Endpoint must support Configuration Requests as a Completer.
- A Legacy Endpoint may support I/O Requests as a Completer.
 - A Legacy Endpoint is permitted to accept I/O Requests to either or both of locations 80h and 84h, without regard to that Endpoint's I/O decode configuration.
- A Legacy Endpoint may generate I/O Requests.
- A Legacy Endpoint may support Lock memory semantics as a Completer if that is required by the device's legacy software support requirements.
- A Legacy Endpoint must not issue a Locked Request.

- A Legacy Endpoint may implement Extended Configuration Space Capabilities, but such Capabilities may be ignored by software.
- A Legacy Endpoint operating as the Requester of a Memory Transaction is not required to be capable of generating addresses 4 GB or greater.
- A Legacy Endpoint is required to support MSI or MSI-X or both if an interrupt resource is requested. If MSI is implemented, a Legacy Endpoint is permitted to support either the 32-bit or 64-bit Message Address version of the MSI Capability structure.
- A Legacy Endpoint is permitted to support 32-bit addressing for Base Address Registers that request memory resources.
- A Legacy Endpoint must appear within one of the hierarchy domains originated by the Root Complex.

1.3.2.2 PCI Express Endpoint Rules §

- A PCI Express Endpoint must be a Function with a Type 00h Configuration Space header.
- A PCI Express Endpoint must support Configuration Requests as a Completer.
- A PCI Express Endpoint must not depend on operating system allocation of I/O resources claimed through BAR(s).
- A PCI Express Endpoint must not generate I/O Requests.
- A PCI Express Endpoint must not support Locked Requests as a Completer or generate them as a Requester. PCI Express-compliant device drivers and applications must be written to prevent the use of lock semantics when accessing a PCI Express Endpoint.
- A PCI Express Endpoint operating as the Requester of a Memory Transaction is required to be capable of generating addresses greater than 4 GB.
- A PCI Express Endpoint is required to support MSI or MSI-X or both if an interrupt resource is requested. If MSI is implemented, a PCI Express Endpoint must support the 64-bit Message Address version of the MSI Capability structure.
- A PCI Express Endpoint requesting memory resources through a BAR must set the BAR's Prefetchable bit unless the range contains locations with read side-effects or locations in which the Function does not tolerate write merging. See § Section 7.5.1.2.1 for additional guidance on having the Prefetchable bit Set.
- For a PCI Express Endpoint, 64-bit addressing must be supported for all BARs that have the Prefetchable bit Set. 32-bit addressing is permitted for all BARs that do not have the Prefetchable bit Set.
- The minimum memory address range requested by a BAR is 128 bytes.
- A PCI Express Endpoint must appear within one of the hierarchy domains originated by the Root Complex.

1.3.2.3 Root Complex Integrated Endpoint Rules §

- A Root Complex Integrated Endpoint (RCiEP) is implemented on internal logic of Root Complexes that contains the Root Ports.
- An RCiEP must be a Function with a Type 00h Configuration Space header.
- An RCiEP must support Configuration Requests as a Completer.
- An RCiEP must not require I/O resources claimed through BAR(s).
- An RCiEP must not generate I/O Requests.

- An RCiEP must not support Locked Requests as a Completer or generate them as a Requester. PCI Express-compliant device drivers and applications must be written to prevent the use of lock semantics when accessing an RCiEP.
- An RCiEP operating as the Requester of a Memory Transaction is required to be capable of generating addresses equal to or greater than the Host is capable of handling as a Completer.
- An RCiEP is required to support MSI or MSI-X or both if an interrupt resource is requested. If MSI is implemented, an RCiEP is permitted to support either the 32-bit or 64-bit Message Address version of the MSI Capability structure.
- An RCiEP is permitted to support 32-bit addressing for Base Address Registers that request memory resources.
- An RCiEP must not implement Link Capabilities, Link Status, Link Control, Link Capabilities 2, Link Status 2, and Link Control 2 registers in the PCI Express Extended Capability.
- If an RCiEP is associated with an optional Root Complex Event Collector it must signal PME and error conditions through the Root Complex Event Collector.
- An RCiEP must not be associated with more than one Root Complex Event Collector.
- An RCiEP does not implement Active State Power Management.
- An RCiEP may not be hot-plugged independent of the Root Complex as a whole.
- An RCiEP must not appear in any of the hierarchy domains exposed by the Root Complex.
- An RCiEP must not appear in Switches.

1.3.3 Switch §

A Switch is defined as a logical assembly of multiple virtual PCI-to-PCI Bridge devices as illustrated in § Figure 1-3. All Switches are governed by the following base rules.

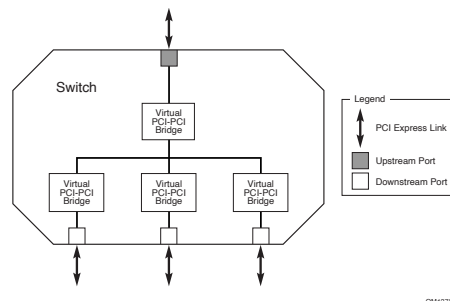

Figure 1-3 Logical Block Diagram of a Switch §

- Switches appear to configuration software as two or more logical PCI-to-PCI Bridges.
- A Switch forwards transactions using PCI Bridge mechanisms; e.g., address-based routing except when engaged in a Multicast, as defined in § Section 6.14 .
- Except as noted in this document, a Switch must forward all types of Transaction Layer Packets (TLPs) between any set of Ports.
- Locked Requests must be supported as specified in § Section 6.5 . Switches are not required to support Downstream Ports as initiating Ports for Locked Requests.
- Each enabled Switch Port must comply with the Flow Control specification within this document.

- A Switch is not allowed to split a packet into smaller packets, e.g., a single packet with a 256-byte payload must not be divided into two packets of 128 bytes payload each.
- Arbitration between Ingress Ports (inbound Link) of a Switch may be implemented using round robin or weighted round robin when contention occurs on the same Virtual Channel. This is described in more detail later within the specification.
- Endpoints (represented by Type 00h Configuration Space headers) must not appear to configuration software on the Switch's internal bus as peers of the virtual PCI-to-PCI Bridges representing the Switch Downstream Ports.

1.3.4 Root Complex Event Collector §

- A Root Complex Event Collector (RCEC) provides support for terminating error and PME messages from RCiEPs.
- A Root Complex Event Collector must follow all rules for an RCiEP (unless otherwise specified).
- A Root Complex Event Collector is not required to decode any memory or I/O resources.
- A Root Complex Event Collector is identified by its Device/Port Type value (see § Section 7.5.3.2).
- A Root Complex Event Collector has the Base Class 08h, Sub-Class 07h and Programming Interface 00h.³
- A Root Complex Event Collector resides on a Bus in the Root Complex. Multiple Root Complex Event Collectors are permitted to reside on a single Bus.
- A Root Complex Event Collector explicitly declares supported RCiEPs through the Root Complex Event Collector Endpoint Association Extended Capability.
- Root Complex Event Collectors are optional.

1.3.5 PCI Express to PCI/PCI-X Bridge §

- A PCI Express to PCI/PCI-X Bridge provides a connection between a PCI Express fabric and a PCI/PCI-X hierarchy.

1.4 Hardware/Software Model for Discovery, Configuration and Operation §

The PCI/PCIe hardware/software model includes architectural constructs necessary to discover, configure, and use a Function, without needing Function-specific knowledge. Key elements include:

- A configuration model which provides system software the means to discover hardware Functions available in a system
- Mechanisms to perform basic resource allocation for addressable resources such as memory space and interrupts
- Enable/disable controls for Function response to received Requests, and initiation of Requests
- Well-defined ordering and flow control models to support the consistent and robust implementation of hardware/software interfaces

3. Since an earlier version of this specification used Sub-Class 06h for this purpose, an implementation is still permitted to use Sub-Class 06h, but this is strongly discouraged.

The PCI Express configuration model supports two mechanisms:

- PCI-compatible configuration mechanism: The PCI-compatible mechanism supports 100% binary compatibility with Conventional PCI aware operating systems and their corresponding bus enumeration and configuration software.
- PCI Express enhanced configuration mechanism: The enhanced mechanism is provided to increase the size of available Configuration Space and to optimize access mechanisms.

Each PCI Express Link is mapped through a virtual PCI-to-PCI Bridge structure and has a Logical Bus associated with it. The virtual PCI-to-PCI Bridge structure may be part of a PCI Express Root Complex Port, a Switch Upstream Port, or a Switch Downstream Port. A Root Port is a virtual PCI-to-PCI Bridge structure that originates a PCI Express hierarchy domain from a PCI Express Root Complex. Devices are mapped into Configuration Space such that each will respond to a particular Device Number.

1.5 PCI Express Layering Overview §

This document specifies the architecture in terms of three discrete logical layers: the Transaction Layer, the Data Link Layer, and the Physical Layer. Each of these layers is divided into two sections: one that processes outbound (to be transmitted) information and one that processes inbound (received) information, as shown in § Figure 1-4.

The fundamental goal of this layering definition is to facilitate the reader's understanding of the specification. Note that this layering does not imply a particular PCI Express implementation.

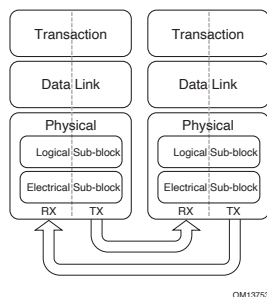

Figure 1-4 High-Level Layering Diagram §

PCI Express uses packets to communicate information between components. Packets are formed in the Transaction and Data Link Layers to carry the information from the transmitting component to the receiving component. As the transmitted packets flow through the other layers, they are extended with additional information necessary to handle packets at those layers. At the receiving side the reverse process occurs and packets get transformed from their Physical Layer representation to the Data Link Layer representation and finally (for Transaction Layer Packets) to the form that can be processed by the Transaction Layer of the receiving device. § Figure 1-5 shows the conceptual flow of transaction level packet information through the layers.

Figure 1-5 Packet Flow Through the Layers §

Note that a simpler form of packet communication is supported between two Data Link Layers (connected to the same Link) for the purpose of Link management.

1.5.1 Transaction Layer §

The upper Layer of the architecture is the Transaction Layer. The Transaction Layer's primary responsibility is the assembly and disassembly of TLPs. TLPs are used to communicate transactions, such as read and write, as well as certain types of events. The Transaction Layer is also responsible for managing credit-based flow control for TLPs.

Every request packet requiring a response packet is implemented as a Split Transaction. Each packet has a unique identifier that enables response packets to be directed to the correct originator. The packet format supports different forms of addressing depending on the type of the transaction (Memory, I/O, Configuration, and Message). The Packets may also have attributes such as No Snoop, Relaxed Ordering, and ID-Based Ordering (IDO).

The Transaction Layer supports four address spaces: it includes the three PCI address spaces (memory, I/O, and configuration) and adds Message Space. This specification uses Message Space to support all prior sideband signals, such as interrupts, power-management requests, and so on, as in-band Message transactions. You could think of PCI Express Message transactions as “virtual wires” since their effect is to eliminate the wide array of sideband signals currently used in a platform implementation.

1.5.2 Data Link Layer §

The middle Layer in the stack, the Data Link Layer, serves as an intermediate stage between the Transaction Layer and the Physical Layer. The primary responsibilities of the Data Link Layer include Link management and data integrity, including error detection and error correction.

The transmission side of the Data Link Layer accepts TLPs assembled by the Transaction Layer, calculates and applies a data protection code and TLP sequence number, and submits them to Physical Layer for transmission across the Link. The receiving Data Link Layer is responsible for checking the integrity of received TLPs and for submitting them to the Transaction Layer for further processing. On detection of TLP error(s), this Layer is responsible for requesting retransmission of TLPs until information is correctly received, or the Link is determined to have failed.

The Data Link Layer also generates and consumes packets that are used for Link management functions. To differentiate these packets from those used by the Transaction Layer (TLP), the term Data Link Layer Packet (DLLP) will be used when referring to packets that are generated and consumed at the Data Link Layer.

1.5.3 Physical Layer §

The Physical Layer includes all circuitry for interface operation, including driver and input buffers, parallel-to-serial and serial-to-parallel conversion, PLL(s), and impedance matching circuitry. It also includes logical functions related to

interface initialization and maintenance. The Physical Layer exchanges information with the Data Link Layer in an implementation specific format. This Layer is responsible for converting information received from the Data Link Layer into an appropriate serialized format and transmitting it across the PCI Express Link at a frequency and width compatible with the component connected to the other side of the Link.

The PCI Express architecture has “hooks” to support future performance enhancements via speed upgrades and advanced encoding techniques. The future speeds, encoding techniques or media may only impact the Physical Layer definition.

1.5.4 Layer Functions and Services §

1.5.4.1 Transaction Layer Services §

The Transaction Layer, in the process of generating and receiving TLPs, exchanges Flow Control information with its complementary Transaction Layer on the other side of the Link. It is also responsible for supporting both software and hardware-initiated power management.

Initialization and configuration functions require the Transaction Layer to:

- Store Link configuration information generated by the processor or management device,
- Store Link capabilities generated by Physical Layer hardware negotiation of width and operational frequency.

A Transaction Layer’s Packet generation and processing services require it to:

- Generate TLPs from device core Requests
- Convert received Request TLPs into Requests for the device core,
- Convert received Completion Packets into a payload, or status information, deliverable to the core,
- Detect unsupported TLPs and invoke appropriate mechanisms for handling them,
- If end-to-end data integrity is supported, generate the end-to-end data integrity CRC and update the TLP header accordingly.

Flow Control services:

- The Transaction Layer tracks Flow Control credits for TLPs across the Link.
- Transaction credit status is periodically transmitted to the remote Transaction Layer using transport services of the Data Link Layer.
- Remote Flow Control information is used to throttle TLP transmission.

Ordering rules:

- PCI/PCI-X compliant producer/consumer ordering model,
- Extensions to support Relaxed Ordering,
- Extensions to support ID-Based Ordering,
- Support for UIO ordering model.

Power management services:

- Software-controlled power management through mechanisms, as dictated by system software.

- Hardware-controlled autonomous power management minimizes power during full-on power states.

Virtual Channels and Traffic Class:

- The combination of Virtual Channel mechanism and Traffic Class identification is provided to support differentiated services and QoS support for certain classes of applications. They are also used to provide separate ordering domains for UIO and non-UIO Virtual Channels.
- Virtual Channels: Virtual Channels provide a means to support multiple independent logical data flows over given common physical resources of the Link. Conceptually this involves multiplexing different data flows onto a single physical Link.
- Traffic Class: The Traffic Class is a Transaction Layer Packet label that is transmitted unmodified end-to-end through the fabric. At every service point (e.g., Switch) within the fabric, Traffic Class labels are used to apply appropriate servicing policies. Each Traffic Class label defines a unique ordering domain - no ordering guarantees are provided for packets that contain different Traffic Class labels.

1.5.4.2 Data Link Layer Services §

The Data Link Layer is responsible for reliably exchanging information with its counterpart on the opposite side of the Link.

Initialization and power management services:

- Accept power state Requests from the Transaction Layer and convey to the Physical Layer
- Convey active/reset/disconnected/power managed state to the Transaction Layer

Data protection, error checking, and retry services:

- CRC generation
- Transmitted TLP storage for Data Link level retry
- Error checking
- TLP acknowledgement and retry Messages
- Error indication for error reporting and logging

1.5.4.3 Physical Layer Services §

Interface initialization, maintenance control, and status tracking:

- Reset/Hot-Plug control/status
- Interconnect power management
- Width and Lane mapping negotiation
- Lane polarity inversion

Symbol and special Ordered Set generation:

- 8b/10b encoding/decoding
- Embedded clock tuning and alignment

Block and special Ordered Set generation:

- 128b/130b encoding/decoding
- 1b/1b encoding/decoding
- Link Equalization

Symbol transmission and alignment:

- Transmission circuits
- Reception circuits
- Elastic buffer at receiving side
- Multi-Lane de-skew (for widths > x1) at receiving side

System Design For Testability (DFT) support features:

- Compliance Pattern (see § Section 4.2.9 , § Section 4.2.11 , and § Section 4.2.14)
- Modified Compliance Pattern (see § Section 4.2.10 , § Section 4.2.12 , and § Section 4.2.15)
- Jitter Measurement Pattern (see § Section 4.2.13 and § Section 4.2.16)
- Flit Error Injection (see § Section 7.8.13)

1.5.4.4 Inter-Layer Interfaces §

1.5.4.4.1 Transaction/Data Link Interface §

The Transaction to Data Link interface provides:

- Byte or multi-byte data to be sent across the Link
 - Local TLP-transfer handshake mechanism
 - TLP boundary information
- Requested power state for the Link

The Data Link to Transaction interface provides:

- Byte or multi-byte data received from the PCI Express Link
- TLP framing information for the received byte
- Actual power state for the Link
- Link status information

1.5.4.4.2 Data Link/Physical Interface §

The Data Link to Physical interface provides:

- Byte or multi-byte wide data to be sent across the Link
 - Data transfer handshake mechanism

- TLP and DLLP boundary information for bytes
- Requested power state for the Link

The Physical to Data Link interface provides:

- Byte or multi-byte wide data received from the PCI Express Link
- TLP and DLLP framing information for data
- Indication of errors detected by the Physical Layer
- Actual power state for the Link
- Connection status information

2. Transaction Layer Specification §

2.1 Transaction Layer Overview §

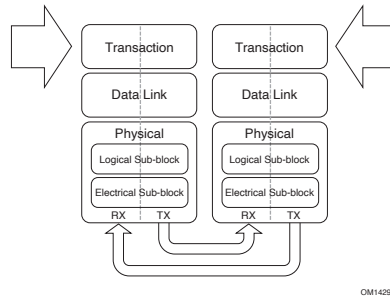

Figure 2-1 Layering Diagram Highlighting the Transaction Layer §

At a high level, the key aspects of the Transaction Layer are:

- A pipelined full Split-Transaction protocol
- Mechanisms for differentiating the ordering and processing requirements of Transaction Layer Packets (TLPs)
- Credit-based flow control
- Optional support for data poisoning and end-to-end data integrity detection.

The Transaction Layer comprehends the following:

- TLP construction and processing
- Association of transaction-level mechanisms with device resources including:
 - Flow Control
 - Virtual Channel management
- Rules for ordering and management of TLPs
 - PCI/PCI-X compatible ordering
 - Traffic Class differentiation
 - UIO Ordering

This chapter specifies the behaviors associated with the Transaction Layer.

2.1.1 Address Spaces, Transaction Types, and Usage §

Transactions form the basis for information transfer between a Requester and Completer. Four address spaces are defined, and different Transaction types are defined, each with its own unique intended usage, as shown in [Table 2-1](#).

Table 2-1 Transaction Types for Different Address Spaces §

Address Space	Transaction Types	Basic Usage
Memory	Read Write	Transfer data to/from a memory-mapped location
I/O	Read Write	Transfer data to/from an I/O-mapped location
Configuration	Read Write	Device Function configuration/setup
Message	Baseline (including Vendor Defined)	From event signaling mechanism to general purpose messaging

Details about the rules associated with usage of these address formats and the associated TLP formats are described later in this chapter.

2.1.1.1 Memory Transactions §

Memory Transactions include the following types:

- Read Request/Completion
- Write Request (and Completions for UIO)
- Deferrable Memory Write Request/Completion
- AtomicOp Request/Completion

Memory Transactions use two different address formats:

- Short Address Format: 32-bit address
- Long Address Format: 64-bit address

Certain Memory Transactions can optionally include a PASID TLP Prefix (Non-Flit Mode) or OHC (Flit Mode) containing the Process Address Space ID (PASID). See § Section 6.20 for details.

Certain Memory Transactions are required to use only 64-bit address formats.

2.1.1.2 I/O Transactions §

PCI Express supports I/O Space for compatibility with legacy devices that require their use. Future revisions of this specification may deprecate the use of I/O Space. I/O Transactions include the following types:

- Read Request/Completion
- Write Request/Completion

I/O Transactions use a single address format:

- Short Address Format: 32-bit address

2.1.1.3 Configuration Transactions §

Configuration Transactions are used to access configuration registers of Functions within devices.

Configuration Transactions include the following types:

- Read Request/Completion
- Write Request/Completion

2.1.1.4 Message Transactions §

The Message Transactions, or simply Messages, are used to support in-band communication of events between devices.

In addition to specific Messages defined in this document, PCI Express provides support for Vendor-Defined Messages using specified Message codes. Except for Vendor-Defined Messages that use the PCI-SIG® Vendor ID (0001h), the definition of specific Vendor-Defined Messages is outside the scope of this document.

This specification establishes a standard framework within which vendors can specify their own Vendor-Defined Messages tailored to fit the specific requirements of their platforms (see § Section 2.2.8.6).

Note that these Vendor-Defined Messages are not guaranteed to be interoperable with components from different vendors.

2.1.2 Packet Format Overview §

Transactions consist of Requests and Completions, which are communicated using packets. § Figure 2-2 shows a high level serialized view of a TLP, consisting of one or more optional TLP Prefixes, a TLP header, a data payload (for some types of packets), and an optional TLP Digest. § Figure 2-3 shows a more detailed view of the TLP. The following sections of this chapter define the detailed structure of the packet headers and digest.

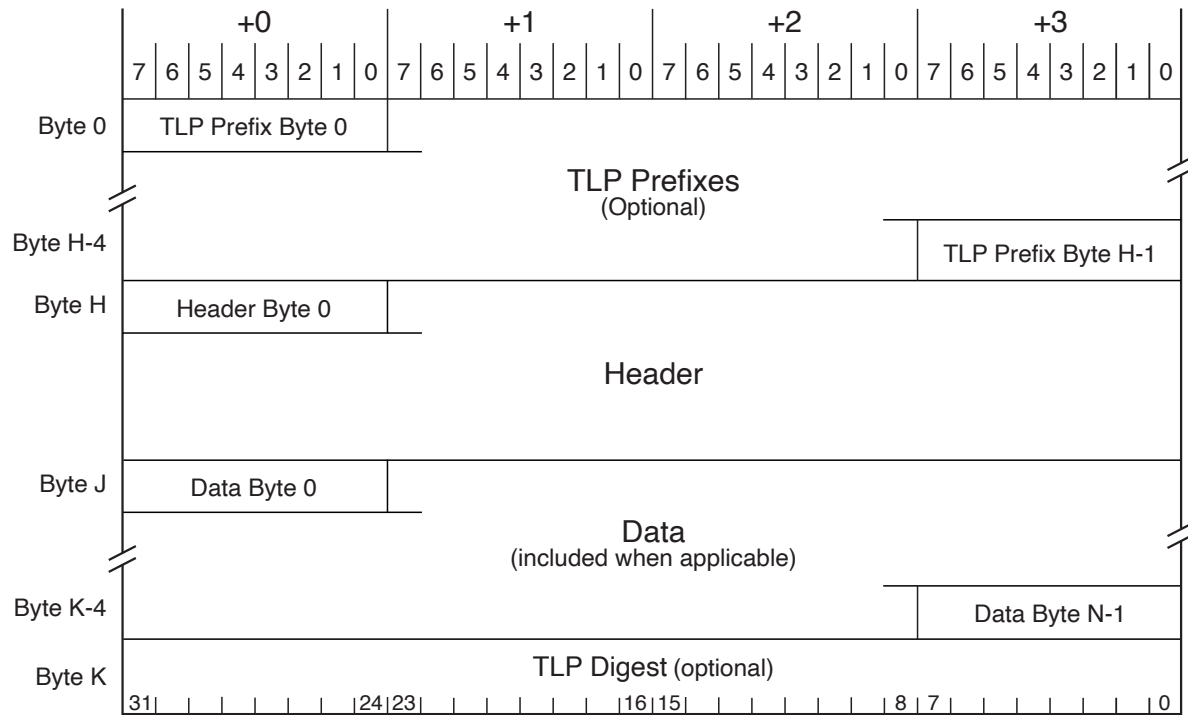

OM14547A

Figure 2-2 Serial View of a TLP §

PCI Express conceptually transfers information as a serialized stream of bytes as shown in § Figure 2-2. Note that at the byte level, information is transmitted/received over the interconnect with the left-most byte of the TLP as shown in § Figure 2-2 being transmitted/received first (byte 0 if one or more optional TLP Prefixes are present else byte H). Refer to § Section 4.2 for details on how individual bytes of the packet are encoded and transmitted over the physical media.

Detailed layouts of the TLP Prefix, TLP Header and TLP Digest (presented in generic form in § Figure 2-3) are drawn with the lower numbered bytes on the left rather than on the right as has traditionally been depicted in other PCI specifications. The header layout is optimized for performance on a serialized interconnect, driven by the requirement that the most time critical information be transferred first. For example, within the TLP header, the most significant byte of the address field is transferred first so that it may be used for early address decode.

OM13756A

Figure 2-3 Generic TLP Format - Non-Flit Mode §

The data payload within a TLP is depicted with the lowest addressed byte (byte J in § Figure 2-3) shown to the upper left. Detailed layouts depicting data structure organization (such as the Configuration Space depictions in § Chapter 7.) retain the traditional PCI byte layout with the lowest addressed byte shown on the right. Regardless of depiction, all bytes are conceptually transmitted over the Link in increasing byte number order.

Depending on the type of a packet, the header for that packet will include some of the following types of fields:

- Format of the packet
- Type of the packet
- Length for any associated data
- Transaction Descriptor, including:
 - Transaction ID
 - Attributes
 - Traffic Class
- Address/routing information
- Byte Enables
- Message encoding
- Completion status

2.2 Transaction Layer Protocol - Packet Definition §

PCI Express uses a packet based protocol to exchange information between the Transaction Layers of the two components communicating with each other over the Link. PCI Express supports the following basic transaction types: Memory, I/O, Configuration, and Messages. Two addressing formats for Memory Requests are supported: 32 bit and 64 bit.

A **UIO TLP** is a TLP that is associated with a UIO Virtual Channel.

Transactions are carried using Requests and Completions. Completions are used only where required, for example, to return read data, or to acknowledge Completion of I/O and Configuration Write Transactions. All UIO Requests require Completions. Completions are associated with their corresponding Requests by the value in the Transaction ID field of the Packet header.

All TLP fields marked Reserved (sometimes abbreviated as R) must be filled with all 0's when a TLP is formed. Values in such fields must be ignored by Receivers and forwarded unmodified by Switches. Note that for certain fields there are both specified and Reserved values - the handling of Reserved values in these cases is specified separately for each case.

There are different header formats for Non-Flit Mode (NFM) and Flit Mode (FM). Routing elements must translate between the FM and NFM TLP formats when the Ingress Port and Egress Port are in different modes. In some cases translation is not possible, and the handling of such cases is also defined in this Chapter.

2.2.1 Common Packet Header Fields §

2.2.1.1 Common Packet Header Fields for Non-Flit Mode §

All TLP prefixes and headers contain the following fields (see § Figure 2-4):

- Fmt[2:0] - Format of TLP (see § Table 2-2) - bits 7:5 of byte 0
- Type[4:0] - Type of TLP - bits 4:0 of byte 0

Figure 2-4 Fields Present in All TLPs §

The Fmt field(s) indicates the presence of one or more TLP Prefixes and the Type field(s) indicates the associated TLP Prefix type(s).

The Fmt and Type fields of the TLP Header provide the information required to determine the size of the remaining part of the TLP Header, and if the packet contains a data payload following the header.

The Fmt, Type, TD, and Length fields of the TLP Header contain all information necessary to determine the overall size of the non-prefix portion of the TLP. The Type field, in addition to defining the type of the TLP also determines how the TLP is routed by a Switch. Different types of TLPs are discussed in more detail in the following sections.

- Permitted Fmt[2:0] and Type[4:0] field values are shown in § Table 2-3.
 - All other encodings are Reserved (see § Section 2.3).
- TC[2:0] - Traffic Class (see § Section 2.2.6.6) - bits [6:4] of byte 1
- R (byte 1 bit 1) - Reserved; formerly was the Lightweight Notification (LN) bit, but is now available for reassignment.
- TLP Hints (TH) - 1b indicates the presence of TLP Processing Hints (TPH) in the TLP header and optional TPH TLP Prefix (if present) - bit 0 of byte 1 (see § Section 2.2.7.1.1)
- Attr[1:0] - Attributes (see § Section 2.2.6.3) - bits [5:4] of byte 2
- Attr[2] - Attribute (see § Section 2.2.6.3) - bit 2 of byte 1 (shown as A2 in figures)
- TD - 1b indicates presence of TLP Digest in the form of a single Double Word (DW) at the end of the TLP (see § Section 2.2.3) - bit 7 of byte 2
- Error Poisoned (EP) - indicates the TLP is poisoned (see § Section 2.7) - bit 6 of byte 2
- Length[9:0] - Length of data payload, or of data referenced, in DW (see § Table 2-4) - bits 1:0 of byte 2 concatenated with bits 7:0 of byte 3
 - TLP data must be 4-byte naturally aligned and in increments of 4-byte DW.
 - Reserved for TLPs that do not contain or refer to data payloads, including Cpl, CplLk, and Messages (except as specified)

Figure 2-5 Fields Present in All Non-Flit Mode TLP Headers §

Table 2-2 Fmt[2:0] Field Values §

Fmt[2:0]	Corresponding TLP Format
000b	3 DW header, no data
001b	4 DW header, no data
010b	3 DW header, with data
011b	4 DW header, with data
100b	TLP Prefix
	All encodings not shown above are Reserved (see § Section 2.3).

Table 2-3 Fmt[2:0] and Type[4:0] Field Encodings §

TLP Type	Fmt [2:0] 4 (b)	Type [4:0] (b)	Description
MRd	000 001	0 0000	Memory Read Request

4. Requests with two Fmt[2:0] values shown can use either 32 bits (the first value) or 64 bits (the second value) Addressing Packet formats.

TLP Type	Fmt [2:0] (b)	Type [4:0] (b)	Description
MRdLk	000 001	0 0001	Memory Read Request-Locked
MWr	010 011	0 0000	Memory Write Request
IORd	000	0 0010	I/O Read Request
IOWr	010	0 0010	I/O Write Request
CfgRd0	000	0 0100	<u>Type 0 Configuration Read Request</u>
CfgWr0	010	0 0100	<u>Type 0 Configuration Write Request</u>
CfgRd1	000	0 0101	<u>Type 1 Configuration Read Request</u>
CfgWr1	010	0 0101	<u>Type 1 Configuration Write Request</u>
TCfgRd	000	1 1011	Deprecated TLP Type ⁵
DMWr	010 011	1 1011	Deferrable Memory Write Request ⁶
Msg	001	1 0r ₂ r ₁ r ₀	Message Request - The sub-field r[2:0] specifies the Message routing mechanism (see § Table 2-20).
MsgD	011	1 0r ₂ r ₁ r ₀	Message Request with data payload - The sub-field r[2:0] specifies the Message routing mechanism (see § Table 2-20).
Cpl	000	0 1010	Completion without Data - Used for I/O, Configuration Write, and Deferrable Memory Write Completions with any Completion Status. Also used for AtomicOp Completions and Read Completions (I/O, Configuration, or Memory) with Completion Status other than Successful Completion.
CplD	010	0 1010	Completion with Data - Used for Memory, I/O, and Configuration Read Completions. Also used for AtomicOp Completions.
CplLk	000	0 1011	Completion for Locked Memory Read without Data - Used only in error case.
CplDLk	010	0 1011	Completion for Locked Memory Read - Otherwise like CplD.
FetchAdd	010 011	0 1100	Fetch and Add AtomicOp Request
Swap	010 011	0 1101	Unconditional Swap AtomicOp Request
CAS	010 011	0 1110	Compare and Swap AtomicOp Request
LPrfx	100	0 L ₃ L ₂ L ₁ L ₀	Local TLP Prefix - The sub-field L[3:0] specifies the Local TLP Prefix type (see § Table 2-38).
EPrfx	100	1 E ₃ E ₂ E ₁ E ₀	End-End TLP Prefix - The sub-field E[3:0] specifies the End-End TLP Prefix type (see § Table 2-39).

5. Deprecated TLP Types: previously used for Trusted Configuration Space (TCS), which is no longer supported by this specification. If a Receiver does not implement TCS, the Receiver must treat such Requests as Malformed Packets.

6. This TLP Type value was previously used for Trusted Configuration Space (TCS) Writes, which are no longer supported by this specification.

TLP Type	Fmt [2:0] (b)	Type [4:0] (b)	Description
			All encodings not shown above are Reserved (see § Section 2.3).

Table 2-4 Length[9:0] Field Encoding §

Length[9:0]	Corresponding TLP Data Payload Size
00 0000 0001b	1 DW
00 0000 0010b	2 DW
...	...
11 1111 1111b	1023 DW
00 0000 0000b	1024 DW

2.2.1.2 Common Packet Header Fields for Flit Mode §

The TLP grammar is defined as:

- zero or more 1DW Local TLP prefixes⁷
- TLP Header Base with size indicated by Type[7:0] field, followed by zero to 7 DW of Orthogonal Header Content (OHC) as indicated by OHC[4:0] field
- TLP data payload of 0 to 1024DW
- TLP Trailer, if present as indicated by TS[2:0] field

It is required to transmit NOP TLPs while TLP transmission is active if there are no other TLPs to transmit. NOP TLPs must be discarded without effect by the Receiver. All header fields other than the Type field are Reserved for NOP TLPs.

Other notable differences between Flit Mode and Non-Flit Mode TLPs include the following:

- Content that in Non-Flit Mode is included in End-to-End TLP prefixes is now incorporated within the header, as OHC.
- In Flit Mode, Steering Tags are not overloaded with the Byte Enables. The PH, Steering Tags, and AMA/AV fields are consolidated in OHC.

All Flit Mode TLPs contain the same fields in the first DW of the Header Base (see § Figure 2-6)

Figure 2-6 First DW of Header Base §

§ Table 2-5 defines the values for the Type[7:0] field for Flit Mode.

⁷ Sequencing requirements between Local Vendor Defined TLP Prefixes and the Flit Mode Local TLP Prefix are implementation specific.

- The Type[7:0] field must be fully decoded by all Receivers regardless of which specific encodings are supported.
- All Receivers must handle Flow Control for all Type[7:0] field encodings as specified.
 - For TLPs, where the FC Type is none, Receivers are not required to buffer the TLP, and must silently discard the TLP; for other FC Types:
 - Switch Ports must buffer and route TLPs, including Reserved entries, as specified.
 - Endpoint Upstream Ports and Root Ports are required to buffer, including for Header Logging, up to the largest Header Base size plus all OHC content, but are permitted, after accounting for Flow Control, to discard Header Base and OHC content that is not supported by the Port and not including that information in header logging.
- For all Reserved entries, TLP routing must be handled as indicated in the Description field, and the Header Base fields used for routing are at the same location within the Header as with the non-Reserved Header Base formats.
 - Entries marked “Local ... Terminate at receiver” must be discarded at the Receiving Port.
- Endpoint Upstream Ports and Root Ports must handle received TLPs using Reserved Type[7:0] encodings of FC Type PR and NPR as Unsupported Requests, and of FC Type CPL as Unexpected Completions.
- UIO Requests using FC Type PR are referred to as UIO PR-FC TLPs; UIO Requests using FC Type NPR are referred to as UIO NPR-FC TLPs.

In the Translation Rule column, an entry of “1:1” indicates that there is no change in meaning or behavior when translating between Non-Flit Mode and Flit Mode in either direction. For TLPs that cannot be translated, those not handled by the Ingress Port must be handled by the Egress Port as follows, logging a TLP Translation Egress Blocked error when an error is reported.

- PR FC Type: block at Egress; if TLP is UIO, report no error, else handle as Uncorrectable
- NPR FC Type: block at Egress; report no error
- CPL FC Type: block at Egress; handle as Uncorrectable

UIO is defined only for FM, and no translation of UIO TLPs to NFM is permitted. UIO TLPs targeting an Egress Port in NFM must be handled as described in the preceding paragraph. Note that error cases involving UIO VC mis-matches are addressed in § Section 2.5.2 .

UIO TLPs are indicated as UIO in the Description column. Entries marked Reserved in the description column do not have an assigned VC restriction. A restriction, if required, will be specified when those entries become defined. Entries #0, #141-143 do not have an assigned VC restriction. All other entries are non-UIO TLPs.

Table 2-5 Flit Mode TLP Header Type Encodings §

#	Type								Description	Name	FC Type	Data Payload?	Header Base Size (DW)	New for Flit Mode	Translation Rule
	7	6	5	4	3	2	1	0

- 001b – 1DW Trailer containing ECRC
- 010b – 1DW Trailer – Content Reserved
- 011b – 2DW Trailer – Content Reserved
- 100b – 2DW Trailer – Content Reserved
- 101b – 3DW Trailer with IDE MAC if and only if OHC-C present and indicates IDE TLP; Else 3DW Trailer – Content Reserved
- 110b – 4DW Trailer with IDE MAC and PCRC if and only if OHC-C present and indicates IDE TLP; Else 4DW Trailer – Content Reserved
- 111b – 5DW Trailer – Content Reserved

The definitions of the TC, Attr and Length fields in Flit Mode are the same as in Non-Flit Mode.

Bit 1 in byte 1 of Non-Flit Mode is now Reserved, but it was the LN bit associated with the now deprecated Lightweight Notification (LN) protocol. This bit is not supported in Flit Mode. Thus, it must be ignored when translating from Non-Flit Mode to Flit Mode, and it must be set to 0b when translating from Flit Mode to Non-Flit Mode.

The OHC[4:0] field indicates the presence of “Orthogonal Header Content” (OHC) encoded as:

- 0 0000b = No OHC present
- x xxx1b = OHC-A present
- x xx1xb = OHC-B present
- x x1xxb = OHC-C present
- 0 0xxx b = No OHC-E present
- 0 1xxx b = OHC-E1 present
- 1 0xxx b = OHC-E2 present
- 1 1xxx b = OHC-E4 present

When present, OHC must follow the Header Base. It is permitted for any combination of OHC content to be present, but, when present, must follow the Header Base, in A-B-C-E order. The contents of the OHC in some cases varies depending on the TLP type.

For specific TLP types, as defined in this specification, specific OHC content must be included by the Transmitter. Receivers must check for violations of these rules. If a Receiver determines that a Request violates a rule requiring specific OHC content, the Request must be handled as an Unsupported Request. If a Receiver determines that a Completion violates a rule requiring specific OHC content, the Completion must be handled as an Unexpected Completion.

Table 2-6 OHC-A Included Fields for OHC-A1 through OHC-A5 (see § Figure 2-7 through § Figure 2-11) §

Name	Required for	Byte Enables	PASID, PV	ER, PMR	Destination Segment, DSV	Completer Segment	Completion Status	Lower Address[1:0]	NW Flag
<u>OHC-A1</u>	Memory Requests with explicit Byte Enables and/or PASID Address Routed Messages with PASID and Route to Root Complex Messages with PASID Translation Requests	Y	Y	Y					Y
<u>OHC-A2</u>	IO Requests	Y							
<u>OHC-A3</u>	Configuration Requests	Y			Y				
<u>OHC-A4</u>	ID-Routed Messages that require Destination Segment and/or PASID		Y		Y				
<u>OHC-A5</u>	Completions when required as defined in § Section 2.2.9.2				Y	Y	Y	Y	
OHC-Ax	Others	When OHC-A is present on other TLPs, all OHC-A bits are Reserved							

Figure 2-7 **OHC-A1** §In OHC-A1

- The ER bit is Execute Requested, and the PMR bit is Privileged Mode Requested (see § Section 6.20). These bits are Reserved for all Requests other than Translation Requests (see § Section 10.2.2 and Page Requests (see § Section 10.4).
- When OHC-A1 is included with a TLP, if the PASID is not known or has not been assigned, then the PV ("PASID Valid") bit must be Clear.
- The ER and PMR bits are Reserved if PV is Clear.
- The PASID field is Reserved if PV is Clear.
- The NW bit is No Write (NW). This bit is Reserved for all Requests other than Translation Requests.
- OHC-A1 is required as specified in § Section 2.2.5.2 .

Figure 2-8 **OHC-A2** §In OHC-A2:

1. OHC-A2 is required as specified in § Section 2.2.5.2 .

Figure 2-9 **OHC-A3** §In OHC-A3:

- Destination Segment is Reserved if DSV is Clear.
- OHC-A3 is required as specified in § Section 2.2.5.2 .

Figure 2-10 **OHC-A4** §In **OHC-A4**:

- When **OHC-A4** is included with a TLP, if the PASID is not known or has not been assigned, then the PV ("PASID Valid") bit must be Clear.
- The PASID field is Reserved if PV is Clear.
- The Destination Segment field is Reserved if DSV is Clear.
- **OHC-A4** must be included in ID Routed Messages when Destination Segment or PASID is required.

Figure 2-11 **OHC-A5** §In **OHC-A5**:

- LA[1:0] is Lower Address[1:0].
- The Destination Segment field is Reserved if DSV is Clear.
- **OHC-A5** is required as specified in § Section 2.2.9.2.

Figure 2-12 **OHC-B** §In **OHC-B**:

- **OHC-B** is defined for Address Routed Requests only. When **OHC-B** is present on other TLPs, all **OHC-B** bits are Reserved.
- When TLP Processing Hints (TPH) are used **OHC-B** must be included with the appropriate PH and ST values.
- The PH and ST fields are qualified by the HV[1:0] ("Hints Valid") field, defined as:

- 00b: PH[1:0], ST[15:0] are not valid and are Reserved
- 01b: PH[1:0] and ST[7:0] are valid, ST[15:8] is not valid and is Reserved
- 10b: Reserved encoding, Receivers must treat as 00b.
- 11b: PH[1:0] and ST[15:0] are valid
- AMA[2:0] is Reserved when AV is Clear.

Figure 2-13 OHC-C §

For OHC-C:

- The Requester Segment field is Reserved when RSV is Clear.
- IDE TLPs must include OHC-C.
 - If Sub-Stream is 000b, 001b, or 010b, the PR_Sent_Counter, Stream_ID, K, and T fields are meaningful (see § Section 6.33.5)
 - If Sub-Stream is 011b-110b, receiver behavior is undefined.
 - For IDE Completion TLPs, the Requester Segment field is Reserved and the RSV bit must be Clear.
- Non-IDE Request TLPs must, in some cases, also include OHC-C to indicate the Requester Segment (see Segment Rules below). When a non-IDE Completion TLP includes OHC-C, the Requester Segment field is Reserved and the RSV bit must be Clear
 - Non-IDE TLPs with OHC-C are identified by the Sub Stream value of 111b. (see § Section 6.33.5)
 - If Sub-Stream is 111b, the PR_Sent_Counter, Stream_ID, K, and T fields are Reserved.
- Note: OHC-C does not include the M and P bits present in the IDE TLP Prefix. In Flit Mode, the presence of a MAC/PCRC is indicated using the TS field.

Because IDE TLPs cannot be modified between the two Partner Ports, the IDE Partner Ports and the path between them must operate entirely in Non-Flit Mode or in Flit mode. Root Complexes that support peer-to-peer and Switches cannot modify IDE TLPs associated with Flow-Through Selective IDE Streams, making TLP Translation impossible. If an IDE TLP is directed out an Egress Port operating in a different mode from the Ingress Port, the IDE TLP must be dropped, and the result must be reported as a Misrouted IDE TLP error.

It is permitted to configure a Root Complex or Switch such that the Ingress Port is a terminus for an IDE connection and the Egress Port another terminus, such that the TLP is passed through the RC/Switch unprotected by IDE. Doing this requires that the RC/Switch to be trusted, and requires the Root/Switch Ports to have the ability to act as an IDE Terminus, not simply to support Flow-Through IDE.

In Flit Mode, NOP TLPs must never be transmitted as IDE TLPs. Receivers are not required to check for violations of this rule, but, if checked, Receivers must handle NOP TLPs received as IDE TLPs as Malformed TLPs.

Segment Rules:

In Flit Mode, it is possible, and in some cases required, to include Segment fields in TLPs. One benefit of the Segment fields is to enable routing Route-by-ID TLPs between Hierarchies, which are, by definition, in different Segments. Root

Complexes are the only place where peer-to-peer Requests will traverse from one Hierarchy to another. Peer-to-peer Route-by-ID Message Requests can traverse Hierarchies when the Requester includes a valid Destination Segment field. Memory Requests are address routed between Hierarchies, but the associated Completions are ID routed. To aid in Root Complex routing of Completions between Hierarchies, FM Completions can include the Destination Segment field which reflects the value of the Requester Segment field from the associated NP or UIO Memory Request. This allows a Root Complex to route Non-Posted or UIO Memory Requests between Hierarchies without the need to assume ownership of each outstanding transaction for the purpose of routing the associated Completions back to the Hierarchy of the original Requester. This can lead to performance improvements for peer-to-peer transfers between Hierarchies.

A second use of the Segment fields is to improve error logging. When FM TLP headers are logged in the AER Capability structure the Segment fields will be included. The Segment fields improve traceability when identical Requester/Completer IDs exist in different Hierarchies. The rules in this section allow the Segment fields to be omitted in some cases to reduce FM TLP overhead. It should be noted that omitting the Segment fields in these cases could forfeit the improved error-logging traceability benefit. It is permitted to use implementation specific mechanisms to select when optional Segment fields are included (e.g., during debug) while still achieving optimal performance during normal operation by omitting non-required Segment fields.

These fields, which exist only in FM, are used to communicate Segment information:

- The Requester Segment field indicates the Hierarchy in which the Requester is located. This field exists in OHC-C and is sometimes included in Memory and Message Requests.
 - The Requester Segment Valid (RSV) bit, when Set, indicates that the Requester Segment field is valid.
 - When Requester Segment Valid (RSV) is Clear then the Requester Segment field is Reserved.
 - For TLPs with OHC-C that are not IDE TLPs, the Sub-Stream[2:0] field must be 111b, and the Stream ID, PR_Sent_Counter, K and T fields/bits are Reserved.
 - In earlier versions of this specification, Sub-Stream was 4 bits in Symbol 3, bits 7:4. Bit 7 is now Reserved. If TEE-IO Supported is Set, components must implement bit 7 as Reserved. If TEE-IO Supported is Clear, components are permitted to treat bit 7 as part of Sub-Stream
 - IDE Requests (see § Section 6.33) other than Configuration Requests must include Requester Segment in OHC-C.
- The Completer Segment field indicates the Hierarchy in which the Completer is located. This field exists in OHC-A5 and is sometimes included in Completions.
- The Destination Segment field indicates the Hierarchy to which the TLP should be routed for ID Based Routing. In Configuration Write Requests this field is also used to configure the Segment of the completing Function. Configuration Requests in FM always include this field in OHC-A3 unless the Request had previously traversed a NFM Link. Route-by-ID Message Requests sometimes include this field in OHC-A4. Completions sometimes include this field in OHC-A5.
 - The Destination Segment Valid (DSV) bit, when Set, indicates that the Destination Segment field is valid.
 - When Destination Segment Valid (DSV) is Clear then the Destination Segment field is Reserved.

In addition to the following rules that apply specifically to Root Complexes, Requesters and Completers within Root Complexes must also follow the rules later in this section that apply to Requesters and Completers.

- All Configuration Requests transmitted by a Root Port in Flit Mode, including those initiated through the SFI Configuration Access Method, must include OHC-A3 with the DSV bit set and a valid Destination Segment. The Destination Segment is necessary for the Completer to capture its Segment as described in § Section 2.2.6.2
 - The Root Complex must indicate the correct Segment value in the Destination Segment field, even if only one Segment is implemented.

- Completions associated with Configuration Requests must be identifiable solely by Transaction ID when received at a RP. Such Completions will not include a Destination Segment field because Configuration Requests do not include a Requester Segment field.

IMPLEMENTATION NOTE: ROOT COMPLEX SUPPORT FOR PEER-TO-PEER NON-POSTED MEMORY TRANSACTIONS THAT TRAVERSE HIERARCHIES §

Because Segment fields aren't communicated across Links in NFM, Root Complexes take on additional burden for peer-to-peer non-UIO NP Memory Requests that cross from one Hierarchy to another. With the loss of the Requester Segment field when a Request is translated to NFM, the Requester ID that remains in the original NP Memory Request might be indistinguishable from that of other Requesters within the hierarchy domain. Unless all Links along the path from the egress RP to the Completer are known to be in FM, Root Complexes must replace the Requester ID in peer-to-peer NP Memory Requests that cross from one Hierarchy to another. The Requester ID supplied by the Root Complex must be an ID associated with the Root Complex itself. This action is sometimes called "taking ownership" of the NP Request. It is necessary for the Root Complex to take ownership of such Requests to ensure that the Requester ID remains unique within the hierarchy domain of the egress RP, and that the associated Completions can be routed correctly by any Switches within that hierarchy domain. The egress RP also must track all such outstanding NP Memory Requests in order to route the associated Completion(s) to the Hierarchy of the original Requester within the Root Complex, as well as to restore the original Requester ID (Destination BDF/BF in FM) within the Completion(s).

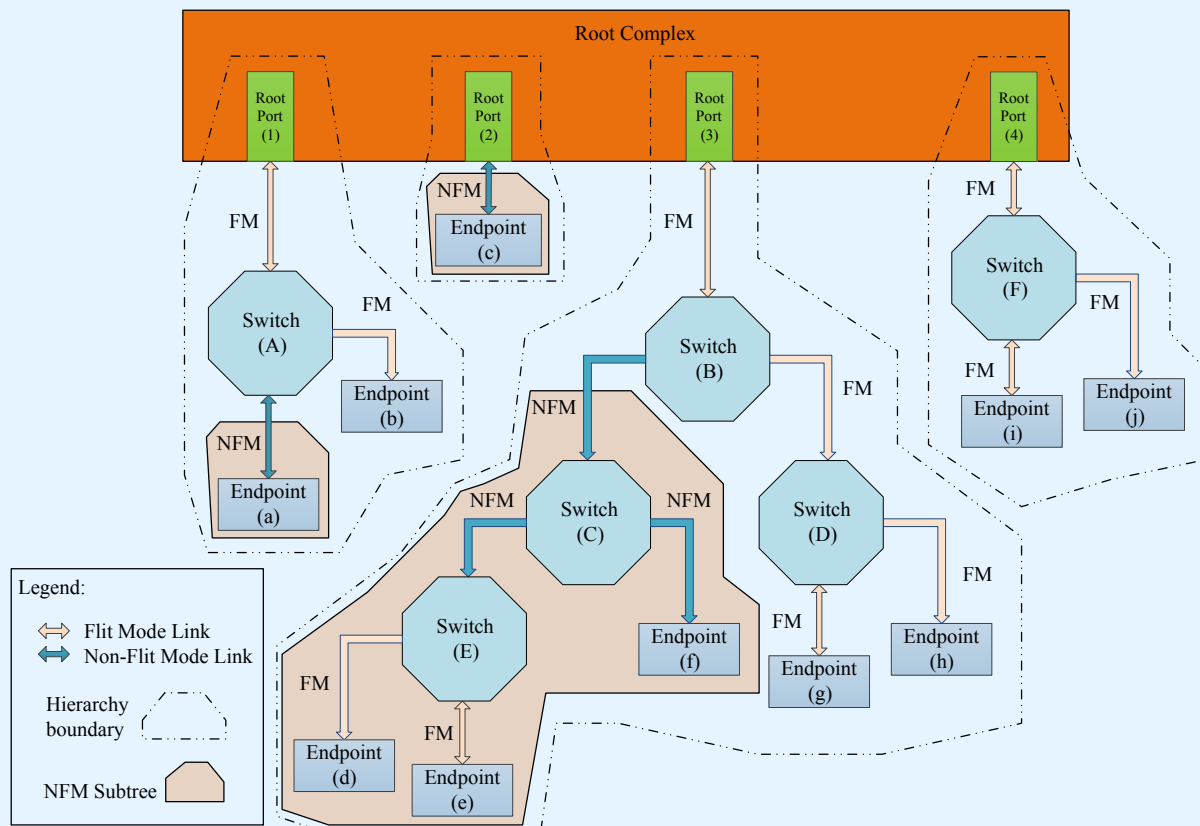

Figure 2-14 Example Topology Illustrating Multiple Segments and NFM Subtrees §

The No NFM Subtree Below This Root Port bit defaults to Clear to indicate that one or more NFM subtree(s) may exist below a Root Port. Referring to the example shown in § Figure 2-14, each Root Port is in a unique Segment/Hierarchy, and Root Ports 1 through 3 have NFM subtrees below the Root Port. For RP 2, the Link immediately below the RP is in NFM, but for RP 1 and 3 the Root Port cannot directly determine the existence of a NFM subtree within its hierarchy domain, and so the default value of the No NFM Subtree Below This Root Port bit ensures that the Root Complex will take ownership of NP Requests Egressing from those Root Ports. In all cases, it is necessary that system software ensure the No NFM Subtree Below This Root Port bit for a Root Port is Clear in cases where the Root Port has one or more NFM Links or subtrees below it.

However, Root Port 4 does not have any NFM Links below it, and therefore it is not necessary for the Root Complex to take ownership of NP Requests Egressing that Root Port. It is strongly recommended that system software Set the No NFM Subtree Below This Root Port bit in such cases, and it is strongly recommended that Root Complex implementations use the value in the No NFM Subtree Below This Root Port bit to avoid taking ownership of NP Requests when it is not necessary to do so.

Note that for non-IDE Requests directed Upstream to the RC, the existence of a NFM Link between the original Requester and the Root Port is not a factor, because the RC inherently knows the Hierarchy of the Requester based on the Ingress RP of the Request, and can add the Requester Segment if needed.

Regardless of the value of the No NFM Subtree Below This Root Port bit, a Root Complex need not apply NP Memory Request tracking mechanisms for peer-to-peer Selective IDE Stream transactions that cross from one Hierarchy to another, and IDE TLPs cannot in any case be modified between the two IDE Partner Ports. When a Selective IDE Stream is established passing peer-to-peer between Hierarchies, software must ensure that the RC supports such routing, and that the entire path between the two Partner Ports is entirely in FM.

A NFM device could be hot-added into a subtree for which the No NFM Subtree Below This Root Port bit had previously been Set. In such cases it is necessary for system software to Clear the No NFM Subtree Below This Root Port bit prior to allowing the hot-added NFM device to act as a Completer for any NP Memory Request passing peer-to-peer through the RC.

- It is not permitted to configure a Selective IDE Stream passing peer-to-peer between different Hierarchies unless it is known that the RC supports flow-through IDE between the two Root Ports, and that all Links on the path between the two Partner Ports, including both the Root Ports, are in FM.
 - Root Complexes are not required to support Selective IDE Streams passing peer-to-peer through the RC.
 - If a condition exists that precludes the RC from passing an IDE TLP associated with a Selective IDE Stream configured to flow-through the RC, then the RC must treat the TLP as a Misrouted IDE TLP error at either the Ingress Port or the Egress Port.
- If a Message or Memory Request received at a RP includes a Requester Segment that does not match the Hierarchy associated with the receiving RP, the Request must be handled by the RP as an Unsupported Request.
- A RP is permitted to add a Requester Segment indication to a non-IDE Memory Write Request, or a non-IDE Route by Address Message Request, passing peer-to-peer through the RC if that TLP did not include a Requester Segment at the ingress RP, where the Requester Segment must correspond to the Segment of the Ingress RP.
- Route by ID Message Requests received at a RP without a Destination Segment, or received in NFM, are implied to be destined for a Completer within the same Hierarchy as the Ingress RP.
- When taking ownership of an NP or UIO Memory Request passing peer-to-peer through the RC:
 - The Requester ID in the Request must be replaced with one associated with the Root Complex.

- The Request must either use the Requester Segment value associated with the hierarchy domain of the Egress RP, or must not include a Requester Segment.
- The RC is permitted to replace the Tag in the Request, and must ensure the Transaction ID satisfies uniqueness requirements for Requests associated with the same Requester ID used for taking ownership.
 - For non-UIO Requests, the RC is permitted to change the size of the Tag. If this is done, it is permitted to use implementation specific means to determine what size of tag is appropriate.
 - The Tag in the Completion(s) must be restored to the Tag from the original Request, as received at the Ingress RP, before returning those Completion(s).
- Completions associated with the Request must be identifiable solely by Transaction ID when received at the RP. Such Completions will not include a Destination Segment if the RP did not include a Requester Segment in the Request or if a NFM Link exists between the RP and the Completer.
- The Requester ID value in the Completion(s) must be restored to the Requester ID from the original Request, as received at the Ingress RP, before returning those Completion(s).
- If the RP that received the Request is in FM and OHC-A5 is returned to the Requester with the Completion(s):
 - The Destination Segment must be set to 00h and the DSV bit must be clear in OHC-A5 that is returned to the original Requester.
 - The Completer Segment field must not be modified if the RP receiving the Completion is in FM and OHC-A5 was received with the Completion. The Completer Segment in OHC-A5 returned to the Requester must be set to 00h if the RP receiving the Completion is in NFM or if OHC-A5 was not received with the Completion.
- When passing an NP or UIO Memory Request peer-to-peer through the RC without taking ownership:
 - The Requester ID and Tag in the Request must not be modified.
 - For non-IDE NP Memory Requests passing peer-to-peer through the RC that do not include a Requester Segment at the Ingress RP, the RC must add a Requester Segment indication at the Egress RP, using the Segment value associated with the Ingress RP.
 - Any Completion received with the DSV bit set and a Destination Segment not matching the value associated with the hierarchy domain of the receiving RP must be routed through the RC to the specified Hierarchy.
 - The Requester ID and Tag fields returned to the Requester must not be modified from the values received with the Completion in the destination hierarchy domain.
 - If the RP that received the Request is in FM and OHC-A5 is returned to the Requester with the Completion(s) the DSV bit, Destination Segment, and Completer Segment fields must not be modified from the values received with OHC-A5 in the destination hierarchy domain.

RP Segment Exceptions – There are specific cases where a RP is not required to include Segment information:

- A RP is not required to include the Requester Segment field in any non-IDE Memory Request initiated by a Requester within the Root Complex.
- A RP is not required to include a Requester Segment field with Memory Write Requests passing peer-to-peer through the RC.
- A RP is not required to include a Requester Segment field with NP Memory Requests passing peer-to-peer through the RC if the Egress RP is taking ownership of the Request.
- A RP is not required to include the Completer Segment or Destination Segment fields in Completions associated with NP Memory Requests targeting system memory or another element of the Root Complex itself. OHC-A5 must be included if required as described in § Section 2.2.9.2 .

- A RP is not required to include the Completer Segment or Destination Segment fields in Completions associated with NP Memory Requests passing peer-to-peer through the RC. OHC-A5 must be included if required as described in § Section 2.2.9.2 .

Each Switch exists entirely within a single Hierarchy by definition. However, Switches are required to comprehend Segment fields in some TLP types for routing purposes. The following rules apply to Switches:

- For TLPs in FM for both the Ingress and Egress Ports, Switches must never modify, add, or remove any Segment field or the DSV/RSV bit(s) within the TLP.
- For Configuration Requests initiated in FM through the SFI Configuration Access Method on a Switch Downstream Port, the Destination Segment and DSV fields must reflect the values received in the associated Configuration Write or Read Request to the SFI CAM Data Register.
- A Switch for which Segment Captured is Set must handle as a TLP Translation Egress Blocked error an NP Memory Request received at the Upstream Port destined for a Downstream Port in NFM that includes a Requester Segment that does not match the Switch's captured Segment value.
 - The Request must not be forwarded to the Downstream Port.
- If a condition exists that precludes the Switch from passing an IDE TLP associated with a Selective IDE Stream configured to flow-through the Switch without modification, then the Switch must handle the TLP as a Misrouted IDE TLP error at either the Ingress Port or the Egress Port.
- When a Switch must translate a TLP from NFM to FM:
 - If Segment Captured is Clear, OHC-C must not be added to a Request.
 - If Segment Captured is Set, the Switch is permitted to add OHC-C to Memory and Message Requests with the Requester Segment containing the value established when the Switch itself was configured.
 - OHC-C must not be added to Configuration Requests.
 - If any OHC-A with DSV and Destination Segment fields is added, the DSV bit must be Clear and the Destination Segment must be 00h.
 - For a Completion that requires OHC-A5 (see § Section 2.2.9.2),
 - if Segment Captured is Set, then the Switch must apply in the Completer Segment field the Segment value established when the Switch itself was configured,
 - if Segment Captured is Clear, then the Switch must apply in the Completer Segment field the value 00h.
- Switches must route Configuration Requests solely by the BDF fields (Destination BDF/BF in FM); the Destination Segment field must not be considered for routing.
- A Switch for which Segment Captured is Set must route Completions and Route by ID Message Requests Upstream if DSV Set and the Destination Segment does not match the Switch's captured Segment value.
- Completions and Route by ID Message Requests must be routed solely by Requester ID / Destination BDF / Destination Device ID if the Ingress Port is in NFM, a Destination Segment is not included (DSV bit is clear), or the included Destination Segment matches the Switch's captured Segment value.
- A Switch for which Segment Captured is Clear must signal a TLP Translation Egress Blocked error if a Completion or Route by ID Message Request is received with DSV Set, and the TLP must not be forwarded.
- A Switch for which Segment Captured is Clear must signal a TLP Translation Egress Blocked error if a received Message or Memory Request includes a Requester Segment. The Request must not be forwarded.
- A Switch for which Segment Captured is Set must signal a TLP Translation Egress Blocked error if a Message or Memory Request received on a Downstream Port includes a Requester Segment that does not match the Switch's captured Segment value. The Request must not be forwarded.

- When reordering Completions with other Completions, Switches are permitted to consider Destination Segment fields included in the Completions as effectively part of the Transaction ID. When not included, the Destination Segment is implied to be the same Segment where the Completion exists.
- When reordering TLPs based on ID Based Ordering (IDO), Switches must consider Requester Segment fields included in Requests, and Destination Segment fields included in Completions, as effectively part of the Transaction ID. When the Destination Segment is not included, for reordering purposes the Destination Segment must be considered to be the same Segment where the Completion exists. When the Requester Segment is not included in a Request, Switches must assume a matching value for IDO purposes.

The following rules apply to Requesters:

- When the Requester Segment field is included in a Request it must be set to the value captured from a Configuration Write Request as described in [§ Section 2.2.6.2](#).
- When the Segment Captured bit is Clear all non-IDE Message and Memory Requests initiated by the Requester must not include OHC-C.
- When the Segment Captured bit is Set all Message Requests initiated by the Requester must include OHC-C with Requester Segment.
- When the Segment Captured bit is Set a Requester is permitted to include OHC-C with Requester Segment in Memory Requests.
- When the Segment Captured bit is Clear, Route by ID Message Requests initiated by the Requester must not include a Destination Segment (the DSV bit must be clear).
- When the Segment Captured bit is Set a Requester is required to include a Destination Segment, and set the DSV bit, in Route by ID Message Requests destined for a different Hierarchy. Requesters use implementation specific means to determine the Hierarchy to which a Route by ID Message Request should be routed. When the Segment Captured bit is Set the Destination Segment is required in ATS Invalidate Request, Invalidate Completion, and PRG Response Messages even if the target is in the same Hierarchy. For other Route by ID Message Requests the Destination Segment is optional when the Segment Captured bit is Set and the Requester knows, by definition or through programming, that the target of the Request is in the same Hierarchy.
- Requesters must accept any value in the Destination Segment field (if present) in received Completions.
- A Requester is not required to include the Requester Segment field in any non-IDE Memory Request.

The following rules apply to Completers:

- Completers must capture their Segment value from Configuration Write Requests as described in [§ Section 2.2.6.2](#).
- When the Segment Captured bit is Clear, Completers must set the Completer Segment field to 00h in any [OHC-A5](#) that is included in a Completion.
- When the Segment Captured bit is Set, Completers must set the Completer Segment field in any [OHC-A5](#) that is included in a Completion to the Segment value that was captured as described in [§ Section 2.2.6.2](#).
 - If the Completion associated with the first Configuration Write Request includes [OHC-A5](#), the Completer Segment field must be set to the value captured from that Request.
- Completers must clear the DSV bit and set the Destination Segment field to 00h in any [OHC-A5](#) that is included with a Completion associated with a Configuration Request.
- For an NP or UIO Memory Request received without a Requester Segment field, Completers must clear the DSV bit and set the Destination Segment field to 00h in any [OHC-A5](#) that is included with the associated Completion(s).

- For an NP or UIO Memory Request received with a Requester Segment field, Completers must set the DSV bit and set the Destination Segment field to the value of the received Requester Segment in any OHC-A5 that is included with the associated Completion(s). See RP Segment Exceptions for cases where RPs are not required to include Segment information.
- When the Segment Captured bit is Set and an NP Memory Request is received with a Requester Segment value not matching the Completer's captured Segment value, all Completions associated with the Request must include OHC-A5.
- Completers must not qualify the acceptance of a Route by ID Message Request based on the value of the Destination Segment field in the Request.
- Completers must include OHC-A5 with a Completion if required as described in § Section 2.2.9.2 and § Section 6.33.4.
- Completers must not include OHC-A5 with a Completion when all of the following are true:
 - Completion Status is successful.
 - Lower Address[1:0] equal to 00b.
 - The Completer's Segment Captured bit is Clear.
- Completers are permitted to not include OHC-A5 with a Completion when all of the following are true:
 - Completion Status is successful.
 - Lower Address[1:0] equal to 00b.
 - The Completer's Segment Captured bit is Set.
 - The associated Request either did not include a Requester Segment field or included a Requester Segment field matching the Completer's captured Segment value.
 - TEE-IO Supported is Clear or Completion is not on a Selective IDE Stream. See § Section 6.33.4.

2.2.2 TLPs with Data Payloads - Rules §

- Length is specified as an integral number of DW
- Length[9:0] is Reserved for all Messages except those that explicitly refer to a data length
 - Refer to the Message Code tables in § Section 2.2.8.
- A Function transmitting a TLP with a data payload must not allow the data payload length as indicated by the TLP's Length field to exceed the Function's applicable MPS setting. If the Function's Mixed_MPS_Supported bit is Clear or the target is host memory, the applicable MPS setting must be the Function's computed Tx_MPS_Limit, as defined below. If the Mixed_MPS_Supported bit is Set, the Function must have an implementation specific mechanism capable of supporting different MPS settings for different targets, and must handle both Request and Completion TLPs. Target-specific MPS settings are permitted to be above or below the Function's Tx_MPS_Limit, but they must never exceed the Function's Max_Payload_Size Supported field value. The Function's Tx_MPS_Limit is determined as follows:
 - For a single-Function device, the Tx_MPS_Limit must be its Max_Payload_Size field value, its "MPS setting".
 - Otherwise, for an ARI Device, the Tx_MPS_Limit must be the MPS setting in Function 0. The MPS settings in other Functions of an MFD must be ignored.
 - Otherwise, for a Function in a non-ARI MFD whose MPS settings are identical across all Functions, the Tx_MPS_Limit must be the common MPS setting.
 - Otherwise, for a Function in a non-ARI MFD whose MPS settings are not identical across all Functions, the Tx_MPS_Limit must be the MPS setting in an implementation specific Function.

- Transmitter implementations are encouraged to use the MPS setting from the Function that generated the transaction, or else the smallest MPS setting across all Functions.
 - Software should not configure the MPS setting in different Functions to different values unless software is aware of the specific implementation.
- MPS settings apply only to TLPs with data payloads; Memory Read Requests are not restricted in length by MPS settings. The size of the Memory Read Request is controlled by the TLP's Length field.
- The data payload size in a Received TLP as indicated by the TLP's Length field must not exceed a computed Rx_MPS_Limit for the receiving Function, as determined by MPS-related parameters as indicated below.
 - Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, the TLP must be handled as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).
 - In Flit Mode, Receivers must handle the full range of the Length field for the purpose of determining the total size of each TLP and deciding which symbol is the start of the next TLP.
 - In the receiving Function, if the Rx_MPS_Fixed bit is Set, the Rx_MPS_Limit must be the Max_Payload_Size Supported field. Otherwise, the Rx_MPS_Limit must be determined by the Max_Payload_Size field (the "MPS setting") in one or more Functions as follows:
 - For a single-Function device, the Rx_MPS_Limit must be its MPS setting.
 - Otherwise, for an ARI Device, the Rx_MPS_Limit must be the MPS setting in Function 0. MPS settings in other Functions must be ignored.
 - Otherwise, for an Upstream Port associated with a non-ARI MFD whose MPS settings are identical across all Functions, the Rx_MPS_Limit must be the common MPS setting.
 - Otherwise, for an Upstream Port associated with a non-ARI MFD whose MPS settings are not identical across all Functions, the Rx_MPS_Limit must be the MPS setting in an implementation specific Function.
 - Receiver implementations are encouraged to use the MPS setting from the Function targeted by the transaction, or else the largest MPS setting across all Functions.
 - Software should not configure the MPS setting in different Functions to different values unless software is aware of the specific implementation.
- For TLPs that include data, the value in the Length field and the actual amount of data included in the TLP must match.
 - In NFM, Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, the TLP is a Malformed TLP.
 - This is a Reported Error associated with the Receiving Port (see § Section 6.2).
- The value in the Length field applies only to data - the TLP Digest is not included in the Length.
- When a data payload associated with a byte address is included in a TLP other than an AtomicOp Request or an AtomicOp Completion, the first byte of data following the header corresponds to the byte address closest to zero and the succeeding bytes are in increasing byte address sequence.
 - Example: For a 16-byte write to location 100h, the first byte following the header would be the byte to be written to location 100h, and the second byte would be written to location 101h, and so on, with the final byte written to location 10Fh.
- The data payload in AtomicOp Requests and AtomicOp Completions must be formatted such that the first byte of data following the TLP header is the least significant byte of the first data value, and subsequent bytes of data are strictly increasing in significance. With Compare And Swap (CAS) Requests, the second data value immediately follows the first data value, and must be in the same format.

- The endian format used by AtomicOp Completers to read and write data at the target location is implementation specific, and is permitted to be whatever the Completer determines is appropriate for the target memory (e.g., little endian, big endian, etc.). Endian format capability reporting and controls for AtomicOp Completers are outside the scope of this specification.
- Little endian example: For a 64-bit (8-byte) Swap Request targeting location 100h with the target memory in little endian format, the first byte following the header is written to location 100h, the second byte is written to location 101h, and so on, with the final byte written to location 107h. Note that before performing the writes, the Completer first reads the target memory locations so it can return the original value in the Completion. The byte address correspondence to the data in the Completion is identical to that in the Request.
- Big endian example: For a 64-bit (8-byte) Swap Request targeting location 100h with the target memory in big endian format, the first byte following the header is written to location 107h, the second byte is written to location 106h, and so on, with the final byte written to location 100h. Note that before performing the writes, the Completer first reads the target memory locations so it can return the original value in the Completion. The byte address correspondence to the data in the Completion is identical to that in the Request.
- § Figure 2-15 shows little endian and big endian examples of Completer target memory access for a 64-bit (8-byte) FetchAdd. The bytes in the operands and results are numbered 0-7, with byte 0 being least significant and byte 7 being most significant. In each case, the Completer fetches the target memory operand using the appropriate endian format. Next, AtomicOp compute logic in the Completer performs the FetchAdd operation using the original target memory value and the “add” value from the FetchAdd Request. Finally, the Completer stores the FetchAdd result back to target memory using the same endian format used for the fetch.

Figure 2-15 Examples of Completer Target Memory Access for FetchAdd §

IMPLEMENTATION NOTE:

ENDIAN FORMAT SUPPORT BY RC ATOMICOP COMPLETERS §

One key reason for permitting an AtomicOp Completer to access target memory using an endian format of its choice is so that PCI Express devices targeting host memory with AtomicOps can interoperate with host software that uses atomic operation instructions (or instruction sequences). Some host environments have limited endian format support with atomic operations, and by supporting the “right” endian format(s), an RC AtomicOp Completer may significantly improve interoperability.

For an RC with AtomicOp Completer capability on a platform supporting little-endian-only processors, there is little envisioned benefit for the RC AtomicOp Completer to support any endian format other than little endian. For an RC with AtomicOp Completer capability on a platform supporting bi-endian processors, there may be benefit in supporting both big endian and little endian formats, and perhaps having the endian format configurable for different regions of host memory.

There is no PCI Express requirement that an RC AtomicOp Completer support the host processor's “native” format (if there is one), nor is there necessarily significant benefit to doing so. For example, some processors can use load-link/store-conditional or similar instruction sequences to do atomic operations in non-native endian formats and thus not need the RC AtomicOp Completer to support alternative endian formats.

IMPLEMENTATION NOTE:

MAINTAINING ALIGNMENT IN DATA PAYLOADS §

§ Section 2.3.1.1 discusses rules for forming Read Completions respecting certain natural address boundaries. Memory Write performance can be significantly improved by respecting similar address boundaries in the formation of the Write Request. Specifically, forming Write Requests such that natural address boundaries of 64 or 128 bytes are respected will help to improve system performance.

2.2.3 TLP Digest Rules - Non-Flit Mode Only §

- For any TLP, a value of 1b in the TD bit indicates the presence of the TLP Digest field including an end-to-end CRC (ECRC) value at the end of the TLP.
 - A TLP where the TD bit value does not correspond with the observed size (accounting for the data payload, if present) is a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).
- If an intermediate or ultimate PCI Express Receiver of the TLP does not support ECRC checking, the Receiver must ignore the TLP Digest⁸.
 - If the Receiver of the TLP supports ECRC checking, the Receiver interprets the value in the TLP Digest field as an ECRC value, according to the rules in § Section 2.7.1.

8. An exception is an Intermediate Receiver forwarding a Multicast TLP out an Egress Port with MC_Overlay enabled. See § Section 6.14.5.

2.2.4 Routing and Addressing Rules §

There are three principal mechanisms for TLP routing: address, ID, and implicit. This section defines the rules for the address and ID routing mechanisms. Implicit routing is used only with Message Requests, and is covered in § Section 2.2.8.

2.2.4.1 Address-Based Routing Rules §

- Address routing is used with Memory, I/O Requests and Address Routed Messages.
- in NFM, two address formats are specified:
 - a 32-bit format with a 3 DW header (see § Figure 2-16)
 - a 64-bit format with a 4 DW header (see § Figure 2-17)
- In FM, five address formats are specified:
 - a 32-bit format with a 3 DW header (see § Figure 2-18)
 - a 64-bit format with a 4 DW header (see § Figure 2-19)
 - a 64-bit format with a 5 DW header (see § Figure 2-20)
 - a 64-bit format with a 6 DW header (see § Figure 2-21)
 - a 64-bit format with a 7 DW header (see § Figure 2-22)

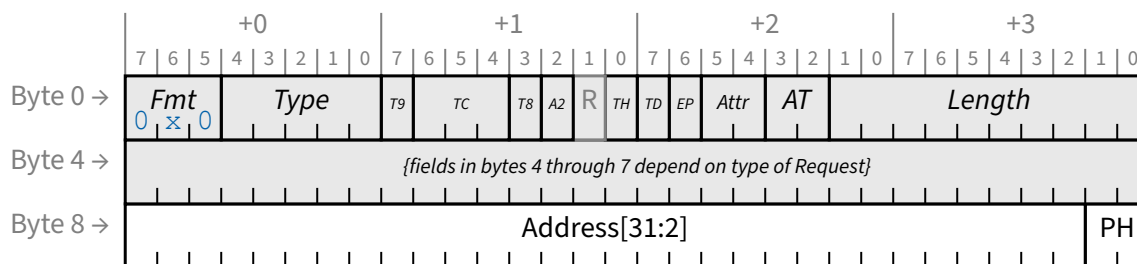

Figure 2-16 32-bit Address Routing - Non-Flit Mode §

Figure 2-17 64-bit Address Routing - Non-Flit Mode §

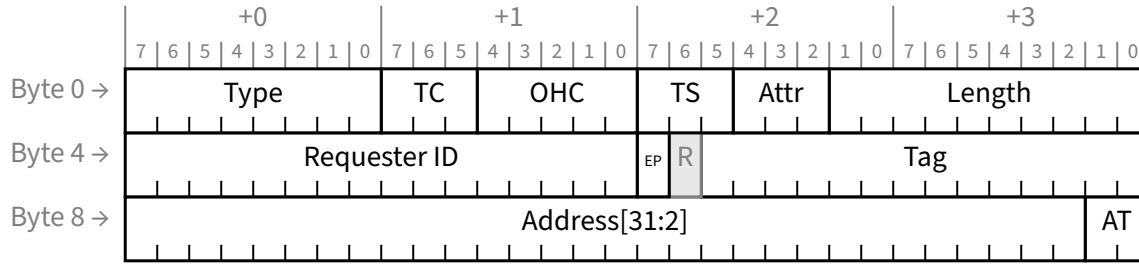

Figure 2-18 32-bit Address Routing - Flit Mode §

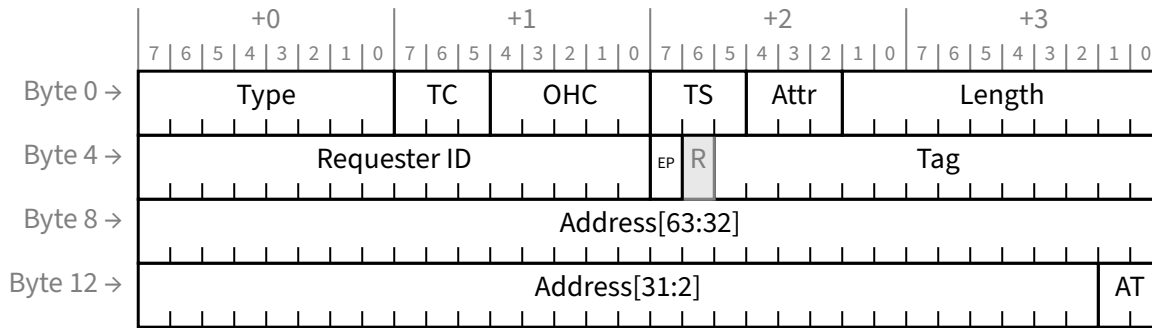

Figure 2-19 64-bit Address Routing - Flit Mode §

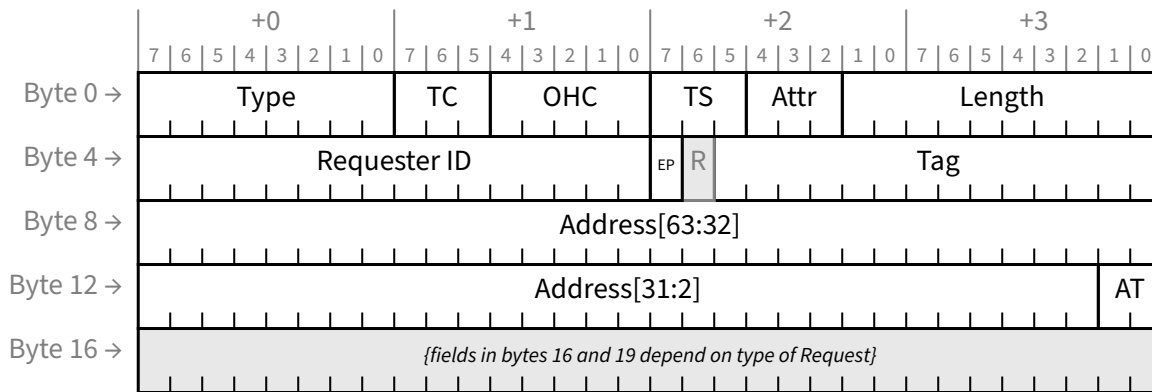

Figure 2-20 64-bit Address Routing - Flit Mode - 5 DW §

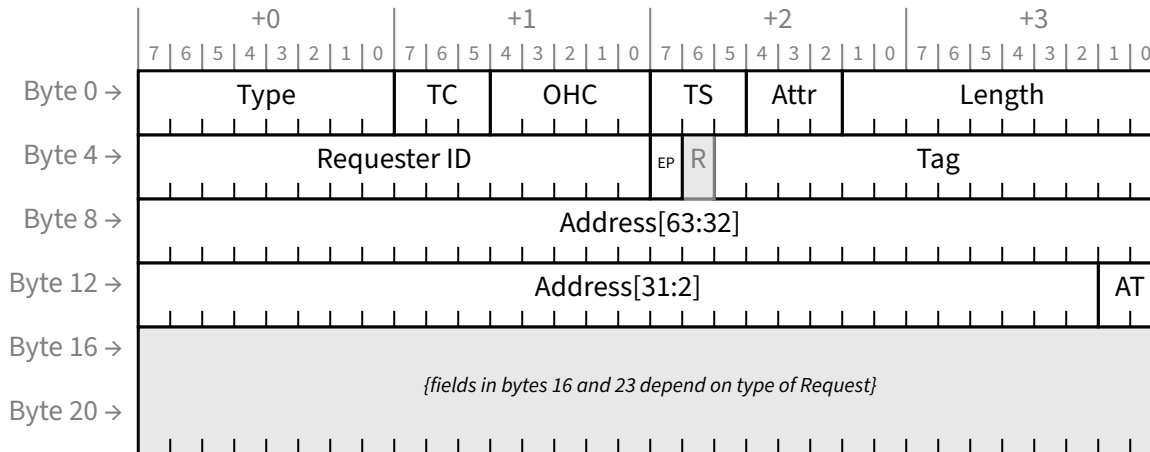

Figure 2-21 64-bit Address Routing - Flit Mode - 6 DW §

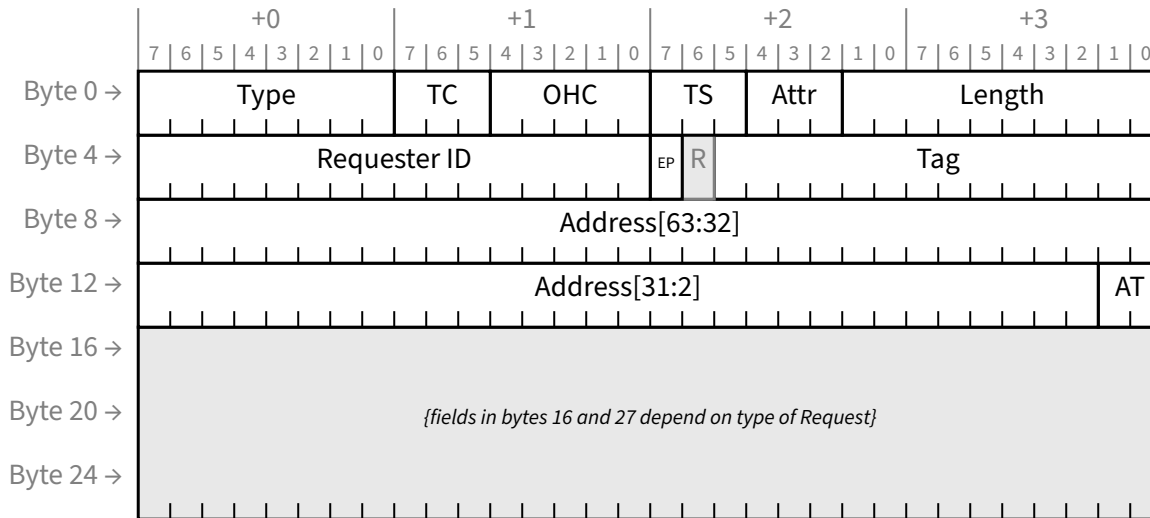

Figure 2-22 64-bit Address Routing - Flit Mode - 7 DW §

- For Memory Read, Memory Write, DMWr, and AtomicOp Requests, the Address Type (AT) field is encoded as shown in § Table 10-1. For Address Routed Messages in Flit Mode, the Address Type (AT) field is encoded as shown in § Table 10-1 with the exception that the value of 01b is reserved. For all other Requests, the AT field is Reserved unless explicitly stated otherwise.
- If TH is Set, the PH field is encoded as shown in § Table 2-18. If TH is Clear, the PH field is Reserved.
- Address mapping to the TLP header is shown in § Table 2-7.

Table 2-7 Address Field Mapping §

Address Bits	32-bit Addressing	64-bit Addressing
63:56	Not Applicable	Bits 7:0 of Byte 8

Address Bits	32-bit Addressing	64-bit Addressing
55:48	Not Applicable	Bits 7:0 of Byte 9
47:40	Not Applicable	Bits 7:0 of Byte 10
39:32	Not Applicable	Bits 7:0 of Byte 11
31:24	Bits 7:0 of Byte 8	Bits 7:0 of Byte 12
23:16	Bits 7:0 of Byte 9	Bits 7:0 of Byte 13
15:8	Bits 7:0 of Byte 10	Bits 7:0 of Byte 14
7:2	Bits 7:2 of Byte 11	Bits 7:2 of Byte 15

- Except when explicitly required otherwise, non-UIO Memory Read, Memory Write, DMWr, and AtomicOp Requests use both formats.
 - For Addresses below 4 GB, Requesters must use the 32-bit format. The behavior of the Receiver is not specified if a 64-bit format Request addressing below 4 GB (i.e., with the upper 32 bits of address all 0) is received.
- The following address routed Requests must use 64-bit addressing (when addressing below 4 GB the upper 32 address bits must be to 0000 0000h):
 - All Address Routed UIO Requests
 - IDE TLPs with partial header encryption
 - This *MUST@FLIT* include Address Routed Messages. See § Table 2-20.⁹
- I/O Read Requests and I/O Write Requests use the 32-bit format.
- All agents must decode all address bits in the header - address aliasing is not allowed.

IMPLEMENTATION NOTE: PREVENTION OF ADDRESS ALIASING §

For correct software operation, full address decoding is required even in systems where it may be known to the system hardware architect/designer that fewer than 64 bits of address are actually meaningful in the system.

2.2.4.2 ID Based Routing Rules §

- ID routing is used with Configuration Requests, with ID Routed Messages, and with Completions. This specification defines several Messages that are ID Routed (see § Table F-1). Other specifications are permitted to define additional ID Routed Messages.
- ID routing uses the Bus, Device, and Function Numbers (as applicable) to specify the destination for the TLP:
 - For non-ARI Routing IDs, Bus, Device, and (3-bit) Function Number to TLP header mapping is shown in § Table 2-8, § Figure 2-23, and § Figure 2-25.
 - For ARI Routing IDs, the Bus and (8-bit) Function Number to TLP header mapping is shown in § Table 2-9, § Figure 2-24, and § Figure 2-26.

9. Earlier versions of this specification did not specify address routed message behavior when the address was below 4 GB.

- In FM, Completions and ID Routed Messages with a different destination Hierarchy than the Hierarchy in which they originate must be routed to the destination Hierarchy using the Destination Segment field and then routed within the destination Hierarchy by the destination Bus, Device, and Function Numbers.
- In NFM, two ID routing formats are specified, one used with a 4 DW header (see § Figure 2-23 and § Figure 2-24) and one used with a 3 DW header (see § Figure 2-26 and § Figure 2-24).
 - Header field locations are the same for both formats (see § Table 2-8 and § Table 2-9).
- In FM, five ID routing formats are specified:
 - One with a 3 DW header (see § Figure 2-27)
 - One with a 4 DW header (see § Figure 2-28)
 - One with a 5 DW Header (see § Figure 2-29)
 - One with a 6 DW Header (see § Figure 2-30)
 - One with a 7 DW Header (see § Figure 2-31)

Table 2-8 Header Field Locations for non-ARI ID Routing - Non-Flit Mode §

Field	Header Location
Bus Number[7:0]	Bits 7:0 of Byte 8
Device Number[4:0]	Bits 7:3 of Byte 9
Function Number[2:0]	Bits 2:0 of Byte 9

Table 2-9 Header Field Locations for ARI ID Routing §

Field	Header Location
Bus Number[7:0]	Bits 7:0 of Byte 8
Function Number[7:0]	Bits 7:0 of Byte 9

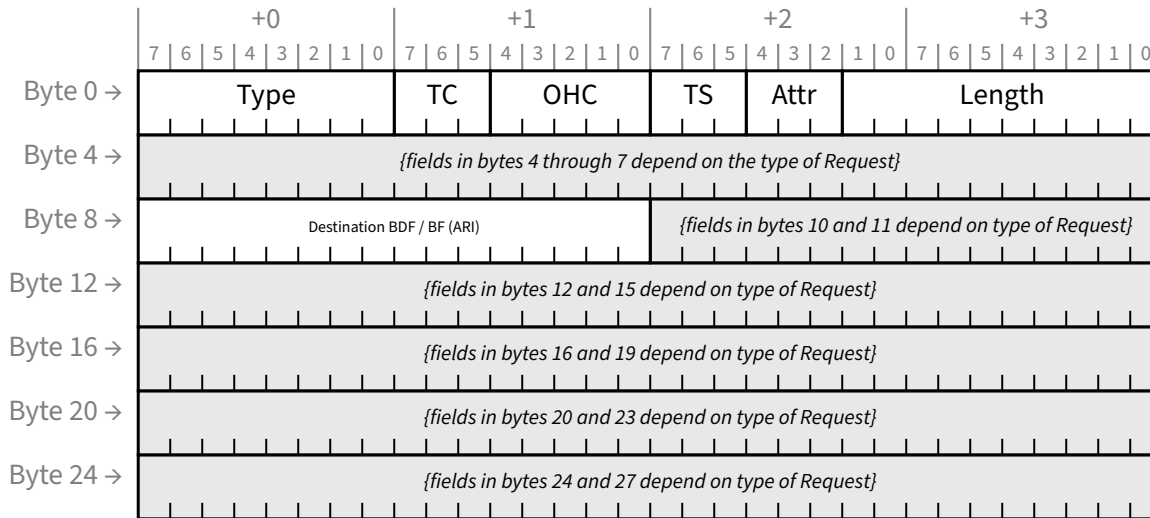

Figure 2-31 ID Routing with 7 DW Header - Flit Mode §

2.2.5 First/Last DW Byte Enables Rules §

The general function of TLP Byte Enables is similar in Non-Flit Mode and Flit Mode, however the detailed rules differ.

IMPLEMENTATION NOTE:

SECURITY ISSUES ASSOCIATED WITH NON-ENABLED BYTES §

The data included with a Write or Read Completion necessarily is DW aligned, and so in cases where some bytes are not enabled, the content of the non-enabled bytes is undefined. To optimize platform security, it is strongly recommended that non-enabled bytes be filled with zeros to avoid data being inadvertently leaked (“leaky bytes”).

As a best practice, it is strongly recommended that devices receiving non-enabled bytes also ensure that the values provided in those bytes are discarded by hardware, such that the values cannot be visible to software. Hardware that fails to do so can provide a path for an attacker to observe confidential data without the need for physical access to a system.

2.2.5.1 Byte Enable Rules for Non-Flit Mode §

Byte Enables are included with Memory, I/O, and Configuration Requests. This section defines the corresponding rules. Byte Enables, when present in the Request header, are located in byte 7 of the header (see § Figure 2-32). For Memory Read Requests and DMW_r Requests that have the TH bit Set, the Byte Enable fields are repurposed to carry the ST[7:0] field (refer to § Section 2.2.7.1.1 for details), and values for the Byte Enables are implied as defined below. The TH bit must only be Set in Memory Read Requests and DMW_r Requests when it is acceptable to complete those Requests as if all bytes for the requested data were enabled.

- For Memory Read Requests and DMW_r Requests that have the TH bit Set, the following values are implied for the Byte Enables. See § Section 2.2.7 for additional requirements.
 - If the Length field for this Request indicates a length of 1 DW, then the value for the First DW Byte Enables is implied to be 1111b and the value for the Last DW Byte Enables is implied to be 0000b.
 - If the Length field for this Request indicates a length of greater than 1 DW, then the value for the First DW Byte Enables and the Last DW Byte Enables is implied to be 1111b.

IMPLEMENTATION NOTE:

READ REQUEST WITH TPH TO NON-PREFETCHABLE SPACE §

Memory Read Requests with the TH bit Set and that target Non-Prefetchable Memory Space should only be issued when it can be guaranteed that completion of such reads will not create undesirable side effects. See § Section 7.5.1.2.1 for consideration of certain BARs that may have the Prefetchable bit Set even though they map some locations with read side-effects.

Figure 2-32 Location of Byte Enables in TLP Header - Non-Flit Mode §

- The First DW BE[3:0] field contains Byte Enables for the first (or only) DW referenced by a Request.
 - If the Length field for a Request indicates a length of greater than 1 DW, this field must not equal 0000b.
- The Last DW BE[3:0] field contains Byte Enables for the last DW of a Request.
 - If the Length field for a Request indicates a length of 1 DW, this field must equal 0000b.
 - If the Length field for a Request indicates a length of greater than 1 DW, this field must not equal 0000b.
- For each bit of the Byte Enables fields:
 - a value of 0b indicates that the corresponding byte of data must not be written or, if non-prefetchable, must not be read at the Completer.
 - a value of 1b indicates that the corresponding byte of data must be written or read at the Completer.
- Non-contiguous Byte Enables (enabled bytes separated by non-enabled bytes) are permitted in the First DW BE field for all Requests with length of 1 DW.
 - Non-contiguous Byte Enable examples: 1010b, 0101b, 1001b, 1011b, 1101b
- Non-contiguous Byte Enables are permitted in both Byte Enables fields for Quad Word (QW) aligned Memory Requests with length of 2 DW (1 QW).
- All non-QW aligned Memory Requests with length of 2 DW (1 QW) and Memory Requests with length of 3 DW or more must enable only bytes that are contiguous with the data between the first and last DW of the Request.

- Contiguous Byte Enables examples:
First DW BE: 1100b, Last DW BE: 0011b

First DW BE: 1000b, Last DW BE: 0111b
- § Table 2-10 shows the correspondence between the bits of the Byte Enables fields, their location in the Request header, and the corresponding bytes of the referenced data.

Table 2-10 Byte Enables Location and Correspondence §

Byte Enables	Header Location	Affected Data Byte ¹⁰
First DW BE[0]	Bit 0 of Byte 7	Byte 0
First DW BE[1]	Bit 1 of Byte 7	Byte 1
First DW BE[2]	Bit 2 of Byte 7	Byte 2
First DW BE[3]	Bit 3 of Byte 7	Byte 3
Last DW BE[0]	Bit 4 of Byte 7	Byte N-4
Last DW BE[1]	Bit 5 of Byte 7	Byte N-3
Last DW BE[2]	Bit 6 of Byte 7	Byte N-2
Last DW BE[3]	Bit 7 of Byte 7	Byte N-1

- A Write Request with a length of 1 DW with no bytes enabled is permitted, and has no effect at the Completer unless otherwise specified.

IMPLEMENTATION NOTE: ZERO-LENGTH WRITE §

A Memory Write Request of 1 DW with no bytes enabled, or “zero-length Write,” may be used by devices under certain protocols, in order to achieve an intended side effect.

- If a Read Request of 1 DW specifies that no bytes are enabled to be read (First DW BE[3:0] field = 0000b), the corresponding Completion must specify a length of 1 DW, and include a data payload of 1 DW.
The contents of the data payload within the Completion packet is unspecified and may be any value.
- Receiver/Completer behavior is undefined for a TLP violating the Byte Enables rules specified in this section.
- Receivers may optionally check for violations of the Byte Enables rules specified in this section. If a Receiver implementing such checks determines that a TLP violates one or more Byte Enables rules, the TLP is a Malformed TLP. These checks are independently optional (see § Section 6.2.3.4).
 - If Byte Enables rules are checked, a violation is a reported error associated with the Receiving Port (see § Section 6.2).

10. Assuming the data referenced is N bytes in length (Byte 0 to Byte N-1). Note that last DW Byte Enables are used only if the data length is greater than one DW.

IMPLEMENTATION NOTE:

ZERO-LENGTH READ §

A Memory Read Request of 1 DW with no bytes enabled, or “zero-length Read,” may be used by devices as a type of flush Request. For a Requester, the flush semantic allows a device to ensure that previously issued Posted Writes have been completed at their PCI Express destination. To be effective in all cases, the address for the zero-length Read must target the same device as the Posted Writes that are being flushed. One recommended approach is using the same address as one of the Posted Writes being flushed.

The flush semantic has wide application, and all Completers must implement the functionality associated with this semantic. Since a Requester may use the flush semantic without comprehending the characteristics of the Completer, Completers must ensure that zero-length reads do not have side-effects. This is really just a specific case of the rule that in a non-prefetchable space, non-enabled bytes must not be read at the Completer. Note that the flush applies only to traffic in the same Traffic Class as the zero-length Read.

2.2.5.2 Byte Enable Rules for Flit Mode §

Except as defined in this section, all Byte Enable Rules in Flit Mode are the same as in Non-Flit Mode.

For all Memory Requests, it is permitted for OHC-A1 (see § Figure 2-7) to be present. OHC-A1 must be included for Requests that require any of the fields included in OHC-A1. For Memory Requests, when OHC-A1 is not present, the value of the Last DW Byte Enable field must be treated as 1111b for Requests with Length greater than or equal to 2 DW, and the value of the 1st DW Byte Enable field must be treated as 1111b. If a Request requires Byte Enables field values other than these, then OHC-A1 must be present. When OHC-A1 is present, the PASID, PMR and ER fields are valid if and only if the PV bit is Set.

OHC-A2 must be included for all IO Requests.

OHC-A3 must be included for all Configuration Requests.

In all cases where OHC-A is present, the Byte Enable fields must be handled as defined in § Section 2.2.5.1 .

2.2.6 Transaction Descriptor §

2.2.6.1 Overview §

The Transaction Descriptor is a mechanism for carrying Transaction information between the Requester and the Completer. Transaction Descriptors are composed of three fields:

- Transaction ID - identifies outstanding Transactions
- Attributes field - specifies characteristics of the Transaction
- Traffic Class (TC) field - associates Transaction with type of required service

§ Figure 2-33 shows the fields of the Transaction Descriptor. Note that these fields are shown together to highlight their relationship as parts of a single logical entity. The fields are not contiguous in the packet header.

Figure 2-33 Transaction Descriptor §

2.2.6.2 Transaction Descriptor - Transaction ID Field §

The Transaction ID field consists of two major sub-fields: Requester ID and Tag as shown in § Figure 2-34.

Figure 2-34 Transaction ID §

In some cases (defined below) the Traffic Class (TC) is also included in the Transaction ID.

The Transaction ID is used to associate Completions with Requests. There are three groups of Request/Completion types for which the Transaction ID has differing rules. The groups are distinguished by the Completion Type expected for the Request type(s) in that group. Each group forms a distinct namespace, and there is no requirement for Transaction ID uniqueness between groups. These groups and their high-level requirements are:

- Group I: Cpl / CpID, which apply to Non-UIO Requests:
 - The Transaction ID consists of Requester ID[15:0] and Tag[13:0] ¹¹
 - Requesters must assign Tag values such that Transaction ID values are unique for all outstanding Non-Posted Requests in Group I, without regard to TC or any other field.
- Group II: UIOWrCpl, which applies to UIO Memory Write (UIOMWr) Requests:
 - The Transaction ID consists of the TC[2:0], Requester ID[15:0] and Tag[13:0].
 - Requesters are permitted to assign Tag values such that multiple outstanding Requests in Group II have the same Transaction ID (see § Section 2.2.9.2)
- Group III: UIORdCpID and UIORdCpl, which apply to UIO Memory Read (UIOMRd) Requests:
 - The Transaction ID consists of the TC[2:0], Requester ID[15:0] and Tag[13:0].

11. Not all Tag bits are used in all cases – detailed rules follow.

- Requesters must assign Tag values such that Transaction ID values are unique for all outstanding Requests in Group III.

Four Tag sizes are architected for operation: 14-bit, 10-bit, 8-Bit and 5-bit. A given Function may support different Tag sizes when operating as a Requester versus operating as a Completer. Below are the rules regarding operational Tag sizes. Also see the “[Considerations for Implementing Larger-Tag Capabilities](#)” Implementation Note later in this section.

- 14-Bit Tags and 10-Bit Tags are referred to as “larger” Tags.
- 8-Bit Tags and 5-Bit Tags are referred to as “smaller” Tags.
- All Functions must support 8-Bit Tag Completer capability.
 - UIO Completers must support 14-bit Tags.
- A Function that supports Flit Mode must support 14-Bit Tag Completer capability, and thus it automatically supports 10-Bit Tag Completer capability.
- Functions¹² (including those in Switches) that support 16.0 GT/s data rates or greater must support 10-Bit Tag Completer capability.
- A Function must not support 14-Bit Tag Requester capability unless it supports 14-Bit Tag Completer capability.
- A Function must not support 10-Bit Tag Requester capability unless it supports 10-Bit Tag Completer capability.
- In Non-Flit Mode, Tag[8] and Tag[9], are not contiguous with other Tag field bits in the TLP Header. These bits were Reserved prior to 10-Bit Tags being architected. Requesters in Non-Flit Mode that do not support 10-Bit Tag Requester capability must set Tag[9:8] to 00b.
- RCs containing elements that indicate support for 14-Bit Tag Completer capability or 10-Bit Tag Completer capability must handle supported Tag-sized Requests correctly by all registers and memory regions supported as targets of PCIe Requesters; e.g., host memory targeted by DMA Requests or MMIO regions in RCiEPs.
 - Each RP indicating support must handle such Requests received by its Ingress Port.
 - Each RCiEP indicating support must handle such Requests coming from supported internal paths, including those coming through RPs.
- If an RC contains RCiEPs that indicate support for 14-Bit Tag Requester capability or 10-Bit Tag Requester capability, the RC must handle Requests from those RCiEPs correctly by all registers and memory regions supported as targets of those RCiEPs; e.g., host memory targeted by DMA Requests or MMIO regions in RCiEPs.
- Receivers/Completers must handle 8-bit Tag values correctly regardless of the setting of their Extended Tag Field Enable bit (see § Section 7.5.3.4). Refer to the *PCI Express to PCI/PCI-X Bridge Specification* for details on the bridge handling of Extended Tags.
- Receivers/Completers that support 14-Bit Tag Completer capability or 10-Bit Tag Completer capability must handle the supported Tag-size values correctly, regardless of their corresponding Tag Requester Enable bit setting. See § Section 7.5.3.16.
- 14-Bit Tag capability and 10-Bit Tag capability are not architected for PCI Express to PCI/PCI-X Bridges, and they must not indicate the associated Tag Requester capability or Tag Completer capability.
- If one or both larger-Tag Requester Enable bits are Set, the following rules apply.
 - If both larger-Tag Requester Enable bits are Set in an Endpoint¹³, then 14-Bit Tags are permitted for Requests that target host memory. An implementation specific hardware mechanism in the Endpoint is permitted to limit those Requests to 10-Bit Tags or smaller Tags, but generic software or firmware should not Set the 14-Bit Tag Requester Enable bit unless the host supports 14-Bit Tag Completer capability for host memory.

12. An exception is PCI Express to PCI/PCI-X Bridges, since 10-Bit Tag capability is not architected for these Functions.

13. This includes PCI Express Endpoints, Legacy PCI Express Endpoints, and Root Complex Integrated Endpoints.

- If an Endpoint ¹⁴ supports sending Requests to other Endpoints (as opposed to host memory), the Endpoint must not send larger-Tag Requests to another given Endpoint unless an implementation specific mechanism determines that the Endpoint supports the corresponding larger Tag Completer capability. Not sending larger-Tag Requests to other Endpoints at all may be acceptable for some implementations. More sophisticated mechanisms are outside the scope of this specification.
- If a PIO Requester has larger-Tag Requester capability, how the Requester determines when to use larger Tags versus smaller Tags is outside the scope of this specification. One example approach is to use smaller Tags for all PIO Requests and use larger Tags for integrated data-mover engines that use the same Requester ID. A similar approach might be used for integrated hardware that takes ownership of P2P requests.
- With 14-Bit Tags, determination of valid Tag values is complicated by inconsistencies in previous versions of this specification. The strongly recommended behavior is for all Tag[13:10] values except 0000b to be valid, and for 14-Bit Requesters not to generate Tag values with Tag[13:10] equal to 0000b. This enables a Requester to determine if a Completion it receives that should have a 14-Bit Tag contains an invalid Tag value. However, for backward compatibility with previous versions of this specification, 14-bit Requesters are permitted to generate any Tag[13:8] values except 00 0000b, and such Tag values are valid.
- With 10-Bit Tags, all Tag[9:8] values except 00b are valid. 10-Bit Tag values with Tag[9:8] equal to 00b are invalid, and must not be generated by the Requester. This enables a Requester to determine if a Completion it receives that should have a 10-Bit Tag contains an invalid Tag value, usually caused by the Completer not supporting 10-Bit Tag Completer capability.
- If a Requester sends a larger-Tag Request to a Completer that lacks the associated larger-Tag Completer capability, the returned Completion(s) will have Tags with invalid Tag values. Such Completions will be handled as Unexpected Completions ¹⁵, which by default are Advisory Non-Fatal Errors. The Requester must follow standard PCI Express error handling requirements.
- When a Requester handles a Completion with an invalid Tag as an Unexpected Completion, the original Request will likely incur a Completion Timeout. If the Requester handles the Completion Timeout condition in some device-specific manner that avoids data corruption, the Requester is permitted to suppress handling the Completion Timeout by standard PCI Express error handling mechanisms as required otherwise.
- If a Requester supports sending larger-Tag Requests to some Completers and smaller-Tag Requests to other Completers concurrently, the Requester must honor the Extended Tag Field Enable bit setting for the smaller-Tag Requests. That is, if the bit is Clear, only the lower 5 bits of the Tag field may be non-Zero; if the bit is Set, only the lower 8 bits of the Tag field may be non-Zero.
- If a Requester supports sending larger-Tag Requests to some Completers and smaller-Tag Requests to other Completers concurrently, the Requester must ensure that no outstanding larger Tags can alias to an outstanding smaller Tag if any larger-Tag Request is completed by a Completer that lacks larger-Tag Completer capability. See the "Using Larger Tags and Smaller Tags Concurrently" Implementation Note later in this section.
- The default value of the Extended Tag Field Enable bit is implementation specific. The default value of the 14-Bit Tag Requester Enable bit and the 10-Bit Tag Requester Enable bit is 0b.
- Receiver/Completer behavior is undefined if multiple uncompleted Requests other than UIO Memory Writes, are issued from the same Requester with non-unique Transaction ID values. In FM, Completers must be designed to handle simultaneous uncompleted Requests with non-unique Transaction ID values from Requesters that reside in different Hierarchies, as indicated by implied or explicit Segment numbers associated with each Request.

14. This includes PCI Express Endpoints, Legacy PCI Express Endpoints, and Root Complex Integrated Endpoints.

15. If a Completion has a higher precedence error, that error should be reported instead.

- If Phantom Function Numbers are used to extend the number of outstanding Requests, the combination of the Phantom Function Number and the Tag field must be unique for all outstanding Requests that require a Completion for that Requester, without regard to TC or any other field.
- If Shadow Functions are used to extend the number of outstanding Requests, the combination of the Shadow Function Number and the Tag field must be unique for all outstanding Requests that require a Completion for that Requester, without regard to TC or any other field.
- § Table 2-11 indicates how the three tag enable bits determine the maximum tag size and permitted tag value ranges a Requester must use for different Completers and their associated paths. For a given combination of Tag enable settings, a Requester must use a Tag size within its enabled maximum and within the Tag capabilities of the Completer and its associated path. For each Request, the Requester is permitted to use a Tag size smaller than the greatest common Tag size supported by the Completer/path, but the Requester must still abide by the permitted Tag value range for the Tag size that it uses.

Table 2-11 Tag Enables, Sizes, and Permitted Ranges for non-UIO Transactions [§]

14-bit Tag Requester Enable	10-bit Tag Requester Enable	Extended Tag Field Enable	Maximum Request Tag size	Permitted range for an 8-bit Tag Completer/path	Permitted range for a 10-bit Tag Completer/path	Permitted range for a 14-bit Tag Completer/path
0	0	0	5 bits	0 to 31	0 to 31	0 to 31
0	0	1	8 bits	0 to 255	0 to 255	0 to 255
0	1	0	10 bits	0 to 31	256 to 1023	256 to 1023
0	1	1	10 bits	0 to 255	256 to 1023	256 to 1023
1	0	0	14 bits	0 to 31	0 to 31	1024 to 16383
1	0	1	14 bits	0 to 255	0 to 255	1024 to 16383
1	1	0	14 bits	0 to 31	256 to 1023	1024 to 16383 ¹⁶
1	1	1	14 bits	0 to 255	256 to 1023	1024 to 16383 ¹⁷

Notes:

1. The permitted range for a 5-bit Tag Completer/path is always 0 to 31, so there is no column in the table to indicate this.
 2. The "X-bit Tag Completer/path" is the greatest common Tag size capability of the Completer and all routing elements along the path between the Requester and the targeted Completer. If a routing element is not the targeted Completer, but detects an Uncorrectable Error with a Request, the routing element may serve as the Completer for the Request.
 3. If a Requester supports sending larger-Tag Requests to some Completers and smaller-Tag Requests to other Completers concurrently, the Requester must ensure that no outstanding larger Tags can alias to an outstanding smaller Tag if any larger-Tag Request is completed by a Completer that lacks larger-Tag Completer capability.
- For Posted Requests, the Tag[13:8] field is Reserved in Non-Flit Mode, and Tag[13:0] is Reserved in Flit Mode.
 - An exception to this rule is allowed for the uses defined in [MCTP-VDM].

16. The permitted range of 1024 to 16383 is strongly recommended, but for backward compatibility with previous versions of this specification, 256 to 16383 is permitted.

17. The permitted range of 1024 to 16383 is strongly recommended, but for backward compatibility with previous versions of this specification, 256 to 16383 is permitted.

- In Non-Flit Mode, for Posted Requests with the TH bit Set, the Tag[7:0] field is repurposed for the ST[7:0] field (refer to § Section 2.2.7.1.1 for details). For Posted Requests with the TH bit Clear, the Tag[7:0] field is undefined and may contain any value. (Refer to § Table F-1 for exceptions to this rule for certain Vendor-Defined Messages.)
 - For Posted Requests with the TH field Clear, the value in the Tag[7:0] field must not affect Receiver processing of the Request.
 - For Posted Requests with the TH bit Set, the value in the ST[7:0] field may affect Completer processing of the Request (refer to 2.2.7.1 for details).
- A Transaction ID must be unique for each pending Transaction within a Hierarchy.
- Transaction ID is included with all Requests and Completions.
- The Requester ID is a 16-bit value that is unique for every PCI Express Function within a Hierarchy.
- Functions must capture the Bus and Device Numbers¹⁸ supplied with all Type 0 Configuration Write Requests completed by the Function and supply these numbers in the Bus and Device Number fields of the Requester ID¹⁹ for all Requests initiated without the use of Shadow Functions by the Device/Function. See § Section 7.9.25, for details of how the Requester ID may be modified by the use of Shadow Functions. It is recommended that Numbers are captured for successfully completed Requests only.

Exception: The assignment of Bus and Device Numbers to the Devices within a Root Complex, and Device Numbers to the Downstream Ports within a Switch, may be done in an implementation specific way.

Note that the Bus Number and Device Number²⁰ may be changed at run time, and so it is necessary to re-capture this information with each and every Type 0 Configuration Write Request to the Device.

Configuration Write Requests addressed to unimplemented Functions *MUST@FLIT* not affect captured Bus and Device Numbers for implemented Functions.

- When generating Requests on their own behalf (for example, for error reporting), Switches must use the Requester ID associated with the primary side of the bridge logically associated with the Port (see § Section 7.1) causing the Request generation.
- Prior to the initial Configuration Write to a Function, the Function is not permitted to initiate Non-Posted Requests. (A valid Requester ID is required to properly route the resulting completions.)
 - Exception: Functions within a Root Complex are permitted to initiate Requests prior to software-initiated configuration for accesses to system boot device(s).
Note that this rule and the exception are consistent with the existing PCI model for system initialization and configuration.
- Each Function associated with a Device must be designed to respond to a unique Function Number for Configuration Requests addressing that Device. Note: Each non-ARI Device may contain up to eight Functions. Each ARI Device may contain up to 256 Functions.
- A Switch must forward Requests without modifying the Transaction ID, except when this is not possible due to any non-zero Tag[13:10] bits. For a Request from an Ingress Port operating in FM targeting an Egress Port operating in NFM, the presence of any non-zero Tag[13:10] bits must be handled by the Egress Port first by blocking the TLP and then reporting a TLP Translation Egress Blocked error for a Posted Request or reporting no error for a Non-Posted Request. Such Tag bits cannot be conveyed in NFM.
- In some circumstances, a PCI Express to PCI/PCI-X Bridge is required to generate Transaction IDs for Requests it forwards from a PCI or PCI-X bus.

18. In ARI Devices, Functions are only required to capture the Bus Number. ARI Devices are permitted to retain the captured Bus Number on either a per-Device or a per-Function basis. If the captured Bus Number is retained on a per-Device basis, all Functions are required to update and use the common Bus Number.

19. An ARI Requester ID does not contain a Device Number field. See § Section 2.2.4.2.

20. With ARI Devices, only the Bus Number can change.

- In Flit Mode, Functions must capture the value of the Destination Segment supplied with all Type 0 Configuration Write Requests successfully completed by the Function. It is permitted for each Function of a Device to independently capture the Destination Segment value, or for all Functions of a Device to use the value captured by Function 0. All Functions within a Switch share a common Segment value that is captured by Functions associated with the Upstream Port. Functions also must capture the DSV bit in Type 0 Configuration Write Requests as described in the Segment Captured bit description in § Section 7.7.9.4 .
 - The Segment is effectively an extension of the Requester ID, but is formally defined as a distinct field to avoid confusion with the use of the term Transaction ID in Non-Flit Mode operation.
 - In systems that support multiple Segments, each Hierarchy must be associated with a single Segment. It is permitted for multiple hierarchy domains to be associated with a single Segment.
- In Flit-Mode, in some circumstances, the captured Segment is also explicitly indicated in a TLP, which enables the Transaction ID to be unique between Hierarchies.

IMPLEMENTATION NOTE: INCREASING THE NUMBER OF OUTSTANDING REQUESTS USING PHANTOM FUNCTIONS OR SHADOW FUNCTIONS §

To increase the maximum possible number of outstanding Requests requiring Completion beyond that possible using Tag bits alone, a device may, if the Phantom Functions Enable bit is Set (see § Section 7.5.3.4), or the Shadow Functions Enable bit is Set (see § Section 7.9.25.3), use Function Numbers not assigned to implemented Functions to logically extend the Tag identifier. For a single-Function Device, this can allow a significant increase in the maximum number of outstanding Requests.

When the Phantom Functions Enable bit is Set, unclaimed Function Numbers are referred to as Phantom Function Numbers.

Phantom Functions have a number of architectural limitations, including a lack of support by ARI Devices, Virtual Functions (VFs), and Physical Functions (PFs) when VFs are enabled. In addition, Address Translation Services (ATS) and ID-Based Ordering (IDO) do not comprehend Phantom Functions. Shadow Functions have fewer limitations. Thus, for many implementations, the use of larger Tags and Shadow Functions are better ways to increase the number of outstanding Non-Posted Requests.

IMPLEMENTATION NOTE: CONSIDERATIONS FOR IMPLEMENTING LARGER-TAG CAPABILITIES §

The use of "larger" (i.e., 10-bit or 14-bit) Tags enables a Requester to increase its number of outstanding Non-Posted Requests (NPRs) substantially, which for very high rates of NPRs or very large round-trip times can avoid Tag availability from becoming a bottleneck. The following formula gives the basic relationship between payload bandwidth, number of outstanding NPRs, and other factors:

$BW = S * N / RTT$, where

BW = payload bandwidth

S = transaction payload size

N = number of outstanding NPRs

RTT = transaction round-trip time

Generally only high-speed Requesters on high-speed Links using relatively small transactions will benefit from increasing their number of outstanding NPRs beyond 256, although this can also help maintain performance in configurations where the transaction round-trip time is high.

In configurations where a Requester with larger-Tag Requester capability needs to target multiple Completers, one needs to ensure that the Requester sends larger-Tag Requests only to Completers that have sufficient larger-Tag Completer capability. This is greatly simplified if all Completers have larger-Tag capability.

For general industry enablement of larger Tags, it is strongly recommended that all Functions²¹ support larger-Tag Completer capability. With new implementations, Completers that don't need to operate on higher numbers of NPRs concurrently themselves can generally track larger Tags internally and return them in Completions with modest incremental investment.

Completers that actually process higher numbers of NPRs concurrently may require substantial additional hardware resources, but the full performance benefits of larger Tags generally can't be realized unless Completers actually do process higher numbers of NPRs concurrently.

For platforms where the RC supports larger-Tag Completer capability, it is strongly recommended for platform firmware or operating system software that configures PCIe hierarchies to Set one of the larger-Tag Requester Enable bits automatically in Endpoints with larger-Tag Requester capability. This enables the important class of larger-Tag capable adapters that send Memory Read Requests only to host memory.

For Endpoints other than RCiEPs, one can determine if the RC supports larger-Tag Completer capability for each one by checking the larger-Tag Completer Supported bits in its associated RP. RCiEPs have no associated RP, so for this reason they are not permitted to have one of their larger-Tag Requester Supported bits Set unless the RC supports sufficient larger-Tag Completer capability for them. Thus, software does not need to perform a separate check for RCiEPs.

Non-Flit Mode Switches that lack 10-bit Tag Completer capability are still able to forward NPRs and Completions carrying 10-bit Tags correctly, since the two new Tag bits are in TLP Header bits that were formerly Reserved, and Switches are required to forward Reserved TLP Header bits without modification. However, if such a Switch detects an error with an NPR carrying a 10-bit Tag, and that Switch handles the error by acting as the Completer for the NPR, the resulting Completion will have an invalid 10-bit Tag. Thus, it is strongly recommended that Non-Flit Mode Switches between any components using 10-bit Tags support 10-bit Completer capability. Note that Switches supporting 16.0 GT/s data rates or greater must support 10-bit Tag Completer capability.

21. An exception is PCI Express to PCI/PCI-X Bridges, since larger-Tag capability is not architected for these Functions.

For configurations where a Requester with larger-Tag Requester capability targets Completers where some do and some do not have sufficient larger-Tag Completer capability, how the Requester determines which NPRs include larger Tags is outside the scope of this specification.

IMPLEMENTATION NOTE: USING LARGER TAGS AND SMALLER TAGS CONCURRENTLY §

As stated earlier in this section, if a Requester supports sending larger-Tag Requests to some Completers and smaller-Tag Requests to other Completers concurrently, the Requester must ensure that no outstanding larger Tags can alias to an outstanding smaller Tag if any larger-Tag Request is completed by a Completer that lacks sufficient larger-Tag Completer capability.

For 10-bit Tags, one implementation approach is to have the Requester partition its 8-bit Tag space into 2 regions: one that will only be used for smaller Tags (8-bit or 5-bit Tags), and one that will only be used for the lower 8 bits of 10-bit Tags. Note that this forces a tradeoff between the Tag space available for 10-bit Tags and smaller Tags.

For example, if a Requester partitions its 8-bit Tag space to use only the lowest 4 bits for smaller Tags, this supports up to 16 outstanding smaller Tags, and it reduces the 10-bit Tag space by 3×16 values, supporting $768 - 48 = 720$ outstanding 10-bit Tags. Many other partitioning options are possible, all of which reduce the total number of outstanding Requests. In general, reserving N values for smaller Tags reduces 10-bit Tag space by $3 \times N$ values, and the total for smaller Tags plus 10-bit Tags ends up being $768 - 2 \times N$.

Similar implementation approaches for 14-Bit Tags are possible, and they are straight-forward if only 14-Bit and 8-Bit/5-Bit Tags are supported. If a Requester implementation needs to handle 14-Bit, 10-Bit, and 8-Bit/5-Bit Tag sizes concurrently, the general approach of partitioning the Requester's Tag spaces still works, but the complexity increases significantly.

2.2.6.3 Transaction Descriptor - Attributes Field §

The Attributes field is used to provide additional information that allows modification of the default handling of Transactions. These modifications apply to different aspects of handling the Transactions within the system, such as:

- Ordering
- Hardware coherency management (snoop)

Attributes are hints that allow, but do not require, optimizations in the handling of traffic. The level of optimization support is dependent on the target applications of particular PCI Express peripherals and platform building blocks. In Flit Mode the Attributes Field is contiguous in the TLP Header. In Non-Flit Mode, attribute bit 2 is sometimes labeled A2 and is not adjacent to bits 1 and 0 (see § Figure 2-36 and § Figure 2-37).

Figure 2-35 Attributes Field of Transaction Descriptor §

2.2.6.4 Relaxed Ordering and ID-Based Ordering Attributes §

§ Table 2-12 defines the states of the Relaxed Ordering and ID-Based Ordering attribute fields. These attributes are discussed in § Section 2.4 . Note that Relaxed Ordering and ID-Based Ordering attributes are not adjacent in location (see § Figure 2-5).

Table 2-12 Ordering Attributes §

Attribute Bit [2]	Attribute Bit [1]	Ordering Type	Ordering Model
0	0	Default Ordering	PCI Strongly Ordered Model
0	1	Relaxed Ordering	PCI-X Relaxed Ordering Model
1	0	ID-Based Ordering	Independent ordering based on Requester/Completer ID
1	1	Relaxed Ordering plus ID-Based Ordering	Logical “OR” of Relaxed Ordering and IDO

Attribute bit [1] is not applicable and must be Clear for Configuration Requests, I/O Requests, Memory Requests that are Message Signaled Interrupts, and Message Requests (except where specifically permitted).

Attribute bit [2], IDO, is Reserved for Configuration Requests and I/O Requests. IDO is not Reserved for all Memory Requests, including Message Signaled Interrupts (MSI/MSI-X). IDO is not Reserved for Message Requests unless specifically prohibited. A Requester is permitted to Set IDO only if the IDO Request Enable bit in the Device Control 2 register is Set.

The value of the IDO bit must not be considered by Receivers when determining if a TLP is a Malformed Packet.

A Completer is permitted to Set IDO only if the IDO Completion Enable bit in the Device Control 2 register is Set. It is not required to copy the value of IDO from the Request into the Completion(s) for that Request. If the Completer has IDO enabled, it is recommended that the Completer set IDO for all Completions, unless there is a specific reason not to (see § Appendix E.).

A Root Complex that supports forwarding TLPs peer-to-peer between Root Ports is not required to preserve the IDO bit from the Ingress to Egress Port.

2.2.6.5 No Snoop Attribute §

§ Table 2-13 defines the states of the No Snoop attribute field. Note that the No Snoop attribute does not alter Transaction ordering.

Table 2-13 Cache Coherency Management Attribute §

No Snoop Attribute (b)	Cache Coherency Management Type	Coherency Model
0	Default	Hardware enforced cache coherency expected
1	No Snoop	Hardware enforced cache coherency not expected

This attribute is not applicable and must be Clear for Configuration Requests, I/O Requests, Memory Requests that are Message Signaled Interrupts, and Message Requests (except where specifically permitted).

2.2.6.6 Transaction Descriptor - Traffic Class Field §

The Traffic Class (TC) is a 3-bit field that allows differentiation of transactions into eight traffic classes.

Together with the PCI Express Virtual Channel support, the TC mechanism is a fundamental element for enabling differentiated traffic servicing. Every PCI Express Transaction Layer Packet uses TC information as an Invariant label that is carried end to end within the PCI Express fabric. As the packet traverses across the fabric, this information is used at every Link and within each Switch element to make decisions with regards to proper servicing of the traffic. A key aspect of servicing is the routing of the packets based on their TC labels through corresponding Virtual Channels. § Section 2.5 covers the details of the VC mechanism.

§ Table 2-14 defines the TC encodings.

Table 2-14 Definition of TC Field Encodings §

TC Field Value (b)	Definition
000	TC0: Best Effort service class (General Purpose I/O) (Default TC - must be supported by every PCI Express device)
001 to 111	TC1 to TC7: Differentiated service classes (Differentiation based on Weighted-Round-Robin (WRR) and/or priority)

It is up to the system software to determine TC labeling and TC/VC mapping in order to provide differentiated services that meet target platform requirements.

The concept of Traffic Class applies only within the PCI Express interconnect fabric. Specific requirements of how PCI Express TC service policies are translated into policies on non-PCI Express interconnects is outside of the scope of this specification.

2.2.7 Memory, I/O, and Configuration Request Rules §

The general requirements for Memory, I/O, and Configuration Requests similar in Non-Flit Mode and Flit Mode, however some specific rules differ. Rules that are common between Non-Flit Mode and Flit-Mode follow, with rules that are specific to each in subsequent sub-sections.

2.2.7.1 Non-Flit Mode §

The following rule applies to all Memory, I/O, and Configuration Requests. Additional rules specific to each type of Request follow.

- All Memory, I/O, and Configuration Requests include the following fields in addition to the common header fields:
 - Requester ID[15:0] and Tag[9:0], forming the Transaction ID. In Non-Flit Mode, the Tag field is 10 bits.
 - Last DW BE[3:0] and First DW BE[3:0]. For Memory Read Requests, DMWr Requests, and AtomicOp Requests with the TH bit Set, the byte location for the Last DW BE[3:0] and First DW BE [3:0] fields in the header are repurposed to carry ST[7:0] field.
 - For Memory Read Requests and DMWr Requests with the TH bit Clear, see [§ Section 2.2.5](#) for First/Last DW Byte Enable Rules.
 - For AtomicOp Requests and DMWr Requests with TH bit Set, the values for the DW BE fields are implied to be Reserved. For AtomicOp Requests with TH bit Clear, the DW BE fields are Reserved.

For Memory Requests, the following rules apply:

- Memory Requests route by address, using either 64-bit or 32-bit Addressing (see [§ Figure 2-36](#) and [§ Figure 2-37](#)).
- For Memory Read Requests, Length must not exceed the value specified by Max_Read_Request_Size (see [§ Section 7.5.3.4](#)).
- For AtomicOp Requests, architected operand sizes and their associated Length field values are specified in [§ Table 2-15](#). If a Completer supports AtomicOps, the following rules apply. The Completer must check the Length field value. If the value does not match an architected value, the Completer must handle the TLP as a Malformed TLP. Otherwise, if the value does not match an operand size that the Completer supports, the Completer must handle the TLP as an Unsupported Request (UR). This is a reported error associated with the Receiving Port (see [§ Section 6.2](#)).

Table 2-15 Length Field Values for AtomicOp Requests §

AtomicOp Request	Length Field Value for Architected Operand Sizes		
	32 Bits	64 Bits	128 Bits
FetchAdd, Swap	1 DW	2 DW	N/A
CAS	2 DW	4 DW	8 DW

- A FetchAdd Request contains one operand, the “add” value.
- A Swap Request contains one operand, the “swap” value.
- A CAS Request contains two operands. The first in the data area is the “compare” value, and the second is the “swap” value.
- For AtomicOp Requests, the Address must be naturally aligned with the operand size. The Completer must check for violations of this rule. If a TLP violates this rule, the TLP is a Malformed TLP. This is a reported error associated with the Receiving Port (see [§ Section 6.2](#)).
- Requests must not specify an Address/Length combination that causes a Memory Space access to cross a 4-KB boundary.
 - Receivers may optionally check for violations of this rule. If a Receiver implementing this check determines that a TLP violates this rule, the TLP is a Malformed TLP.
 - If checked, this is a reported error associated with the Receiving Port (see [§ Section 6.2](#)).
 - It is recommended that this optional check only occur in Completers and never in intermediate Receivers.

- Intermediate Receivers are not permitted to implement this check for TLPs with Reserved Type values (see § Table 2-5). The relationship between the TLP Length field and the length of the affected memory range depends on the Request Type (for an example where they are different, see AtomicOp CAS Request).
- For AtomicOp Requests, the mandatory Completer check for natural alignment of the Address (see above) already guarantees that the access will not cross a 4-KB boundary, so a separate 4-KB boundary check is not necessary.
- If a 4-KB boundary check is performed for AtomicOp CAS Requests, this check must comprehend that the TLP Length value is based on the size of two operands, whereas the access to Memory Space is based on the size of one operand.

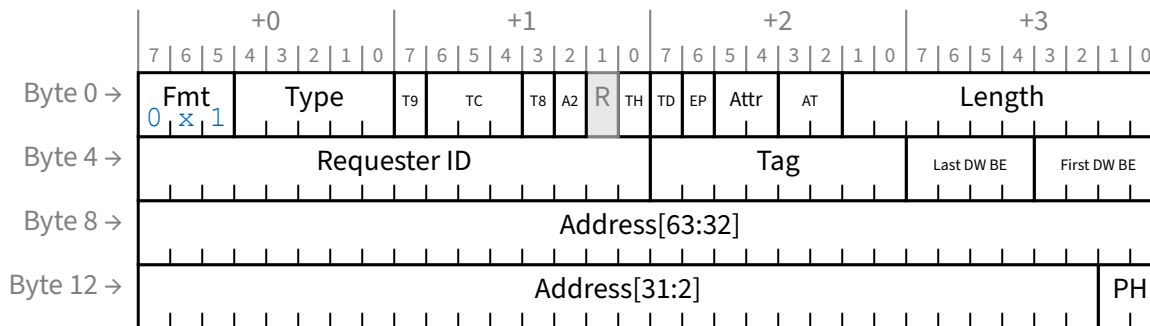

Figure 2-36 Request Header Format for 64-bit Addressing of Memory §

Figure 2-37 Request Header Format for 32-bit Addressing of Memory §

IMPLEMENTATION NOTE: GENERATION OF 64-BIT ADDRESSES §

It is strongly recommended that PCI Express Endpoints be capable of generating the full range of 64-bit addresses. However, if a PCI Express Endpoint supports a smaller address range, and is unable to reach the full address range required by a given platform environment, the corresponding device driver must ensure that all Memory Transaction target buffers fall within the address range supported by the Endpoint. The exact means of ensuring this is platform and operating system specific, and beyond the scope of this specification.

For I/O Requests, the following rules apply:

- I/O Requests route by address, using 32-bit Addressing (see § Figure 2-38)
- I/O Requests have the following restrictions:
 - TC[2:0] must be 000b
 - TH is not applicable to I/O Request and the bit is Reserved
 - Attr[2] is Reserved
 - Attr[1:0] must be 00b
 - AT[1:0] must be 00b. Receivers are not required or encouraged to check this.
 - Length[9:0] must be 00 0000 0001b
 - Last DW BE[3:0] must be 0000b

Receivers may optionally check for violations of these rules (but must not check Reserved bits). These checks are independently optional (see § Section 6.2.3.4). If a Receiver implementing these checks determines that a TLP violates these rules, the TLP is a Malformed TLP.

- If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

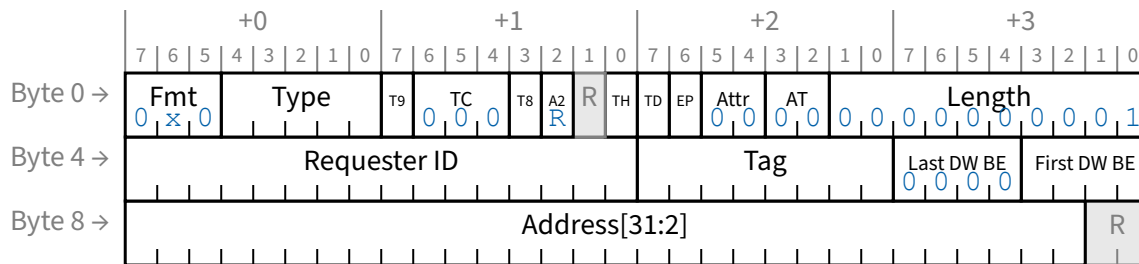

Figure 2-38 Request Header Format for I/O Transactions - Non-Flit Mode §

For Configuration Requests, the following rules apply:

- Configuration Requests route by ID, and use a 3 DW header.
- In addition to the header fields included in all Memory, I/O, and Configuration Requests and the ID routing fields, Configuration Requests contain the following additional fields (see § Figure 2-39).
 - Register Number[5:0]
 - Extended Register Number[3:0]
- Configuration Requests have the following restrictions:
 - TC[2:0] must be 000b
 - TH is not applicable to Configuration Requests and the bit is Reserved
 - Attr[2] is Reserved
 - Attr[1:0] must be 00b
 - AT[1:0] must be 00b. Receivers are not required or encouraged to check this.
 - Length[9:0] must be 00 0000 0001b
 - Last DW BE[3:0] must be 0000b

Receivers may optionally check for violations of these rules (but must not check reserved bits). These checks are independently optional (see § Section 6.2.3.4). If a Receiver implementing these checks determines that a TLP violates these rules, the TLP is a Malformed TLP.

- If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

Figure 2-39 Request Header Format for Configuration Transactions - Non-Flit Mode §

MSI/MSI-X mechanisms use Memory Write Requests to represent interrupt Messages (see § Section 6.1.4). The Request format used for MSI/MSI-X transactions is identical to the Memory Write Request format defined above, and MSI/MSI-X Requests are indistinguishable from memory writes with regard to ordering, Flow Control, and data integrity.

2.2.7.1.1 TPH Rules §

- Two formats are specified for TPH. The Baseline TPH format (see § Figure 2-41 and § Figure 2-42) must be used for all Requests that provide TPH. The format with the optional TPH TLP Prefix extends the TPH fields (see § Figure 2-40) to provide additional bits for the Steering Tag (ST) field.

Figure 2-40 TPH TLP Prefix §

- The optional TPH TLP Prefix is used to provide additional TPH information.
 - The presence of a TPH TLP Prefix is determined by decoding byte 0.

Table 2-16 TPH TLP Prefix
Bit Mapping §

Fields	TPH TLP Prefix
ST[15:8]	Bits 7:0 of byte 1
AMA[2:0]	Bits 7:5 of byte 2
AV	Bit 4 of byte 2

Fields	TPH TLP Prefix
Reserved	Bits 3:0 of byte 2
Reserved	Bits 7:0 of byte 3

- The TPH TLP Prefix is used to send a non-Zero value for any of:
 - AMA
 - ST[15:8]
- For Requests that target Memory Space, a value of 1b in the TH bit indicates the presence of TPH in the TLP header and optional TPH TLP Prefix (if present).
 - The TH bit must be Set for Requests that provide TPH.
 - The TH bit is permitted to be Set for Requests with a TPH TLP Prefix. When the TH bit is 1b, then ST[15:8] is present and meaningful in the TPH TLP Prefix.
 - When the TH bit is Clear, the PH field is Reserved.
 - The TH bit and the PH field are not applicable and are Reserved for all other Requests.
- For Requests that target Memory Space, the TPH TLP Prefix may be present if the value of the TH bit is 0b. When the AMA Valid (AV) bit is 1b and the TPH TLP Prefix is present, AMA is present and meaningful in the TPH TLP Prefix.
- For Requests that target Memory Space with the AT field not set to 10b, the AMA field in the TPH TLP Prefix is Reserved.
- The Processing Hints (PH) fields mapping is shown in § Figure 2-41, § Figure 2-42 and § Table 2-17.

Figure 2-41 Location of PH[1:0] in a 4 DW Request Header - Non-Flit Mode §

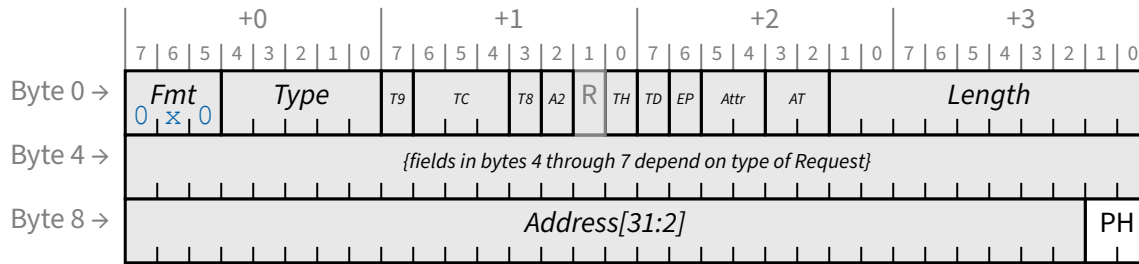

Figure 2-42 Location of PH[1:0] in a 3 DW Request Header - Non-Flit Mode §

Table 2-17 Location of PH[1:0] in TLP Header §

PH	32-bit Addressing	64-bit Addressing
1:0	Bits 1:0 of Byte 11	Bits 1:0 of Byte 15

- The PH[1:0] field provides information about the data access patterns and is defined as described in § Table 2-18.

Table 2-18 Processing Hint Encoding §

PH[1:0] (b)	Processing Hint	Description
00	Bi-directional data structure	Indicates frequent read and/or write access to data by Host and device
01	Requester	Indicates frequent read and/or write access to data by device
10	Target	Indicates frequent read and/or write access to data by Host
11	Target with Priority	Indicates frequent read and/or write access by Host and indicates high temporal locality for accessed data

The Steering Tag (ST) fields are mapped to the TLP header as shown in § Figure 2-43, § Figure 2-44 and § Table 2-19.

Figure 2-43 Location of ST[7:0] in the Memory Write Request Header - Non-Flit Mode §

Figure 2-44 Location of ST[7:0] in Memory Read, DMWr, and AtomicOp Request Headers - Non-Flit Mode §

Table 2-19 Location of ST[7:0] in TLP Headers §

ST Bits	Memory Write Request	Memory Read Request or AtomicOp Request
7:0	Bits 7:0 of Byte 6	Bits 7:0 of Byte 7

- ST[7:0] field carries the Steering Tag value
 - A value of Zero indicates no Steering Tag preference
 - A total of 255 unique Steering Tag values are provided
- A Function that does not support the TPH Completer or Routing capability and receives a transaction with the TH bit Set is required to ignore the TH bit and handle the Request in the same way as Requests of the same transaction type without the TH bit Set.

2.2.7.2 Flit Mode §

Except as stated, rules that apply in Non-Flit Mode also apply in Flit Mode.

- All Memory, I/O, and Configuration Requests include the following fields in addition to the common header fields:
 - A Transaction ID, consisting of Requester ID[15:0] and Tag[13:0], and, for Memory Requests, sometimes also including the Requester Segment[7:0]
- Byte Enable rules are in § Section 2.2.5.2.
- For non-UIO Memory Requests, including AtomicOp and DMWr, the rules for the formation and processing of Header Fields are the same as in Non-Flit Mode.
- For UIO Requests, the rules for the formation and processing of Header Fields are the same as in Non-Flit Mode with the following exception:
 - Attr[2:1], corresponding to IDO and RO in non-UIO Memory Requests, are Reserved
 - AT[1:0] value of 01b is Reserved (See § Section 10.2.2)
 - When multiple outstanding Group II UIO Requests are issued using the same Transaction ID (see § Section 2.2.6.2), all outstanding Requests using a given Transaction ID must have the same value for Attr[0] (i.e., No Snoop).
- For IO Requests, the rules for the formation and processing of Header Fields are the same as in Non-Flit Mode.
- Configuration Requests must include OHC-A3.
- Configuration Requests must only include OHC-C when they are associated with an IDE stream.
- UIO Requests are only defined for Flit Mode.

- The following figures illustrate currently defined Flit Mode Request Headers:
 - Reserved Requests (as indicated in § Table 2-5), are defined in § Section 2.2.4.1 and § Section 2.2.4.2 .

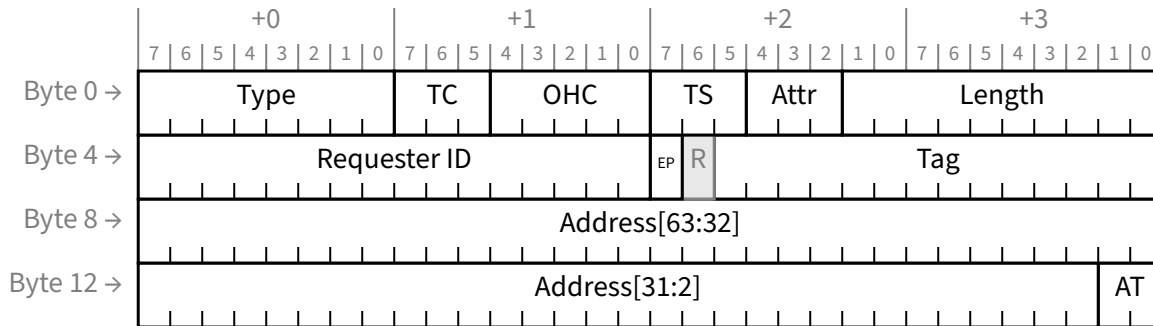

Figure 2-45 Flit Mode Mem64 Request §

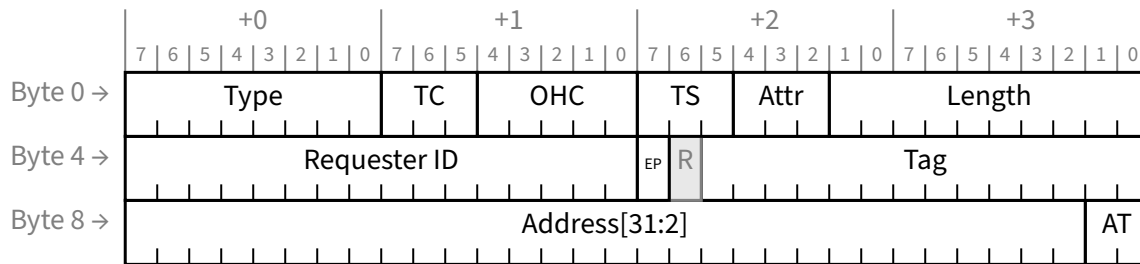

Figure 2-46 Flit Mode Mem32 Request §

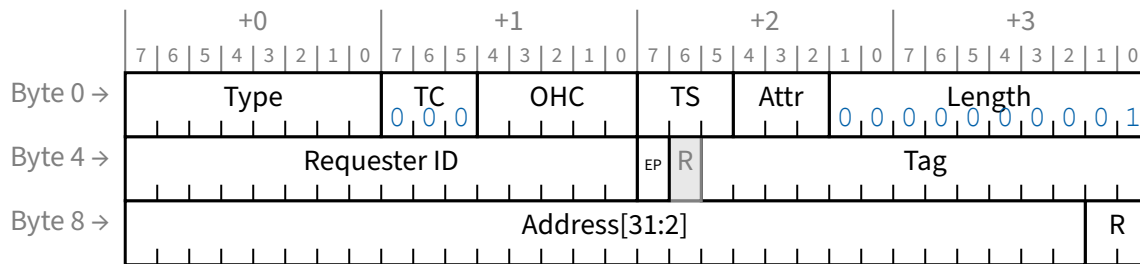

Figure 2-47 Flit Mode IO Request §

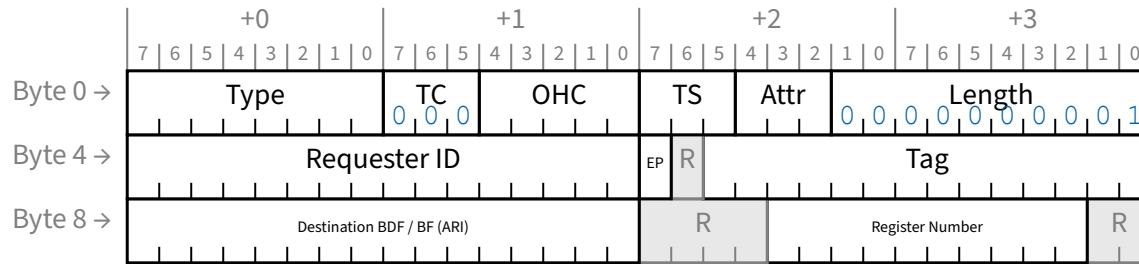

Figure 2-48 Flit Mode Configuration Request §

2.2.8 Message Request Rules §

This document defines the following groups of Messages:

- INTx Interrupt Signaling
- Power Management
- Error Signaling
- Locked Transaction Support
- Slot Power Limit Support
- Vendor-Defined Messages
- Latency Tolerance Reporting (LTR) Messages
- Optimized Buffer Flush/Fill (OBFF) Messages
- Device Readiness Status (DRS) Messages
- Function Readiness Status (FRS) Messages
- Hierarchy ID Messages
- Precision Time Measurement (PTM) Messages
- Integrity and Data Encryption (IDE) Messages

The following rules apply to all Message Requests. Additional rules specific to each type of Message follow.

- All Message Requests include the following fields in addition to the common header fields (see § Figure 2-49 and § Figure 2-50):
 - Requester ID[15:0]
 - Message Code[7:0] - Indicates the particular Message embodied in the Request.
 - EP - For Messages with data only, indicates data payload is poisoned (see § Section 2.7); Reserved for Messages without data.
- All Message Requests use the Msg or MsgD TLP Type.
- The Message Code field must be fully decoded (Message aliasing is not permitted).
- The Attr[2] field is not Reserved unless specifically indicated as Reserved.
- Except as noted, the Attr[1:0] field is Reserved.
- Except as noted, TH is not applicable to Message Requests and the bit is Reserved.

- AT[1:0] must be 00b except for Routed by Address Messages in Flit Mode (see § Table 2-20). Receivers are not required or encouraged to check this.
- Bytes 8 through 15 are Reserved unless specifically defined.
- Bytes 8 through 15 must be copied intact during Translation between Flit Mode and Non-Flit Mode, regardless of Message Code.
- Byte 6, bits 6:0 must be copied intact during Translation between Flit Mode and Non-Flit Mode, regardless of Message Code.
- Message Requests are posted and do not require Completion.
- Message Requests follow the same ordering rules as Memory Write Requests.

Many types of Messages, including Vendor-Defined Messages, are potentially usable in non-D0 states, and it is strongly recommended that the handling of Messages by Ports be the same when the Port's Bridge Function is in D1, D2, and D3_{Hot} as it is in D0. It is strongly recommended that Type 0 Functions support the generation and reception of Messages in non-D0 states.

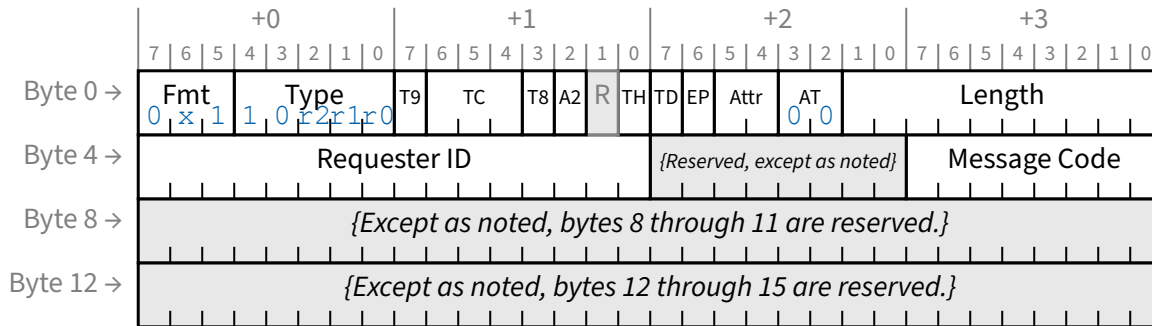

Figure 2-49 Message Request Header - Non-Flit Mode §

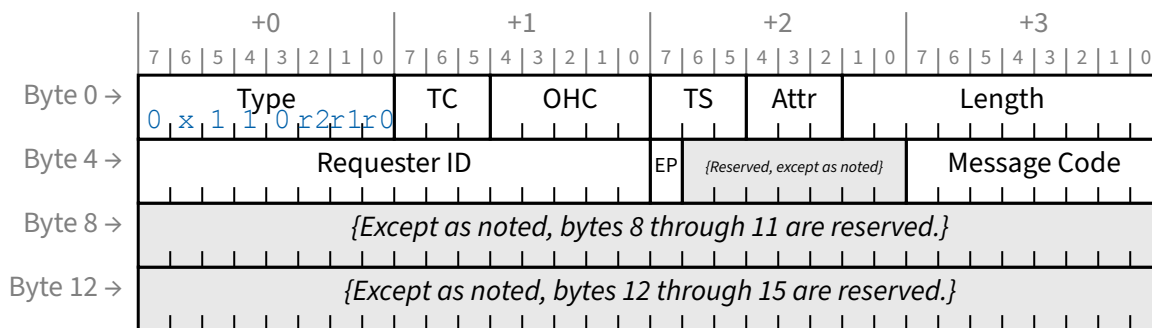

Figure 2-50 Message Request Header - Flit Mode §

In addition to address and ID routing, Messages support several other routing mechanisms. These mechanisms are referred to as “implicit” because no address or ID specifies the destination, but rather the destination is implied by the routing type. The following rules cover Message routing mechanisms:

- Message routing is determined using the r[2:0] sub-field of the Type field

- Message Routing r[2:0] values are defined in § Table 2-20
- Permitted values are defined in the following sections for each Message

Table 2-20 Message Routing §

r[2:0] (b)	Description	Bytes 8 to 15 ²²
000	Routed to Root Complex	Reserved
001	Routed by Address + AT, in Flit Mode ²³	Address/AT
010	Routed by ID	See § Section 2.2.4.2
011	Broadcast from Root Complex	Reserved
100	Local - Terminate at Receiver	Reserved
101	Gathered and routed to Root Complex ²⁴	Reserved
110 to 111	Reserved - Terminate at Receiver	Reserved

In Flit Mode, when Route by ID is used and the Destination Segment is different from the Requester Segment, OHC-A4 must be present and include the Destination Segment in byte 0 and DSV must be Set. DSV is permitted to be Set when the Destination Segment is the same as the Requester Segment. DSV must be Clear when Route by ID is not used. When DSV is clear, the Destination Segment field must be set to 00h. OHC-A4 must be present for Route by ID Messages that require PASID. OHC-A1 must be present for Routed to Root Complex Messages that require PASID, ER or PMR.

2.2.8.1 INTx Interrupt Signaling - Rules §

A Message Signaled Interrupt (MSI or MSI-X) is the preferred interrupt signaling mechanism in PCI Express (see § Section 6.1). However, in some systems, there may be Functions that cannot support the MSI or MSI-X mechanisms. The INTx virtual wire interrupt signaling mechanism is used to support Legacy Endpoints and PCI Express/PCI(-X) Bridges in cases where the MSI or MSI-X mechanisms cannot be used. Switches must support this mechanism. The following rules apply to the INTx Interrupt Signaling mechanism:

- The INTx mechanism uses eight distinct Messages (see § Table 2-21).
- Assert_INTx/Deassert_INTx Messages do not include a data payload (TLP Type is Msg).
- The Length field is Reserved.
- With Assert_INTx/Deassert_INTx Messages, the Function Number field in the Requester ID must be 0. Note that the Function Number field is a different size for non-ARI and ARI Requester IDs.
- Assert_INTx/Deassert_INTx Messages are only issued by Upstream Ports.
 - Receivers may optionally check for violations of this rule. If a Receiver implementing this check determines that an Assert_INTx/Deassert_INTx violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).
- Assert_INTx and Deassert_INTx interrupt Messages must use the default Traffic Class designator (TC0). Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.

22. Except as noted, e.g., Vendor-Defined Messages.

23. Note that no Messages defined in this document use Address routing.

24. This routing type is used only for PME_TO_Ack, and is described in § Section 5.3.3.2.1.

- This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-21 INTx Mechanism Messages §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support ²⁵				Description/Comments
			RC	Ep	Sw	Br	
Assert_INTA	0010 0000	100	All:				Assert INTA virtual wire
			r		tr		Note: These Messages are used for Conventional PCI-compatible INTx emulation.
			As Required:				
				t		t	
Assert_INTB	0010 0001	100	All:				Assert INTB virtual wire
			r		tr		
			As Required:				
				t		t	
Assert_INTC	0010 0010	100	All:				Assert INTC virtual wire
			r		tr		
			As Required:				
				t		t	
Assert_INTD	0010 0011	100	All:				Assert INTD virtual wire
			r		tr		
			As Required:				
				t		t	
Deassert_INTA	0010 0100	100	All:				Deassert INTA virtual wire
			r		tr		
			As Required:				
				t		t	
Deassert_INTB	0010 0101	100	All:				Deassert INTB virtual wire
			r		tr		
			As Required:				
				t		t	
Deassert_INTC	0010 0110	100	All:				Deassert INTC virtual wire
			r		tr		

25. Abbreviations: RC = Root Complex Sw = Switch (only used with “Link” routing) Ep = Endpoint Br = PCI Express (primary) to PCI/PCI-X (secondary) Bridge r = Supports as Receiver t = Supports as Transmitter

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
			As Required:				
				t		t	
Deassert_INTD	0010 0111	100	All:				Deassert INTD virtual wire
			r		tr		
			As Required:				
				t		t	

The Assert_INTx/Deassert_INTx Message pairs constitute four “virtual wires” for each of the legacy PCI interrupts designated A, B, C, and D. The following rules describe the operation of these virtual wires:

- The components at both ends of each Link must track the logical state of the four virtual wires using the Assert/Deassert Messages to represent the active and inactive transitions (respectively) of each corresponding virtual wire.
 - An Assert_INTx represents the active going transition of the INTx (x = A, B, C, or D) virtual wire
 - A Deassert_INTx represents the inactive going transition of the INTx (x = A, B, C, or D) virtual wire
- When the local logical state of an INTx virtual wire changes at an Upstream Port, the Port must communicate this change in state to the Downstream Port on the other side of the same Link using the appropriate Assert_INTx or Deassert_INTx Message.

Note: Duplicate Assert_INTx/Deassert_INTx Messages have no effect, but are not errors.

- INTx Interrupt Signaling is disabled when the Interrupt Disable bit of the Command register (see [§ Section 7.5.1.1.3](#)) is Set.
 - Any INTx virtual wires that are active when the Interrupt Disable bit is Set must be deasserted by transmitting the appropriate Deassert_INTx Message(s).
- Virtual and actual PCI to PCI Bridges must map the virtual wires tracked on the secondary side of the Bridge according to the Device Number of the device on the secondary side of the Bridge, as shown in [§ Table 2-22](#).
- Switches must track the state of the four virtual wires independently for each Downstream Port, and present a “collapsed” set of virtual wires on its Upstream Port.
- If a Switch Downstream Port goes to DL_Down status, the INTx virtual wires associated with that Port must be deasserted, and the Switch Upstream Port virtual wire state updated accordingly.
 - If this results in deassertion of any Upstream INTx virtual wires, the appropriate Deassert_INTx Message(s) must be sent by the Upstream Port.
- The Root Complex must track the state of the four INTx virtual wires independently for each of its Downstream Ports, and map these virtual signals to system interrupt resources.
 - Details of this mapping are system implementation specific.
- If a Downstream Port of the Root Complex goes to DL_Down status, the INTx virtual wires associated with that Port must be deasserted, and any associated system interrupt resource request(s) must be discarded.

Table 2-22 Bridge Mapping for INTx Virtual Wires §

Requester ID[7:3] from the Assert_INTx/Deassert_INTx Message received on Secondary Side of Bridge (Interrupt Source ²⁶) If ARI Forwarding is enabled, the value 0 must be used instead of Requester ID[7:3].	INTx Virtual Wire on Secondary Side of Bridge	Mapping to INTx Virtual Wire on Primary Side of Bridge

	INTB	INTA
	INTC	INTB
	INTD	INTC

IMPLEMENTATION NOTE: SYSTEM INTERRUPT MAPPING §

Note that system software (including BIOS and operating system) needs to comprehend the remapping of legacy interrupts (INTx mechanism) in the entire topology of the system (including hierarchically connected Switches and subordinate PCI Express/PCI Bridges) to establish proper correlation between PCI Express device interrupt and associated interrupt resources in the system interrupt controller. The remapping described by § Table 2-22 is applied hierarchically at every Switch. In addition, PCI Express/PCI and PCI/PCI Bridges perform a similar mapping function.

26. The Requester ID of an Assert_INTx/Deassert_INTx Message will correspond to the Transmitter of the Message on that Link, and not necessarily to the original source of the interrupt.

IMPLEMENTATION NOTE: VIRTUAL WIRE MAPPING FOR INTX INTERRUPTS FROM ARI DEVICES §

The implied Device Number for an ARI Device is 0. When ARI-aware software (including BIOS and operating system) enables ARI Forwarding in the Downstream Port immediately above an ARI Device in order to access its Extended Functions, software must comprehend that the Downstream Port will use Device Number 0 for the virtual wire mappings of INTx interrupts coming from all Functions of the ARI Device. If non-ARI-aware software attempts to determine the virtual wire mappings for Extended Functions, it can come up with incorrect mappings by examining the traditional Device Number field and finding it to be non-0.

2.2.8.2 Power Management Messages §

These Messages are used to support PCI Express power management, which is described in detail in § Chapter 5. . The following rules define the Power Management Messages:

- § Table 2-23 defines the Power Management Messages.
- Power Management Messages do not include a data payload (TLP Type is Msg).
- The Length field is Reserved.
- With PM_Active_State_Nak Messages, the Function Number field in the Requester ID must contain the Function Number of the Downstream Port that sent the Message, or else 000b for compatibility with earlier revisions of this specification.
- With PME_TO_Ack Messages, the Function Number field in the Requester ID must be Reserved, or else for compatibility with earlier revisions of this specification must contain the Function Number of one of the Functions associated with the Upstream Port. Note that the Function Number field is a different size for non-ARI and ARI Requester IDs.
- Power Management Messages must use the default Traffic Class designator (TC0). Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-23 Power Management Messages §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
PM_Active_State_Nak	0001 0100	100	t	r	tr	r	Terminate at Receiver
PM_PME	0001 1000	000	All:				Sent Upstream by PME-requesting component. Propagates Upstream.
			r		tr	t	
			If PME supported:				
			t				

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
PME_Turn_Off	0001 1001	011	t	r		r	Broadcast Downstream
PME_TO_Ack	0001 1011	101	r	t		t	Sent Upstream by Upstream Port. See § Section 5.3.3.2.1 .
			(Note: Switch handling is special)				

2.2.8.3 Error Signaling Messages §

Error Signaling Messages are used to signal errors that occur on specific transactions and errors that are not necessarily associated with a particular transaction. These Messages are initiated by the agent that detected the error.

- § Table 2-24 defines the Error Signaling Messages.
- Error Signaling Messages do not include a data payload (TLP Type is Msg).
- The Length field is Reserved.
- With Error Signaling Messages, the Function Number field in the Requester ID must indicate which Function is signaling the error. Note that the Function Number field is a different size for non-ARI and ARI Requester IDs.
- Error Signaling Messages must use the default Traffic Class designator (TC0) Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-24 Error Signaling Messages §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
ERR_COR	0011 0000	000	r	t	tr	t	This Message is issued when the Function or Device detects a correctable error on the PCI Express interface.
ERR_NONFATAL	0011 0001	000	r	t	tr	t	This Message is issued when the Function or Device detects a Non-Fatal, uncorrectable error on the PCI Express interface.
ERR_FATAL	0011 0011	000	r	t	tr	t	This Message is issued when the Function or Device detects a Fatal, uncorrectable error on the PCI Express interface.

The initiator of the Message is identified with the Requester ID of the Message header. The Root Complex translates these error Messages into platform level events. Refer to § Section 6.2 for details on uses for these Messages.

- ERR_COR Messages have an ERR_COR Subclass (ECS) field in the Message header that enables different subclasses to be distinguished from each other. See § Figure 2-51. ERR_NONFATAL and ERR_FATAL Messages do not have the ECS field.

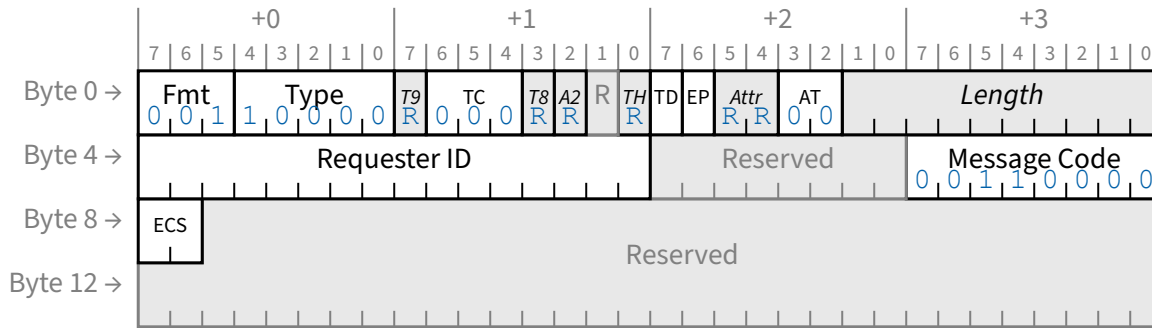

Figure 2-51 **ERR_COR Message - Non-Flit Mode** §

Figure 2-52 **ERR_COR Message - Flit Mode** §

- The ERR_COR Subclass (ECS) field is encoded as shown in § Table 2-25, indicating the ERR_COR Message subclass.

Table 2-25 **ERR_COR Subclass (ECS) Field Encodings** §

ECS Coding	Description
00	ECS Legacy - The value inherently used if a Requester does not support ECS capability. ECS-capable Requesters must not use this value. See § Section 7.5.3.3 .
01	ECS SIG_SFW - Must be used by an ECS-capable Requester when signaling a DPC or SFI event with an ERR_COR Message.
10	ECS SIG_OS - Must be used by an ECS-capable Requester when signaling an AER or RP PIO event with an ERR_COR Message.
11	ECS Extended - Intended for possible future use. Requesters must not use this value. Receivers must handle the signal internally the same as ECS SIG_OS.

2.2.8.4 Locked Transactions Support §

The Unlock Message is used to support Lock Transaction sequences. Refer to § Section 6.5 for details on Lock Transaction sequences. The following rules apply to the formation of the Unlock Message:

- § Table 2-26 defines the Unlock Messages.
- The Unlock Message does not include a data payload (TLP Type is Msg).
- The Length field is Reserved.
- With Unlock Messages, the Function Number field in the Requester ID is Reserved.
- The Unlock Message must use the default Traffic Class designator (TC0). Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-26 Unlock Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
Unlock	0000 0000	011	t	r	tr	r	Unlock Completer

2.2.8.5 Slot Power Limit Support §

This Message is used to convey a slot power limitation value from a Downstream Port (of a Root Complex or a Switch) to an Upstream Port of a component (with Endpoint, Switch, or PCI Express-PCI Bridge Functions) attached to the same Link.

- § Table 2-27 defines the Set_Slot_Power_Limit Message.
- The Set_Slot_Power_Limit Message includes a 1 DW data payload (TLP Type is MsgD).
- The Set_Slot_Power_Limit Message must use the default Traffic Class designator (TC0). Receivers must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-27 Set_Slot_Power_Limit Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
Set_Slot_Power_Limit	0101 0000	100	t	r	tr	r	Set Slot Power Limit in Upstream Port

The Set_Slot_Power_Limit Message includes a one DW data payload. The data payload is copied from the Slot Capabilities register of the Downstream Port and is written into the Device Capabilities register of the Upstream Port on the other side of the Link. Bits 1:0 of Byte 1 of the data payload map to the Slot Power Limit Scale field and bits 7:0 of Byte 0 map to the Slot Power Limit Value field. Bits 7:0 of Byte 3, 7:0 of Byte 2, and 7:2 of Byte 1 of the data payload must all be set to zero by the Transmitter and ignored by the Receiver. This Message must be sent automatically by the Downstream Port (of a Root Complex or a Switch) when one of the following events occurs:

- On a Configuration Write to the Slot Capabilities register (see § Section 7.5.3.9) when the Data Link Layer reports DL_Up status.
- Any time when a Link transitions from a non-DL_Up status to a DL_Up status (see § Section 2.9.2) and the Auto Slot Power Limit Disable bit is Clear in the Slot Control Register. This transmission is optional if the Slot Capabilities register has not yet been initialized.

The component on the other side of the Link (with Endpoint, Switch, or Bridge Functions) that receives Set_Slot_Power_Limit Message must copy the values in the data payload into the Device Capabilities register associated with the component's Upstream Port. PCI Express components that are targeted exclusively for integration on the system planar (e.g., system board) as well as components that are targeted for integration on an adapter where power consumption of the entire adapter is below the lowest power limit specified for the adapter form factor (as defined in the corresponding form factor specification) are permitted to hardwire the value of all 0's in the Captured Slot Power Limit Scale and Captured Slot Power Limit Value fields of the Device Capabilities Register, and are not required to copy the Set_Slot_Power_Limit Message payload into that register.

For more details on Power Limit control mechanism see § Section 6.9 .

2.2.8.6 Vendor-Defined Messages §

The Vendor-Defined Messages allow expansion of PCI Express messaging capabilities, either as a general extension to [PCIe] or a vendor-specific extension. This section defines the rules associated with these Messages generically.

- The Vendor-Defined Messages (see § Table 2-28) use the header format shown in § Figure 2-53.
 - The Requester ID is implementation specific. The Requester ID field *MUST@FLIT* contain the value associated with the Requester.²⁷
 - If the Route by ID routing is used, bytes 8 and 9 form a 16-bit field for the destination ID
 - otherwise these bytes are Reserved.
 - Bytes 10 and 11 form a 16-bit field for the Vendor ID, as defined by PCI-SIG[®], of the vendor defining the Message.
 - Bytes 12 through 15 are available for vendor definition.
 - The low 7 bits of byte 6 is available for vendor definition. Byte 6, bit 7 is Reserved in Non-Flit Mode and is the EP bit in Flit Mode.

Table 2-28 Vendor-Defined Messages §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
Vendor-Defined Type 0	0111 1110	000, 010, 011, 100	See Note 1.				Triggers detection of UR by Completer if not implemented.
Vendor-Defined Type 1	0111 1111	000, 010, 011, 100	See Note 1.				Silently discarded by Completer if not implemented.

1. Note 1: Transmission by Endpoint/Root Complex/Bridge is implementation specific. Switches must forward received Messages using Routing r[2:0] field values of 000b, 010b, and 011b.

27. ACS Source Validation (see § Section 6.12.1.1) checks the Requester ID on all Requests, including Vendor-Defined Messages. This validation depends on the Requester ID properly identifying the Requester.

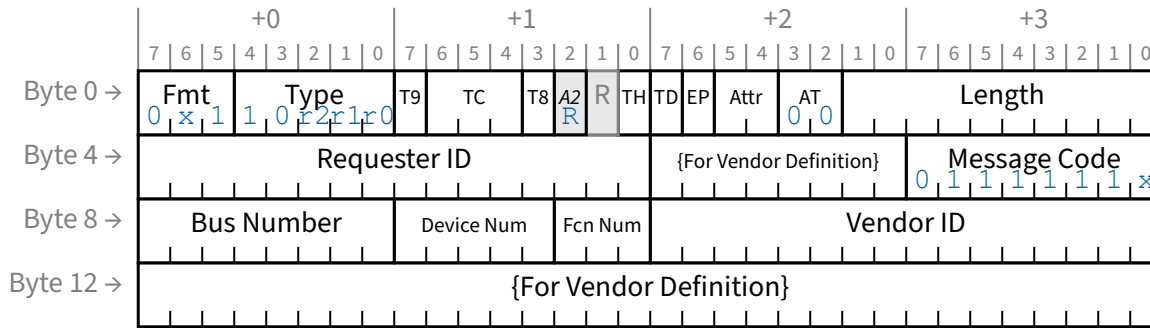

Figure 2-53 Header for Vendor-Defined Messages - Non-Flit Mode §

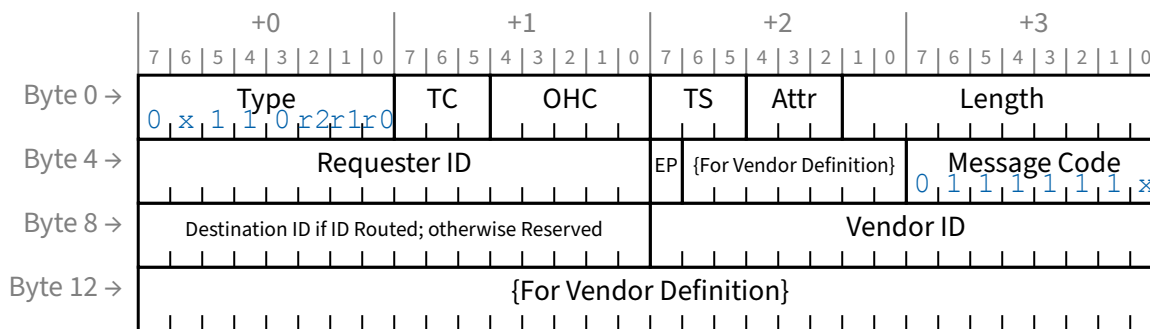

Figure 2-54 Header for Vendor-Defined Messages - Flit Mode §

- A data payload may be included with either type of Vendor-Defined Message (TLP type is Msg if no data payload is included or MsgD if a data payload is included).
- For both types of Vendor-Defined Messages, the Attr[1:0] and Attr[2] fields are not Reserved.
- Messages defined by different vendors or by PCI-SIG are distinguished by the value in the Vendor ID field.
 - The further differentiation of Messages defined by a particular vendor is beyond the scope of this document.
 - Support for Messages defined by a particular vendor is implementation specific, and beyond the scope of this document.
- Completers silently discard Vendor-Defined Type 1 Messages that they are not designed to receive - this is not an error condition.
 - When an ID Routed Message targeting a Function that is not implemented is detected, it is implementation specific whether that message is silently discarded or signals Unsupported Request.
- Completers handle the receipt of an unsupported Vendor-Defined Type 0 Message as an Unsupported Request, and the error is reported according to § Section 6.2 .

[PCIe-to-PCI-PCI-X-Bridge] defines additional requirements for Vendor-Defined Messages that are designed to be interoperable with PCI-X Device ID Messages. This includes restrictions on the contents of the Tag[7:0] field and the Length[9:0] field as well as specific use of Bytes 12 through 15 of the message header. Vendor-Defined Messages intended for use solely within a PCI Express environment (i.e., not intended to address targets behind a PCI Express to

PCI/PCI-X Bridge) are not subject to the additional rules. Refer to [PCIe-to-PCI-PCI-X-Bridge] for details. Refer to § Section 2.2.6.2 for considerations regarding larger-Tag capabilities.

2.2.8.6.1 PCI-SIG Defined VDMs §

PCI-SIG-Defined VDMs are Vendor-Defined Type 1 Messages that use the PCI-SIG® Vendor ID (0001h). As a Vendor-Defined Type 1 Message, each is silently discarded by a Completer if the Completer does not implement it.

Beyond the rules for other Vendor-Defined Type 1 Messages, the following rules apply to the formation of the PCI-SIG-Defined VDMs:

- PCI-SIG-Defined VDMs use the Header format shown in § Figure 2-55.
- The Requester ID field must contain the value associated with the Requester.
- The Message Code must be 01111111b.
- The Vendor ID must be 0001h, which is assigned to the PCI-SIG.
- The Subtype field distinguishes the specific PCI-SIG-Defined VDMs. See § Appendix F. for a list of PCI-SIG-Defined VDMs.

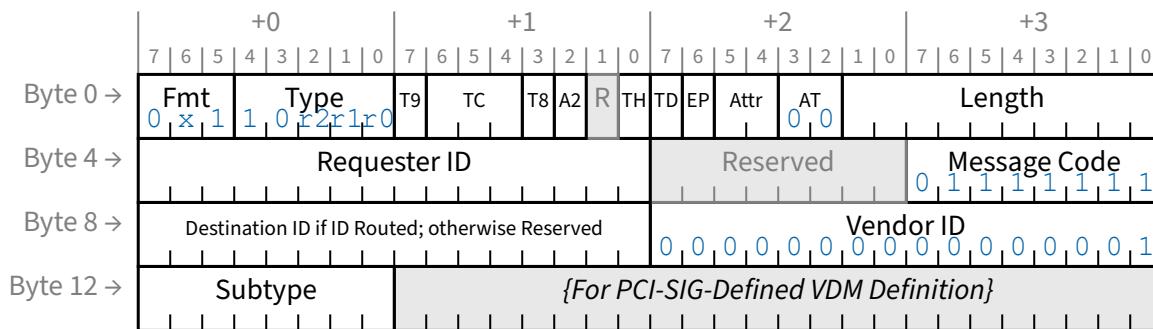

Figure 2-55 Header for PCI-SIG-Defined VDMs - Non-Flit Mode §

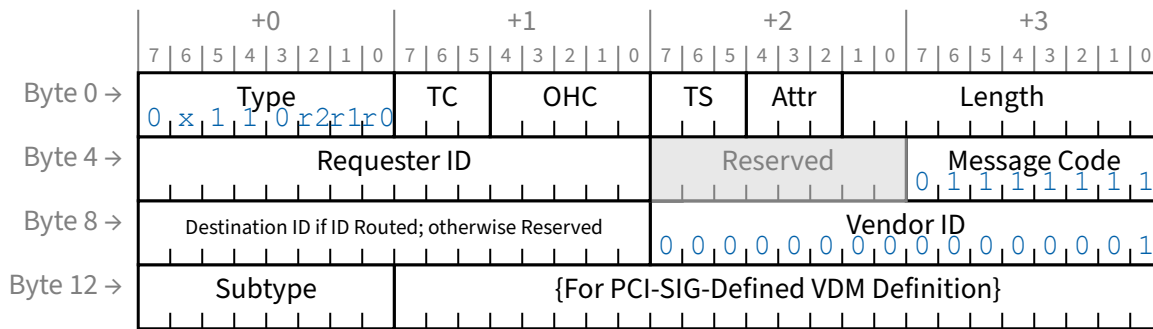

Figure 2-56 Header for PCI-SIG-Defined VDMs - Flit Mode §

2.2.8.6.2 Device Readiness Status (DRS) Message §

The Device Readiness Status (DRS) protocol (see § Section 6.22.1) uses the PCI-SIG-Defined VDM mechanism (see § Section 2.2.8.6.1). The DRS Message is a PCI-SIG-Defined VDM (Vendor-Defined Type 1 Message) with no payload.

Beyond the rules for other PCI-SIG-Defined VDMs, the following rules apply to the formation of DRS Messages:

- § Table 2-29 and § Figure 2-57 illustrate and define the DRS Message.
- The TLP Type must be Msg.
- The TC[2:0] field must be 000b.
- The Attr[2:0] field is Reserved.
- The Tag field is Reserved.
- The Subtype field must be 08h.
- The Message Routing field must be set to 100b - Local - Terminate at Receiver.

Receivers may optionally check for violations of these rules (but must not check reserved bits). These checks are independently optional (see § Section 6.2.3.4). If a Receiver implementing these checks determines that a TLP violates these rules, the TLP is a Malformed TLP.

- If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-29 DRS Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
DRS Message	0111 1111	100	r	t	tr		Device Readiness Status

The format of the DRS Message is shown in § Figure 2-57 below:

Figure 2-57 DRS Message - Non-Flit Mode §

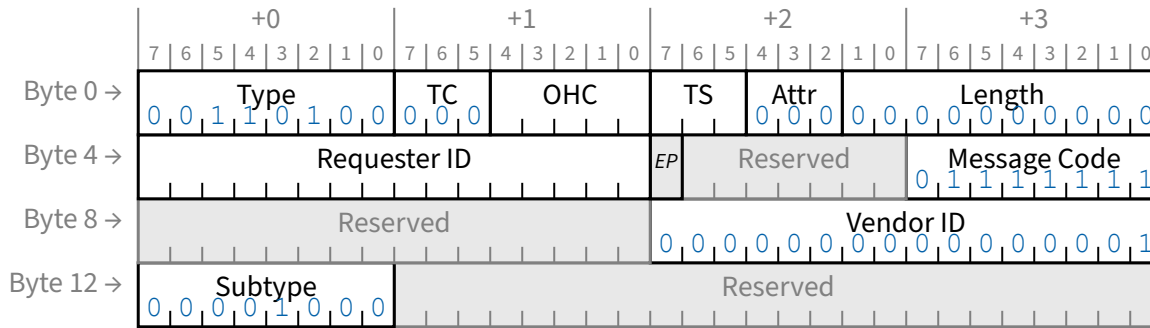

Figure 2-58 DRS Message - Flit Mode §

2.2.8.6.3 Function Readiness Status Message (FRS Message) §

The Function Readiness Status (FRS) protocol (see § Section 6.22.2) uses the PCI-SIG-Defined VDM mechanism (see § Section 2.2.8.6.1). The FRS message is a PCI-SIG-Defined VDM (Vendor-Defined Type 1 Message) with no payload.

Beyond the rules for other PCI-SIG-Defined VDMs, the following rules apply to the formation of FRS Messages:

§ Table 2-30 and § Figure 2-59 illustrate and define the FRS Message.

- The TLP Type must be Msg.
- The TC[2:0] field must be 000b.
- The Attr[2:0] field is Reserved.
- The Tag field is Reserved.
- The Subtype field must be 09h.
- The FRS Reason[3:0] field indicates why the FRS Message was generated:

0001b: DRS Message Received

The Downstream Port indicated by the Message Requester ID received a DRS Message and has the DRS Signaling Control field in the Link Control Register set to DRS to FRS Signaling Enabled

0010b: D3_{Hot} to D0 Transition Completed

A D3_{Hot} to D0 transition has completed, and the Function indicated by the Message Requester ID is now Configuration-Ready and has returned to the D0_{uninitialized} or D0_{active} state depending on the setting of the No_Soft_Reset bit (see § Section 7.5.2.2)

0011b: FLR Completed

An FLR has completed, and the Function indicated by the Message Requester ID is now Configuration-Ready

1000b: VF Enabled

The Message Requester ID indicates a Physical Function (PF) - All Virtual Functions (VFs) associated with that PF are now Configuration-Ready

1001b: VF Disabled

The Message Requester ID indicates a PF - All VFs associated with that PF have been disabled and the Single Root I/O Virtualization (SR-IOV) data structures in that PF may now be accessed.

Others:

All other values Reserved

- The Message Routing field must be Cleared to 000b - Routed to Root Complex

Receivers may optionally check for violations of these rules (but must not check reserved bits). These checks are independently optional (see § Section 6.2.3.4). If a Receiver implementing these checks determines that a TLP violates these rules, the TLP is a Malformed TLP.

- If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-30 FRS Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
FRS Message	0111 1111	000	r	t	tr		Function Readiness Status

The format of the FRS Message is shown in § Figure 2-59 and § Figure 2-60 below:

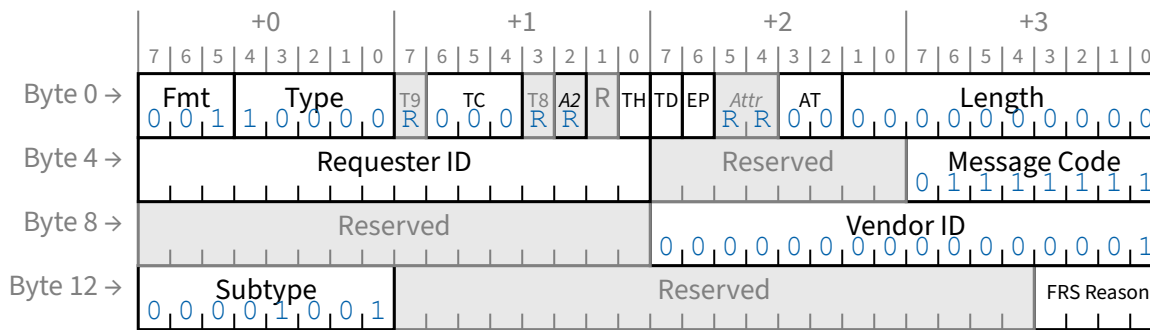

Figure 2-59 FRS Message - Non-Flit Mode §

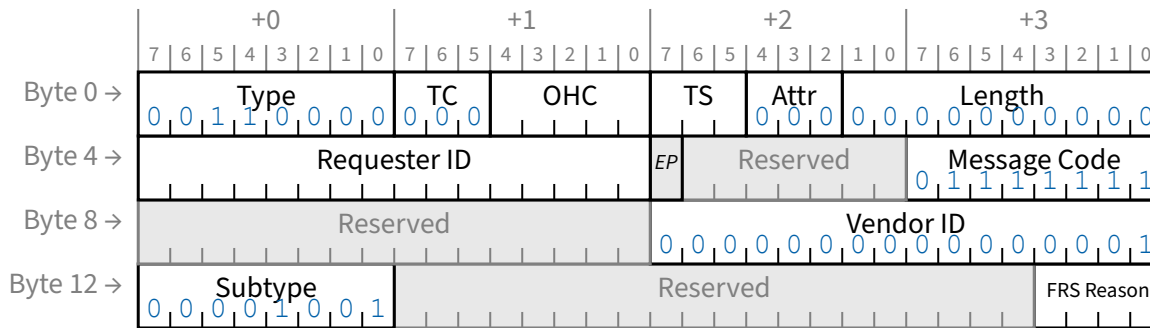

Figure 2-60 FRS Message - Flit Mode §

2.2.8.6.4 Hierarchy ID Message §

Hierarchy ID uses the PCI-SIG-Defined VDM mechanism (see § Section 2.2.8.6.1). The Hierarchy ID Message is a PCI-SIG-Defined VDM (Vendor-Defined Type 1 Message) with payload (MsgD).

Beyond the rules for other PCI-SIG-Defined VDMs, the following rules apply to the formation of Hierarchy ID Messages:

- § Table 2-31 and § Figure 2-61 illustrate and define the Hierarchy ID Message.
- The TLP Type must be MsgD.
- Each Message must include a 4-DWORD data payload.
- The Length field must be 4.
- The TC[2:0] field must be 000b.
- The Attr[2:0] field is Reserved.
- The Tag field is Reserved.
- The Subtype field is 01h.
- The Message Routing field must be 011b - Broadcast from Root Complex.

Receivers may optionally check for violations of these rules (but must not check reserved bits). These checks are independently optional (see § Section 6.2.3.4). If a Receiver implementing these checks determines that a TLP violates these rules, the TLP is a Malformed TLP.

- If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

The payload of each Hierarchy ID Message contains the lower 128-bits of the System GUID.

For details of the Hierarchy ID, GUID Authority ID, and System GUID fields see § Section 6.25.

Table 2-31 Hierarchy ID Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
Hierarchy ID Message	0111 1111	011	t	r	tr		Hierarchy ID

The format of the Hierarchy ID Message is shown in § Figure 2-61 and § Figure 2-62 below:

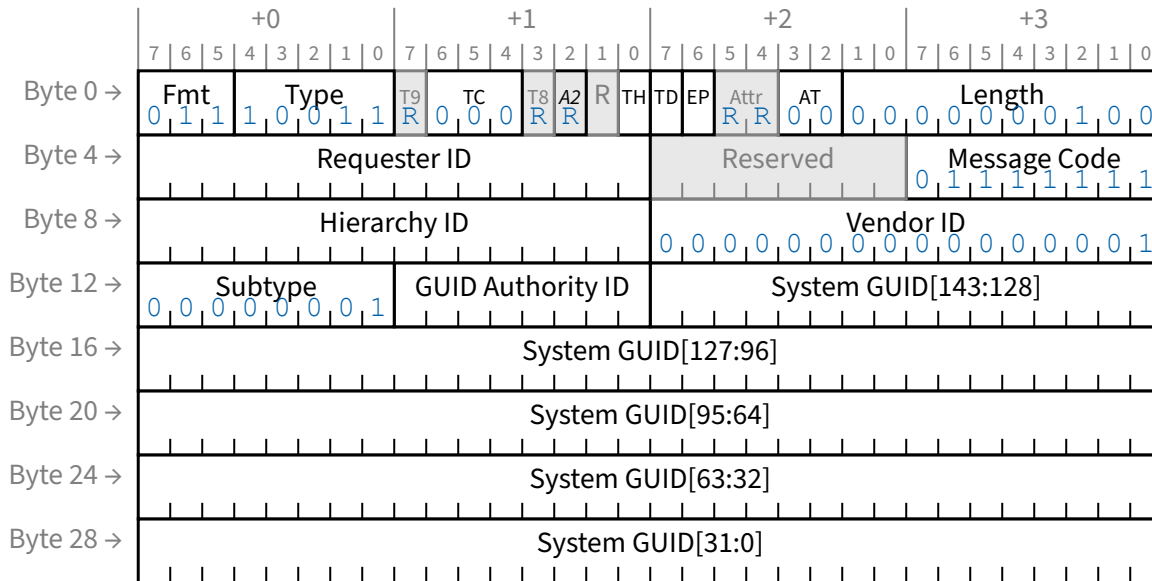

Figure 2-61 Hierarchy ID Message - Non-Flit Mode §

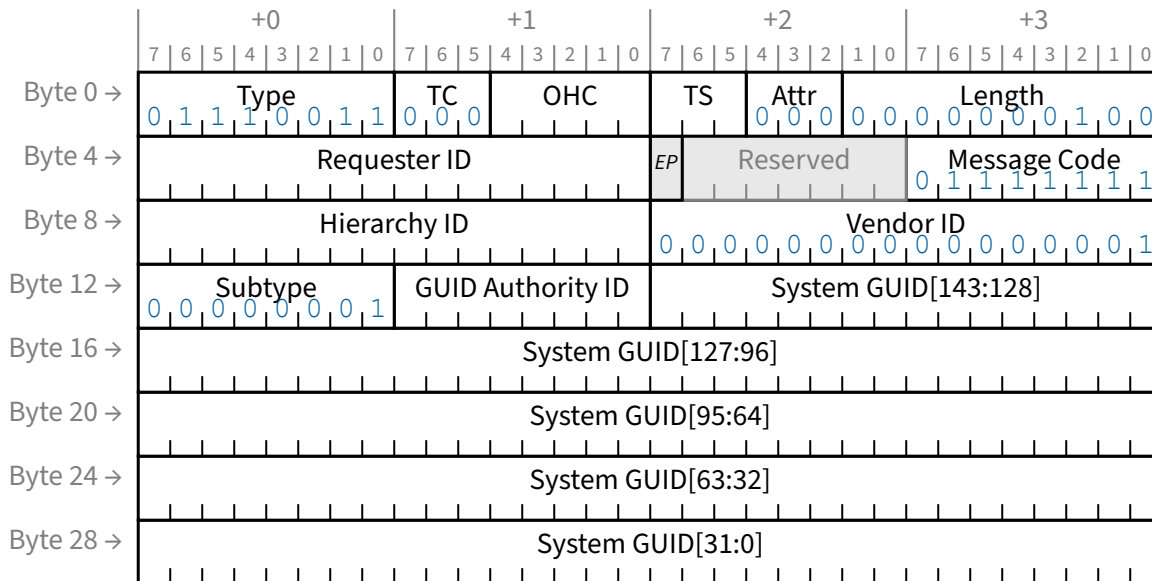

Figure 2-62 Hierarchy ID Message - Flit Mode §

2.2.8.7 Ignored Messages §

The messages listed in § Table 2-32 were previously used for a mechanism (Hot-Plug Signaling) that is no longer supported. Transmitters *MUST@FLIT* not transmit these messages. If message transmission is implemented, it must conform to the requirements of [PCIe-1.0a].

Beyond normal Link-Layer processing and mandatory checking for properly-formed TLPs, Receivers *MUST@FLIT* not process these messages further (i.e., carry out their originally architected Transaction-Layer functionality). If complete processing of these messages is implemented, Receivers must process these messages in conformance with the requirements [PCIe-1.0a].

Ignored messages listed in § Table 2-32 are handled by the Receiver as follows:

- The Physical and Data Link Layers must handle these messages identical to handling any other TLP.
- The Transaction Layer must account for flow control credit but take no other action in response to these messages.

Table 2-32 Ignored Messages §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
			RC	Ep	Sw	Br	
Ignored Message	0100 0001	100					
Ignored Message	0100 0011	100					
Ignored Message	0100 0000	100					
Ignored Message	0100 0101	100					
Ignored Message	0100 0111	100					
Ignored Message	0100 0100	100					
Ignored Message	0100 1000	100					

2.2.8.8 Latency Tolerance Reporting (LTR) Message §

The LTR Message is optionally used to report device behaviors regarding its tolerance of Read/Write service latencies. Refer to § Section 6.18 for details on LTR. The following rules apply to the formation of the LTR Message:

- § Table 2-33 defines the LTR Message.
- The LTR Message does not include a data payload (the TLP Type is Msg).
- The Length field is Reserved.
- The LTR Message must use the default Traffic Class designator (TC0). Receivers that implement LTR support must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-33 LTR Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support ¹				Description/Comments
			RC	Ep	Sw	Br	
LTR	0001 0000	100	r	t	tr		Latency Tolerance Reporting

Notes:

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support ¹				Description/Comments
			RC	Ep	Sw	Br	

- Support for LTR is optional. Functions that support LTR must implement the reporting and enable mechanisms described in § Chapter 7. .

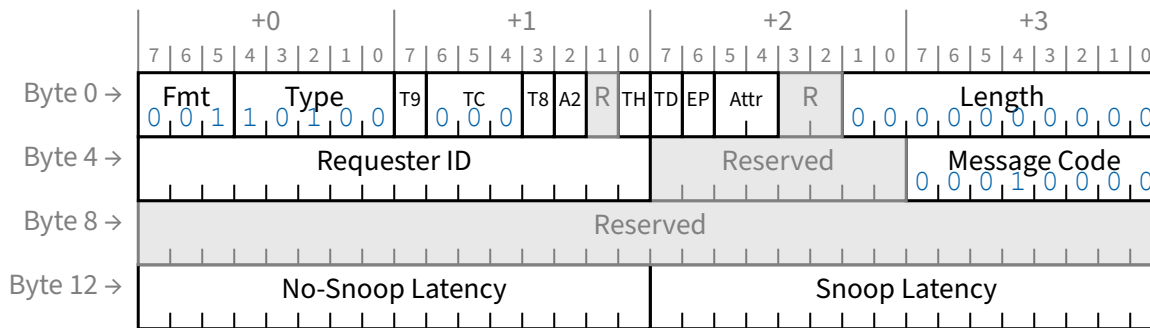

Figure 2-63 LTR Message - Non-Flit Mode §

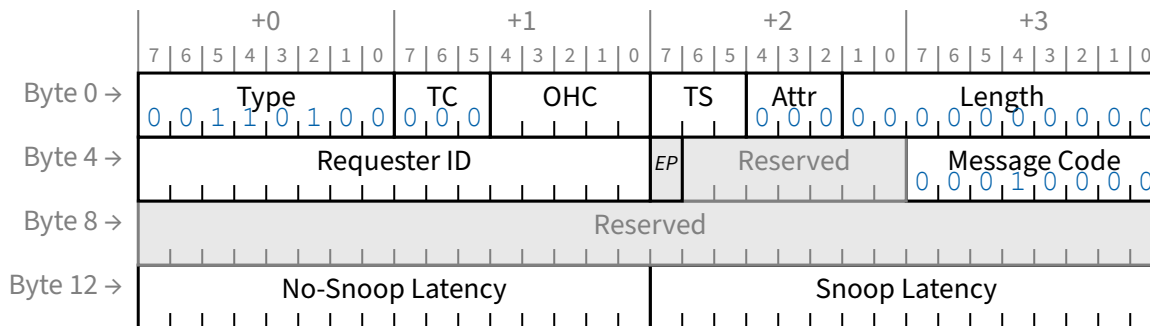

Figure 2-64 LTR Message - Flit Mode §

2.2.8.9 Optimized Buffer Flush/Fill (OBFF) Message §

The OBFF Message is optionally used to report platform central resource states to Endpoints. This mechanism is described in detail in § Section 6.19 .

The following rules apply to the formation of the OBFF Message:

- § Table 2-34 defines the OBFF Message.
- The OBFF Message does not include a data payload (TLP Type is Msg).
- The Length field is Reserved.
- The Requester ID must be set to the Transmitting Port's ID.

- The OBFF Message must use the default Traffic Class designator (TC0). Receivers that implement OBFF support must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-34 OBFF Message §

Name	Code[7:0] (b)	Routing r[2:0] (b)	Support ¹				Description/Comments
			RC	Ep	Sw	Br	
OBFF	0001 0010	100	t	r	tr		Optimized Buffer Flush/Fill

Notes:

- Support for OBFF is optional. Functions that support OBFF must implement the reporting and enable mechanisms described in § Chapter 7. , Software Initialization and Configuration.

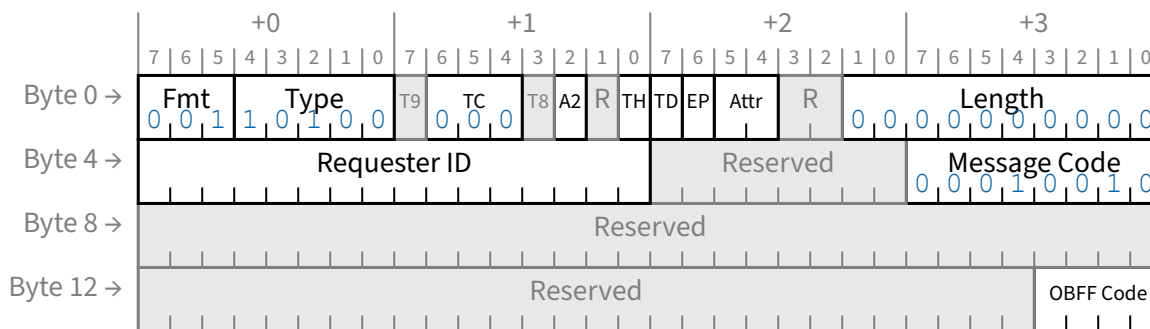

Figure 2-65 OBFF Message - Non-Flit Mode §

Figure 2-66 OBFF Message - Flit Mode §

2.2.8.10 Precision Time Measurement (PTM) Messages §

§ Table 2-35 defines the PTM Messages.

- The PTM Request and PTM Response Messages must use a TLP Type of Msg, and must not include a data payload. The Length field is reserved.
 - § Figure 2-67 illustrates the format of the PTM Request and Response Messages.
- The PTM ResponseD Message must use a TLP Type of MsgD, and must include a 64 bit PTM Master Time field in bytes 8 through 15 of the TLP header and a 1 DW data payload containing the 32 bit Propagation Delay field.
 - § Figure 2-68 illustrates the format of the PTM ResponseD Message.
 - Refer to § Section 6.21.3.2 for details regarding how to populate the PTM ResponseD Message.
- The Requester ID must be set to the Transmitting Port's ID.
- A PTM dialog is defined as a matched pair of messages consisting of a PTM Request and the corresponding PTM Response or PTM ResponseD message.
- The PTM Messages must use the default Traffic Class designator (TC0). Receivers implementing PTM must check for violations of this rule. If a Receiver determines that a TLP violates this rule, it must handle the TLP as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see § Section 6.2).

Table 2-35 Precision Time Measurement Messages §

Name	TLP Type	Code[7:0] (b)	Routing r[2:0] (b)	Support				Description/Comments
				RC	EP	Sw	Br	
PTM Request	Msg	0101 0010	100	r	t	tr		Initiates PTM dialog
PTM Response	Msg	0101 0011	100	t	r	tr		Completes current PTM dialog - does not carry timing information
PTM ResponseD	MsgD	0101 0011	100	t	r	tr		Completes current PTM dialog - carries timing information

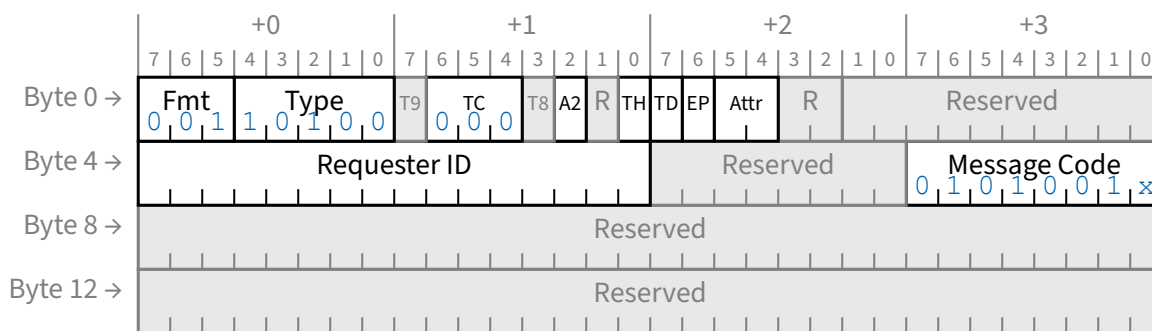

Figure 2-67 PTM Request/Response Message - Non-Flit Mode §

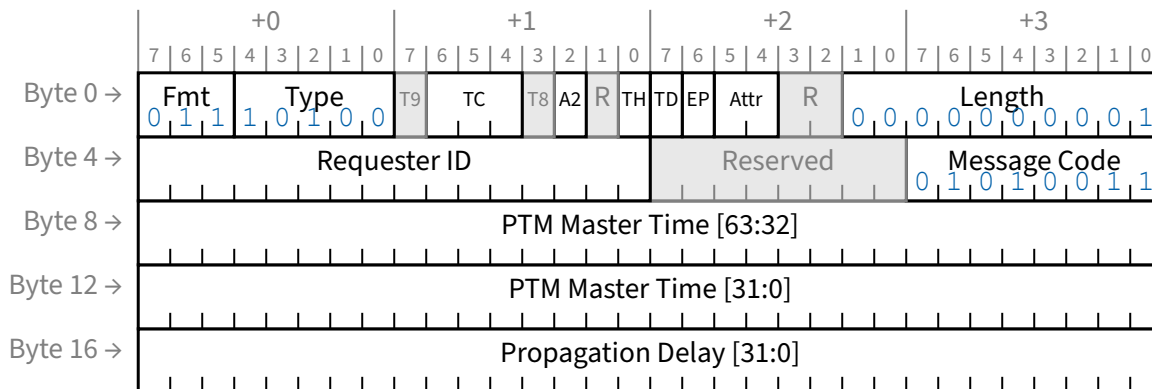

Figure 2-68 PTM ResponseD Message - Non-Flit Mode §

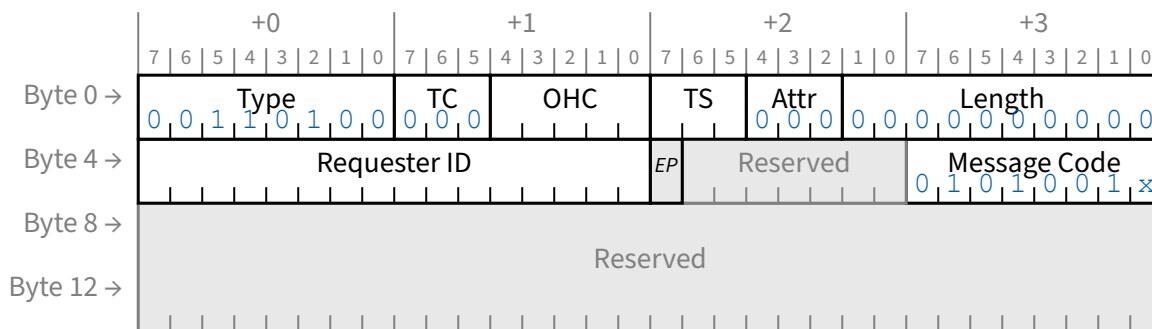

Figure 2-69 PTM Request/Response Message - Flit Mode §

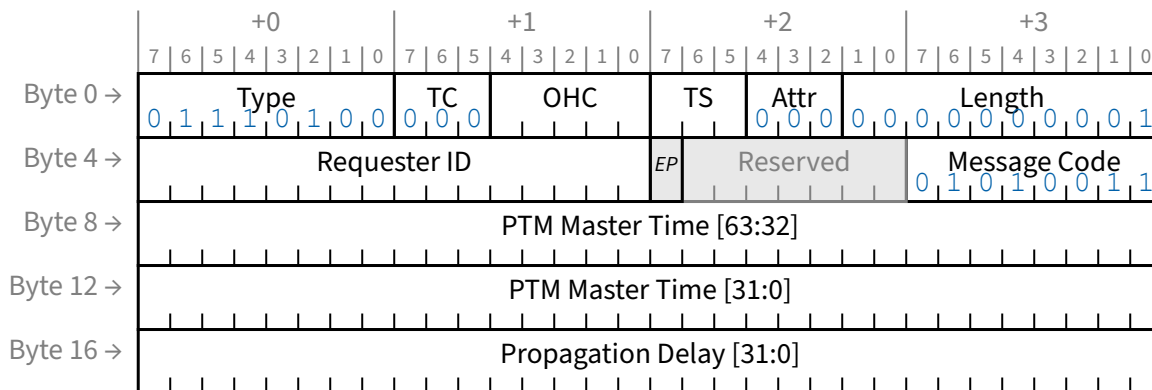

Figure 2-70 PTM ResponseD Message - Flit Mode §

IMPLEMENTATION NOTE: PROPAGATION DELAY[31:0] ENDIANNESS §

The bytes within the Propagation Delay[31:0] field (shown in § Figure 2-68) are such that:

- Data Byte 0 contains Propagation Delay [31:24]
- Data Byte 1 contains Propagation Delay [23:16]
- Data Byte 2 contains Propagation Delay [15:8]
- Data Byte 3 contains Propagation Delay [7:0]

Due to ambiguity in previous versions of this document, some implementations made this interpretation:

- Data Byte 0 contains Propagation Delay [7:0]
- Data Byte 1 contains Propagation Delay [15:8]
- Data Byte 2 contains Propagation Delay [23:16]
- Data Byte 3 contains Propagation Delay [31:24]

As a result, it is recommended that implementations provide mechanisms for adapting to either byte interpretation. One such mechanism is the optional PTM Propagation Delay Adaptation Capability.

2.2.8.11 Integrity and Data Encryption (IDE) Messages §

IDE Messages are used with the optional Integrity and Data Encryption (IDE) mechanism (see § Section 6.33). The following rules apply to the formation of IDE Messages:

- § Table 2-36 defines the IDE Messages.
- The IDE Messages do not include a data payload (TLP Type is Msg).
- The Length field is Reserved.
- The Requester ID must be set to the RID of the Function implementing IDE at the Transmitting Port.
- IDE Sync and IDE Fail Messages associated with a Link IDE Stream must use Local routing (100b).
- IDE Sync and IDE Fail Messages associated with a Selective IDE Stream must use Route by ID (010b), and the Destination ID must contain the value in the RID Base field of the Selective IDE RID Association Register Block.

These Messages must only be Transmitted if the Valid bit is Set in the Selective IDE RID Association Register for the Selective IDE Stream.

- IDE Sync and IDE Fail Messages must use the same Traffic Class designator as the associated IDE Stream.
- IDE Sync Messages are implicitly associated with the same IDE Stream as indicated in the IDE Prefix applied to the IDE Sync Message .

Table 2-36 IDE Messages §

Name	TLP Type	Code[7:0] (b)	Routing r[2:0] (b)	Support ¹				Description/Comments
				RC	EP	Sw	Br	
IDE Sync	Msg	0101 0100	010 / 100	tr	tr	tr		Synchronization of IDE PR Count for the associated IDE Stream
IDE Fail	Msg	0101 0101	010 / 100	tr	tr	tr		Notification of IDE failure for a specific IDE Stream from the detecting Port to the IDE Partner Port

Notes:

- Support for these messages is required when the optional IDE mechanism is implemented

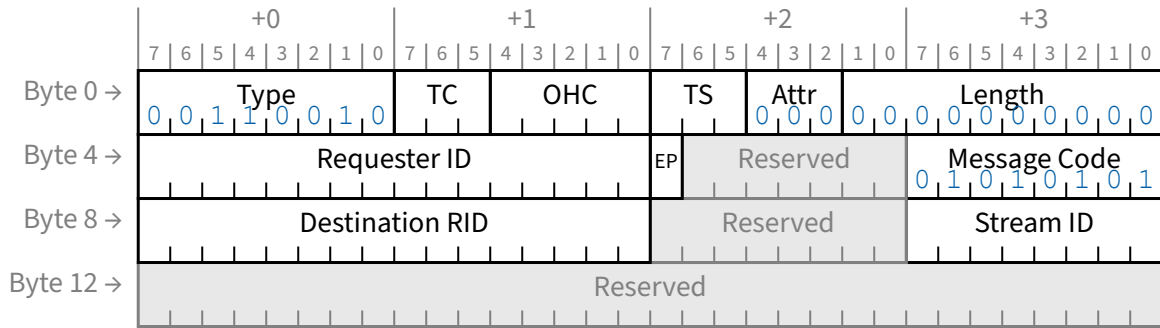

Figure 2-78 IDE Fail Message for Selective IDE Stream - Flit Mode §

2.2.9 Completion Rules §

All Read, Non-Posted Write, UIO, DMWR, and AtomicOp Requests require Completion. Completions include a Completion header that, for some types of Completions, will be followed by some number of DWs of data. The rules for each of the fields of the Completion header are defined in the following sections.

2.2.9.1 Completion Rules for Non-Flit Mode §

- Completions route by ID, and use a 3 DW header.
 - Note that the routing ID fields correspond directly to the Requester ID supplied with the corresponding Request. Thus, for Completions these fields will be referred to collectively as the Requester ID instead of the distinct fields used generically for ID routing.
- In addition to the header fields included in all TLPs and the ID routing fields, Completions contain the following additional fields (see § Figure 2-79):
 - Completer ID[15:0] - Identifies the Completer - described in detail below
 - Completion Status[2:0] - Indicates the status for a Completion (see § Table 2-37)
 - Rules for determining the value in the Completion Status[2:0] field are in § Section 2.3.1 .
 - BCM - Byte Count Modified - this bit must not be set by PCI Express Completers, and may only be set by PCI-X completers
 - Byte Count[11:0] - The remaining Byte Count for Request
 - The Byte Count value is specified as a binary number, with 0000 0000 0001b indicating 1 byte, 1111 1111 1111b indicating 4095 bytes, and 0000 0000 0000b indicating 4096 bytes.
 - For Memory Read Completions, Byte Count[11:0] is set according to the rules in § Section 2.3.1.1 .
 - For AtomicOp Completions, the Byte Count value must equal the associated AtomicOp operand size in bytes.
 - For all other types of Completions, the Byte Count value must be 4.
 - Tag[9:0] - in combination with the Requester ID field, corresponds to the Transaction ID. In Non-Flit Mode, the Tag field is 10 bits.
 - Lower Address[6:0] - lower byte address for starting byte of Completion
 - For Memory Read Completions, the value in this field is the byte address for the first enabled byte of data returned with the Completion (see the rules in § Section 2.3.1.1).
 - For AtomicOp Completions, the Lower Address field is Reserved.
 - This field is set to all 0's for all remaining types of Completions. Receivers may optionally check for violations of this rule. See § Section 2.3.2 , second bullet, for details.

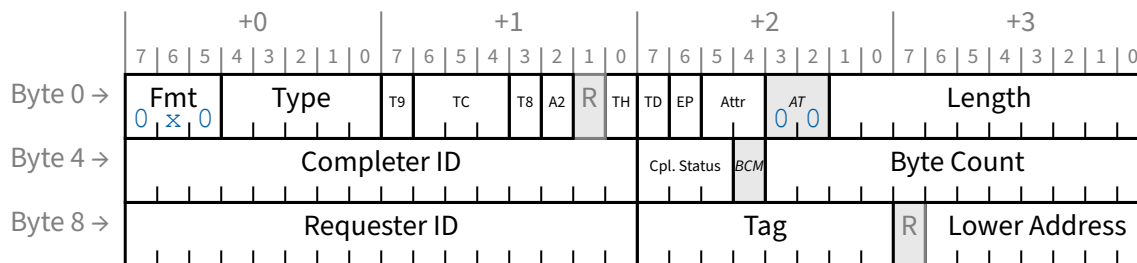

Figure 2-79 Completion Header Format - Non-Flit Mode §

Table 2-37 Completion Status Field Values §

Cpl. Status[2:0] Field Value (b)	Completion Status
000	Successful Completion (SC)
001	Unsupported Request (UR)
010	Request Retry Status (RRS)
100	Completer Abort (CA)
all others	Reserved

- The Completer ID[15:0] is a 16-bit value that is unique for every PCI Express Function within a Hierarchy (see § Figure 2-80 and § Figure 2-81)

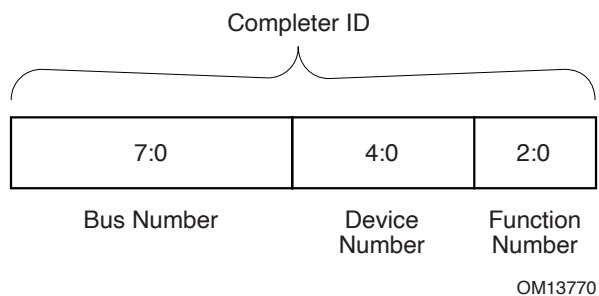

Figure 2-80 (Non-ARI) Completer ID §

Figure 2-81 ARI Completer ID §

- Functions must capture the Bus and Device Numbers²⁸ supplied with all Type 0 Configuration Write Requests completed by the Function, and supply these numbers in the Bus and Device Number fields of the Completer ID²⁹ for all Completions generated by the Device/Function.
 - If a Function must generate a Completion prior to the initial device Configuration Write Request, 0's must be entered into the Bus Number and Device Number fields
 - Note that Bus Number and Device Number may be changed at run time, and so it is necessary to re-capture this information with each and every Configuration Write Request.

28. With ARI Devices, Functions are only required to capture the Bus Number. ARI Devices are permitted to retain the captured Bus Number on either a per-Device or a per-Function basis. See § Section 2.2.6.2.

29. An ARI Completer ID does not contain a Device Number field. See § Section 2.2.4.2.

- Exception: The assignment of Bus Numbers to the Devices within a Root Complex may be done in an implementation specific way.
- In some cases, a Completion with UR Completion Status may be generated by an MFD without associating the Completion with a specific Function within the device - in this case, the Function Number field³⁰ is Reserved.
 - Example: An MFD receives a Read Request that does not target any resource associated with any of the Functions of the device - the device generates a Completion with UR status and sets a value of all 0's in the Function Number field of the Completer ID.
- Completion headers must supply the same values for the Requester ID, Tag, and Traffic Class as were supplied in the header of the corresponding Request.
- Completion headers must supply the same values for the Attribute as were supplied in the header of the corresponding Request, except as explicitly allowed:
 - when IDO is used (see § Section 2.2.6.4)
 - when RO is used in a Translation Completion (see § Section 10.2.3)
- The TH bit is reserved for Completions.
- AT[1:0] must be 00b. Receivers are not required or encouraged to check this.
- The Completer ID field is not meaningful prior to the software initialization and configuration of the completing device (using at least one Configuration Write Request), and for this case the Requester must ignore the value returned in the Completer ID field.
- A Completion including a data payload must specify the actual amount of data returned in that Completion, and must include the amount of data specified.
 - It is a TLP formation error to include more or less data than specified in the Length field, and the resulting TLP is a Malformed TLP.

Note: This is simply a specific case of the general rule requiring the TLP data payload length to match the value in the Length field.

2.2.9.2 Completion Rules for Flit Mode §

In Flit Mode, the rules for non-UIO Completions are the same as in Non-Flit Mode, except as defined in this section. In Flit Mode, Completions must use the Completion Header Base (see § Figure 2-82). UIO Write Completions and UIO Read Completions with Completion Status other than Successful Completion (i.e., without Data) must use the Header Base Format shown in § Figure 2-83. UIO Read Completions with Data must use the UIO Completion Header Base Format shown in § Figure 2-84.

In Flit Mode, the Tag field is 14 bits.

Reserved Completions (as indicated in § Table 2-5), are ID Routed TLPs as defined in § Section 2.2.4.2 .

30. With an ARI Completer ID, the Function Number field is 8 bits.

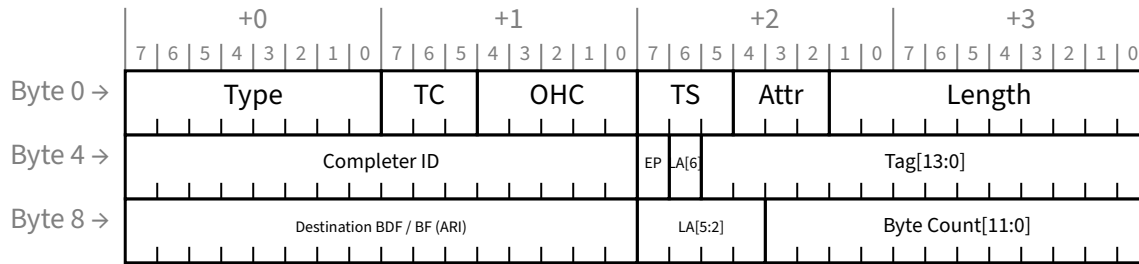

Figure 2-82 Completion Header Base Format - Flit Mode §

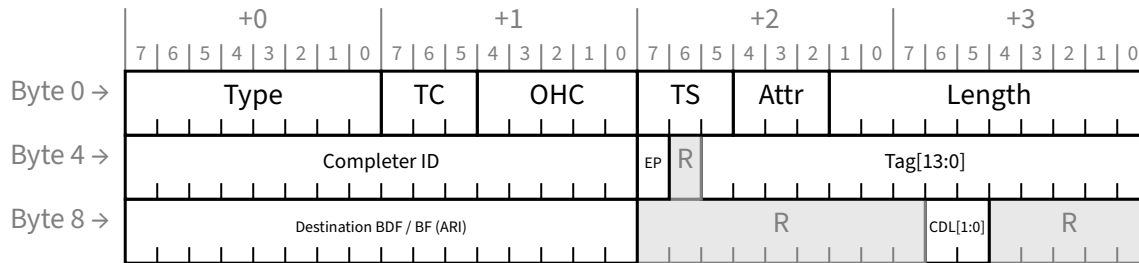

Figure 2-83 Completion Header Base Format - UIOWrCpl and UIORdCpl §

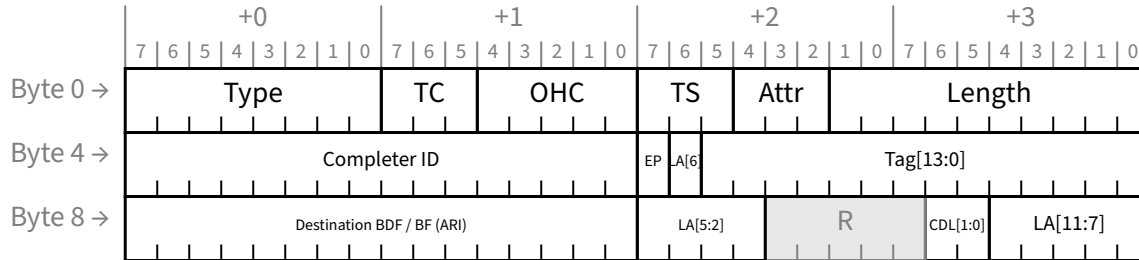

Figure 2-84 Completion Header Base Format - UIORdCplD §

OHC-A5 (see § Figure 2-11) is required for all:

- Unsuccessful Completions
- Non-UIO Completions with Lower Address[1:0] not equal to 00b
- Completions that require the Destination Segment due to the associated Non-Posted Request containing a Requester Segment that does not match the Completer's captured Segment.

When OHC-A5 is not present it is implied that the Completion Status is Successful, that Completer Segment and Destination Segment need not be explicitly indicated (see Segment rules in § Section 2.2.1.2), and that, for non-UIO Completions, the Lower Address[1:0] = 00b.

When OHC-A5 is present:

- the Completion Status and, for non-UIO Completions, Lower Address[1:0] fields must contain valid values
 - For UIO Completions, Lower Address[1:0] is Reserved
- the Completer Segment field must contain the Segment value captured by the Function as described in § Section 2.2.6.2 ; the Completer Segment field must be 00h if Segment Captured is Clear
- if the associated Request did not include a Requester Segment, the Destination Segment field must be 00h and the DSV bit must be clear. If the associated Request included a Requester Segment, the Destination Segment field must reflect the value of the Requester Segment and the DSV bit must be Set. See RP Segment Exceptions for cases where RPs are not required to include Segment information.

The BCM field, present in Non-Flit Mode Completions, is not supported in Flit Mode.

For all UIO Completions:

- The Read Completion Boundary and Write Completion Boundary rules defined in § Section 2.3.1.2 and § Section 2.3.1.3 , respectively, must be followed.
- Length[9:0] indicates the total number of DW represented by this Completion. See § Table 2-4 for values.
 - Regardless of Completion Status, Completers must return Completions corresponding to all DW in a UIO Request.
 - Byte Enables must not be considered when determining the Length value for UIO Completions.
 - For a Zero Length UIO Write (where in the Request, Length is 00_0000_0001b and First Byte Enable 0000b), one DW must be considered to have been written.
- The Tag field value must match the Tag field value for the corresponding UIO Request(s)
 - UIO Write Completions are permitted to be coalesced or split, for a given Transaction ID, provided all DW Completion accounting remains accurate (see § Section 2.3.1.3).
 - UIO Read Completions are permitted to be split, for a given Transaction ID, provided all DW Completion accounting remains accurate (see § Section 2.3.1.2).
- Lower Address [1:0] is Reserved.
- For UIO Completions without Data (see § Figure 2-83)
 - Lower Address [6:2] is Reserved
- For UIO Completions with Data (see § Figure 2-84)
 - Lower Address [11:2] must be present
- The CDL[1:0] field is assigned for use by [CXL]; this field must be treated as Reserved for use cases not covered by [CXL].
- UIO Requesters must accept UIO Completions in any order.
- UIO Memory Request(s) associated with a Transaction ID are considered completed only when the sum of all DW completed, as indicated by the Length[9:0] field value(s) in the Completion(s), equals the sum of all DW expected for the associated Request(s).
 - Only UIO Memory Writes are allowed to have multiple outstanding Requests with the same Transaction ID. If it is necessary for a Requester to ensure that UIO Memory Write Requests issued with a given Transaction ID have completed, the Requester must delay issuing additional Requests with that Transaction ID until it has received Completions accounting for all outstanding UIO Memory Write Requests using that Transaction ID.
- When fully completed, all Requests associated with the same Transaction ID are represented by the same Completion Status. However, individual Completions of a UIO Request may indicate different Completion Status values. At any point where UIO Completions are coalesced, including at the Requester, the coalesced Completion Status is determined according to the following rules:

- UR if any of the UIO Completions have UR Completion Status, or a Reserved Completion Status
- CA if none of the UIO Completions have UR Completions Status, and any have CA Completion Status
- RRS if none of the UIO Completions have UR or CA Completions Status, and any have RRS Completion Status
- SC if all UIO Completions have Successful Completion Status.
- UIO Completions for UIO Read Requests that have a Completion Status other than Successful Completion must use TLP Type UIORdCpl
 - The Length value for UIORdCpl is not constrained by Max Payload Size or Max Read Request Size.
- Attr[2:0], corresponding to IDO, RO and NS in non-UIO Memory Requests, are Reserved
- The EP is Reserved for UIOWrCpl and UIORdCpl.

2.2.10 TLP Prefix Rules §

2.2.10.1 TLP Prefix General Rules - Non-Flit Mode §

In NFM, the following rules apply to any TLP that contains a TLP Prefix:

- For any TLP, a value of 100b in the Fmt[2:0] field in byte 0 of the TLP indicates the presence of a TLP Prefix and the Type[4] bit indicates the type of TLP Prefix.
 - A value of 0b in the Type[4] bit indicates the presence of a Local TLP Prefix
 - A value of 1b in the Type[4] bit indicates the presence of an End-End TLP Prefix
- The format for bytes 1 through 3 of a TLP Prefix is defined by its TLP Prefix type.
- A TLP that contains a TLP Prefix must have an underlying TLP Header. A received TLP that violates this rule is handled as a Malformed TLP. This is a reported error associated with the Receiving Port (see § Section 6.2).
- It is permitted for a TLP to contain more than one TLP Prefix of any type
 - When a combination of Local and End-End TLP Prefixes are present in TLP, it is required that all the Local TLP Prefixes precede any End-End TLP Prefixes. A received TLP that violates this rule is handled as a Malformed TLP. This is a reported error associated with the Receiving Port (see § Section 6.2).
- The size of each TLP Prefix is 1 DW. A TLP Prefix may be repeated to provide space for additional data.
- If the value in the Fmt and Type field indicates the presence of a Local TLP Prefix, handle according to the Local TLP Prefix handling (see § Section 2.2.10.2).
- If the value in the Fmt and Type field indicates the presence of an End-End TLP Prefix, handle according to the End-End TLP Prefix handling (see § Section 2.2.10.4).

2.2.10.2 Local TLP Prefix Processing §

The following rules apply to Local TLP Prefixes:

- In Flit Mode, TLP Prefix types are determined using the Type[7:0] field (see § Table 2-5)
- In Non-Flit Mode, Local TLP Prefix types are determined using the L[3:0] sub-field of the Type field
 - Type[4] must be 0b
 - Local TLP Prefix L[3:0] values are defined in § Table 2-38

Table 2-38 Local TLP Prefix Types §

Local TLP Prefix Type	L[3:0] (b)	Description
MR-IOV	0000	MR-IOV TLP Prefix - Refer to [MR-IOV] for details.
FlitModePrefix	1101	Flit Mode Local TLP Prefix - See § Section 2.2.10.3
VendPrefixL0	1110	Vendor Defined Local TLP Prefix - Refer to § Section 2.2.10.2.1 for further details.
VendPrefixL1	1111	Vendor Defined Local TLP Prefix - Refer to § Section 2.2.10.2.1 for further details.
		All other encodings are Reserved.

- The size, routing, and flow control rules are specific to each Local TLP Prefix type.
- It is an error to receive a TLP with a Local TLP Prefix type not supported by the Receiver. If the Extended Fmt Field Supported bit is Set, TLPs in violation of this rule are handled as a Malformed TLP unless explicitly stated differently in another specification. This is a reported error associated with the Receiving Port (see § Section 6.2). If the Extended Fmt Field Supported bit is Clear, behavior is device specific.
- No Local TLP Prefixes are protected by ECRC even if the underlying TLP is protected by ECRC.

2.2.10.2.1 Vendor Defined Local TLP Prefix §

As described in § Table 2-38, Types VendPrefixL0 and VendPrefixL1 are defined for use as Vendor Defined Local TLP Prefixes. To maximize interoperability and flexibility the following rules are applied to such prefixes:

- Components must not send TLPs containing Vendor Defined Local TLP Prefixes unless this has been explicitly enabled (using vendor-specific mechanisms).
- Components that support any usage of Vendor Defined Local TLP Prefixes must support the 3-bit definition of the Fmt field and have the Extended Fmt Field Supported bit Set (see § Section 7.5.3.15).
- It is recommended that components be configurable (using vendor-specific mechanisms) so that all vendor defined prefixes can be sent using either of the two Vendor Defined Local TLP Prefix encodings. Such configuration need not be symmetric (for example each end of a Link could transmit the same Prefix using a different encoding).

2.2.10.3 Flit Mode Local TLP Prefix §

This prefix (see § Figure 2-85) is only permitted when operating in Flit Mode.

Figure 2-85 Flit Mode Local TLP Prefix §

If the Flit Mode Local TLP Prefix is applied to a NFM TLP, this is an error that *MUST@FLIT* be handled as a Malformed TLP. It is permitted to apply the Flit Mode Local TLP Prefix to any FM TLP, but it is strongly recommended that the Flit Mode Local TLP Prefix is only applied to TLPs that specifically require the Prefix to be present.

The Flit Mode Local TLP Prefix includes:

- **TLP Uses Dedicated Credits** – This bit when Set indicates that the associated TLP must be handled using dedicated flow control credits. If this bit is Clear, or if the Flit Mode Local TLP Prefix is not present, the associated TLP must be handled using shared flow control credits.

2.2.10.4 End-End TLP Prefix Processing - Non-Flit Mode §

The following rules apply to End-End TLP Prefixes

- End-End TLP Prefix types are determined using the E[3:0] sub-field of the Type field
 - Type[4] must be 1b
 - End-End TLP Prefix E[3:0] values are defined in § Table 2-39

Table 2-39 End-End TLP Prefix Types §

End-End TLP Prefix Type	E[3:0] (b)	Description
TPH	0000	TPH - Refer to <u>§ Section 2.2.7.1.1</u> and <u>§ Section 6.17</u> for further details.
PASID	0001	PASID - Refer to <u>§ Section 6.20</u> for further details.
IDE	0010	Identifies an IDE TLP - Refer to <u>§ Section 6.33</u> for further details.
VendPrefixE0	1110	Vendor Defined End-End TLP Prefix - Refer to <u>§ Section 2.2.10.4.1</u> for further details.
VendPrefixE1	1111	Vendor Defined End-End TLP Prefix - Refer to <u>§ Section 2.2.10.4.1</u> for further details.
		All other encodings are Reserved.

- The maximum number of End-End TLP Prefixes permitted in a TLP is 4:
 - A Receiver supporting TLP Prefixes must check this rule. If a Receiver determines that a TLP violates this rule, the TLP is a Malformed TLP. This is a reported error associated with the Receiving Port (see § Section 6.2).
- The presence of an End-End TLP Prefix does not alter the routing of a TLP. TLPs are routed based on the routing rules covered in § Section 2.2.4.
- Functions indicate how many End-End TLP Prefixes they support by the Max End-End TLP Prefixes field in the Device Capabilities 2 register (see § Section 7.5.3.15).
 - For Root Ports, the Max End-End TLP Prefixes field is permitted to return a value indicating support for fewer End-End TLP Prefixes than what the Root Port hardware actually implements; however, the error handling semantics must still be based on the value contained in the field. TLPs received that contain more End-End TLP Prefixes than are supported by the Root Port must be handled as follows. It is recommended that Requests be handled as Unsupported Requests, but otherwise they must be handled as Malformed TLPs. It is recommended that Completions be handled as Unexpected Completions, but otherwise they must be handled as Malformed TLPs. For TLPs received by the Ingress Port, this is a reported error associated with the Ingress Port. For TLPs received internally to be transmitted out the Egress Port, this is a reported error associated with the Egress Port. See § Section 6.2.

- For all other Function types, TLPs received that contain more End-End TLP Prefixes than are supported by a Function must be handled as Malformed TLPs. This is a reported error associated with the Receiving Port (see § Section 6.2).

Advanced Error Reporting (AER) logging (if supported) occurs as specified in § Section 6.2.4.4 .

- Switches must support forwarding of TLPs with up to 4 End-End TLP Prefixes if the End-End TLP Prefix Supported bit is Set.
- Different Root Ports with the End-End TLP Prefix Supported bit Set are permitted to report different values for Max End-End TLP Prefixes.
- All End-End TLP Prefixes are protected by ECRC if the underlying TLP is protected by ECRC.
- It is an error to receive a TLP with an End-End TLP Prefix by a Receiver that does not support End-End TLP Prefixes. A TLP in violation of this rule is handled as a Malformed TLP. This is a reported error associated with the Receiving Port (see § Section 6.2).
- Software should ensure that TLPs containing End-End TLP Prefixes are not sent to components that do not support them. Components where the Extended Fmt Field Supported bit is Clear may misinterpret TLPs containing TLP Prefixes.
- If one Function of an Upstream Port has the End-End TLP Prefix Supported bit Set, all Functions of that Upstream Port must handle the receipt of a Request addressed to them that contains an unsupported End-End TLP Prefix type as an Unsupported Request. This is a reported error associated with the Receiving Port (see § Section 6.2).
- If one Function of an Upstream Port has the End-End TLP Prefix Supported bit Set, all Functions of that Upstream Port must handle the receipt of a Completion addressed to them that contains an unsupported End-End TLP Prefix type as an Unexpected Completion. This is a reported error associated with the Receiving Port (see § Section 6.2).
- For Routing Elements, the End-End TLP Prefix Blocking bit in each Egress Port determines whether TLPs containing End-End TLP Prefixes can be transmitted via that Egress Port (see § Section 7.5.3.16). If forwarding is blocked the entire TLP is dropped and a TLP Prefix Blocked Error is reported. If the blocked TLP is a Non-Posted Request, the Egress Port returns a Completion with Unsupported Request Completion Status. The TLP Prefix Blocked Error is a reported error associated with the Egress Port (see § Section 6.2).
- For routing elements where Multicast is enabled (see § Section 6.14). End-End TLP Prefixes are replicated in all Multicast copies of a TLP. TLP Prefix Egress Blocking of Multicast packets is performed independently at each Egress Port.

2.2.10.4.1 Vendor Defined End-End TLP Prefix §

As described in § Table 2-39, Types VendPrefixE0 and VendPrefixE1 are defined for use as Vendor Defined End-End TLP Prefixes. To maximize interoperability and flexibility the following rules are applied to such prefixes:

- Components must not send TLPs containing Vendor Defined End-End TLP Prefixes unless this has been explicitly enabled (using vendor-specific mechanisms).
- It is recommended that components be configurable (using vendor-specific mechanisms) to use either of the two Vendor Defined End-End TLP Prefix encodings. Doing so allows two different Vendor Defined End-End TLP Prefixes to be in use simultaneously within a single PCI Express topology while not requiring that every source understand the ultimate destination of every TLP it sends.

2.2.10.4.2 Root Ports with End-End TLP Prefix Supported §

Support for peer-to-peer routing of TLPs containing End-End TLP Prefixes between Root Ports is optional and implementation dependent. If an RC supports End-End TLP Prefix routing capability between two or more Root Ports, it must indicate that capability in each associated Root Port via the End-End TLP Prefix Supported bit in the Device Capabilities 2 register.

An RC is not required to support End-End TLP Prefix routing between all pairs of Root Ports that have the End-End TLP Prefix Supported bit Set. A Request with End-End TLP Prefixes that would require routing between unsupported pairs of Root Ports must be handled as a UR. A Completion with End-End TLP Prefixes that would require routing between unsupported pairs of Root Ports must be handled as an Unexpected Completion (UC). In both cases, this error is reported by the “sending” Port.

The End-End TLP Prefix Supported bit must be Set for any Root Port that supports forwarding of TLPs with End-End TLP Prefixes initiated by host software or Root Complex Integrated Endpoints (RCiEPs). The End-End TLP Prefix Supported bit must be Set for any Root Ports that support forwarding of TLPs with End-End TLP Prefixes received on their Ingress Port to RCiEPs.

Different Root Ports with the End-End TLP Prefix Supported bit Set are permitted to report different values for Max End-End TLP Prefixes.

An RC that splits a TLP into smaller TLPs when performing peer-to-peer routing between Root Ports must replicate the original TLP's End-End TLP Prefixes in each of the smaller TLPs (see § Section 1.3.1).

2.2.11 OHC-E Rules - Flit Mode §

End-End TLP Prefixes in Non-Flit Mode are replaced by OHC-E in Flit Mode (see § Figure 2-86, § Figure 2-87, and § Figure 2-88).

Figure 2-86 OHC-E1 §

Figure 2-87 OHC-E2 §

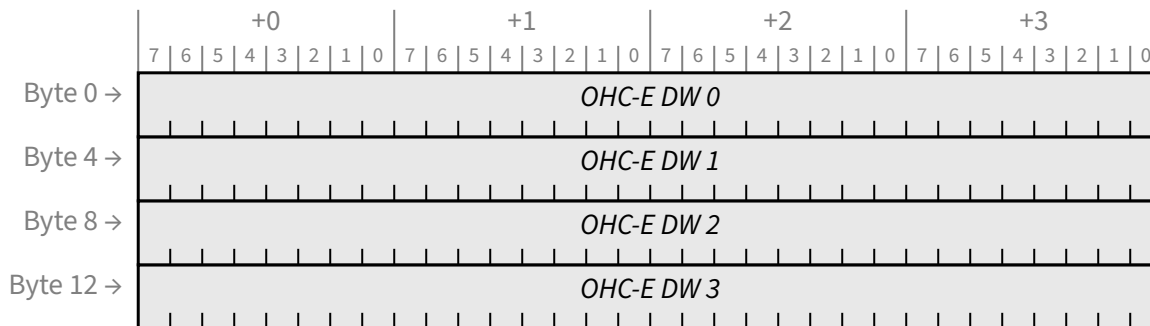

Figure 2-88 OHC-E4 §

OHC-E is used to convey content that would otherwise use E-E Prefixes 0011 to 1111.

- For each DW of OHC-E, Byte 0, bits [7:4] indicate the format of the remainder of the DW and are encoded:
 - 0000b - No Entry - The remainder of the DW is Reserved
 - 0001b - E-E Prefix DW - The remainder of the DW is defined as follows:
 - Byte 0, bits [3:0] take the value of E[3:0] in the corresponding E-E Prefix (see § Table 2-39), with the exception that encodings 0000b-0010b are Reserved.
 - Bytes 1, 2 and 3 take the value of bytes 1, 2 and 3 in the corresponding E-E Prefix.
 - 0010b-1111b - Reserved - Receivers must handle as No Entry

OHC-E must be populated without gaps, starting with the first DW. Any No Entry DWs must be populated at the end. Transmitters must use the smallest possible OHC-E and avoid unnecessary No Entry DWs. When translating VendPrefixE0 or VendPrefixE1 from NFM to FM or vice-versa, the same relative sequence must be preserved.

RC support for peer-to-peer routing of TLPs containing OHC-E content between Root Ports is optional and implementation dependent. If an RC supports OHC-E routing capability between two or more Root Ports, it must indicate that capability in each associated Root Port via the End-End TLP Prefix Supported bit in the Device Capabilities 2 register.

If a Function sets the End-End TLP Prefix Supported bit but does not support OHC-E, it shall handle the received TLP that has OHC-E as Unsupported Request or Unexpected Completion. The Function is permitted to drop OHC-E content during header logging for the error. This behavior is consistent with the rules stated in § Section 2.2.1.2 for Endpoint Upstream Ports and Root Ports, but with extension of the rule for switch ports as well when they don't support OHC-E.

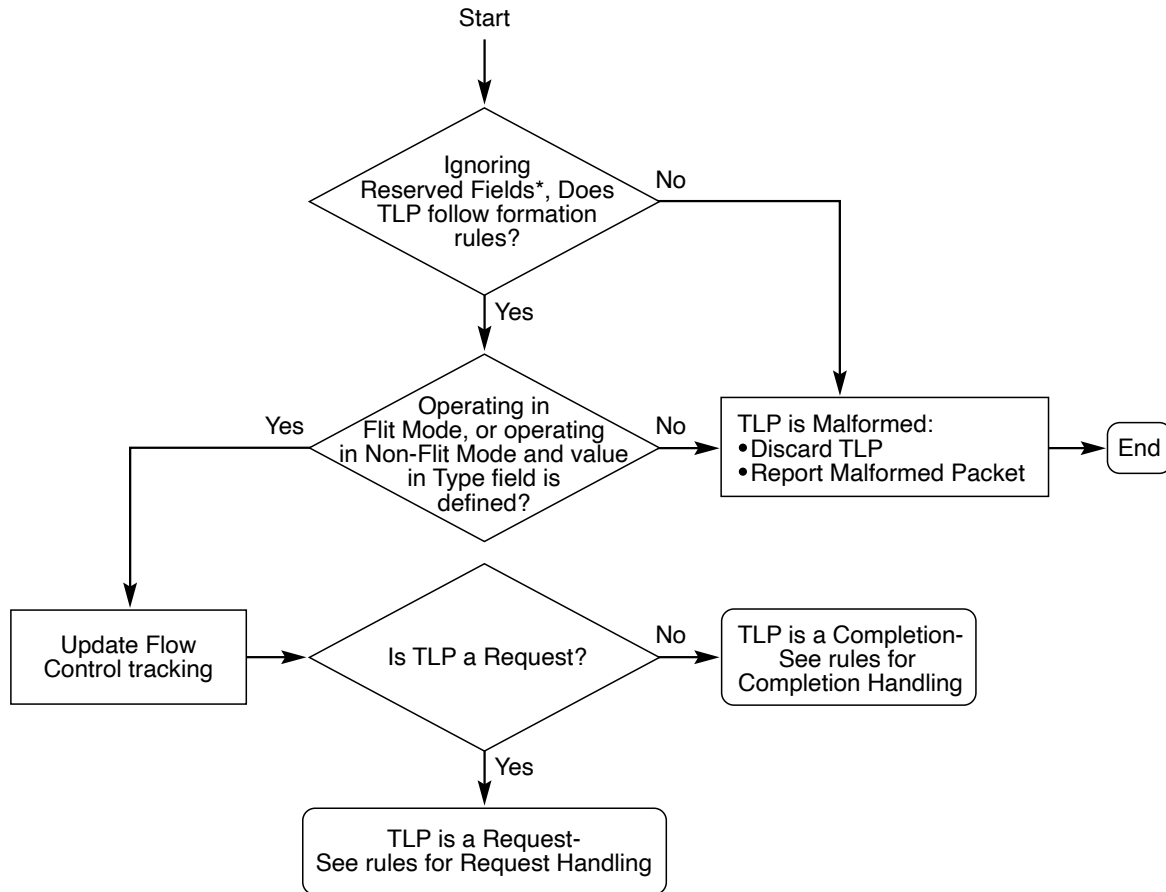

2.3 Handling of Received TLPs §

This section describes how all Received TLPs are handled when they are delivered to the Receive Transaction Layer from the Receive Data Link Layer, after the Data Link Layer has validated the integrity of the received TLP. The rules are diagrammed in the flowchart shown in § Figure 2-89.

- Values in Reserved fields must be ignored by the Receiver.
- In Non-Flit Mode, if the value in the Fmt field indicates the presence of at least one TLP Prefix:
 - Detect if additional TLP Prefixes are present in the header by checking the Fmt field in the first byte of subsequent DWs until the Fmt field does not match that of a TLP Prefix.

- Handle all received TLP Prefixes according to TLP Prefix Handling Rules (see § Section 2.2.10.1).
- In Flit Mode, if the value in the Type field indicates the presence of at least one Local TLP Prefix:
 - Detect if additional Local TLP Prefixes are present in subsequent DWs.
 - Handle all received Local TLP Prefixes according to TLP Prefix Handling Rules (see § Section 2.2.10.3).
- In Non-Flit Mode, if the Extended Fmt Field Supported bit is Set, Received TLPs that use encodings of Fmt and Type that are Reserved are Malformed TLPs (see § Table 2-1 and § Table 2-3).
 - This is a reported error associated with the Receiving Port (see § Section 6.2).
- In Non-Flit Mode, if the Extended Fmt Field Supported bit is Clear, processing of Received TLPs that have Fmt[2] Set is undefined.³¹
- In Non-Flit Mode, all Received TLPs with Fmt[2] Clear and that use undefined Type field values are Malformed TLPs.
This is a reported error associated with the Receiving Port (see § Section 6.2).
- All Received Malformed TLPs must be discarded.
 - Received Malformed TLPs that are ambiguous with respect to which buffer to release or are mapped to an uninitialized or disabled Virtual Channel must be discarded without updating Receiver Flow Control information.
 - All other Received Malformed TLPs must be discarded, optionally not updating Receiver Flow Control information.
- Otherwise, update Receiver Flow Control tracking information (see § Section 2.6).
- If the value in the Type field indicates the TLP is a Request, handle according to Request Handling Rules, otherwise, the TLP is a Completion so handle according to Completion Handling Rules (see § Section 2.3.2).

31. An earlier version of this specification reserved the bit now defined for Fmt[2].

*TLP fields which are marked Reserved are not checked at the Receiver

OM13771B

Figure 2-89 Flowchart for Handling of Received TLPs §

Switches must process both TLPs that address resources within the Switch as well as TLPs that address resources residing outside the Switch. Switches handle all TLPs that address internal resources of the Switch according to the rules above. TLPs that pass through the Switch, or that address the Switch as well as passing through it, are handled according to the following rules (see § Figure 2-90):

- If the value in the Type field indicates the TLP is not a Msg or MsgD Request, the TLP must be routed according to the routing mechanism used (see § Section 2.2.4.1 and § Section 2.2.4.2).
- Switches route Completions using the information in the Requester ID field of the Completion.
- If the value in the Type field indicates the TLP is a Msg or MsgD Request, route the Request according to the routing mechanism indicated in the r[2:0] sub-field of the Type field.
 - If the value in r[2:0] indicates the Msg/MsgD is routed to the Root Complex (000b), the Switch must route the Msg/MsgD to the Upstream Port of the Switch.
 - It is an error to receive a Msg/MsgD Request specifying 000b routing at the Upstream Port of a Switch. Switches may check for violations of this rule - TLPs in violation are Malformed TLPs. If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

- If the value in r[2:0] indicates the Msg/MsgD is routed by address (001b), the Switch must route the Msg/MsgD in the same way it would route a Memory Request by address.
- If the value in r[2:0] indicates the Msg/MsgD is routed by ID (010b), the Switch must route the Msg/MsgD in the same way it would route a Completion by ID.
- If the value in r[2:0] indicates the Msg/MsgD is a broadcast from the Root Complex (011b), the Switch must route the Msg/MsgD to all Downstream Ports of the Switch.
 - It is an error to receive a Msg/MsgD Request specifying 011b routing at the Downstream Port of a Switch. Switches may check for violations of this rule - TLPs in violation are Malformed TLPs. If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).
- If the value in r[2:0] indicates the Msg/MsgD terminates at the Receiver (100b or a Reserved value), or if the Message Code field value is defined and corresponds to a Message that must be comprehended by the Switch, the Switch must process the Message according to the Message processing rules.
- If the value in r[2:0] indicates Gathered and routed to Root Complex (101b), see § Section 5.3.3.2.1 for Message handling rules.
- It is an error to receive any Msg/MsgD Request other than a PME_TO_Ack that specifies 101b routing. It is an error to receive a PME_TO_Ack at the Upstream Port of a Switch. Switches may optionally check for violations of these rules. These checks are independently optional (see § Section 6.2.3.4). If checked, violations are Malformed TLPs, and are reported errors associated with the Receiving Port (see § Section 6.2).

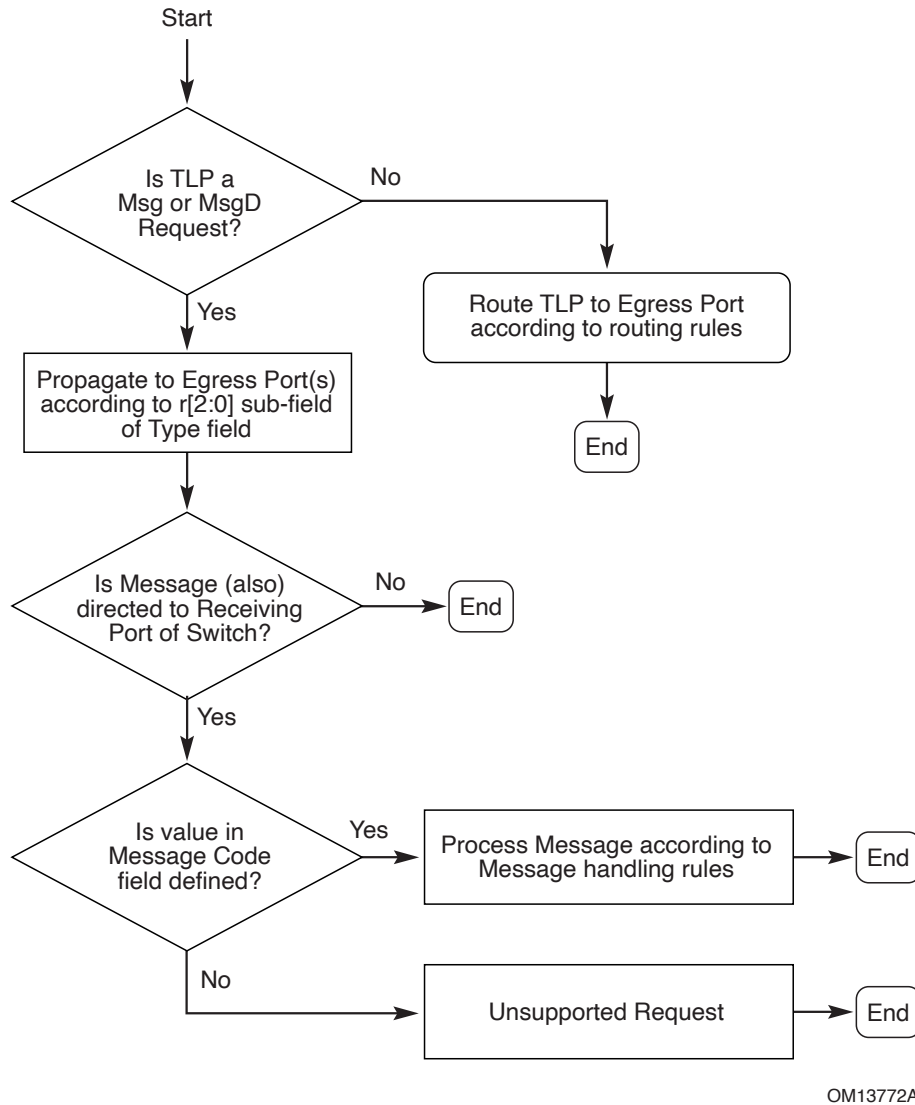

Figure 2-90 Flowchart for Switch Handling of TLPs §

2.3.1 Request Handling Rules §

This section describes how Received Requests are handled, following the initial processing done with all TLPs. The rules are diagrammed in the flowchart shown in § Figure 2-91.

- If the Request Type is defined in § Table 2-2, and § Table 2-3 (NFM), or is a non-Reserved value in § Table 2-5 (FM), but is not supported (by design or because of configuration settings) by the device, the Request must be handled as an Unsupported Request (UR). This is an error associated with the Receiving Port (see § Section 6.2)
 - If the Request requires a Completion, a Completion Status of UR must be returned (see § Section 2.2.9).
- For a Receiver that decodes UIO Type values, if the Request is a UIO Request, but the Receiver cannot forward or process the Request, then the Request must be dropped.

- In Flit Mode, if the Receiver is the ultimate destination of the TLP, and the Type value is defined in [§ Table 2-3](#) as a Reserved value, the Request must be discarded following the update of flow control credits.

IMPLEMENTATION NOTE: WHEN REQUESTS ARE TERMINATED USING UNSUPPORTED REQUEST [§](#)

In Conventional PCI, a device “claims” a request on the bus by asserting DEVSEL#. If no device claims a request after a set number of clocks, the request is terminated as a Master Abort. Since PCI Express is a point to point interconnect, there is no equivalent mechanism for claiming a request on a Link, since all transmissions by one component are always sent to the other component on the Link. Therefore, it is necessary for the receiver of a request to determine if the request should be claimed. If the request is not claimed, then it is handled as an Unsupported Request, which is the PCI Express equivalent of Conventional PCI's Master Abort termination. In general, one can determine the correct behavior by asking the question: *Would the device assert DEVSEL# for this request in conventional PCI?*

For device Functions with Type 0 headers (all types of Endpoints), it is relatively simple to answer this question. For Memory and I/O Requests, this determination is based on the address ranges the Function has been programmed to respond to. For Configuration requests, the Type 0 request format indicates the device is by definition the “target”, although the device will still not claim the Configuration Request if it addresses an unimplemented Function.

For device Functions with Type 1 headers (Root Ports, Switches and Bridges), the same question can generally be applied, but since the behavior of a conventional PCI bridge is more complicated than that of a Type 0 Function, it is somewhat more difficult to determine the answers. One must consider Root Ports and Switch Ports as if they were actually composed of conventional PCI to PCI bridges, and then at each stage consider the configuration settings of the virtual bridge to determine the correct behavior.

PCI Express Messages do not exist in conventional PCI, so the above guideline cannot be applied. This specification describes specifically for each type of Message when a device must handle the request as an Unsupported Request. Messages pass through Root and Switch Ports unaffected by conventional PCI control mechanisms including Bus Master Enable and power state setting.

Note that CA, which is the PCI Express equivalent to Target Abort, is used only to indicate a serious error that makes the Completer permanently unable to respond to a request that it would otherwise have normally responded to. Since Target Abort is used in conventional PCI only when a target has asserted DEVSEL#, it is incorrect to use a CA for any case where a Conventional PCI target would have ignored a request by not asserting DEVSEL#.

- If the Request is a Message, and the Message Code, routing field, or Msg / MsgD indication corresponds to a combination that is undefined, or that corresponds to a Message not supported by the device Function (other than Vendor-Defined Type 1, which is not treated as an error - see [§ Table F-1](#)), the Request is an Unsupported Request (UR). This is a reported error associated with the Receiving Port and is reported according to [§ Section 6.2](#)
 - If the Message Code is a supported value, process the Message according to the corresponding Message processing rules; if the Message Code is an Ignored Message and the Receiver is ignoring it, ignore the Message without reporting any error (see [§ Section 2.2.8.7](#))
- If the Request is a Message with a routing field that indicates Routed by ID, and if the Request is received by a device Function with Type 0 headers, the device *MUST@FLIT* be treated as the target of the Message regardless

of the Bus Number and, for non-ARI Devices, the Device Number specified in the Destination ID field of the Request

- If the Function specified in the Destination ID field is unimplemented, the Request *MUST@FLIT* be handled as an Unsupported Request (UR) and is a reported error associated with the Receiving Port (see § Section 6.2).
- Earlier versions of this specification recommended ignoring the Bus Number and Device Number fields with the Destination ID comparison in certain cases. While this behavior is still permitted, it is no longer recommended.

If the Request is not a Message, and is a supported Type, specific implementations may be optimized based on a defined programming model that ensures that certain types of (otherwise legal) Requests will never occur. Such implementations may take advantage of the following rule:

- If the Request violates the programming model of the device Function, the Function may optionally treat the Request as a Completer Abort, instead of handling the Request normally
 - If the Request is treated as a Completer Abort, this is a reported error associated with the Function (see § Section 6.2)
 - If the Request requires Completion, a Completion Status of CA is returned (see § Section 2.2.9)

IMPLEMENTATION NOTE: OPTIMIZATIONS BASED ON RESTRICTED PROGRAMMING MODEL §

When a device's programming model restricts (versus what is otherwise permitted in PCI Express) the characteristics of a Request, that device is permitted to return a UR or a CA Completion Status, or to terminate the Request in a suitable implementation-specific way for any Request that violates the programming model. Examples include unaligned or wrong-size access to a register block and unsupported size of request to a Memory Space.

Generally, devices are able to rely on a restricted programming model when all communication will be between the device's driver software and the device itself. Devices directly accessed via other software (e.g., operating system, application software) may not be able to rely on a restricted programming.

Devices that implement legacy capabilities should be designed to support all types of Requests that are possible in the existing usage model for the device. If this is not done, the device may fail to operate with existing software.

If the Request arrives between the time an FLR has been initiated and the completion of the FLR by the targeted Function, the Request is permitted to be silently discarded (following update of flow control credits) without logging or signaling it as an error. It is recommended that the Request be handled as an Unsupported Request (UR).

- For DMWr Requests, refer to the rules in § Section 6.32 .
- Otherwise (supported Request Type, not a DMWr, not a Message), process the Request
 - If the Completer is permanently unable to process the Request due to a device-specific error condition the Completer must, if possible, handle the Request as a Completer Abort
 - This is a reported error associated with the Receiving Function, if the error can be isolated to a specific Function in the component, or to the Receiving Port if the error cannot be isolated (see § Section 6.2)

- For Configuration Requests, if Device Readiness Status (DRS) is supported³², then:
 - Following any DRS Event (see § Section 6.22), once the Link is in L0, a Function associated with an Upstream Port *MUST@FLIT* return a Completion Status of RRS until the Upstream Port has transmitted a Device Readiness Status Message.
 - Once the Upstream Port has transmitted a Device Readiness Status Message, all non-VF Functions of the Upstream Port must respond to all properly formed Configuration Requests with a Completion Status of Successful Completion.
- For Configuration Requests only, if Device Readiness Status is not supported, following reset it is permitted for a Function to terminate the request and indicate that it is temporarily unable to process the Request, but will be able to process the Request in the future - in this case, the Request Retry Status (RRS) Completion Status must be used (see § Section 6.6). Valid reset conditions after which a device/Function is permitted to return RRS in response to a Configuration Request are:
 - Cold, Warm, and Hot Resets
 - FLRs
 - A reset initiated in response to a $D3_{Hot}$ to $D0_{uninitialized}$ device state transition
- A device Function is explicitly not permitted to return RRS in response to a Configuration Request following a software-initiated reset (other than an FLR) of the device, e.g., by the device's software driver writing to a device-specific reset bit. A device Function is not permitted to return RRS in response to a Configuration Request after it has indicated that it is Configuration-Ready (see § Section 6.22) without an intervening valid reset (i.e., FLR or Conventional Reset) condition, or if the Immediate Readiness bit in the Function's Status register is Set. Additionally, a device Function is not permitted to return RRS in response to a Configuration Request after having previously returned a Successful Completion without an intervening valid reset (i.e., FLR or Conventional Reset) condition.
- A Function that implements the Readiness Time Reporting Extended Capability must not return RRS in response to Configuration Requests that are received after the relevant times reported in that Extended Capability.
- In the process of servicing the Request, the Completer may determine that the (otherwise acceptable) Request must be handled as an error, in which case the Request is handled according to the type of the error
 - Example: A PCI Express/PCI Bridge may initially accept a Request because it specifies a Memory Space range mapped to the secondary side of the Bridge, but the Request may Master Abort or Target Abort on the PCI side of the Bridge. From the PCI Express perspective, the status of the Request in this case is UR (for Master Abort) or CA (for Target Abort). If the Request requires Completion on PCI Express, the corresponding Completion Status is returned.
- If the Request is a type that requires a Completion to be returned, generate a Completion according to the rules for Completion formation (see § Section 2.2.9)
 - The Completion Status is determined by the result of handling the Request
 - If the Request has an ECRC Check Failed error, then it is implementation specific whether to return a Completion or not. If a Completion is returned, the Completion *MUST@FLIT* have a UR Completion Status.
- Under normal operating conditions, PCI Express Endpoints and Legacy Endpoints must never delay the acceptance of a Posted Request for more than 10 μ s, which is called the **Posted Request Acceptance Limit**. The device must either (a) be designed to process received Posted Requests and return associated Flow Control credits within the necessary time limit, or (b) rely on a restricted programming model to ensure that a Posted

32. If Flit Mode is supported then Device Readiness Status must be supported.

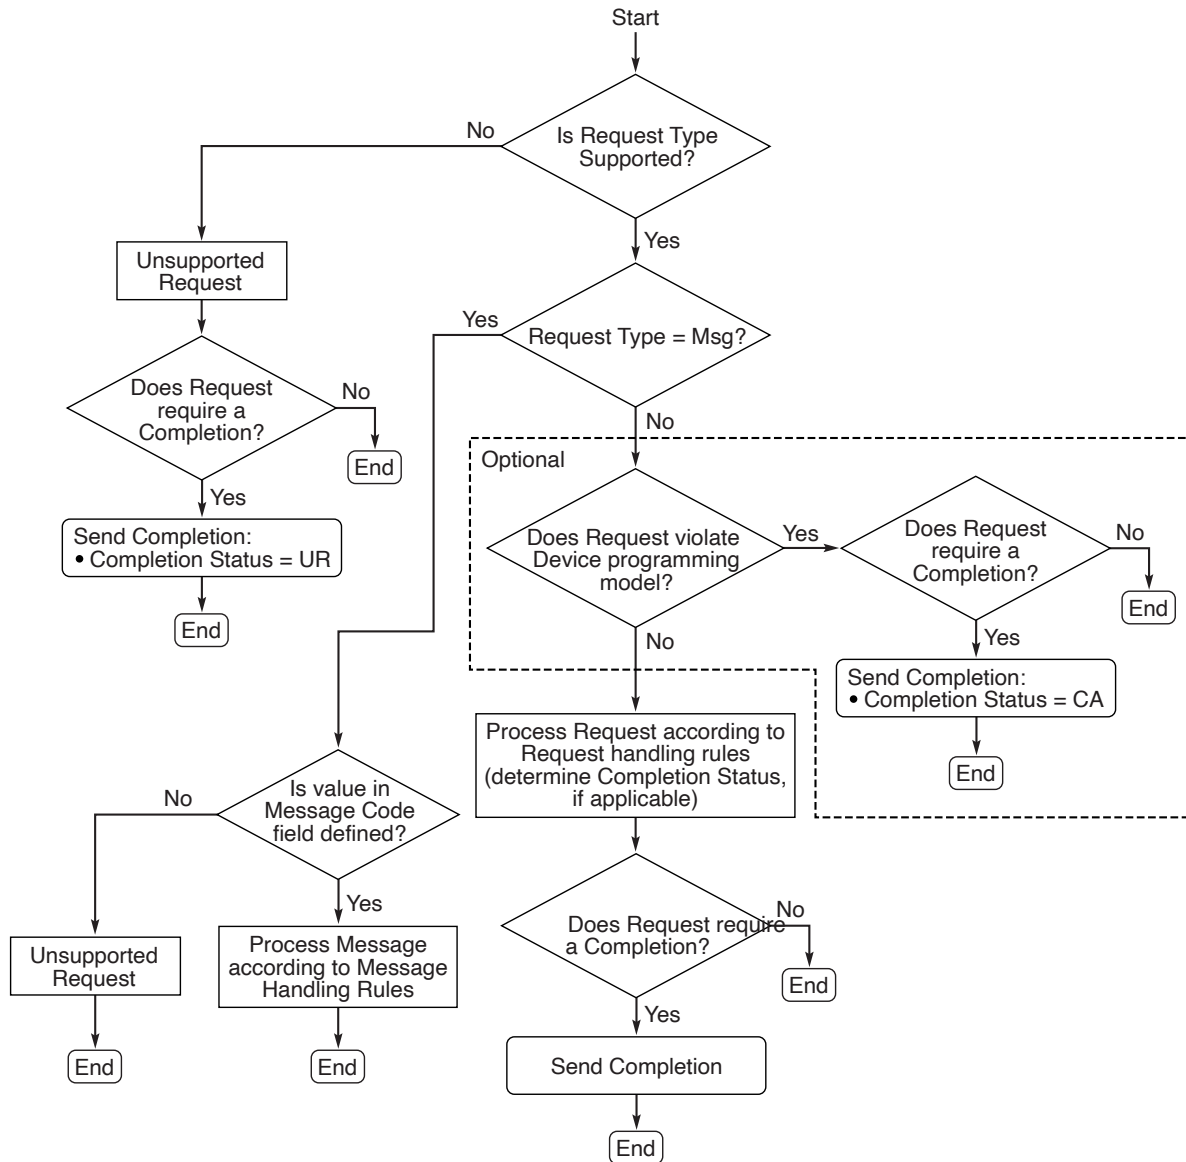

Request is never initiated to the Endpoint either by software or by other devices while the Endpoint is unable to accept a new Posted Request within the necessary time limit.

- The following are not considered normal operating conditions under which the Posted Request Acceptance Limit applies:
 - The period immediately following a Fundamental Reset (see § Section 6.6)
 - TLP retransmissions or Link retraining
 - One or more dropped Flow Control Packets (FCPs)
 - The device being in a diagnostic mode
 - The device being in a device-specific mode that is not intended for normal use
- The following are considered normal operating conditions, but any delays they cause do not count against the Posted Request Acceptance Limit:
 - Upstream TLP traffic delaying Upstream FCPs
 - The Link coming out of a low-power state
 - Arbitration with traffic on other VCs
- Though not a requirement, it is strongly recommended that RCiEPs also honor the Posted Request Acceptance Limit.
- If the device/Function supports being a target for I/O Write Requests, which are Non-Posted Requests, it is strongly recommended that each associated Completion be returned within the same time limit as for Posted Request acceptance, although this is not a requirement.
- If the device/Function supports being a target for DMWr Requests, each associated Completion must be returned within the Posted Request Acceptance Limit³³

IMPLEMENTATION NOTE: RESTRICTED PROGRAMMING MODEL FOR MEETING THE POSTED REQUEST ACCEPTANCE LIMIT §

Some hardware designs may not be able to process every DMWr or Posted Request within the required Posted Request Acceptance Limit. An example is writing to a command queue where commands can take longer than the acceptance time limit to complete. Subsequent writes to such a device when it is currently processing a previous write could experience acceptance delays that exceed the limit. Such devices may rely on a restricted programming model, where the device driver limits the rate of DMWr/memory writes issued to the device, the driver polls the device to determine buffer availability before issuing the transaction, or the driver implements some other software-based flow control mechanism.

33. Although DMWr is a Non-Posted Request, the Posted Request Acceptance Limit is applied because many (but not all) of the same concerns apply as with Posted Requests. The name Posted Request Acceptance Limit is retained for historical reasons.

OM13773

Figure 2-91 Flowchart for Handling of Received Request §

IMPLEMENTATION NOTE:

REQUEST RETRY STATUS FOR CONFIGURATION REQUESTS §

Some devices require a lengthy self-initialization sequence to complete before they are able to service Configuration Requests. In specified circumstances it is permitted for a device/Function to “hold off” initial configuration via the Request Retry Status (RRS) Completion Status mechanism. A device in receipt of a Configuration Request following a valid reset condition may respond with an RRS Completion Status to terminate the Request, and thus effectively stall the Configuration Request until such time that the subsystem has completed local initialization and is ready to communicate with the host. Note that it is only legal in specified circumstances to respond with an RRS Completion Status in response to a Configuration Request. Readiness Notifications (see § Section 6.22) and Immediate Readiness (see § Section 7.5.1.1.4 and § Section 7.5.2.1) also forbid the use of RRS Completion Status in response to a Configuration Request in certain situations.

Receipt by the Requester of a Completion with RRS Completion Status terminates the Configuration Request. Further action by the Root Complex regarding the original Configuration Request is specified in § Section 2.3.2 .

Root Complexes that implement Configuration RRS Software Visibility have the ability to report the receipt of RRS Completion Status for a Configuration Request to software, enabling software to attend to other tasks rather than being stalled while the device completes its self-initialization. Software that intends to take advantage of this mechanism must ensure that the first access made to a device following a valid reset condition is a Configuration Read Request accessing both bytes of the Vendor ID field in the device's Configuration Space header. For this case only, the Root Complex, if enabled, will synthesize a special read-data value for the Vendor ID field to indicate to software that RRS Completion Status has been returned by the device in response to a Configuration Request. For Configuration Requests to other addresses, or when Configuration RRS Software Visibility is not enabled, the Root Complex will generally re-issue the Configuration Request until it completes with a status other than RRS as described in § Section 2.3.2 .

Systems that contain PCIe components whose self-initialization time may require them to return a RRS Completion Status in response to a Configuration Request (by the rules in § Section 6.6) should provide some mechanism for re-issuing Configuration Requests terminated with RRS status. In systems running legacy PCI/PCI-X based software, the Root Complex must re-issue the Configuration Request using a hardware mechanism to ensure proper enumeration of the system.

Refer to § Section 6.6 for more information on reset.

2.3.1.1 Data Return for Non-UIO Read Requests §

- Individual Completions for Memory Read Requests may provide less than the full amount of data Requested so long as all Completions for a given Request when combined return exactly the amount of data Requested in the Read Request.
 - Completions for different Requests cannot be combined.
 - I/O and Configuration Reads must be completed with exactly one Completion.
 - A Completion with Completion Status other than Successful Completion must:
 - be of type Cpl or CplLk,
 - for a Read Request, including an ATS Translation Request, be the final Completion returned.
- Completions must not include more data than permitted by the Transmitting Function's Tx_MPS_Limit.
 - A Receiving Function must check for violations of its Rx_MPS_Limit.

- See [§ Section 2.2.2](#) for important details with both Transmitters and Receivers.

Note: This is simply a specific case of the rules that apply to all TLPs with [data payloads](#)

- Memory Read Requests may be completed with one, or in some cases, multiple Completions
- [Read Completion Boundary \(RCB\)](#) determines the naturally aligned address boundaries on which a Completer is permitted to break up the response for a single Read Request into multiple Completions.
 - For a Root Complex, RCB is 64 bytes or 128 bytes.
 - This value is reported [Read Completion Boundary](#) field in the [Link Control Register](#) (see [§ Section 7.5.3.7](#)).

Note: Bridges and Endpoints may implement a corresponding command bit that may be set by system software to indicate the RCB value for the Root Complex, allowing the Bridge or Endpoint to optimize its behavior when the Root Complex's RCB is 128 bytes.

- For all other System Elements, RCB is 128 bytes.
- Completions for Requests that do not cross the naturally aligned address boundaries at integer multiples of RCB bytes must include all data specified in the Request.
- Requests that do cross the address boundaries at integer multiples of RCB bytes are permitted to be completed using more than one Completion subject to the following rules:
 - The first Completion must start with the address specified in the Request, and if successful must end at one of the following:
 - The address that satisfies the entire Request
 - An address boundary between the start and end of the Request at an integer multiple of RCB bytes
 - If the final Completion is successful, it must end at the address that satisfies the entire Request
 - All Completions between, but not including, the first and final Completions must be an integer multiple of RCB bytes in length
- Receivers may optionally check for violations of RCB. If a Receiver implementing this check determines that a Completion violates this rule, it must handle the Completion as a Malformed TLP.
 - This is a reported error associated with the Receiving Port (see [§ Section 6.2](#)).
- Multiple Memory Read Completions for a single Read Request must return data in increasing address order.
- If all the Memory Read Completions for a single Read Request have a Successful Completion Status, the sum of their payloads must equal the size requested. See [§ Section 10.2.4](#) for an exception for Memory Reads that are ATS Translation Requests.
- For each Memory Read Completion, the Byte Count field must indicate the remaining number of bytes required to complete the Request including the number of bytes returned with the Completion, except when the BCM bit is Set.³⁴
 - The total number of bytes required to complete a Memory Read Request is calculated as shown in [§ Table 2-40](#).
 - If a Memory Read Request is completed using multiple Completions, the Byte Count value for each successive Completion is the value indicated by the preceding Completion minus the number of bytes returned with the preceding Completion.

34. Only PCI-X completers Set the BCM bit. PCI Express completers are not permitted to set the BCM bit. In Flit Mode, the BCM bit is deprecated. When translating from Non-Flit Mode to Flit Mode, if the BCM bit is 1b a TLP Translation Egress Blocked error must be indicated. When translating from Flit Mode to Non-Flit Mode the BCM bit must be Clear in the Non-Flit Mode Header.

- The Completion Data area begins at the DW address specified by the Request. In the first or only Data DW of the first or only Completion, only the bytes configured as active in the First DW BE field in the Request contain valid data. Bytes configured as inactive in the First DW BE field in the Request will return undefined content.
- In the last Data DW of the last successful Completion, only the bytes configured as active in the Last DW BE field in the Request contain valid data. Bytes configured as inactive in the Last DW BE field in the Request will return undefined content.
- All the Completion Data bytes, including those with undefined content, are included in all CRC calculations.
- § Figure 2-92 presents an example of the above. The example assumes a single Completion TLP is returned.

Request Address (DW)	Byte 0	Byte 1	Byte 2	Byte 3	Request Byte Enables
START	undefined content	undefined content	undefined content		First DW BE: 1000
START + 1					
START + 2					
START + 3		undefined content	undefined content	undefined content	Last DW BE: 0001

Length = 4
Byte Count = 10

Figure 2-92 Example Completion Data when some Byte Enables are 0b §

IMPLEMENTATION NOTE: BCM BIT USAGE §

To satisfy certain PCI-X protocol constraints, a PCI-X Bridge or PCI-X Completer for a PCI-X burst read in some cases will set the Byte Count field in the first PCI-X transaction of the Split Completion sequence to indicate the size of just that first transaction instead of the entire burst read. When this occurs, the PCI-X Bridge/PCI-X Completer will also Set the BCM bit in that first PCI-X transaction, to indicate that the Byte Count field has been modified from its normal usage. Refer to the [PCI-X] for further details.

A PCI Express Memory Read Requester needs to correctly handle the case when a PCI-X Bridge/PCI-X Completer sets the BCM bit. When this occurs, the first Read Completion packet returned to the Requester will have the BCM bit Set, indicating that the Byte Count field reports the size of just that first packet instead of the entire remaining Byte Count. The Requester should not conclude at this point that other packets of the Read Completion are missing.

The BCM bit will never be Set in subsequent packets of the Read Completion, so the Byte Count field in those subsequent packets will always indicate the remaining Byte Count in each instance. Thus, the Requester can use the Byte Count field in these packets to determine if other packets of the Read Completion are missing.

PCI Express Completers will never Set the BCM bit.

The BCM bit is not present in Flit Mode.

Table 2-40 Calculating Byte Count from Length and Byte Enables §

First DW BE[3:0] (b)	Last DW BE[3:0] (b)	Total Byte Count
1x1	0000 ³⁵	4
01x1	0000	3
1x10	0000	3
0011	0000	2
0110	0000	2
1100	0000	2
0001	0000	1
0010	0000	1
0100	0000	1
1000	0000	1
0000	0000	1
xxx1	1xxx	Length ³⁶ * 4
xxx1	01xx	(Length * 4) - 1
xxx1	001x	(Length * 4) - 2
xxx1	0001	(Length * 4) - 3
xx10	1xxx	(Length * 4) - 1
xx10	01xx	(Length * 4) - 2
xx10	001x	(Length * 4) - 3
xx10	0001	(Length * 4) - 4
x100	1xxx	(Length * 4) - 2
x100	01xx	(Length * 4) - 3
x100	001x	(Length * 4) - 4
x100	0001	(Length * 4) - 5
1000	1xxx	(Length * 4) - 3
1000	01xx	(Length * 4) - 4
1000	001x	(Length * 4) - 5
1000	0001	(Length * 4) - 6

35. Note that Last DW BE of 0000b is permitted only with a Length of 1 DW.

36. Length is the number of DW as indicated by the value in the Length field, and is multiplied by 4 to yield a number in bytes.

- For all Memory Read Completions, the Lower Address field must indicate the lower bits of the byte address for the first enabled byte of data returned with the Completion.
 - For the first (or only) Completion, the Completer can generate this field from the least significant 5 bits of the address of the Request concatenated with 2 bits of byte-level address formed as shown in § Table 2-41.
 - For any subsequent Completions, the Lower Address field will always be zero except for Completions generated by a Root Complex with an RCB value of 64 bytes. In this case the least significant 6 bits of the Lower Address field will always be zero and the most significant bit of the Lower Address field will toggle according to the alignment of the 64-byte data payload.

Table 2-41 Calculating Lower Address from First DW BE §

First DW BE[3:0] (b)	Lower Address[1:0] (b)
0000	00
xxx1	00
xx10	01
x100	10
1000	11

- When a Read Completion is generated with a Completion Status other than Successful Completion:
 - No data is included with the Completion
 - The Cpl (or CplLk) encoding is used instead of CplD (or CplDLk)
 - This Completion is the final Completion for the Request
 - The Completer must not transmit additional Completions for this Request
 - Example: Completer split the Request into four parts for servicing; the second Completion had a Completer Abort Completion Status; the Completer terminated servicing for the Request, and did not Transmit the remaining two Completions.
 - The Byte Count field must indicate the remaining number of bytes that would be required to complete the Request (as if the Completion Status were Successful Completion)
 - The Lower Address field must indicate the lower bits of the byte address for the first enabled byte of data that would have been returned with the Completion if the Completion Status were Successful Completion

IMPLEMENTATION NOTE: RESTRICTED PROGRAMMING MODEL §

When a device's programming model restricts (vs. what is otherwise permitted in PCI Express) the size and/or alignment of Read Requests directed to the device, that device is permitted to use a Completer Abort Completion Status for Read Requests that violate the programming model. An implication of this is that such devices, generally devices where all communication will be between the device's driver software and the device itself, need not necessarily implement the buffering required to generate Completions of length RCB. However, in all cases, the boundaries specified by RCB must be respected for all reads that the device will complete with Successful Completion status.

Examples:

1. Memory Read Request with Address of 1 0000h and Length of C0h bytes (192 decimal) could be completed by a Root Complex with an RCB value of 64 bytes with one of the following combinations of Completions (bytes):

192 -or- 128, 64 -or- 64, 128 -or- 64, 64

2. Memory Read Request with Address of 1 0000h and Length of C0h bytes (192 decimal) could be completed by a Root Complex with an RCB value of 128 bytes in one of the following combinations of Completions (bytes):

192 -or- 128, 64

3. Memory Read Request with Address of 1 0020h and Length of 100h bytes (256 decimal) could be completed by a Root Complex with an RCB value of 64 bytes in one of the following combinations of Completions (bytes):

256 -or-

32, 224 -or- 32, 64, 160 -or- 32, 64, 64, 96 -or- 32, 64, 64, 32 -or-

32, 64, 128, 32 -or- 32, 128, 96 -or- 32, 128, 64, 32 -or-

96, 160 -or- 96, 128, 32 -or- 96, 64, 96 -or- 96, 64, 64, 32 -or-

160, 96 -or- 160, 64, 32 -or- 224, 32

4. Memory Read Request with Address of 1 0020h and Length of 100h bytes (256 decimal) could be completed by an Endpoint in one of the following combinations of Completions (bytes):

256 -or- 96, 160 -or- 96, 128, 32 -or- 224, 32

2.3.1.2 UIO Read Completions §

- UIO Read Completions must follow the same rules as non-UIO Read Completions, with the following exceptions:
 - Multiple UIO Read Completions for a single UIO Read Request are permitted to be returned in any address order.

2.3.1.3 UIO Write Completions §

- UIO Write Completions must follow these rules:
 - Write Completion Boundary (WCB) is 64B, and indicates the naturally aligned address boundaries on which a Completer is permitted to break up the response for a single UIO Write Request into multiple Completions.
 - Multiple UIO Write Completions for a single UIO Write Request are permitted to be returned in any address order.
- It is permitted for UIO Completers to coalesce UIO Write Completions with the same Transaction ID.
 - Completion coalescing must not exceed the number of DWORDs that can be represented in the Length[9:0] field.
 - It is recommended that UIO Completers coalesce opportunistically, and, in most cases, it is recommended not to delay the return of a UIO Completion in order to coalesce it with a subsequent UIO Completion. Specific policies for UIO Completion coalescing are implementation-specific.
- Switches are not permitted to coalesce UIO Completions.

2.3.2 Completion Handling Rules §

- When a device receives a Completion that does not match the Transaction ID for any of the outstanding Requests issued by that device, the Completion is called an “Unexpected Completion”.
- If a received Completion matches the Transaction ID of an outstanding Request, but in other TLP fields does not match the corresponding Request, the Receiver *MUST@FLIT* handle the Completion as an Unexpected Completion.
 - The Requester must not check the IDO Attribute (Attribute Bit 2) in the Completion, since the Completer is not required to copy the value of IDO from the Request into the Completion for that request as stated in § Section 2.2.6.4 and § Section 2.2.9 .
 - However, if the Completion is otherwise properly formed, it is permitted for the Receiver to handle the Completion as an Malformed TLP.
- When an Ingress Port of a Switch receives a Completion that cannot be forwarded, that Ingress Port must handle the Completion as an Unexpected Completion. This includes Completions that target:
 - a non-existent Function in the Device associated with the Upstream Port,
 - a non-existent Device on the Bus associated with the Upstream Port,
 - a non-existent Device or Function on the internal switching fabric, or
 - a Bus Number within the Upstream Port's Bus Number aperture but not claimed by any Downstream Port.
- Receipt of an Unexpected Completion is an error and must be handled according to the following rules:
 - The agent receiving an Unexpected Completion must discard the Completion.
 - An Unexpected Completion is a reported error associated with the Receiving Port (see § Section 6.2).

Note: Unexpected Completions are assumed to occur mainly due to Switch misrouting of the Completion. The Requester of the Request may not receive a Completion for its Request in this case, and the Requester's Completion Timeout mechanism (see § Section 2.8) will terminate the Request.

- Completions with a Completion Status other than Successful Completion or Request Retry Status (in response to Configuration Request) must cause the Requester to:
 - Free Completion buffer space and other resources associated with the Request.
 - Handle the error via a Requester-specific mechanism (see § Section 6.2.3.2.5).

If the Completion arrives between the time an FLR has been initiated and the completion of the FLR by the targeted Function, the Completion is permitted to be handled as an Unexpected Completion or to be silently discarded (following update of flow control credits) without logging or signaling it as an error. Once the FLR has completed, received Completions corresponding to Requests issued prior to the FLR must be handled as Unexpected Completions, unless the Function has been re-enabled to issue Requests.

- Root Complex handling of a Completion with Request Retry Status for a Configuration Request is implementation specific, except for the period following system reset (see § Section 6.6). For Root Complexes that support Configuration RRS Software Visibility, the following rules apply:
 - If Configuration RRS Software Visibility is not enabled, the Root Complex must re-issue the Configuration Request as a new Request.
 - If Configuration RRS Software Visibility is enabled (see below):
 - For a Configuration Read Request that includes both bytes of the Vendor ID field of a device Function's Configuration Space Header, the Root Complex must complete the Request to the host by returning a read-data value of 0001h for the Vendor ID field and all '1's for any additional bytes included in the request. This read-data value has been reserved specifically for this use by the PCI-SIG and does not correspond to any assigned Vendor ID.
 - For a Configuration Write Request or for any other Configuration Read Request, the Root Complex must re-issue the Configuration Request as a new Request.

A Root Complex implementation may choose to limit the number of Configuration Request/RRS Completion Status loops before determining that something is wrong with the target of the Request and taking appropriate action (e.g., complete the Request to system software as a failed transaction).

Configuration RRS Software Visibility may be enabled through the Configuration RRS Software Visibility Enable bit in the Root Control Register (see § Section 7.5.3.12) to control Root Complex behavior on an individual Root Port basis. Alternatively, Root Complex behavior may be managed through the Configuration RRS Software Visibility Enable bit in the Root Complex Register Block (RCRB) Control register as described in § Section 7.9.7.4, permitting the behavior of one or more Root Ports or RCiEPs to be controlled by a single Enable bit. For this alternate case, each Root Port or RCiEP declares its association with a particular Enable bit via an RCRB header association in a Root Complex Link Declaration Capability (see § Section 7.9.8). Each Root Port or RCiEP is permitted to be controlled by at most one Enable bit. Thus, for example, it is prohibited for a Root Port whose Root Control register contains an Enable bit to declare an RCRB header association to an RCRB that also includes an Enable bit in its RCRB Header Capability. The presence of an Enable bit in a Root Port or RCRB Header Capability is indicated by the corresponding Configuration RRS Software Visibility bit (see § Section 7.5.3.13 and § Section 7.9.7.3, respectively).

- Completions with a Reserved Completion Status value are treated as if the Completion Status was Unsupported Request (UR).
- Completions with a Completion Status of Unsupported Request or Completer Abort are reported using the conventional PCI reporting mechanisms (see § Section 7.5.1.1.4).
 - Note that the error condition that triggered the generation of such a Completion is reported by the Completer as described in § Section 6.2.
- When a Completion for a Read, AtomicOp, or DMW Request is received with a Completion Status other than Successful Completion:

- No data is included with the Completion
 - The Cpl (or CplLk) encoding is used instead of CplD (CplDLk)
- This Completion is the final Completion for the Request
 - The Requester must consider the Request terminated, and not expect additional Completions
 - Handling of partial Completions Received earlier is implementation specific

Example: The Requester received 32 bytes of Read data for a 128-byte Read Request it had issued, then it receives a Completion with the Completer Abort Completion Status. The Requester then must free the internal resources that had been allocated for that particular Read Request.

IMPLEMENTATION NOTE: READ DATA VALUES WITH UR COMPLETION STATUS §

Some system configuration software depends on reading a data value of all 1's when a Configuration Read Request is terminated as an Unsupported Request, particularly when probing to determine the existence of a device in the system. A Root Complex intended for use with software that depends on a read-data value of all 1's must synthesize this value when UR Completion Status is returned for a Configuration Read Request.

2.4 Transaction Ordering §

2.4.1 Transaction Ordering Rules for TLPs not using UIO or Flow-Through IDE Streams §

The rules defined in this section apply uniformly to all types of Transactions on PCI Express including Memory, I/O, Configuration, and Messages, except for UIO Requests/Completions (see § Section 2.4.2) and Flow-Through IDE Streams which have modified ordering requirements (see § Section 6.33.4). The ordering rules defined in this table apply within a single Traffic Class (TC). There is no ordering requirement among transactions with different TC labels. Note that this also implies that there is no ordering required between traffic that flows through different Virtual Channels since transactions with the same TC label are not allowed to be mapped to multiple VCs on any PCI Express Link.

For § Table 2-42, the columns represent a first issued transaction and the rows represent a subsequently issued transaction. The table entry indicates the ordering relationship between the two transactions. The table entries are defined as follows:

Yes

The second transaction (row) must be allowed to pass the first (column) to avoid deadlock. (When blocking occurs, the second transaction is required to pass the first transaction. Fairness must be comprehended to prevent starvation.)

Y/N

There are no requirements. The second transaction may optionally pass the first transaction or be blocked by it.

No

The second transaction must not be allowed to pass the first transaction. This is required to support the producer/consumer strong ordering model.

Table 2-42 Ordering Rules Summary §

Row Pass Column?		Posted Request (Col 2)	Non-Posted Request		Completion (Col 5)
			Read Request (Col 3)	NPR with Data (Col 4)	
Posted Request (Row A)		a) No b) <u>Y/N</u>	<u>Yes</u>	<u>Yes</u>	a) <u>Y/N</u> b) <u>Yes</u>
Non-Posted Request	Read Request (Row B)	a) No b) <u>Y/N</u>	<u>Y/N</u>	<u>Y/N</u>	<u>Y/N</u>
	NPR with Data (Row C)	a) No b) <u>Y/N</u>	<u>Y/N</u>	<u>Y/N</u>	<u>Y/N</u>
Completion (Row D)		a) No b) <u>Y/N</u>	<u>Yes</u>	<u>Yes</u>	a) <u>Y/N</u> b) <u>No</u>

Explanation of the row and column headers in § Table 2-42:

A **Posted Request** is a Memory Write Request or a Message Request.

A **Read Request** is a Configuration Read Request, an I/O Read Request, or a Memory Read Request.

An **NPR** (Non-Posted Request) **with Data** is a Configuration Write Request, an I/O Write Request, an AtomicOp Request, or a DMWr.

A **Non-Posted Request** is a Read Request or an NPR with Data.

Explanation of the entries in § Table 2-42:

A2a

A Posted Request must not pass another Posted Request unless A2b applies.

A2b

A Posted Request with RO³⁷ Set is permitted to pass another Posted Request.³⁸ A Posted Request with IDO Set is permitted to pass another Posted Request if the two Requester IDs (including Requester Segment when in FM) are different. Additionally, a Posted Request with IDO Set is permitted to pass another Posted Request with the same Requester ID if both Requests contain a PASID and the two PASID values are different.

A3, A4

A Posted Request must be able to pass Non-Posted Requests to avoid deadlocks.

A5a

A Posted Request is permitted to pass a Completion, but is not required to be able to pass Completions unless A5b applies.

A5b

Inside a PCI Express to PCI/PCI-X Bridge whose PCI/PCI-X bus segment is operating in conventional PCI mode, for transactions traveling in the PCI Express to PCI direction, a Posted Request must be able to pass Completions to avoid deadlock.

B2a

A Read Request must not pass a Posted Request unless B2b applies.

37. In this section, “RO” is an abbreviation for the Relaxed Ordering Attribute field.

38. Some usages are enabled by not implementing this passing (see the No RO-enabled PR-PR Passing bit in § Section 7.5.3.15).

B2b

A Read Request with IDO Set is permitted to pass a Posted Request if the two Requester IDs (including Requester Segment in FM) are different. Additionally, a Read Request with IDO Set is permitted to pass a Posted Request with the same Requester ID if both Requests contain a PASID and the two PASID values are different.

C2a

An NPR with Data must not pass a Posted Request unless C2b applies.

C2b

An NPR with Data and with RO Set³⁹ is permitted to pass Posted Requests. An NPR with Data and with IDO Set is permitted to pass a Posted Request if the two Requester IDs (including Requester Segment in FM) are different. Additionally, an NPR with Data and with IDO Set is permitted to pass a Posted Request with the same Requester ID if both Requests contain a PASID and the two PASID values are different.

B3, B4, C3, C4

A Non-Posted Request is permitted to pass another Non-Posted Request.

B5, C5

A Non-Posted Request is permitted to pass a Completion.

D2a

A Completion must not pass a Posted Request unless D2b applies.

D2b

An I/O or Configuration Write Completion⁴⁰ is permitted to pass a Posted Request. A Completion with RO Set is permitted to pass a Posted Request. A Completion with IDO Set is permitted to pass a Posted Request if the Completer ID of the Completion is different from the Requester ID of the Posted Request.

D3, D4

A Completion must be able to pass Non-Posted Requests to avoid deadlocks.

D5a

Completions with different Transaction IDs are permitted to pass each other.

D5b

Completions with the same Transaction ID must not pass each other. This ensures that multiple Completions associated with a single Memory Read Request will remain in ascending address order.

Additional Rules:

- PCI Express Switches are permitted to allow a Memory Write or Message Request with the Relaxed Ordering bit set to pass any previously posted Memory Write or Message Request moving in the same direction. Switches must forward the Relaxed Ordering attribute unmodified. The Root Complex is also permitted to allow data bytes within the Request to be written to system memory in any order. (The bytes must be written to the correct system memory locations. Only the order in which they are written is unspecified).
- For Root Complex and Switch, Memory Write combining (as defined in the [PCI]) is prohibited.
 - Note: This is required so that devices can be permitted to optimize their receive buffer and control logic for Memory Write sizes matching their natural expected sizes, rather than being required to support the maximum possible Memory Write payload size.
- Combining of Memory Read Requests, and/or Completions for different Requests is prohibited.

39. Note: Not all NPR with Data transactions are permitted to have RO Set.

40. Note: Not all components can distinguish I/O and Configuration Write Completions from other Completions. In particular, routing elements not serving as the associated Requester or Completer generally cannot make this distinction. A component must not apply this rule for I/O and Configuration Write Completions unless it is certain of the associated Request type.

- The No Snoop bit does not affect the required ordering behavior.
- For Root Ports and Switch Downstream Ports, acceptance of a Posted Request or Completion must not depend upon the transmission of a Non-Posted Request within the same traffic class.⁴¹
- For Switch Upstream Ports, acceptance of a Posted Request or Completion must not depend upon the transmission on a Downstream Port of Non-Posted Request within the same traffic class.⁴²
- For Endpoint, Bridge, and Switch Upstream Ports, the acceptance of a Posted Request must not depend upon the transmission of any TLP from that same Upstream Port within the same traffic class.⁴³
- For Endpoint, Bridge, and Switch Upstream Ports, the acceptance of a Non-posted Request must not depend upon the transmission of a Non-Posted Request from that same Upstream Port within the same traffic class.⁴⁴
- For Endpoint, Bridge, and Switch Upstream Ports, the acceptance of a Completion must not depend upon the transmission of any TLP from that same Upstream Port within the same traffic class.⁴⁵

Note that Endpoints are never permitted to block acceptance of a Completion.

- Completions issued for Non-Posted requests must be returned in the same Traffic Class as the corresponding Non-Posted request.
- Root Complexes that support peer-to-peer operation and Switches must enforce these transaction ordering rules for all forwarded traffic.

To ensure deadlock-free operation, devices should not forward traffic from one Virtual Channel to another. The specification of constraints used to avoid deadlock in systems where devices forward or translate transactions between Virtual Channels is outside the scope of this document (see § Appendix D. for a discussion of relevant issues).

41. Satisfying the above rules is a necessary, but not sufficient condition to ensure deadlock free operation. Deadlock free operation is dependent upon the system topology, the number of Virtual Channels supported and the configured Traffic Class to Virtual Channel mappings. Specification of platform and system constraints to ensure deadlock free operation is outside the scope of this specification (see § Appendix D. for a discussion of relevant issues).

42. Satisfying the above rules is a necessary, but not sufficient condition to ensure deadlock free operation. Deadlock free operation is dependent upon the system topology, the number of Virtual Channels supported and the configured Traffic Class to Virtual Channel mappings. Specification of platform and system constraints to ensure deadlock free operation is outside the scope of this specification (see § Appendix D. for a discussion of relevant issues).

43. Satisfying the above rules is a necessary, but not sufficient condition to ensure deadlock free operation. Deadlock free operation is dependent upon the system topology, the number of Virtual Channels supported and the configured Traffic Class to Virtual Channel mappings. Specification of platform and system constraints to ensure deadlock free operation is outside the scope of this specification (see § Appendix D. for a discussion of relevant issues).

44. Satisfying the above rules is a necessary, but not sufficient condition to ensure deadlock free operation. Deadlock free operation is dependent upon the system topology, the number of Virtual Channels supported and the configured Traffic Class to Virtual Channel mappings. Specification of platform and system constraints to ensure deadlock free operation is outside the scope of this specification (see § Appendix D. for a discussion of relevant issues).

45. Satisfying the above rules is a necessary, but not sufficient condition to ensure deadlock free operation. Deadlock free operation is dependent upon the system topology, the number of Virtual Channels supported and the configured Traffic Class to Virtual Channel mappings. Specification of platform and system constraints to ensure deadlock free operation is outside the scope of this specification (see § Appendix D. for a discussion of relevant issues).

IMPLEMENTATION NOTE:

DEADLOCKS CAUSED BY PORT ACCEPTANCE DEPENDENCIES §

With certain configurations and communication paradigms, systems whose Ports have acceptance dependencies may experience deadlocks. In this context, Port acceptance dependencies refer to the Ingress Port making the acceptance of a Posted Request or Completion dependent upon the Egress Port first being able to transmit one or more TLPs. As stated earlier in this section, Endpoints, Bridges, and Switch Upstream Ports are forbidden to have these dependences. However, Downstream Ports are allowed to have these dependencies.

In certain cases, Downstream Port acceptance dependencies are unavoidable. For example, the ACS P2P Request Redirect mechanism may be redirecting some peer-to-peer Posted Requests Upstream through an RP for validation in the Root Complex. Validated Posted Requests are then reflected back down through the same RP so they can make their way to their original targets. The validated Posted Requests set up the acceptance dependency due to this internal looping. For traffic within one system, Downstream Port acceptance dependencies do not contribute to deadlocks. However, for certain types of traffic between systems, Downstream Port acceptance dependencies can contribute to deadlocks.

One general case where this may contribute to deadlocks is when two or more systems have an interconnect that enables each host to map host memory in other hosts for Programmed I/O (PIO) access, as shown on the left side of Figure x. A specific example is when two systems each have a PCIe Switch with one or more integrated by Non-Transparent Bridges (NTBs), and the two systems are connected as shown on the right side of the figure.

Deadlock can occur if each host CPU is doing a heavy stream of Posted Requests to host memory in the opposite host. If Posted Request traffic in each direction gets congested, and the Root Port (RP) in each host stops accepting Posted Requests because the RP can't transmit outbound TLPs, deadlock occurs. The root cause of deadlock in this case is actually the adapter to the system-to-system interconnect setting up an acceptance dependency, which is forbidden for Endpoints. For the example case of PCIe Switches with integrated NTBs, the NTBs are Endpoints, and the Switch Upstream Port has the acceptance dependency. While the Root Port's acceptance dependency is not the root cause of the deadlock, it contributes to the deadlock.

Solutions using this paradigm for intersystem communications will either need to determine that their systems don't have these acceptance dependencies or rely on other mechanisms to avoid these potential deadlocks. Such mechanisms are outside the scope of this specification.

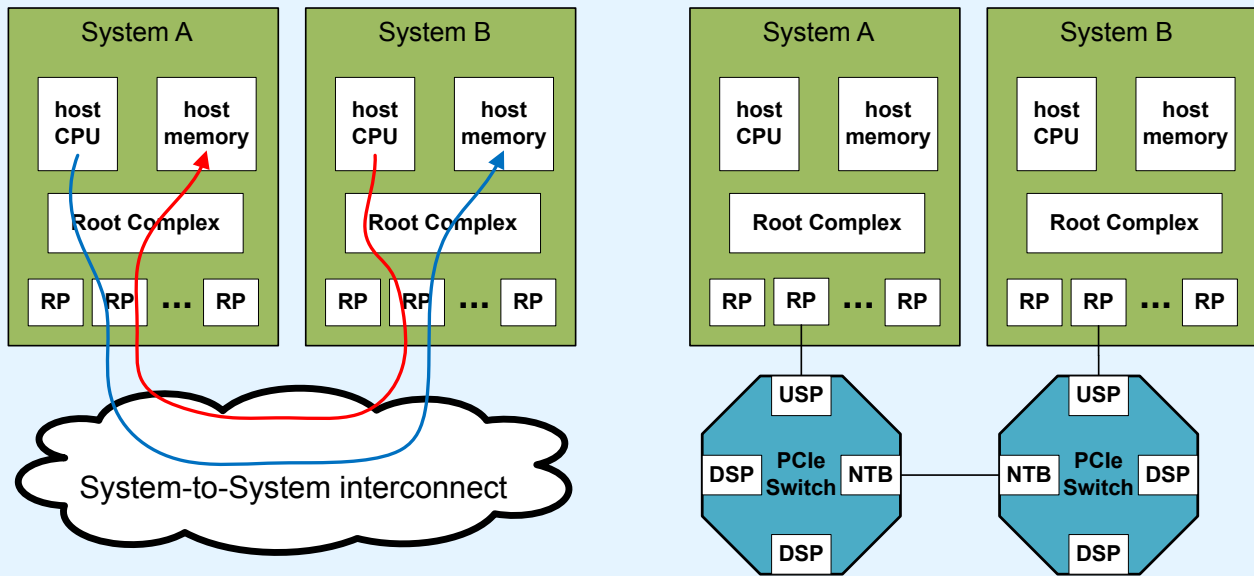

Figure 2-93 Deadlock Examples with Intersystem Interconnects §

IMPLEMENTATION NOTE: LARGE MEMORY READS VS. MULTIPLE SMALLER MEMORY READS §

Note that the rule associated with entry D5b in § Table 2-42 ensures that for a single Memory Read Request serviced with multiple Completions, the Completions will be returned in address order. However, the rule associated with entry D5a permits that different Completions associated with distinct Memory Read Requests may be returned in a different order than the issue order for the Requests. For example, if a device issues a single Memory Read Request for 256 bytes from location 1000h, and the Request is returned using two Completions (see § Section 2.3.1.1) of 128 bytes each, it is guaranteed that the two Completions will return in the following order:

1st Completion returned: Data from 1000h to 107Fh.

2nd Completion returned: Data from 1080h to 10FFh.

However, if the device issues two Memory Read Requests for 128 bytes each, first to location 1000h, then to location 1080h, the two Completions may return in either order:

1st Completion returned: Data from 1000h to 107Fh.

2nd Completion returned: Data from 1080h to 10FFh.

- or -

1st Completion returned: Data from 1080h to 10FFh.

2nd Completion returned: Data from 1000h to 107Fh.

2.4.2 Ordering Rules for UIO §

The rules defined in this section apply to UIO TLPs. UIO and non-UIO TLPs are never mixed within a TC/VC, and ordering dependencies between UIO and non-UIO TLPs are not permitted.

The ordering rules for UIO TLPs are (see § Table 2-43):

- UIO Completions must be allowed to pass UIO Requests
- UIO allows arbitrary reordering for all other cases

Table 2-43 UIO TLP Ordering Rules §

Row Pass Col?	UIO PR-FC TLP (Col U1)	UIO NPR-FC TLP (Col U2)	UIO Completion (Col U3)
UIO PR-FC TLP (Row UA)	Yes/No	Yes/No	Yes/No
UIO NPR-FC TLP (Row UB)	Yes/No	Yes/No	Yes/No
UIO Completion (Row UC)	Yes	Yes	Yes/No

It is recommended that permitted UIO reordering cases be supported and implemented.

The deadlock avoidance rules for UIO TLPs are covered in § Table 2-44 and § Table 2-45.

- For considerations on acceptance dependencies, see IMPLEMENTATION NOTE: DEADLOCKS CAUSED BY PORT ACCEPTANCE DEPENDENCIES
- Downstream Ports include Root Ports and Switch Downstream Ports
- Upstream Ports include Switch Upstream Ports and Endpoint Upstream Ports

Table 2-44 UIO Acceptance Dependency Rules – Downstream Ports §

Row Independent of Col?		Egress transmission		
		UIO Memory Write Request (Col 1)	Other UIO Memory Request (Col 2)	UIO Completion (Col 3)
Ingress Acceptance	UIO Memory Write Request (Row A)	Yes/No	Yes/No	Yes/No
	Other UIO Memory Request (Row B)	Yes/No	Yes/No	Yes/No
	UIO Completion (Row C)	Yes	Yes	Yes/No

Table 2-45 UIO Acceptance Dependency Rules – Upstream Ports §

Row Independent of Col?		Egress transmission		
		UIO Memory Write Request (Col 1)	Other UIO Memory Request (Col 2)	UIO Completion (Col 3)
Ingress Acceptance	UIO Memory Write Request (Row A)	Yes	Yes	Yes/No
	Other UIO Memory Request (Row B)	Yes	Yes	Yes/No
	UIO Completion (Row C)	Yes	Yes	Yes

2.4.3 Update Ordering and Granularity Observed by a Read Transaction §

2.4.3.1 Ordering and Granularity for Non-UIO Reads §

If a Requester using a single transaction reads a block of data from a Completer, and the Completer's data buffer is concurrently being updated, the ordering of multiple updates and granularity of each update reflected in the data returned by the read is outside the scope of this specification, unless otherwise specified (see § Section 6.32). This applies both to updates performed by PCI Express write transactions and updates performed by other mechanisms such as host CPUs updating host memory.

If a Requester using a single transaction reads a block of data from a Completer, and the Completer's data buffer is concurrently being updated by one or more entities not on the PCI Express fabric, the ordering of multiple updates and granularity of each update reflected in the data returned by the read is outside the scope of this specification, unless otherwise specified (see § Section 6.32).

As an example of update ordering, assume that the block of data is in host memory, and a host CPU writes first to location A and then to a different location B. A Requester reading that data block with a single read transaction is not guaranteed to observe those updates in order. In other words, the Requester may observe an updated value in location B and an old value in location A, regardless of the placement of locations A and B within the data block. Unless a Completer makes its own guarantees (outside this specification) with respect to update ordering, a Requester that relies on update ordering must observe the update to location B via one read transaction before initiating a subsequent read to location A to return its updated value.

As an example of update granularity, if a host CPU writes a QW to host memory, a Requester reading that QW from host memory may observe a portion of the QW updated and another portion of it containing the old value.

While not required by this specification, it is strongly recommended that host platforms guarantee that when a host CPU writes aligned DWs or aligned QWs to host memory, the update granularity observed by a PCI Express read will not be smaller than a DW.

IMPLEMENTATION NOTE: NO ORDERING REQUIRED BETWEEN CACHELINES §

A Root Complex serving as a Completer to a single Memory Read that requests multiple cachelines from host memory is permitted to fetch multiple cachelines concurrently, to help facilitate multi-cacheline completions, subject to Tx_MPS_Limit. No ordering relationship between these cacheline fetches is required.

2.4.3.2 Ordering and Granularity for UIO Reads §

If a Requester uses a single UIO Read Request to read a block of data from a Completer, and the Completer's data buffer is concurrently being updated using UIO Write Requests, the granularity of each update reflected in the data returned by the read must, within each 64B aligned block, be observed such that each UIO Write Request is either fully completed or not-at-all completed.

Once a Completer transmits a UIO Read Completion reflecting the updated value resulting from a UIO Write Request to a 64B aligned block, subsequently received UIO Requests must observe the UIO Write as fully completed for that 64B aligned block. Thus, at any other Link or Port between a Requester and Completer, observation of a UIO Read Completion at that Link/Port reflecting the updated value resulting from a UIO Write Request to that 64B aligned block implies that all other UIO Requests passing on that Link/Port will observe the UIO Write as fully completed for that 64B aligned block.

The observed sequence is permitted to be different for each 64B aligned block.

A Completer is permitted to implement, through a restricted programming model, an update granularity of less than 64B for some or all of a resource mapped by means of a BAR. In order to maintain the 64B ordering/granularity requirements, such a Completer is permitted to terminate Requests that exceed this smaller update granularity in an implementation specific way.

2.4.4 Update Ordering and Granularity Provided by a Write Transaction §

2.4.4.1 Ordering and Granularity for Non-UIO Writes §

If a single write transaction containing multiple DWs and the Relaxed Ordering bit Clear is accepted by a Completer, the observed ordering of the updates to locations within the Completer's data buffer must be in increasing address order.

This semantic is required in case a PCI or PCI-X Bridge along the path combines multiple write transactions into the single one. However, the observed granularity of the updates to the Completer's data buffer is outside the scope of this specification.

While not required by this specification, it is strongly recommended that host platforms guarantee that when a PCI Express write updates host memory, the update granularity observed by a host CPU will not be smaller than a DW.

As an example of update ordering and granularity, if a Requester writes a QW to host memory, in some cases a host CPU reading that QW from host memory could observe the first DW updated and the second DW containing the old value.

2.4.4.2 Ordering and Granularity for UIO Writes §

For each 64B naturally aligned block updated in-full or in-part by a single UIO Write Request, all bytes updated within the 64B aligned block must be fully observable or not-at-all observable to any read, whether the read is performed by a PCI Express transaction or another mechanism. The observed sequence is permitted to be different for each 64B aligned block but the observed sequence must be consistent for all readers of a particular 64B aligned block.

Once a Completer has Transmitted a UIO Write Completion for a 64B aligned block, the Completer must ensure that all UIO Requests it receives must observe the UIO Write as fully completed for that 64B aligned block. Thus, at any other Link or Port between a Requester and Completer, observation of a UIO Write Completion at that Link/Port implies that all other UIO Requests passing on that Link/Port will observe the UIO Write as fully completed for that 64B aligned block.

The observed sequence is permitted to be different for each 64B aligned block.

A Completer is permitted to implement, through a restricted programming model, an update granularity of less than 64B for some or all of a resource mapped by means of a BAR. In order to maintain the 64B ordering/granularity requirements, such a Completer is permitted to terminate Requests that exceed this smaller update granularity in an implementation specific way.

2.5 Virtual Channel (VC) Mechanism §

The Virtual Channel (VC) mechanism provides support for carrying, throughout the fabric, traffic that is differentiated using TC labels. The foundations of VCs are independent fabric resources (queues/buffers and associated control logic). These resources are used to move information across Links with fully independent Flow Control between different VCs (Link Flow Control is defined in § Section 2.6). This is key to solving the problem of flow-control induced blocking where a single traffic flow may create a bottleneck for all traffic within the system.

As Link speed increases, the buffer space required to support fully independent Flow Control between different VCs while also supporting full Link bandwidth on any given VC also increases. In Flit Mode, the Shared Flow Control (FC) mechanism can be used to reduce this resource requirement. Flow Control is defined in § Section 2.6 .

Traffic is associated with VCs by mapping packets with particular TC labels to their corresponding VCs. The Streamlined Virtual Channel, Virtual Channel, and Multi-Function Virtual Channel (MFVC) mechanisms allow flexible mapping of TCs onto the VCs. In the simplest form, TCs can be mapped to VCs on a 1:1 basis. To allow performance/cost tradeoffs, PCI Express provides the capability of mapping multiple TCs onto a single VC. § Section 2.5.2 covers details of TC to VC mapping.

A Virtual Channel is established when one or multiple TCs are associated with a physical VC resource designated by Virtual Channel Identification (VC ID). This process is controlled by configuration software as described in § Section 6.3 , § Section 7.9.1 , and § Section 7.9.2 .

In Flit Mode, initially, VC0 is initialized automatically by hardware with a dedicated FC credit pool, and a shared FC pool. As system software enables other VCs, the enabled VCs are also initialized with a dedicated FC credit pool and a Shared FC pool per VC. The Shared FC credits for additional VCs expand the Shared FC pool available to all VCs (and are

permitted to be zero when the appropriate Shared FC credits were granted earlier). When only a single VC is supported and merged credits are not used, there is a single “shared” credit pool and VC0 is initialized with zero dedicated credits. When only a single VC is supported and merged credits are used, there is a single “shared” non-Posted credit pool and VC0 is initialized with zero non-Posted dedicated credits (posted and completion do have dedicated credits).

Once system software has completed enabling all VCs that are to be enabled, it is recommended that system software Set, as appropriate, VC Enablement Completed in the SVC Port Control Register, the All VCs Enabled bit in the Port VC Control Register or the MFVC Port VC Control Register to indicate that VC initialization is completed. Once this bit has been Set, behavior is undefined if additional VCs are enabled or disabled.

The Shared Flow Control Usage Limit mechanism allows system software to manage the allocation of Shared FC by Transmitters, for example to support Quality of Service (QoS) policies.

Support for TCs and VCs beyond the default TC0/VC0 pair is optional although some optional mechanisms also require support for additional TC/VC. The association of TC0 with VC0 is fixed, i.e., hardwired, and must be supported by all components. Therefore, the baseline TC/VC setup does not require any VC-specific hardware or software configuration. In order to ensure interoperability where possible, components that do not implement any of the optional SVC, VC, or MFVC Extended Capability structures must obey the following rules:

- A Requester must only generate requests with TC0 label. (Note that if the Requester initiates requests with a TC label other than TC0, the requests may be treated as malformed by the component on the other side of the Link that implements the extended VC Extended Capability and applies TC Filtering.)
- A Completer must accept requests with TC label other than TC0, and must preserve the TC label. That is, any completion that it generates must have the same TC label as the label of the request.
- A Switch must map all TCs to VC0 and must forward all transactions regardless of the TC label.

Even with the above rules, in some cases interoperability may not be possible, such as when TC/VC mechanisms are used to implement protocols that cannot be mapped onto TC0/VC0. The SVC mechanism and its associated requirements provide a framework for interoperable hardware and software, and it is strongly recommended that hardware implementing support for VCs beyond VC0 support SVC.

A Port containing Functions capable of generating Requests with TC labels other than TC0 must implement suitable SVC, VC, or MFVC Extended Capability structures (as applicable), even if it only supports the default VC. Example Function types are Endpoints and Root Ports. This is required in order to enable mapping of TCs beyond the default configuration. It must follow the TC/VC mapping rules according to the software programming of the SVC, VC, and MFVC Extended Capability structures.

SVC provides explicit support for architecturally-defined TC/VC applications via a combination of hardware requirements and software guidance. Ports supporting UIO must implement the SVC Extended Capability. The TC/VC default HW assignments in § Table 2-46 are mandatory for SVC.

Table 2-46 Streamlined VC (SVC) TC/VC Default Assignments §

TC	VC	Description
TC0	VC0	TC0 VC0 Default TC/VC- configured automatically by hardware – required to be used for certain mechanisms as defined in this specification
TC1	VC1	Reserved
TC2	VC2	Reserved
TC3	VC3	UIO TC/VC (Required if UIO is supported)
TC4	VC4	UIO TC/VC (Optional if UIO is supported)
TC5	VC5	Reserved

TC	VC	Description
TC6	VC6	Reserved
TC7	VC7	Reserved

IMPLEMENTATION NOTE: MULTI-HOST FABRICS AND STREAMLINED VC (SVC) TC/VC DEFAULT ASSIGNMENTS §

When PCIe and/or related switching fabrics support multiple hosts, and one or more fabric Links carry traffic from multiple hosts concurrently, the use of TCs across the fabric and TC/VC mappings on each fabric Link may conflict. E.g., if one host relies on TC3 mapping to a UIO VC while another host relies on TC3 mapping to a non-UIO VC, the resulting behavior is undefined.

To avoid TC conflicts on multi-host fabric Links, it is recommended for system software that configures TC/VC mappings to:

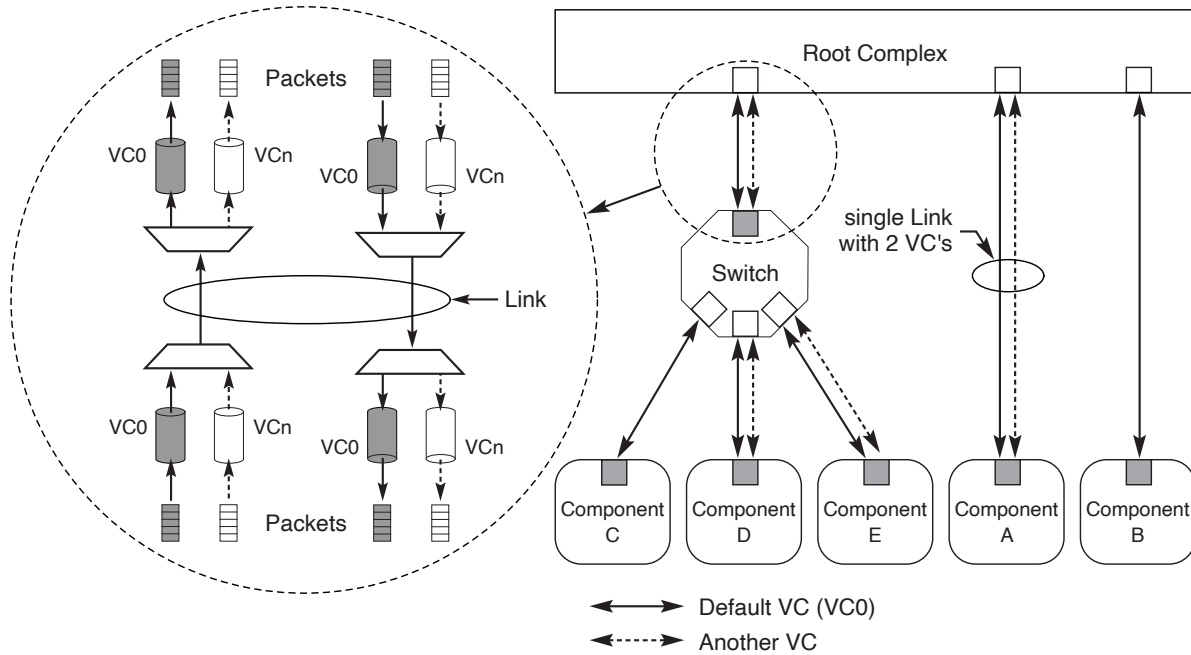

- support Streamlined VC (SVC) Extended Capability,
- preserve any TC/VC assignments already configured in Switch Ports, whether such VCs are enabled or not
- configure and enable TC/VC assignments on each RP to match such Switch Ports, to the extent permitted by RP hardware capability.

This allows a Fabric Manager to preconfigure TC/VC assignments fabric-wide, and rely on OS cooperation.

For cases where a Fabric Manager does not preconfigure TC/VC assignments, § Table 2-46 provides reasonable defaults that can work in envisioned multi-host fabrics.

System software should use the SVC Extended Capability for TC/VC configuration in all hardware that supports SVC. If it enables VCs other than VC0 in hardware that supports only the VC and/or MFVC Extended Capabilities, it should configure enabled TC/VCs to match the SVC default assignments.

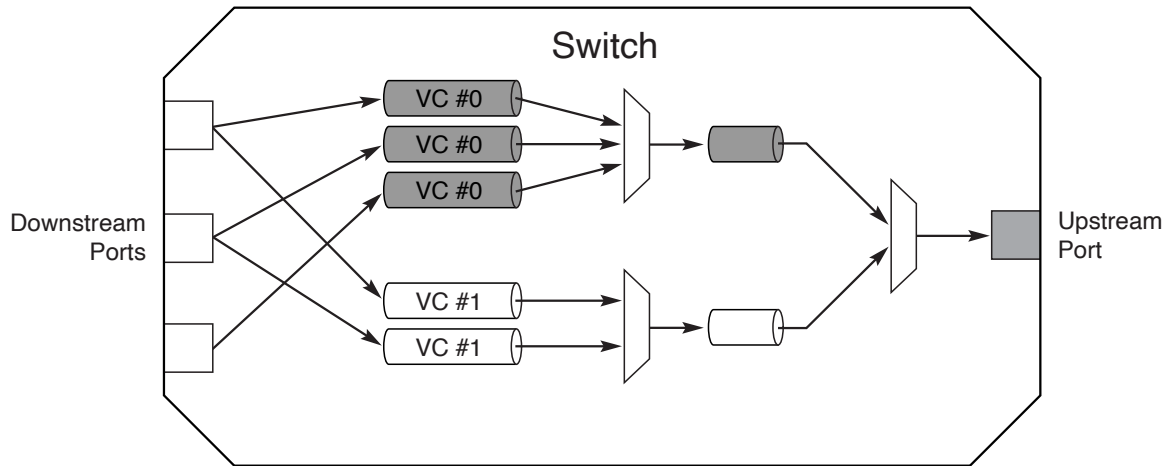

§ Figure 2-94 illustrates the concept of Virtual Channel. Conceptually, traffic that flows through VCs is multiplexed onto a common physical Link resource on the Transmit side and de-multiplexed into separate VC paths on the Receive side.

OM13760

Figure 2-94 Virtual Channel Concept - An Illustration §

Internal to the Switch, every Virtual Channel requires dedicated physical resources (queues/buffers and control logic) that support independent traffic flows inside the Switch. § Figure 2-95 shows conceptually the VC resources within the Switch (shown in § Figure 2-94) that are required to support traffic flow in the Upstream direction.

OM13761

Figure 2-95 Virtual Channel Concept - Switch Internals (Upstream Flow) §

An MFD may implement Virtual Channel resources similar to a subset of those in a Switch, for the purpose of managing the Quality of Service (QoS) for Upstream requests from the different Functions to the device's Upstream Egress Port.

IMPLEMENTATION NOTE: VC AND VC BUFFERING CONSIDERATIONS §

The amount of buffering beyond the architectural minimums per supported VC is implementation specific.

Buffering beyond the architectural minimums is not required to be identical across all VCs on a given Link. That is, an implementation may provide greater buffer depth for selected VCs as a function of implementation usage models and other Link attributes (e.g., Link width and signaling).

Implementations may adjust their buffering per VC based on implementation specific policies derived from configuration and VC enablement. For example, if a four VC implementation has only two VCs enabled, the implementation may assign the non-enabled VC buffering to the enabled VCs to improve fabric efficiency/performance by reducing the probability of fabric backpressure due to Link-level flow control.

The number of VCs supported, and the associated buffering per VC per Port, are not required to be the same for all Ports of a multi-Port component (e.g., a Switch or Root Complex).

2.5.1 Virtual Channel Identification (VC ID) §

PCI Express Ports can support 1 to 8 Virtual Channels - each Port is independently configured/managed therefore allowing implementations to vary the number of VCs supported per Port based on usage model-specific requirements. These VCs are uniquely identified using the VC ID mechanism.

Note that while DLLPs contain VC ID information for Flow Control accounting, TLPs do not. The association of TLPs with VC ID for the purpose of Flow Control accounting is done at each Port of the Link using TC to VC mapping as discussed in § Section 2.5.2.

Rules for assigning VC ID to VC hardware resources within a Port are as follows:

- VC ID assignment must be unique per Port - The same VC ID cannot be assigned to different VC hardware resources within the same Port.
- VC ID assignment must be the same (matching in the terms of numbers of VCs and their IDs) for the two Ports on both sides of a Link.
- If an MFD implements an MFVC Extended Capability structure, its VC hardware resources are distinct from the VC hardware resources associated with any VC Extended Capability structures of its Functions. The VC ID uniqueness requirement (first bullet above) still applies individually for the MFVC and any VC Extended Capability structures. In addition, the VC ID cross-Link matching requirement (second bullet above) applies for the MFVC Extended Capability structure, but not the VC Extended Capability structures of the Functions.
- VC ID 0 is assigned and fixed to the default VC.
- It is permitted to implement VCs that support only specific protocols and/or use models
 - If software maps such VCs in a way that is incompatible with their protocol/use model requirements, the resulting hardware behavior is undefined

2.5.2 TC to VC Mapping §

Every Traffic Class that is supported must be mapped to one of the Virtual Channels. The mapping of TC0 to VC0 is fixed.

The mapping of TCs other than TC0 must obey the following rules:

- One or multiple TCs can be mapped to a VC.
- One TC must not be mapped to multiple VCs in any Port or Endpoint Function.
- TC/VC mapping must be identical for Ports on both sides of a Link.
- If UIO is supported, VC3 must be supported, and it must support UIO, and enabling VC3 is required to use UIO.
- If UIO is supported, and if a second UIO VC is supported, then the second UIO VC must be VC4 (and so VC4 must support UIO traffic); if UIO is enabled using only one VC it must be VC3, if UIO is enabled using two VCs they must be VC3 and VC4.
- If a UIO TLP targets an Egress Port where the TC maps to a non-UIO VC, or a non-UIO TLP targets an Egress Port where the TC maps to a UIO VC, such TLPs must be handled as specified in § Section 2.2.1.2 for other TLPs that cannot be translated. Note that this rule partially overlaps with the rule in § Section 2.2.1.2 regarding a UIO TLP targeting an Egress Port in NFM.

§ Table 2-47 provides an example of TC to VC mapping.

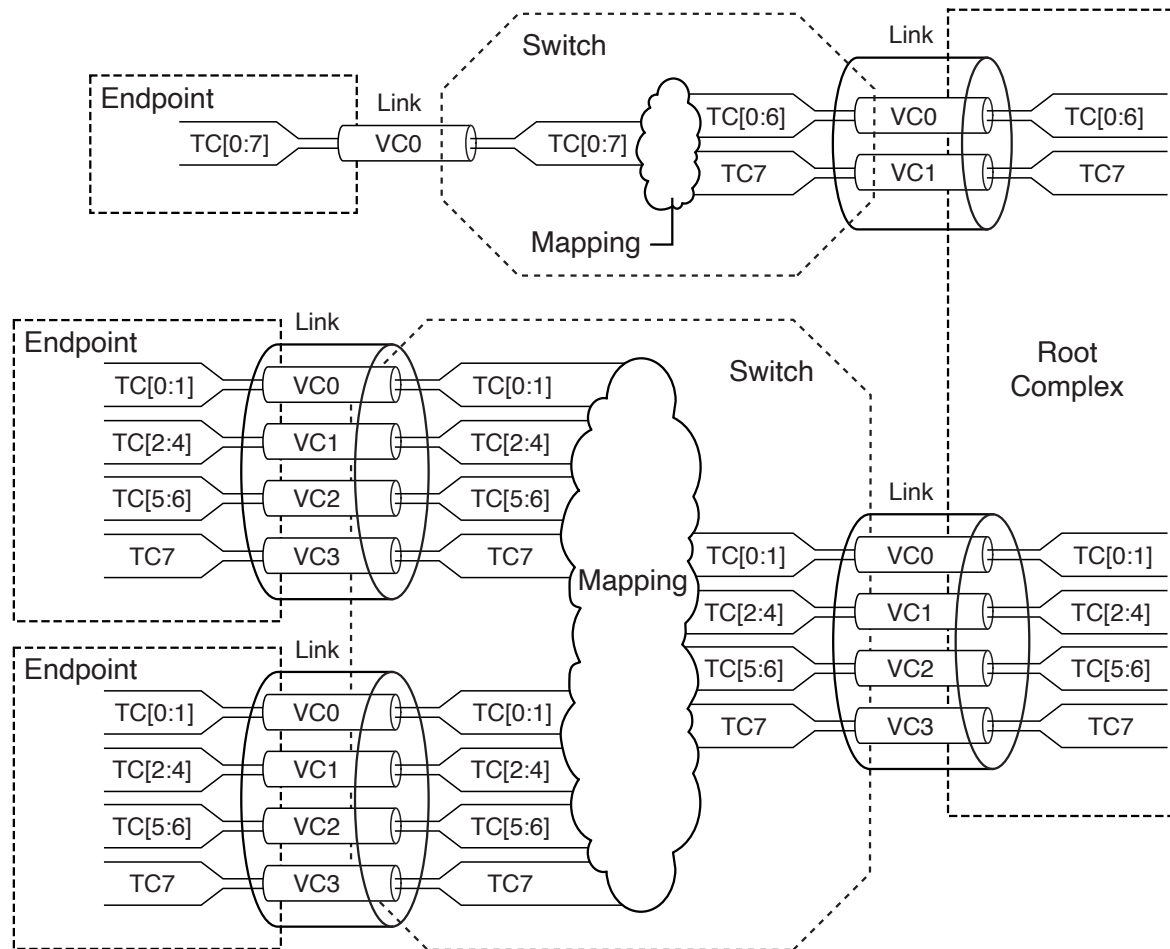

Table 2-47 TC to VC Mapping Example §

Supported VC Configurations	TC/VC Mapping Options
VC0	TC(0-7)/VC0
VC0, VC1	TC(0-6)/VC0, TC7/VC1
VC0-VC3	TC(0-1)/VC0, TC(2-4)/VC1, TC(5-6)/VC2, TC7/VC3
VC0-VC7	TC[0:7]/VC[0:7]

Notes on conventions:

TCn/Vck	TCn mapped to Vck
TC(n-m)/Vck	all TCs in the range n-m mapped to Vck (i.e., to the same VC)
TC[n:m]/VC[n:m]	TCn/VCn, TCn+1/VCn+1, ..., TCm/VCm

§ Figure 2-96 provides a graphical illustration of TC to VC mapping in several different Link configurations. For additional considerations on TC/VC, refer to § Section 6.3 .

OM13762

Figure 2-96 An Example of TC/VC Configurations §

2.5.3 VC and TC Rules §

Here is a summary of key rules associated with the TC/VC mechanism:

- All devices must support the general purpose I/O Traffic Class (i.e., TC0 and must implement the default VC0).
- Each Virtual Channel (VC) has independent Flow Control.
- There are no ordering relationships required between different TCs.
- There are no ordering relationships required between different VCs.
- A Switch's peer-to-peer capability applies to all Virtual Channels supported by the Switch.
- An MFD's peer-to-peer capability between different Functions applies to all Virtual Channels supported by the MFD.
- Transactions with a TC that is not mapped to any enabled VC in an Ingress Port are treated as Malformed TLPs by the receiving device.
- For Switches, transactions with a TC that is not mapped to any of the enabled VCs in the target Egress Port are treated as Malformed TLPs.

- For a Root Port, transactions with a TC that is not mapped to any of the enabled VCs in the target RCRB are treated as Malformed TLPs.
- For MFDs with an MFVC Extended Capability structure, any transaction with a TC that is not mapped to an enabled VC in the MFVC Extended Capability structure is treated as a Malformed TLP.
- Switches must support independent TC/VC mapping configuration for each Port.
- A Root Complex must support independent TC/VC mapping configuration for each RCRB, the associated Root Ports, and any RCiEPs.

For more details on the VC and TC mechanisms, including configuration, mapping, and arbitration, refer to § Section 6.3.

2.6 Ordering and Receive Buffer Flow Control §

Flow Control (FC) is used to prevent overflow of Receiver buffers and to enable compliance with the ordering rules defined in § Section 2.4. Note that the Flow Control mechanism is used by the Requester to track the queue/buffer space available in the agent across the Link as shown in § Figure 2-97. That is, Flow Control is point-to-point (across a Link) and not end-to-end. Flow Control does not imply that a Request has reached its ultimate Completer.

OM13776

Figure 2-97 Relationship Between Requester and Ultimate Completer §

Flow Control is orthogonal to the data integrity mechanisms used to implement reliable information exchange between Transmitter and Receiver. Flow Control can treat the flow of TLP information from Transmitter to Receiver as perfect, since the data integrity mechanisms ensure that corrupted and lost TLPs are corrected through retransmission (see § Section 3.6).

In Non-Flit Mode each Virtual Channel (VC) maintains an independent FC credit pool.

In Flit Mode, the Shared FC mechanism can be used to reduce VC resource requirements. There are two sets of resources associated with each VC: a (typically small) pool of dedicated resources associated independently with each FC/VC (to avoid deadlock by allowing that the Transmitter to transmit at least one TLP in that VC/FC using only dedicated credit(s)), and a portion of the (typically larger) pool of shared resources. The Transmitter gate function (defined later in this section) uses the sum of all Shared FC returned across all VCs. The transmitter gate function also provides a Usage Limit mechanism to avoid over-consumption of buffers by stalled VCs. This Usage Limit mechanism is configured by software and defaults to disabled. To support Usage Limit, credits are returned to the Transmitter indicating the VC for the TLP(s) that, by making forward progress, freed those credits. The FC information is conveyed between two sides of the Link using DLLPs. The VC ID field of the DLLP is used to carry the VC ID that is required for proper Flow Control credit accounting. Additionally, [Merged] FC enables the sharing of buffers for Posted Requests and Completions, further reducing resource requirements.

Flow Control mechanisms used internally within an MFD are outside the scope of this specification.

Flow Control is handled by the Transaction Layer in cooperation with the Data Link Layer. The Transaction Layer performs Flow Control accounting functions for Received TLPs and “gates” TLP Transmissions based on available credits for transmission even if those TLPs are eventually nullified.

Note: Flow Control is a function of the Transaction Layer and, therefore, the following types of information transmitted on the interface are not associated with Flow Control Credits: LCRC, Packet Framing Symbols, other Special Symbols, and Data Link Layer to Data Link Layer inter-communication packets. An implication of this fact is that these types of information must be processed by the Receiver at the rate they arrive (except as explicitly noted in this specification).

Also, any TLPs transferred from the Transaction Layer to the Data Link and Physical Layers must have first passed the Flow Control gate. Thus, both Transmit and Receive Flow Control mechanisms are unaware if the Data Link Layer transmits a TLP repeatedly due to errors on the Link.

2.6.1 Flow Control (FC) Rules §

In this and other sections of this specification, rules are described using conceptual “registers” that a device could use in order to implement a compliant implementation. This description does not imply or require a particular implementation and is used only to clarify the requirements.

- Flow Control (FC) information is transferred using Flow Control Packets (FCPs), which are a type of DLLP (see § Section 3.5), and, in some cases, the Optimized_Update_FC.
- **FC Unit Size** indicates the number of DW covered by one flow control credit:
 - For Data, the FC Unit Size is 4 DW.
 - For Headers in Non-Flit Mode:
 - For Receivers that do not support TLP Prefixes, FC Unit Size is the sum of one maximum-size Header and TLP Digest.
 - For Receivers that support End-End TLP Prefixes, FC Unit Size is the sum of one maximum-size Header, TLP Digest, and the maximum number of End-End TLP Prefixes permitted in a TLP.
 - The management of FC for Receivers that support Local TLP Prefixes is dependent on the Local TLP Prefix type.
 - For Headers in Flit Mode:
 - For Switch Port Receivers, FC Unit Size is the sum of one maximum-size Base Header, OHC-A, OHC-B, OHC-C, OHC-E if supported, and one maximum-size TLP Trailer.
 - For Endpoint Upstream Port and Root Port Receivers, FC Unit Size is the sum of one Base Header of the largest supported size, OHC-A, OHC-B, OHC-C, OHC-E if supported, and one TLP Trailer of the largest size supported.
- For NFM and for dedicated credits in FM, each Virtual Channel has independent FC.
- In FM, each Virtual Channel has some amount of independent FC referred to as dedicated credits, and some amount of shared FC.
 - When only one single VC is implemented and [Merged] is not used, there are no dedicated credits, all flow control uses shared credits (see § Table 3-3, Notes 3 and 4).
- It is permitted for a Transmitter to use dedicated credits when Transmitting a TLP, even when sufficient shared credits are available.
- The Transmitter indicates the use of dedicated credits for a specific TLP by applying the Flit Mode Local TLP Prefix with the TLP Uses Dedicated Credits bit Set.
- Flow Control distinguishes three types of TLPs (note relationship to ordering rules - see § Section 2.4):

- Posted Requests (P) - Messages and Memory Writes
- Non-Posted Requests (NP) - All Reads, I/O Writes, Configuration Writes, AtomicOps, and DMWrS.
- Completions (Cpl) - Associated with corresponding NP Requests
- In addition, Flow Control distinguishes the following types of TLP information within each of the three types:
 - Headers (H)
 - Data (D)
- Thus, there are six types of information tracked by Flow Control for each Virtual Channel, as shown in § Table 2-48.

Table 2-48 Flow Control Credit Types §

Credit Type	Applies to This Type of TLP Information
PH	Posted Request headers
PD	Posted Request Data payload
NPH	Non-Posted Request headers
NPD	Non-Posted Request Data payload
CplH	Completion headers
CplD	Completion Data payload

- TLPs consume Flow Control credits as shown in § Table 2-49.

Table 2-49 TLP Flow Control Credit Consumption §

TLP	Credit Consumed ⁴⁶
Memory, I/O, Configuration Read Request	1 NPH unit
Memory Write Request	1 PH + n PD units ⁴⁷
I/O, Configuration Write Request	1 NPH + 1 NPD Note: size of data written is never more than 1 (aligned) DW
AtomicOp, DMWr Request	1 NPH + n NPD units
Message Requests without data	1 PH unit
Message Requests with data	1 PH + n PD units
Memory Read Completion	1 CplH + n CplD units
I/O, Configuration Read Completions	1 CplH unit + 1 CplD unit
I/O, Configuration Write, and DMWr Completions	1 CplH unit
AtomicOp Completion	1 CplH unit + 1 CplD unit

46. Each header credit implies the ability to accept a TLP Digest along with the corresponding TLP.

47. For all cases where “n” appears, $n = \text{Roundup}(\text{Length}/\text{FC unit size})$. Where Length is the size of the Payload in DW.

TLP	Credit Consumed
	Note: size of data returned is never more than 4 (aligned) DWs.

- FC must be initialized autonomously by hardware only for the default Virtual Channel (VC0).
 - VC0 is initialized when the Data Link Layer is in the DL_Init state following reset (see § Section 3.2 and § Section 3.4).
- When Virtual Channels other than VC0 are enabled by software, each newly enabled VC must follow the Flow Control initialization protocol (see § Section 3.4).
 - Software enables a Virtual Channel by setting the VC Enable bits for that Virtual Channel in both components on a Link (see § Section 7.9.1 and § Section 7.9.2).

Note: It is possible for multiple VCs to be following the Flow Control initialization protocol simultaneously - each follows the initialization protocol as an independent process.

- Software disables a Virtual Channel by clearing the VC Enable bits for that Virtual Channel in both components on a Link.
 - Disabling a Virtual Channel for a component resets the Flow Control tracking mechanisms for that Virtual Channel in that component.
 - In Flit Mode, disabling a Virtual Channel resets the Flow Control tracking mechanisms for dedicated credits for that Virtual Channel in that component and has no effect on Shared Flow Control credit tracking.
 - In Flit Mode, behavior is undefined if a VC is disabled and subsequently re-enabled while the link remains up.
- InitFC1 and InitFC2 FCPs are used only for Flow Control initialization (see § Section 3.4).
- An InitFC1, InitFC2, UpdateFC FCP, or Optimized_Update_FC that specifies a Virtual Channel that is disabled must be discarded without effect.
- During FC initialization for any Virtual Channel, including the default VC initialized as a part of Link initialization, Receivers must initially advertise VC credit values equal to or greater than those shown in Table 2-50.
 - Scaled Flow Control is activated when both Ports on a Link perform the Data Link Feature mechanism with the Scaled Flow Control Supported bit Set (i.e., Local Scaled Flow Control Supported and Remote Scaled Flow Control Supported are both Set, see § Section 3.3).
 - If Scaled Flow Control is not supported or supported but not activated, use the values in the "Scale Factor 1" column.
- If Scaled Flow Control is supported and activated, use the values in the column for the scaling factor associated with that credit type (see § Section 3.4.2).
- For a Multi-Function Device where different Functions have different Rx_MPS_Limit values, the largest Rx_MPS_Limit value across all Functions must be used.
- In Flit Mode, for each Credit Type, shared credit advertisement during initialization must either:
 - Advertise [Infinite.3] on all VCs, or
 - Advertise a combination of [Zero] and non-[Zero] on all VCs.
 - When multiple VCs are supported, it is permitted for all VCs to advertise [Zero] shared credits.
 - All VCs advertising non-[Zero] shared credits must have the same Scale Factor.

- If any VC advertised non-[Zero] shared credits:
 - All VCs advertising [Zero] shared credits must use that Scale Factor in subsequent UpdateFCs.
 - The sum of the advertisements across all VCs must be greater than or equal to the value in § Table 2-50 multiplied by the number of enabled VCs. The § Table 2-50 minimum values do not apply to an individual VC as long as this rule applies.
 - When [Merged] flow control is used, the sum of the Posted advertisements across all VCs must be greater than or equal to the value in § Table 2-50 multiplied by two times the number of enabled VCs (i.e., Posted minimum must account for Completions as well).
- See § Table 3-3 Note 6.
- In Flit Mode, dedicated credits are permitted to use any Scale Factor on any VC for any Credit Type.

Table 2-50 Minimum Initial Flow Control Advertisements⁴⁸ §

Credit Type	Minimum Advertisement		
	No Scaling or Scale Factor 1	Scale Factor 4	Scale Factor 16
PH	Shared credits in Flit Mode: 4 units – credit value of 04h. Otherwise: 1 unit - credit value of 01h.	4 Units - credit value of 01h.	16 Units - credit value of 01h.
PD	Shared credits in Flit Mode: $\text{Ceiling}(\text{Rx_MPS_Limit}/\text{FC Unit Size})+4$. Otherwise: Rx_MPS_Limit divided by FC Unit Size . Example: If the Rx_MPS_Limit is 1024 bytes, the smallest permitted initial credit value would be 040h (44h for shared credits in Flit Mode).	$\text{Ceiling}(\text{Rx_MPS_Limit} / (\text{FC Unit Size} * 4)) + 1$. Example: If the Rx_MPS_Limit is 1024 bytes, the smallest permitted initial credit value would be 011h.	$\text{Ceiling}(\text{Rx_MPS_Limit} / (\text{FC Unit Size} * 16)) + 1$. Example: If the Rx_MPS_Limit is 1024 bytes, the smallest permitted initial credit value would be 005h.
NPH	Shared credits in Flit Mode: 4 units – credit value of 04h. Otherwise: 1 unit - credit value of 01h.	4 Units - credit value of 01h.	16 Units - credit value of 01h.
NPD	Shared credits in Flit Mode: $\text{Max}(\text{Rx_NP_MPS_Limit} / \text{FC Unit Size}, 4)+4$ (Note 3) Otherwise: Rx_NP_MPS_Limit divided by FC Unit Size (Note 3)	$\text{Ceiling}(\text{Rx_NP_MPS_Limit} / (\text{FC Unit Size} * 4)) + 1$ (Note 3)	$\text{Ceiling}(\text{Rx_NP_MPS_Limit} / (\text{FC Unit Size} * 16)) + 1$ (Note 3)
CpH	Root Complex (supporting peer-to-peer traffic between all Root Ports) and Switch: for shared credits in Flit Mode: 4 units – credit value of 04h, otherwise 1 FC unit - credit value of 01h	Root Complex (supporting peer-to-peer traffic between all Root Ports) and Switch: 4 FC units - credit value of 01h	Root Complex (supporting peer-to-peer traffic between all Root Ports) and Switch: 16 FC units - credit value of 01h

48. PCI Express to PCI/PCI-X Bridge requirements are addressed in [PCIe-to-PCI-PCI-X-Bridge].

Credit Type	Minimum Advertisement		
	No Scaling or Scale Factor 1	Scale Factor 4	Scale Factor 16
	<p>Root Complex (not supporting peer-to-peer traffic between all Root Ports) and Endpoint: infinite FC units (Note 1).</p> <p>In Flit Mode, if [Merged] is enabled (see § Section 3.4.1), PH credits are used for Completions in the shared pool.</p>	<p>Root Complex (not supporting peer-to-peer traffic between all Root Ports) and Endpoint: infinite FC units (Note 1).</p> <p>In Flit Mode, if [Merged] is enabled (see § Section 3.4.1), PH credits are used for Completions in the shared pool.</p>	<p>Root Complex (not supporting peer-to-peer traffic between all Root Ports) and Endpoint: infinite FC units (Note 1).</p> <p>In Flit Mode, if [Merged] is enabled (see § Section 3.4.1), PH credits are used for Completions in the shared pool.</p>
CpID	<p>Root Complex (supporting peer-to-peer traffic between all Root Ports) and Switch: for shared credits in Flit Mode $\text{Max}(\text{Rx_MPS_Limit} / \text{FC Unit Size}, 4)+4$ (Note 3), otherwise $\text{Rx_MPS_Limit} / \text{FC Unit Size}$.</p> <p>Root Complex (not supporting peer-to-peer traffic between all Root Ports) and Endpoint: infinite FC units (Note 2).</p> <p>In Flit Mode, if [Merged] is enabled (see § Section 3.4.1), PD credits are used for Completions in the shared pool.</p>	<p>Root Complex (supporting peer-to-peer traffic between all Root Ports) and Switch: $\text{Ceiling}(\text{Rx_MPS_Limit} / (\text{FC Unit Size} * 4)) + 1$.</p> <p>Root Complex (not supporting peer-to-peer traffic between all Root Ports) and Endpoint: infinite FC units (Note 2).</p> <p>In Flit Mode, if [Merged] is enabled (see § Section 3.4.1), PD credits are used for Completions in the shared pool.</p>	<p>Root Complex (supporting peer-to-peer traffic between all Root Ports) and Switch: $\text{Ceiling}(\text{Rx_MPS_Limit} / (\text{FC Unit Size} * 16)) + 1$.</p> <p>Root Complex (not supporting peer-to-peer traffic between all Root Ports) and Endpoint: infinite FC units (Note 2).</p> <p>In Flit Mode, if [Merged] is enabled (see § Section 3.4.1), PD credits are used for Completions in the shared pool.</p>

Notes:

- Infinite header credits is an encoding that is interpreted as infinite by the Transmitter, which will, therefore, never throttle. In Flit Mode the [Infinite.3] encoding is used (see § Table 3-3). In Non-Flit Mode the [Infinite.1] or [Infinite.2] encodings are used (see § Table 3-2).
- Infinite data credits is an encoding that is interpreted as infinite by the Transmitter, which will, therefore, never throttle. In Flit Mode the [Infinite.3] encoding is used (see § Table 3-3). In Non-Flit Mode the [Infinite.1] or [Infinite.2] encodings are used (see § Table 3-2).
- Rx_NP_MPS_Limit** is the maximum size Non-Posted TLP Payload accepted by the Receiver (in DW). Larger of:
 - Payload size supported by any implemented earmarked TLP Type values.
 - Receiver that supports DMWr routing capability or DMWr Completer capability:
 - If DMWr Request Routing Supported is 1: 128 bytes (8 credit units)
 - If DMWr Request Routing Supported is 0 and DMWr Completer Supported is 1 and DMWr Lengths Supported is 00b: 64 bytes (4 credit units)
 - If DMWr Request Routing Supported is 0 and DMWr Completer Supported is 1 and DMWr Lengths Supported is not 00b: 128 bytes (8 credit units)
 - Receiver that supports AtomicOp routing capability or any AtomicOp Completer capability:
 - If AtomicOp Routing Supported is 1: 32 bytes (2 credit units)
 - If AtomicOp Routing Supported is 0 and 128-bit CAS Completer Supported is 0: 16 bytes (1 credit unit)
 - If AtomicOp Routing Supported is 0 and 128-bit CAS Completer Supported is 1: 32 bytes (2 credit units)

Credit Type	Minimum Advertisement		
	No Scaling or Scale Factor 1	Scale Factor 4	Scale Factor 16

- 16 bytes (1 credit unit)

- A Root Complex that supports no peer-to-peer traffic between Root Ports must advertise infinite Completion credits on every Root Port.
- A Root Complex that supports peer-to-peer traffic between some or all of its Root Ports may optionally advertise non-infinite Completion credits on those Root Ports. In this case, the Root Complex must ensure that deadlocks are avoided and forward progress is maintained for completions directed towards the Root Complex. Note that temporary stalls of completion traffic (due to a temporary lack of credit) are possible since Non-Posted requests forwarded by the RC may not have explicitly allocated completion buffer space.
- A Receiver that does not support Scaled Flow Control must never cumulatively issue more than 2047 outstanding unused credits to the Transmitter for data or 127 for header. A Receiver that supports Scaled Flow Control must never cumulatively issue more outstanding unused data or header credits to the Transmitter than the Max Credits values shown in § Table 3-4.
 - Components may optionally check for violations of this rule. If a component implementing this check determines a violation of this rule, the violation is a Flow Control Protocol Error (FCPE).
 - If checked, this is a reported error associated with the Receiving Port (see § Section 6.2)
- If [Infinite.1], [Infinite.2], or [Infinite.3] credit advertisement has been made during initialization, no Flow Control updates are required following initialization.
 - If UpdateFC DLLPs or Optimized_Update_FCs are sent, the credit value fields must be Clear and must be ignored by the Receiver. The Receiver may optionally check for non-zero update values (in violation of this rule). If a component implementing this check determines a violation of this rule, the violation is a Flow Control Protocol Error (FCPE)
 - If checked, this is a reported error associated with the Receiving Port (see § Section 6.2)
- If Scaled Flow Control is activated, the HdrScale and DataScale fields in the UpdateFCs must match the values advertised during initialization (see § Section 3.4.2) with the following exceptions.
 - In Flit Mode, when more than one VC is supported, it is permitted to advertise [Zero] shared credits during initialization. For VCs that initialized with [Zero] shared credits, the HdrScale and DataScale fields in shared credit UpdateFCs must match the non-[Zero] HdrScale and DataScale values used by other VCs. If [Zero] shared credits were advertised on all VCs, the HdrScale and DataScale fields in the corresponding shared credit UpdateFCs are undefined.
 - In Flit Mode, it is permitted to advertise [Merged] shared completion credits during initialization. In this situation, the HdrScale and DataScale fields in shared completion credit UpdateFCs must match the values advertised for shared posted credits during initialization. When [Merged] shared completion credits are advertised, at least one VC must advertise non-[Zero] shared posted completion credits.
 - The Receiver may optionally check for violations of this rule. If a Receiver implementing this check determines a violation of this rule, the violation is a Flow Control Protocol Error (FCPE).
 - If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).
- A received TLP using a VC that is not enabled is a Malformed TLP.
 - VC0 is always enabled.

- For VCs 1-7, a VC is considered enabled when the corresponding VC Enable bit in the VC Resource Control register has been Set, and once FC negotiation for that VC has exited the FC_INIT1 state and progressed to the FC_INIT2 state (see § Section 3.4).
- This is a reported error associated with the Receiving Port (see § Section 6.2).
- TLP transmission using any VC 0-7 is not permitted until initialization for that VC has completed by exiting FC_INIT2 state.

For VCs 1-7, software must use the VC Negotiation Pending bit in the corresponding VC Resource Status Register to ensure that a VC is not used until negotiation has completed by exiting the FC_INIT2 state in both components on a Link.

In Flit Mode, if software disables VC 1-7:

- Dedicated Credit counts are cleared.
- Shared credit counts are not affected. Shared credits are returned as usual when the associated TLPs are consumed by the receiver and are available for use by the remaining VCs.
- Behavior is undefined if software subsequently re-enables VC1-7.

The **[Field Size]** parameter used in the following sections is described in § Table 2-51 (see § Section 3.4.2 for details of Scaled Flow Control).

Table 2-51 [Field Size] Values §

Scaled Flow Control Supported	HdrScale or DataScale	[Field Size] for PH, NPH, CplH	[Field Size] for PD, NPD, CplD
No	x	8	12
Yes	00b	8	12
Yes	01b	8	12
Yes	10b	10	14
Yes	11b	12	16

In Flit Mode, the following rules apply to [Merged] FC credits:

- Receivers are permitted to support [Merged] FC; Transmitters must support [Merged] FC.
- When [Merged] FC is enabled:
 - Shared Completion Header credits are [Merged] with shared Posted Header credits.
 - During FC initialization, shared Posted Header credits must be used to indicate the total [Merged] shared Header credit pool.
 - FC updates must indicate either shared Posted Header credits or shared Completion Header credits according to the type of credit freed by the Receiver.
 - Shared Completion Data credits are [Merged] with shared Posted Data credits.
 - During FC initialization, shared Posted Data credits must be used to indicate the total [Merged] shared Data credit pool.
 - FC updates must indicate either shared Posted Data credits or shared Completion Data credits according to the type of credit freed by the Receiver.
- Dedicated Header credits must not be [Merged].
- Dedicated Data credits must not be [Merged].

- Merging behavior for each link direction is independent. The Receivers on each end of a given Link choose whether or not to merge independently
- Use of [Merged] shared credits must be consistent across VCs. If one VC uses [Merged] shared credits, all VCs must also use [Merged] shared credits.
- Use of [Merged] shared credits must be consistent between Hdr and Data. If Hdr uses [Merged] shared credits, Data must also use [Merged] shared credits.
- When [Merged] FC is enabled, it must be ensured that a Requester's rate of Completion processing be matched to that Requester's rate of issuing the corresponding Requests as measured within a sliding window of not more than 100 μ s.

In Flit Mode, the Receiver must return credits indicating the VC of the buffer(s) freed. If [Merged] FC is enabled, the Receiver must return credits indicating the FC Type of the buffer(s) freed.

When more than one VC advertises shared credits with scale factor 01b, 10b, or 11b, that scale factor must be able to express all allocated shared credits, regardless of VC. For example, if VC0 and VC1 each advertise 120 header credits (i.e., a total of 240 credits), they must do so using a scale factor other than 1 (01b) since that scale factor is limited to 127 outstanding credits.

In Flit Mode, shared credits for Header and Data are managed in credit blocks, where a credit block consists of 4 credits of the appropriate type. Credit blocks are not affected by the scale factor. Credit blocks do not apply to dedicated credits.

Rules for FC accounting with credit blocks:

- In each VC, per FC Type, shared credits must be reserved by the Transmitter and released by the Receiver in units of credit blocks.
- When a single TLP does not fully consume all the credits in a credit block, the remaining credits in the credit block must be allocated for consumption only by TLP(s) in the same VC and of the same FC Type.
 - Credit block allocation must distinguish between Posted and Completion FC Types, regardless of whether [Merged] credits are used for FC accounting.
 - Once a credit block is allocated, it must be held open until fully consumed by TLP(s) in the same VC and of the same FC Type, or until the associated VC is disabled and/or a DL_Down condition is entered.
 - Once a credit block is allocated, it must be applied only for TLP(s) in the same VC and of the same FC Type, even if TLP(s) in other VCs and/or of other FC Types are Transmitted/Received.
- Receivers must advertise credits in units of whole credit blocks.

If Shared credits are infinite for a given FC/VC, Shared and Dedicated credits in all VCs for that FC must be infinite. For Example, if VC0 and VC1 are enabled and Shared Completion Header credits are infinite in VC0:

- Dedicated Completion Header credits in VC0 must be infinite.
- Dedicated Completion Header credits in VC1 must be infinite.
- Shared Completion Header credits in VC1 must be infinite.

IMPLEMENTATION NOTE: MOTIVATION FOR SHARED CREDIT BLOCKS §

Shared FC enables the reduced cost implementation of multiple Virtual Channels by allowing common sets of resources to be shared. However, cost and complexity are increased, relative to the use of only dedicated credits, by the need to track TLPs as they are stored and removed from these shared structures. Because TLPs in different VCs are unordered with respect to each other, and often have different traffic behaviors, shared resource tracking typically requires linked-list structures for tracking TLPs in each VC, and TLP storage quickly becomes fragmented.

If, as is typically the case, the TLP storage is block-oriented, then the additional constraints of efficient block management motivate that TLPs in a given VC can be packed together. However, it is very complex to manage sub-block level out-of-order removal of TLPs in different VCs and the subsequent re-allocation of that freed space. So, by requiring both the Transmitter and Receiver to explicitly recognize credit blocks, the Receiver's buffer management logic is considerably simplified, while maintaining the efficient use of Receiver resources.

§ Figure 2-98 illustrates how a series of received TLPs would be placed into the Receiver's buffers.

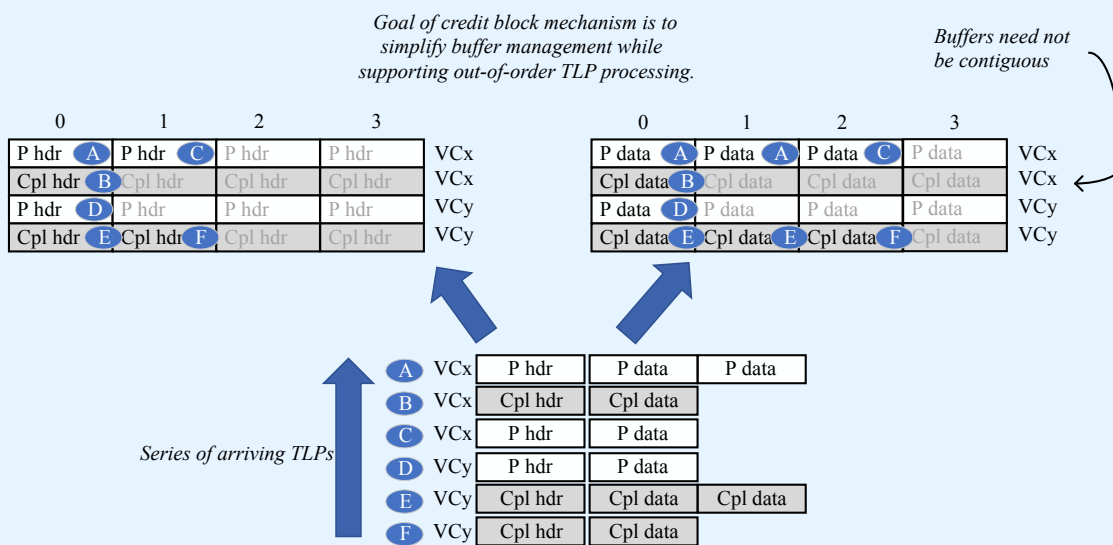

Figure 2-98 Credit Block Example §

2.6.1.1 FC Information Tracked by Transmitter §

- For each type of information tracked, there are two quantities (Non-Flit Mode) or six quantities (Flit Mode) tracked for Flow Control TLP Transmission gating:
 - **CREDITS_CONSUMED** (per VC, all modes)
 - In Non-Flit Mode, CREDITS_CONSUMED is updated for all TLPs.
 - In Flit Mode, CREDITS_CONSUMED is updated for TLPs transmitted using dedicated credits.

- Count of the total number of FC units consumed by TLP Transmissions made since Flow Control initialization, modulo $2^{\text{[Field Size]}}$ (where [Field Size] is defined in § Table 2-51).
- Set to all 0's at interface initialization
- Set to 0 when VC Enable for VC[i] is Cleared.
- Updated for each TLP the Transaction Layer allows to pass the Flow Control gate for Transmission as shown:

$$\text{CREDITS_CONSUMED} := (\text{CREDITS_CONSUMED} + \text{Increment}) \bmod 2^{\text{[Field Size]}}$$

Equation 2-1 CREDITS_CONSUMED §

(Where *Increment* is the size in FC credits of the corresponding part of the TLP passed through the gate, and [Field Size] is defined in § Table 2-51)

- **SHARED_CREDITS_CONSUMED** (per VC, Flit Mode only)
 - In Non-Flit Mode, SHARED_CREDITS_CONSUMED is not used.
 - In Flit Mode, SHARED_CREDITS_CONSUMED is updated for TLPs transmitted using shared credits.
 - Count of the total number of FC units consumed by TLP Transmissions made since Flow Control initialization, modulo $2^{\text{[Field Size]}}$ (where [Field Size] is defined in § Table 2-51).
 - Set to all 0's at interface initialization
 - Updated for each TLP the Transaction Layer allows to pass the Flow Control gate for Transmission using shared credits as shown:

$$\text{SHARED_CREDITS_CONSUMED} := (\text{SHARED_CREDITS_CONSUMED} + \text{Increment}) \bmod 2^{\text{[Field Size]}}$$

Equation 2-2 SHARED_CREDITS_CONSUMED §

(Where *Increment* is the size in FC credits of the corresponding part of the TLP passed through the gate, and [Field Size] is defined in § Table 2-51)

- SHARED_CREDITS_CONSUMED is 0 for VCs that are not implemented or have never been enabled.
- SHARED_CREDITS_CONSUMED is preserved when VC Enable for VC 1-7 is Cleared.
- SHARED_CREDITS_CONSUMED is maintained independently for Posted and Completion credits even when [Merged] was selected by the Receiver.
- **SUM_SHARED_CREDITS_CONSUMED** (per Port, Flit Mode only)

$$\text{SUM_SHARED_CREDITS_CONSUMED} = \left(\sum_{i=0}^{i=7} \text{SHARED_CREDITS_CONSUMED}[i] \right) \bmod 2^{[\text{Field Size}]}$$

Equation 2-3 SUM_SHARED_CREDITS_CONSUMED §

- **SHARED_CREDITS_CONSUMED_CURRENTLY** (per VC, Flit Mode only, abbreviated as **SCCC** below)
 - In Non-Flit Mode, SHARED_CREDITS_CONSUMED_CURRENTLY is not used.
 - In Flit Mode, SHARED_CREDITS_CONSUMED_CURRENTLY is updated for TLPs transmitted using shared credits and for UpdateFCs that return shared credits.
 - Set to all 0's at interface initialization
 - Updated for each TLP the Transaction Layer allows to pass the Flow Control gate for Transmission using shared credits as shown:

$$\text{SCCC}[i] := (\text{SCCC}[i] + \text{Increment}) \bmod 2^{[\text{Field Size}+1]}$$

Equation 2-4 TLP SHARED_CREDITS_CONSUMED_CURRENTLY §

(Where *Increment* is the size in FC credits of the corresponding part of the TLP passed through the gate, and [Field Size] is defined in § Table 2-51)

- Updated for each UpdateFC releasing shared credit from VC[i]:

$$\text{SCCC}[i] := (\text{SCCC}[i] - (\text{UpdateFC value} - \text{SHARED_CREDIT_LIMIT}[i]) \bmod 2^{[\text{Field Size}]}) \bmod 2^{[\text{Field Size}+1]}$$

Equation 2-5 FC SHARED_CREDITS_CONSUMED_CURRENTLY §

- SHARED_CREDITS_CONSUMED_CURRENTLY is preserved when VC Enable for VC 1-7 is Cleared.
- SHARED_CREDITS_CONSUMED_CURRENTLY is maintained independently for Posted and Completion credits even when [Merged] was selected by the Receiver.
- **TOTAL_SHARED_CREDITS_AVAILABLE** (per Port, Flit Mode only)
 - In Non-Flit Mode, TOTAL_SHARED_CREDITS_AVAILABLE is not used.
 - In Flit Mode, TOTAL_SHARED_CREDITS_AVAILABLE contains the sum of the shared credits granted for all VCs during flow control initialization.
 - For [Merged], this initial value for all shared Completion credits is 0.
 - For [Zero], this initial value for that VC is 0.
 - TOTAL_SHARED_CREDITS_AVAILABLE is not affected when VC Enable for VC 1-7 is Cleared.
- **CREDIT_LIMIT** (per VC, all modes)
 - In Non-Flit Mode, CREDIT_LIMIT reflects all credit flow control updates.

- In Flit Mode, CREDIT_LIMIT reflects dedicated credit flow control updates.
- CREDIT_LIMIT contains the most recent number of FC units legally advertised by the Receiver. This quantity represents the total number of FC credits made available by the Receiver since Flow Control initialization, modulo $2^{\text{[Field Size]}}$ (where [Field Size] is defined in § Table 2-51).
- Undefined at interface initialization
- Set to the value indicated during Flow Control initialization
 - For “infinite” credits, this value is 0
- For each FC update received,
 - if CREDIT_LIMIT is not equal to the update value, set CREDIT_LIMIT to the update value
- **SHARED_CREDIT_LIMIT** (per VC, Flit Mode only)
 - In Non-Flit Mode, SHARED_CREDIT_LIMIT is not used.
 - In Flit Mode, SHARED_CREDIT_LIMIT reflects shared credit flow control updates.
 - SHARED_CREDIT_LIMIT contains the most recent number of FC units legally advertised by the Receiver. This quantity represents the total number of shared FC credits made available by the Receiver since Flow Control initialization, modulo $2^{\text{[Field Size]}}$ (where [Field Size] is defined in § Table 2-51).
 - Undefined at interface initialization
 - Set to the value indicated during initial Flow Control initialization.
 - For [Merged], this initial value for all shared Completion credits is 0.
 - For [Zero], this initial value is 0.
 - SHARED_CREDIT_LIMIT is preserved when VC Enable for VC 1-7 is Cleared and also preserved during subsequent Flow Control initialization.
 - For each FC update received,
 - if SHARED_CREDIT_LIMIT is not equal to the update value, set SHARED_CREDIT_LIMIT to the update value
- **SUM_SHARED_CREDIT_LIMIT** (per Port, flit Mode only)
 - In Non-Flit Mode, SUM_SHARED_CREDIT_LIMIT is not used.
 - In Flit Mode, SUM_SHARED_CREDIT_LIMIT is defined by § Equation 2-6.

$$\text{SUM_SHARED_CREDIT_LIMIT} = \left(\sum_{i=0}^{i=7} \text{SHARED_CREDIT_LIMIT}[i] \right) \bmod 2^{\text{[Field Size]}}$$

Equation 2-6 SUM_SHARED_CREDIT_LIMIT §

This equation is not affected by [Merged]. When [Merged] is requested by the receiver, Posted and Completion credits have distinct versions of SUM_SHARED_CREDIT_LIMIT.

- If a Transmitter detects that a TLP it is preparing to transmit is malformed, the Transmitter *MUST@FLIT* discard the TLP and handle the condition as an Uncorrectable Internal Error.

- If a Transmitter detects that a TLP it is preparing to transmit appears to be properly formed but with bad ECRC, the Transmitter *MUST@FLIT* transmit the TLP and update its internal Flow Control credits accordingly.
- The Transmitter gating function must determine if sufficient credits have been advertised to permit the transmission of a given TLP. If the Transmitter does not have enough credits to transmit the TLP, it must block the transmission of the TLP, possibly stalling other TLPs that are using the same Virtual Channel. The Transmitter must follow the ordering and deadlock avoidance rules specified in § Section 2.4 , which require that certain types of TLPs must bypass other specific types of TLPs when the latter are blocked. Note that TLPs using different Virtual Channels have no ordering relationship and must not block each other.
- In Flit Mode, the **shared transmitter gating function** test is performed as follows:
 - Credits must be allocated to specific VCs per the credit block rules defined in § Section 2.6.1 .
 - For each required type of credit, the number of credits required is calculated as:

$$\text{SHARED_CUMULATIVE_CREDITS_REQUIRED} = (\text{SUM_SHARED_CREDITS_CONSUMED} + \text{credit units required for pending TLP}) \bmod 2^{\text{[Field Size]}}$$

Equation 2-7 SHARED_CUMULATIVE_CREDITS_REQUIRED §

This equation is not affected by [Merged]. When [Merged] is requested by the receiver, Posted and Completion credits have distinct versions of SHARED_CUMULATIVE_CREDITS_REQUIRED.

- The transmitter is permitted to transmit a TLP if any of the following are true:
 - SHARED_CREDIT_LIMIT was “infinite” during Flow Control initialization.
 - For Non-Posted credits and for Posted and Completion credits when [Merged] was not requested by the receiver, Shared Flow Control Usage Limit Enable is Clear and, for each type of information in the TLP, § Equation 2-8 is satisfied (using unsigned arithmetic):

$$\frac{(\text{SUM_SHARED_CREDIT_LIMIT} - \text{SHARED_CUMULATIVE_CREDITS_REQUIRED})}{\bmod 2^{\text{[Field Size]}}} < (2^{\text{[Field Size]}})/2$$

Equation 2-8 Shared Transmitter Gate non-[Merged] §

- For Posted and Completion credits when [Merged] was requested by the receiver, Shared Flow Control Usage Limit Enable is Clear and, for each type of information in the TLP, § Equation 2-9 is satisfied (using unsigned arithmetic):

$$\begin{aligned} & (\text{SUM_SHARED_CREDIT_LIMIT_POSTED} \\ & + \text{SUM_SHARED_CREDIT_LIMIT_COMPLETION} \\ & - \text{SHARED_CUMULATIVE_CREDITS_REQUIRED_POSTED} \\ & - \text{SHARED_CUMULATIVE_CREDITS_REQUIRED_COMPLETION}) \\ & \bmod 2^{\text{[Field Size]}} < (2^{\text{[Field Size]}})/2 \end{aligned}$$

Equation 2-9 Shared Transmitter Gate [Merged] §

- For Non-Posted credits and for Posted and Completion credits when [Merged] was not requested by the receiver, Shared Flow Control Usage Limit Enable is Set and, for each type

of information in the TLP, § Equation 2-8 and § Equation 2-10 are both satisfied (using unsigned arithmetic)

$$\text{SCCC} + \text{credit units required for pending TLP} \leq \text{TOTAL_SHARED_CREDITS_AVAILABLE} \times \text{Shared Flow Control Usage Limit} \times 0.125$$

Equation 2-10 Shared Transmitter Usage Limit Gate non-[Merged] §

- For Posted and Completion credits when [Merged] was requested by the receiver, Shared Flow Control Usage Limit Enable is Set and, for each type of information in the TLP, § Equation 2-9 and § Equation 2-11 are both satisfied (using unsigned arithmetic)

$$\text{SCCC} + \text{credit units required for pending TLP} \leq (\text{TOTAL_SHARED_CREDITS_AVAILABLE_POSTED} + \text{TOTAL_SHARED_CREDITS_AVAILABLE_COMPLETION}) \times \text{Shared Flow Control Usage Limit} \times 0.125$$

Equation 2-11 Shared Transmitter Usage Limit Gate [Merged] §

- If the above test does not permit a TLP to be transmitted, continue with the Transmitter gating function test below.
- Shared Flow Control is independent of the VC Arbitration mechanism described in § Section 6.3.3.2 .
- The **Transmitter gating function** test is performed as follows:
 - In Non-Flit Mode, this test applies to all TLPs.
 - In Flit Mode, this test applies to TLPs using dedicated credits. The shared transmitter gating function is used for TLPs using shared credits.
 - For each required type of credit, the number of credits required is calculated as:

$$\text{CUMULATIVE_CREDITS_REQUIRED} = (\text{CREDITS_CONSUMED} + \text{credit units required for pending TLP}) \bmod 2^{\text{[Field Size]}}$$

Equation 2-12 CUMULATIVE_CREDITS_REQUIRED §

- Unless CREDIT_LIMIT was specified as “infinite” during Flow Control initialization, the Transmitter is permitted to Transmit a TLP if, for each type of information in the TLP, the following equation is satisfied (using unsigned arithmetic):

$$(\text{CREDIT_LIMIT} - \text{CUMULATIVE_CREDITS_REQUIRED}) \bmod 2^{\text{[Field Size]}} \leq 2^{\text{[Field Size]}}/2$$

Equation 2-13 Transmitter Gate §

- If CREDIT_LIMIT was specified as “infinite” during Flow Control initialization, then the gating function is unconditionally satisfied for that type of credit.

- In Flit Mode, the TLP is transmitted with a Flit Mode Local TLP Prefix with the TLP Uses Dedicated Credits bit Set. This indicates that the flit is consuming dedicated credits.
- Note that some types of Transactions require more than one type of credit. (For example, Memory Write requests require PH and PD credits.)
- When accounting for credit use and return, information from different TLPs must not be mixed within one credit.
- When some TLP is blocked from Transmission by a lack of FC Credit, Transmitters must follow the ordering rules specified in § Section 2.4 when determining what types of TLPs must be permitted to bypass the stalled TLP.
- The return of FC credits for a Transaction must not be interpreted to mean that the Transaction has completed or achieved system visibility.
 - Flow Control credit return is used for receive buffer management only, and agents must not make any judgment about the Completion status or system visibility of a Transaction based on the return or lack of return of Flow Control information.
- In Non-Flit Mode, when a Transmitter sends a nullified TLP, the Transmitter does not modify CREDITS_CONSUMED for that TLP (see § Section 3.6.2.1).
- In Flit Mode, for all TLPs Transmitted, including nullified TLPs, Transmitters must modify CREDITS_CONSUMED or SHARED_CREDITS_CONSUMED and both SHARED_CREDITS_CONSUMED_CURRENTLY.

2.6.1.2 FC Information Tracked by Receiver §

- For each type of information tracked, the following quantities are tracked for Flow Control TLP Receiver accounting. In Flit Mode, shared and dedicated credit versions of these are tracked independently.
 - **CREDITS_ALLOCATED**
 - Count of the total number of credits granted to the Transmitter since initialization, modulo $2^{\text{[Field Size]}}$ (where [Field Size] is defined in § Table 2-51)
 - Initially set according to the buffer size and allocation policies of the Receiver
 - If [Zero] or [Merged] were advertised by this Receiver, the corresponding CREDITS_ALLOCATED is set to 0
 - This value is included in the InitFC and UpdateFC DLLPs and in the Optimized_Update_FC (see § Section 3.5)
 - Incremented as the Receiver Transaction Layer makes additional receive buffer space available by processing Received TLPs. Optionally permitted to be incremented for dedicated credits or for shared credits when a single VC is using the shared pool, when the Receiver Transaction Layer make additional buffer space available through other mechanisms (e.g., increasing the pool size).
Updated as shown:

$$\text{CREDITS_ALLOCATED} := (\text{CREDITS_ALLOCATED} + \text{Increment}) \bmod 2^{\text{[Field Size]}}$$

Equation 2-14 CREDITS_ALLOCATED §

(Where *Increment* corresponds to the credits made available, and [Field Size] is defined in § Table 2-51)

- For shared credits, CREDITS_ALLOCATED is preserved when VC Enable for VC 1-7 is Cleared and also preserved during subsequent Flow Control initialization.
- **CREDITS_RECEIVED**
 - Mandatory for shared credits in Flit Mode.
 - Otherwise, implemented when the optional error check described below is implemented.
 - Count of the total number of FC units consumed by valid TLPs Received since Flow Control initialization, modulo $2^{\text{[Field Size]}}$ (where [Field Size] is defined in § Table 2-51)
 - Set to all 0's at interface initialization
 - Updated as shown:

$$\text{CREDITS_RECEIVED} := (\text{CREDITS_RECEIVED} + \text{Increment}) \bmod 2^{\text{[Field Size]}}$$

Equation 2-15 CREDITS_RECEIVED §

(Where *Increment* is the size in FC units of the corresponding part of the received TLP, and [Field Size] is defined in § Table 2-51)

for each Received TLP, provided that TLP:

- passes the Data Link Layer integrity checks
- is not malformed or (optionally) is malformed and is not ambiguous with respect to which buffer to release and is mapped to an initialized Virtual Channel
- does not consume more credits than have been allocated (see following rule)

For a TLP with an ECRC Check Failed error, but which otherwise is unambiguous with respect to which buffer to release, CREDITS_RECEIVED *MUST@FLIT* be updated.

- For shared credits, CREDITS_RECEIVED is preserved when VC Enable for VC 1-7 is Cleared and also preserved during subsequent Flow Control initialization.
- In Flit Mode, the receiver accounting is modified as follows:
 - If the TLP contained a Flit Mode Local TLP Prefix with the TLP Uses Dedicated Credits bit Set, update the dedicated CREDITS_ALLOCATED and dedicated CREDITS_RECEIVED for the associated VC.
 - Otherwise, update the shared CREDITS_ALLOCATED and shared CREDITS_RECEIVED for the associated VC.
 - This accounting is not affected by [Merged]. Tracking is independent for Posted and Completion credits.
 - Receivers are permitted to optimize their credit return mechanism to return shared and dedicated credits in a different order. For example, if shared TLP *S* and dedicated TLP *D* have the same credit type and VC and are received and processed in the order *S* followed by *D*, it is permitted to return *dedicated* credits when processing *S* as long as the corresponding *shared* credits are returned later when processing *D*.
- In Non-Flit Mode, if a Receiver implements the CREDITS_RECEIVED counter, then when a nullified TLP is received, the Receiver does not modify CREDITS_RECEIVED for that TLP (see § Section 3.6.2.1).
- In Flit Mode, Receivers that implement the CREDITS_RECEIVED counter modify CREDITS_RECEIVED even for nullified TLPs.
- A Receiver may optionally check for Receiver Overflow errors (TLPs exceeding CREDITS_ALLOCATED):

- For Non-Flit Mode and for dedicated credits in Flit Mode, this is accomplished by checking Equation 2-16 using unsigned arithmetic:

$$\frac{(\text{CREDITS_ALLOCATED} - \text{CREDITS_RECEIVED}) \bmod 2^{[\text{Field Size}]} \geq 2^{[\text{Field Size}]} / 2}{\text{Equation 2-16 Receiver Overflow Error Check Non-Flit / Dedicated} \quad \S}$$

- For shared Non-Posted and for shared Posted and Completion when [Merged] was not advertised by the receiver, this is accomplished by checking Equation 2-17 using unsigned arithmetic:

$$\left(\sum_{i=0}^{i=7} (\text{CREDITS_ALLOCATED}[i] - \text{CREDITS_RECEIVED}[i]) \right) \bmod 2^{[\text{Field Size}]} \geq \frac{2^{[\text{Field Size}]} - 1}{2}$$

$$\text{Equation 2-17 Receiver Overflow Error Check Non-Posted / Not [Merged]} \quad \S$$

- For shared Posted and Completion when [Merged] was advertised by the receiver, this is accomplished, by checking Equation 2-18 using unsigned arithmetic:

$$\text{temp1}[i] \equiv \text{CREDITS_ALLOCATED}_{\text{POSTED}}[i] + \text{CREDITS_ALLOCATED}_{\text{COMPLETION}}[i]$$

$$\text{temp2}[i] \equiv \text{CREDITS_RECIEVED}_{\text{POSTED}}[i] + \text{CREDITS_RECIEVED}_{\text{COMPLETION}}[i]$$

$$\left(\sum_{i=0}^{i=7} (\text{temp1}[i] - \text{temp2}[i]) \right) \bmod 2^{[\text{Field Size}]} \geq \frac{2^{[\text{Field Size}]} - 1}{2}$$

$$\text{Equation 2-18 Receiver Overflow Error Check [Merged]} \quad \S$$

If the check is implemented and this equation evaluates as true, the Receiver must:

- discard the TLP(s) without modifying the CREDITS_RECEIVED

- de-allocate any resources that it had allocated for the TLP(s)

If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).

Note: Following a Receiver Overflow error, Receiver behavior is undefined, but it is encouraged that the Receiver continues to operate, processing Flow Control updates and accepting any TLPs that do not exceed allocated credits.

- For non-infinite NPH, NPD, PH, and CplH types, a Flow Control Update must be scheduled for Transmission each time the following events occur: In Non-Flit Mode, a Flow Control Update is an UpdateFC FCP. In Flit Mode, a Flow Control Update is either an UpdateFC FCP (for NPH, NPD, PH, and CplH, both Shared and Dedicated) or an Optimized_Update_FC (for Shared NPH and PH):
 - a. when scaled flow control is not activated and the number of available FC credits of a particular type is zero and one or more units of that type are made available by TLPs processed,
 - b. when scaled flow control is not activated, the NPD credit drops below 2, the Receiver supports either the AtomicOp routing capability or the 128-bit CAS Completer capability, and one or more NPD credits are made available by TLPs processed,
 - c. when scaled flow control is activated and the number of available FC credits of a particular type is zero or is below the scaled threshold and one or more units of that type are made available by TLPs processed so that the number of available credits is equal to or greater than the scaled threshold:
 - For Non-Flit Mode and for dedicated credits in Flit Mode, this threshold is 1 for HdrScale or DataScale of 01b, 4 for HdrScale or DataScale of 10b, and 16 for HdrScale or DataScale of 11b.
 - For shared credits in Flit Mode, this threshold is 4 for HdrScale or DataScale of 01b, 4 for HdrScale or DataScale of 10b, and 16 for HdrScale or DataScale of 11b.
 - d. when scaled flow control is activated in Non-Flit Mode and for dedicated credits in Flit Mode, the DataScale used for NPD is 01b, the NPD credit drops below 2, the Receiver supports either the AtomicOp routing capability or the 128-bit CAS Completer capability, and one or more NPD credits are made available by TLPs processed.
 - e. For shared Non-Posted Data credits in Flit Mode, when the DataScale used for NPD is 01b, the NPD credit drops below 4, and 4 or more NPD credits are made available by TLPs processed.
- For non-infinite PD and CplD types, when the number of available credits is less than the number needed for the Rx_MPS_Limit, a Flow Control Update must be scheduled for Transmission each time one or more units of that type are made available by TLPs processed. In Non-Flit Mode, a Flow Control Update is an UpdateFC FCP. In Flit Mode, a Flow Control Update is either an UpdateFC FCP or an Optimized_Update_FC (for PD type).
 - For a Multi-Function Device where different Functions have different Rx_MPS_Limit values, the largest Rx_MPS_Limit value across all Functions must be used.

When multiple TLPs have been received, and some of the TLP(s) received consumed dedicated credits while other TLPs(s) consumed shared credits, the Receiver must return all consumed dedicated credits prior to returning shared credits consumed by TLPs received after the TLP(s) received using dedicated credits. The Receiver is permitted to return the dedicated credits consumed prior to returning shared credits consumed by TLPs received after the TLP(s) using dedicated credits.

IMPLEMENTATION NOTE: RECEIVER HANDLING OF CREDIT RETURN FOR DEDICATED & SHARED CREDITS §

The purpose of having some amount of Dedicated Credit per VC is to ensure that one VC cannot completely block another VC by consuming all available Shared Credit. To maintain this property it is necessary for the Receiver to ensure that Dedicated Credit is returned in a timely way - such that dedicated credits are returned at or before when the associated TLP(s) is(/are) consumed. In some implementations, buffers may be shared between Dedicated and Shared credits, and the distinction between the two types of Credits lies in how the buffer space is accounted for. In such implementations, it may be desirable to change the accounting for buffer space consumed using shared credits so that dedicated credits can be returned earlier to the Transmitter. To illustrate how this could work, consider the following example - TLPs A, B, C, and D are Received and consumed in that order. C uses dedicated credits while A, B, and D use shared credits.

- If $size_A \geq size_C$, the receiver can return the dedicated credits for C when A is consumed.
- If $size_B \geq size_C$, the receiver can return the dedicated credits for C when B is consumed.
- If $size_A + size_B \geq size_C$, the receiver can return the dedicated credits for C when B is consumed.
- The receiver is not permitted to delay the return of the dedicated credits for C to follow the time when D is consumed.

Other rules related to Flow Control:

- UpdateFC FCPs and Optimized_Update_FCs are permitted to be scheduled for Transmission more frequently than is required
- When the Link is in the L0 or L0s Link state, Update FCPs or Optimized_Update_FCs for each enabled type of non-infinite FC credit must be scheduled for transmission at least once every $30 \mu s$ (-0%/+50%), except in Non-Flit Mode when the Extended Synch bit is Set, in which case the limit is $120 \mu s$ (-0%/+50%).
 - This rule is optional when [Zero] dedicated FC credits are required as shown in § Table 3-3.
 - A timeout mechanism *MUST@FLIT* be implemented. If implemented, such a mechanism must:
 - be active only when the Link is in the L0 or L0s Link state
 - use a timer with a limit of $200 \mu s$ (-0%/+50%), where the timer is reset by the receipt of any Init or Update FCP. Alternately, the timer may be reset by the receipt of any DLLP (see § Section 3.5)
 - upon timer expiration, instruct the Physical Layer to retrain the Link (via the LTSSM Recovery state, § Section 4.2.7.4)
 - in Non-Flit Mode, if an Infinite Credit advertisement has been made during initialization for all three FC types, this timeout mechanism must be disabled for that VC
 - in Flit Mode, if an Infinite Credit advertisement has been made during initialization for all six FC types, this timeout mechanism must be disabled for that VC

IMPLEMENTATION NOTE: USE OF “INFINITE” FC ADVERTISEMENT §

For a given implementation it is possible that not all of the queue types need to be physically implemented in hardware for all Virtual Channels. For example, in a Device that does not support Flit Mode and whose Functions have no AtomicOp Completer, AtomicOp Routing capability, DMWr Completer, or DMWr Routing capability, there is no need to implement a Non-Posted Data queue for Virtual Channels other than VC0, since Non-Posted Requests with data are only allowed on Virtual Channel 0 for such Devices. For unimplemented queues, the Receiver can eliminate the need to present the appearance of tracking Flow Control credits by advertising infinite Flow Control credits during initialization.

IMPLEMENTATION NOTE:

NON-FLIT MODE FLOW CONTROL UPDATE LATENCY §

For components subject to receiving streams of TLPs, it is desirable to implement receive buffers larger than the minimum size required to prevent Transmitter throttling due to lack of available credits. Likewise, it is desirable to transmit UpdateFC FCPs such that the time required to send, receive and process the UpdateFC prevents Transmitter throttling. Recommended maximum values for UpdateFC transmission latency during normal operation are shown in § Table 2-52, § Table 2-53, and § Table 2-54. Note that the values given in these tables do not account for any delays caused by the Receiver or Transmitter being in L0s, in Recovery, or for any delays caused by Retimers (see § Section 4.3.8) . For improved performance and/or power-saving, it may be desirable to use a Flow Control update policy that is more sophisticated than a simple timer. Any such policy is implementation specific, and beyond the scope of this document.

The values in the Tables are measured starting from when the Receiver Transaction Layer makes additional receive buffer space available by processing a received TLP, to when the first Symbol of the corresponding UpdateFC DLLP is transmitted.

For a Multi-Function Device where different Functions have different Rx_MPS_Limit values, it is strongly recommended that the smallest Rx_MPS_Limit value across all Functions be used.

Table 2-52 Maximum UpdateFC Transmission Latency Guidelines for 2.5 GT/s (Symbol Times) §

2.7 End-to-End Data Integrity §

Data integrity across a Link is provided by the Data Link Layer for NFM and by the Physical Layer Logical Block for FM. As TLPs are routed through intermediate components (i.e., Switches) a TLP may become corrupted, and the Link data integrity mechanisms will not detect such corruption. To ensure end-to-end data integrity detection in systems that require high data reliability, a Transaction Layer end-to-end 32-bit CRC (ECRC) can be applied to a TLP. The ECRC covers all bits that do not change as the TLP traverses the path (invariant fields). The ECRC is generated by the Transaction Layer in the source component, and checked (if supported) by the ultimate PCI Express Receiver, and optionally by intermediate Receivers. A Switch that supports ECRC checking must check ECRC on TLPs targeting the Switch itself. Such a Switch can optionally check ECRC on TLPs that it forwards. On TLPs that the Switch forwards, the Switch must preserve the error detecting properties of the ECRC, regardless of whether the Switch checks the ECRC, or if the ECRC check fails.⁴⁹

In some cases, the data in a TLP payload is known to be corrupt at the time the TLP is generated, or may become corrupted while passing through an intermediate component, such as a Switch. In these cases, error forwarding, also known as data poisoning, can be used to indicate the corruption to the device consuming the data. In FM, there are two different mechanisms for data poisoning, in support of distinct use models.

2.7.1 ECRC Rules §

The capability to generate and check ECRC is reported to software, and the ability to do so is enabled by software (see § Section 7.8.4.7).

49. An exception is a Multicast TLP that an Egress Port is modifying due to the MC_Overlay mechanism. See § Section 6.14.5.

- If a device Function is enabled to generate ECRC, it must calculate and apply ECRC for all TLPs originated by the Function
- For non-IDE TLPs that do not require FM/NFM translation, Switches must pass TLPs with ECRC unchanged from the Ingress Port to the Egress Port ⁵⁰
 - For non-IDE TLPs that require FM/NFM translation, Switches must apply ECRC to the translated TLP and must ensure that the error detection capability of ECRC is maintained between the Ingress and Egress Ports; how this is done is outside the scope of this specification.
 - These rules do not apply for IDE TLPs, for which ECRC is not supported and FM/NFM translation is not possible.
- If a device supports ECRC generation/checking, at least one of its Functions must support Advanced Error Reporting (AER) (see § Section 6.2)
- If a device Function is enabled to check ECRC, it must do so for all TLPs with ECRC where the device is the ultimate PCI Express Receiver
 - Note that it is still possible for the Function to receive TLPs without ECRC, and these are processed normally - this is not an error

Note that a Switch may optionally perform ECRC checking on TLPs passing through the Switch. ECRC Errors detected by the Switch are reported as described in § Table 6-5, but do not alter the TLPs' passage through the Switch. ⁵¹

A 32-bit ECRC is calculated for the TLP (End-End TLP Prefixes/OHC, header, and data payload), but not, in FM, including any Trailer, using the following algorithm and appended to the end of the TLP (see § Figure 2-3):

- The ECRC value is calculated using the following algorithm (see § Figure 2-99)
- The polynomial used has coefficients expressed as 04C1 1DB7h
- The seed value (initial value for ECRC storage registers) is FFFF FFFFh
- All header fields, all End-End TLP Prefixes/OHC (if present), and the entire data payload (if present) are included in the ECRC calculation.
- Local TLP Prefixes (if present) are not included in the ECRC calculation.
- All Variant bits must be treated as Set for ECRC calculations.
- In Non-Flit Mode, the following bits are Variant:
 - TLP Header symbol 0, bit 0. This is bit 0 of the Type field ⁵². This bit in an End-End TLP Prefix is invariant.
 - TLP Header symbol 2, bit 6. This is either the EP bit or Reserved.
- In Flit Mode, the following bits are Variant:
 - TLP Header symbol 0, bit 0. This is bit 0 of the Type field ⁵³.
 - TLP Header symbol 6, bit 7. This is either the EP bit or Reserved.
- All other fields are Invariant
- ECRC calculation starts with bit 0 of byte 0 and proceeds from bit 0 to bit 7 of each byte of the TLP
- The result of the ECRC calculation is complemented, and the complemented result bits are mapped into the 32-bit TLP Digest field (NFM), or Trailer (FM), as shown in § Table 2-55.

50. An exception is a Multicast TLP that an Egress Port is modifying due to the MC_Overlay mechanism. See § Section 6.14.5.

51. An exception is a Multicast TLP that an Egress Port is modifying due to the MC_Overlay mechanism. See § Section 6.14.5.

52. Bit 0 of the Type field changes when a Configuration Request is changed from Type 1 to Type 0.

53. Bit 0 of the Type field changes when a Configuration Request is changed from Type 1 to Type 0.

ECRC Result Bit	Corresponding Bit Position in the 32-bit TLP ECRC Field
30	25
31	24

- In NFM, the 32-bit ECRC value is placed in the TLP Digest field at the end of the TLP (see § Figure 2-3). In FM, the 32-bit ECRC value is placed in the TLP Trailer.
- For TLPs including a TLP Digest field used for an ECRC value, Receivers that support end-to-end data integrity checking check the ECRC value in the TLP Digest field by:
 - applying the same algorithm used for ECRC calculation (above) to the received TLP, not including the 32-bit TLP Digest field of the received TLP, and then:
 - comparing the calculated result with the value in the TLP Digest field of the received TLP.
- Receivers that support end-to-end data integrity checks report violations as an ECRC Error. This reported error is associated with the Receiving Port (see § Section 6.2).

Beyond the stated error reporting semantics contained elsewhere in this specification, how ultimate PCI Express Receivers make use of the end-to-end data integrity check provided through the ECRC is beyond the scope of this document. Intermediate Receivers are still required to forward TLPs whose ECRC checks fail. A PCI Express-to-PCI/PCI-X Bridge is classified as an ultimate PCI Express Receiver with regard to ECRC checking.

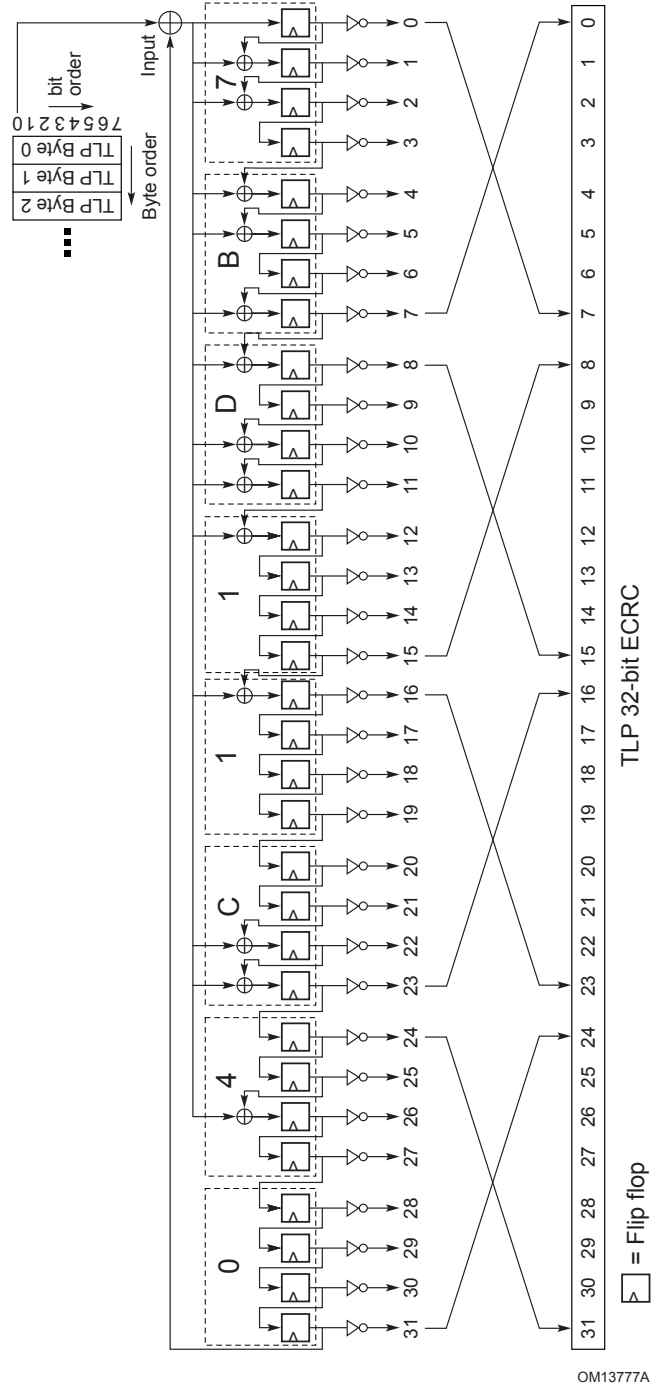

Figure 2-99 Calculation of 32-bit ECRC for TLP End to End Data Integrity Protection §

IMPLEMENTATION NOTE: PROTECTION OF TD BIT INSIDE SWITCHES (NFM) §

It is of utmost importance that Switches insure and maintain the integrity of the TD bit in TLPs that they receive and forward (i.e., by applying a special internal protection mechanism), since corruption of the TD bit will cause the ultimate target device to misinterpret the presence or absence of the TLP Digest field.

Similarly, it is strongly recommended that Switches provide internal protection to other Variant bits in TLPs that they receive and forward, as the end-to-end integrity of Variant bits is not sustained by the ECRC.

IMPLEMENTATION NOTE: DATA LINK LAYER DOES NOT HAVE INTERNAL TLP VISIBILITY (NFM) §

Since the Data Link Layer does not process the TLP header (it determines the start and end of the TLP based on indications from the Physical Layer), it is not aware of the existence of the TLP Digest field, and simply passes it to the Transaction Layer as a part of the TLP.

2.7.2 Error Forwarding (Data Poisoning) §

Error Forwarding (also known as data poisoning), is indicated by Setting the EP bit, or additionally, in FM, through the use of Physical Layer Logical Block mechanisms. In FM, either or both mechanisms are permitted to be applied to a TLP with a data payload, and the requirements defined in this specification for Receiver handling of poisoned TLPs are the same regardless of the poisoning mechanism applied. It is permitted for Receivers to additionally implement differentiated handling based on the type of poisoning mechanism applied, but such handling is outside the scope of this specification.

The rules for the use of the EP bit are specified in § Section 2.7.2.1 . The rules for the use of Physical Layer Logical Block mechanisms for data poisoning are specified in § Section 4.2.3.4 . Here are some examples of cases where Error Forwarding might be used:

- Example #1: A read from parity or ECC-protected memory encounters an uncorrectable error (EP bit)
- Example #2: An error detected at the source of a write directed towards system memory (EP bit)
- Example #3: Data integrity error on an internal data buffer or cache within a routing element (EP bit or Physical Layer Logical Block)

Considerations for the use of Error Forwarding

- Error Forwarding is only used for Read Completion Data, AtomicOp Completion Data, AtomicOp Request Data, or Write Data, never for the cases when the error is in the “header” (request phase, address/command, etc.). Requests/Completions with header errors cannot be forwarded in general since true destination cannot be positively known and, therefore, forwarding may cause direct or side effects such as data corruption, system failures, etc.
- Error Forwarding is used for controlled propagation of errors through the system, system diagnostics, etc.

- Note that Error forwarding does not cause Data Link Layer Retry - Poisoned TLPs will be retried only if there are transmission errors on the Link as determined by the TLP error detection mechanisms in the Data Link Layer.
 - The Poisoned TLP may ultimately cause the originator of the request to re-issue it (at the Transaction Layer or above) in the case of read operation or to take some other action. Such use of Error Forwarding information is beyond the scope of this specification.

2.7.2.1 Rules For Use of Data Poisoning §

- Support for TLP poisoning in a Transmitter is optional.
 - In FM, a Transmitter is permitted to support only the EP bit mechanism, only the Physical Layer Logical Block mechanism, or both, or neither.
- Data poisoning applies only to the data payload⁵⁴ within a Write Request (Posted or Non-Posted), a Message with Data, an AtomicOp Request, a Read Completion, or an AtomicOp Completion.
- Poisoning of a TLP with a data payload in the Transaction Layer is indicated by a Set EP bit.
- When a routing element is translating a TLP from NFM to FM, if the EP bit is Set in the NFM TLP, then the EP bit must be Set in the FM TLP.
- When a routing element is translating a TLP from FM to NFM, if either poisoning mechanism has been applied to the FM TLP, then the EP bit must be Set in the NFM TLP.
- Transmitters are only permitted to poison TLPs that include a data payload. In FM, the EP bit is Reserved for TLPs that do not include a data payload. In NFM, the behavior of the Receiver is not specified if poisoning is indicated for any TLP that does not include a data payload.
- For IDE TLPs:
 - Only the original Transmitting Port is permitted to poison a TLP and must do so using the EP bit.
 - It is not permitted to use Physical Layer Logical Block mechanisms to poison a TLP; if data corruption is detected in an IDE TLP after the time the MAC has been generated, the IDE TLP must be forwarded without consideration of the detected corruption.
- If a Transmitter supports data poisoning, TLPs that are known at the Transaction Layer of the Transmitter to include a bad data payload must use the EP bit poison mechanism.
- For a routing element that supports data poisoning, if a non-IDE TLP is Received as poisoned using Physical Layer Logical Block mechanisms, that TLP must be transmitted at the Egress Port marked as poisoned using the EP bit mechanism.
- If a Downstream Port supports Poisoned TLP Egress Blocking, the Poisoned TLP Egress Blocking Enable bit is Set, and a poisoned TLP targets going out the Egress Port, the Port must handle the TLP as a Poisoned TLP Egress Blocked error unless there is a higher precedence error. See § Section 6.2.3.2.3, § Section 6.2.5, and § Section 7.9.14.3. Further:
 - The Port must not transmit the TLP.
 - If DPC is not triggered and the TLP is a Non-Posted Request received on a non-UIO VC, the Port must return a Completion with Unsupported Request Completion Status. See § Section 6.2.3.2.4.1.
 - If DPC is triggered the Port must behave as described in § Section 2.9.3.
- For ultimate Completers:
 - The following Requests with poisoned data payload must not modify the value of the target location:
 - Configuration Write Request

54. A data payload includes TLPs with no bytes enabled (e.g., zero-length writes).

- Any of the following that target a control register or control structure in the Completer: I/O Write Request, Memory Write Request, or non-vendor-defined Message with data
- AtomicOp Request
- DMWr Request (see § Section 6.32)

Unless there is a higher precedence error, a Completer must handle these Requests as a Poisoned TLP Received error⁵⁵, and the Completer must also return a Completion with a Completion Status of Unsupported Request (UR) if the Request is Non-Posted (see § Section 6.2.3.2.3, § Section 6.2.3.2.4, and § Section 6.2.5). Regardless of the severity of the reported error, the reported error must be handled as an uncorrectable error, not an Advisory Non-Fatal Error.

A Switch must route these Requests the same way it would route the same Request if it were not poisoned, unless a Request targets a location in the Switch itself, in which case the Switch is the Completer for that Request and must follow the above rules.

For some applications it may be desirable for the Completer to use poisoned data in Write Requests that do not target control registers or control structures - such use is not forbidden. Similarly, it may be desirable for the Requester to use data marked poisoned in Completions - such use is also not forbidden. The appropriate use of poisoned information is application specific, and is not discussed in this document.

This document does not define any mechanism for determining which part or parts of the data payload of a Poisoned TLP are actually corrupt and which, if any, are not corrupt.

2.8 Completion Timeout Mechanism §

In any split transaction protocol, there is a risk associated with the failure of a Requester to receive an expected Completion. To allow Requesters to attempt recovery from this situation in a standard manner, the Completion Timeout mechanism is defined. This mechanism is intended to be activated only when there is no reasonable expectation that the Completion will be returned, and should never occur under normal operating conditions. Note that the values specified here do not reflect expected service latencies, and must not be used to estimate typical response times.

PCI Express device Functions that issue Requests requiring Completions must implement the Completion Timeout mechanism. An exception is made for Configuration Requests (see below). The Completion Timeout mechanism is activated for each Request that requires one or more Completions when the Request is transmitted. Since Switches do not autonomously initiate Requests that need Completions, the requirement for Completion Timeout support is limited only to Root Complexes, PCI Express-PCI Bridges, and Endpoints.

The Completion Timeout mechanism may be disabled by configuration software by means of the Completion Timeout Disable mechanism (see § Section 7.5.3.15 and § Section 7.5.3.16).

The Completion Timeout limit is set in the Completion Timeout Value field of the Device Control 2 register. A Completion Timeout is a reported error associated with the Requester Function (see § Section 6.2). If the Completion Timeout programming mechanism is not supported, the Function *MUST@FLIT* implement a timeout value in the range 40 ms to 50 ms; when Flit Mode Supported is Clear, the Function must implement a timeout value in the range 50 μ s to 50 ms, and it is strongly recommended that the value be at least 10 ms.

A Request for which there are multiple Completions must be considered completed only when all Completions have been received by the Requester.

For a Memory Read Request, if some, but not all, requested data is returned before the Completion Timeout timer expires, the Requester is permitted to keep or to discard the data that was returned prior to timer expiration.

55. Due to ambiguous language in earlier versions of this specification, a component is permitted to handle this error as an Unsupported Request, but this is strongly discouraged.

Completion Timeout expiration for a UIO Request does not necessarily indicate that the Request, or portions of the Request, succeeded or failed.

For a series of UIO Requests using the same Transaction ID, the Completion Timeout mechanism must be restarted for each UIO Request issued.

Completion Timeouts for Configuration Requests have special requirements for the support of PCI Express to PCI/PCI-X Bridges. PCI Express to PCI/PCI-X Bridges, by default, are not enabled to return Request Retry Status (RRS) for Configuration Requests to a PCI/PCI-X device behind the Bridge. This may result in lengthy completion delays that must be comprehended by the Completion Timeout value in the Root Complex. System software may enable PCI Express to PCI/PCI-X Bridges to return RRS for Configuration Requests by setting the Bridge Configuration Retry Enable bit in the Device Control register, subject to the restrictions noted in the [PCIe-to-PCI-PCI-X-Bridge].

IMPLEMENTATION NOTE:

COMPLETION TIMEOUT PREFIX/HEADER LOG CAPABLE §

The prefix/header of the Request TLP associated with a Completion Timeout may optionally be recorded by Requesters that implement the AER Capability. Support for recording of the prefix/header is indicated by the value of the Completion Timeout Prefix/Header Log Capable bit in the Advanced Error Capabilities and Control register.

A Completion Timeout may be the result of improper configuration, system failure, or async removal (see § Section 6.7.6). In order for host software to distinguish a Completion Timeout error after which continued normal operation is not possible (e.g., after one caused by improper configuration or a system failure) from one where continued normal operation is possible (e.g., after an async removal), it is strongly encouraged that Requesters log the Request TLP prefix/header associated with the Completion Timeout.

2.9 Link Status Dependencies §

2.9.1 Transaction Layer Behavior in DL_Down Status §

DL_Down status indicates that there is no connection with another component on the Link, or that the connection with the other component has been lost and is not recoverable by the Physical or Data Link Layers. This section specifies the Transaction Layer's behavior if DPC has not been triggered and the Data Link Layer reports DL_Down status to the Transaction Layer, indicating that the Link is non-operational. § Section 2.9.3 specifies the behavior if DPC has been triggered.

- For a Port with DL_Down status, the Transaction Layer is not required to accept received TLPs from the Data Link Layer, provided that these TLPs have not been acknowledged by the Data Link Layer. Such TLPs do not modify receive Flow Control credits.

For a Downstream Port, DL_Down status is handled by:

- Initializing back to their default state any buffers or internal states associated with outstanding requests transmitted Downstream
 - Port configuration registers must not be affected, except as required to update status associated with the transition to DL_Down.

- For Non-Posted Requests, forming completions for any Requests submitted by the device core for Transmission, returning Unsupported Request Completion Status, then discarding the Requests
 - This is a reported error associated with the Function for the (virtual) Bridge associated with the Port (see § Section 6.2). For Root Ports, the reporting of this error is optional.
 - Non-Posted Requests already being processed by the Transaction Layer, for which it may not be practical to return Completions, are discarded.
Note: This is equivalent to the case where the Request had been Transmitted but not yet Completed before the Link status became DL_Down.
 - These cases are handled by the Requester using the Completion Timeout mechanism.
- Note: The point at which a Non-Posted Request becomes “uncompletable” is implementation specific.
- The Port must terminate any PME_Turn_Off handshake Requests targeting the Port in such a way that the Port is considered to have acknowledged the PME_Turn_Off request (see the Implementation Note in § Section 5.3.3.2.1).
 - The Port must handle Vendor-Defined Message Requests as described in § Section 2.2.8.6 (e.g., silently discard Vendor-Defined Type 1 Messages Requests that it is not designed to receive) since the DL_Down prevents the Request from reaching its targeted Function.
 - For all other Posted Requests, discarding the Requests
 - This is a reported error associated with the Function for the (virtual) Bridge associated with the Port (see § Section 6.2), and must be reported as an Unsupported Request. For Root Ports, the reporting of this error is optional.
 - For a Posted Request already being processed by the Transaction Layer, the Port is permitted not to report the error.
Note: This is equivalent to the case where the Request had been Transmitted before the Link status became DL_Down
- Note: The point at which a Posted Request becomes “unreportable” is implementation specific.
- Discarding all Completions submitted by the device core for Transmission

For an Upstream Port, DL_Down status is handled as a reset by:

- Returning all PCI Express-specific registers, state machines and externally observable state to the specified default or initial conditions (except for registers defined as sticky - see § Section 7.4)
- Discarding all TLPs being processed
- For Switch and Bridge propagating hot reset to all associated Downstream Ports. In Switches that support Link speeds greater than 5.0 GT/s, the Upstream Port must direct the LTSSM of each Downstream Port to the Hot Reset state, but not hold the LTSSMs in that state. This permits each Downstream Port to begin Link training immediately after its hot reset completes. This behavior is recommended for all Switches.

2.9.2 Transaction Layer Behavior in DL_Up Status §

DL_Up status indicates that a connection has been established with another component on the associated Link. This section specifies the Transaction Layer's behavior when the Data Link Layer reports entry to the DL_Up status to the Transaction Layer, indicating that the Link is operational. The Transaction Layer of a Port with DL_Up status must accept received TLPs that conform to the other rules of this specification.

For a Downstream Port on a Root Complex or a Switch:

- When transitioning from a non-DL_Up status to a DL_Up status and the Auto Slot Power Limit Disable bit is Clear in the Slot Control Register, the Port must initiate the transmission of a Set_Slot_Power_Limit Message to the other component on the Link to convey the value programmed in the Slot Power Limit Scale and Slot Power Limit Value fields of the Slot Capabilities Register. This Transmission is optional if the Slot Capabilities Register has not yet been initialized.

2.9.3 Transaction Layer Behavior During Downstream Port Containment §

During Downstream Port Containment (DPC), the LTSSM associated with the Downstream Port is directed to the Disabled state. Once it reaches the Disabled state, it remains there as long as the DPC Trigger Status bit in the DPC Status Register is Set. See § Section 6.2.11 for requirements on how long software must leave the Downstream Port in DPC. This section specifies the Transaction Layer's behavior once DPC has been triggered, and as long as the Downstream Port remains in DPC.

- Once DPC has been triggered, no additional (Upstream) TLPs are accepted from the Data Link Layer.
- If the condition that triggered DPC was associated with an Upstream TLP, any subsequent Upstream TLPs that were already accepted from the Data Link Layer must be discarded silently.

The Downstream Port handles (Downstream) TLPs submitted by the device core in the following manner.

- If the condition that triggered DPC was associated with a Downstream TLP, any prior Downstream TLPs are permitted to be dropped silently or transmitted before the Link goes down. Otherwise, the following rules apply.
 - For each Non-Posted Request, the Port must return a Completion and discard the Request silently. The Completer ID field must contain the value associated with the Downstream Port.
 - If the DPC Completion Control bit is Set in the DPC Control Register, then Completions are generated with Unsupported Request (UR) Completion Status.
 - If the DPC Completion Control bit is Clear, Completions are generated with Completer Abort (CA) Completion Status.
 - The Port must terminate any PME_Turn_Off handshake Requests targeting the Port in such a way that the Port is considered to have acknowledged the PME_Turn_Off Request (see the Implementation Note in § Section 5.3.3.2.1).
 - The Port must handle Vendor-Defined Message Requests as described in § Section 2.2.8.6. (e.g., silently discard Vendor Defined_Type 1 Message Requests that it is not designed to receive) since the DL_Down prevents the Request from reaching its targeted Function.
 - For all other Posted Requests and Completions, the Port must silently discard the TLP.

For any outstanding Non-Posted Requests where DPC being triggered prevents their associated Completions from being returned, the following apply:

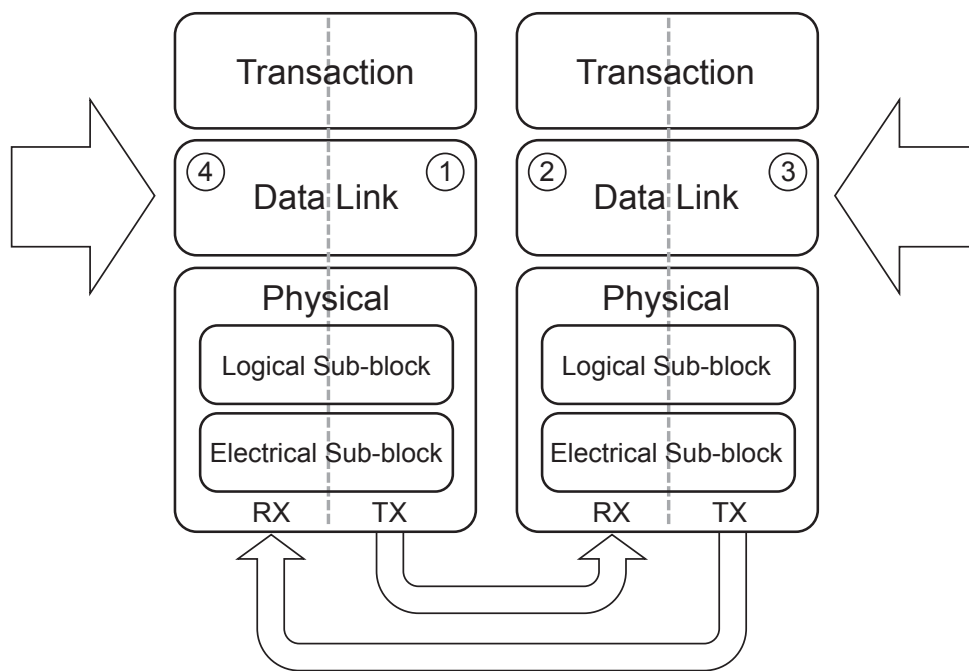

- For Root Ports that support RP Extensions for DPC, the Root Port may track certain Non-Posted Requests, and when DPC is triggered, synthesize a Completion for each tracked Request. This helps avoid Completion Timeouts that would otherwise occur as a side-effect of DPC being triggered. Each synthesized Completion must have a UR or CA Completion Status as determined by the DPC Completion Control bit. The set of Non-Posted Requests that get tracked is implementation specific, but it is strongly recommended that all Non-Posted Requests that are generated by host processor instructions (e.g., “read”, “write”, “load”, “store”, or one that corresponds to an AtomicOp) be tracked. Other candidates for tracking include peer-to-peer Requests coming from other Root Ports and Requests coming from RCiEPs.

- Otherwise, the associated Requesters may encounter Completion Timeouts. The software solution stack should comprehend and account for this possibility.

3. Data Link Layer Specification §

The Data Link Layer acts as an intermediate stage between the Transaction Layer and the Physical Layer. Its primary responsibility is to provide a reliable mechanism for exchanging Transaction Layer Packets (TLPs) between the two components on a Link.

3.1 Data Link Layer Overview §

OM13778A

Figure 3-1 Layering Diagram Highlighting the Data Link Layer §

The Data Link Layer is responsible for reliably conveying TLPs supplied by the Transaction Layer across a PCI Express Link to the other component's Transaction Layer. Services provided by the Data Link Layer include:

Data Exchange:

- Accept TLPs for transmission from the Transmit Transaction Layer and convey them to the Transmit Physical Layer
- Accept TLPs received over the Link from the Physical Layer and convey them to the Receive Transaction Layer

Error Detection and Retry (Non-Flit Mode):

- TLP Sequence Number and LCRC generation
- Transmitted TLP storage for Data Link Layer Retry

- Data integrity checking for TLPs and Data Link Layer Packets (DLLPs)
- Positive and negative acknowledgement DLLPs
- Error indications for error reporting and logging mechanisms
- Link Acknowledgement Timeout replay mechanism

Initialization and power management:

- Track Link state and convey active/reset/disconnected state to Transaction Layer

DLLPs are:

- used for Link Management functions including TLP acknowledgement, power management, and exchange of Flow Control information.
- transferred between Data Link Layers of the two directly connected components on a Link

DLLPs are sent point-to-point, between the two components on one Link. TLPs are routed from one component to another, potentially through one or more intermediate components.

In Non-Flit Mode, Data integrity checking for DLLPs and TLPs is done using a CRC included with each packet sent across the Link. DLLPs use a 16-bit CRC and TLPs (which can be much longer than DLLPs) use a 32-bit LCRC. TLPs additionally include a sequence number, which is used to detect cases where one or more entire TLPs have been lost.

- Received DLLPs that fail the CRC check are discarded. The mechanisms that use DLLPs may suffer a performance penalty from this loss of information, but are self-repairing such that a successive DLLP will supersede any information lost.
- TLPs that fail the data integrity checks (LCRC and sequence number), or that are lost in transmission from one component to another, are re-sent by the Transmitter. The Transmitter stores a copy of all TLPs sent, re-sending these copies when required, and purges the copies only when it receives a positive acknowledgement of error-free receipt from the other component. If a positive acknowledgement has not been received within a specified time period, the Transmitter will automatically start re-transmission. The Receiver can request an immediate re-transmission using a negative acknowledgement.

In Flit Mode, both DLLPs and TLPs are sent using Flits. Flits contain the data integrity checks (LCRC, FEC, and sequence number). Replay occurs at the Flit level (see § Section 4.2.3.4 and § Section 4.2.3.4.2.1).

The Data Link Layer appears as an information conduit with varying latency to the Transaction Layer. On any given individual Link all TLPs fed into the Transmit Data Link Layer (1 and 3) will appear at the output of the Receive Data Link Layer (2 and 4) in the same order at a later time, as illustrated in § Figure 3-1. The latency will depend on a number of factors, including pipeline latencies, width and operational frequency of the Link, transmission of electrical signals across the Link, and delays caused by Data Link Layer Retry. As a result of these delays, the Transmit Data Link Layer (1 and 3) can apply backpressure to the Transmit Transaction Layer, and the Receive Data Link Layer (2 and 4) communicates the presence or absence of valid information to the Receive Transaction Layer.

3.2 Data Link Control and Management State Machine §

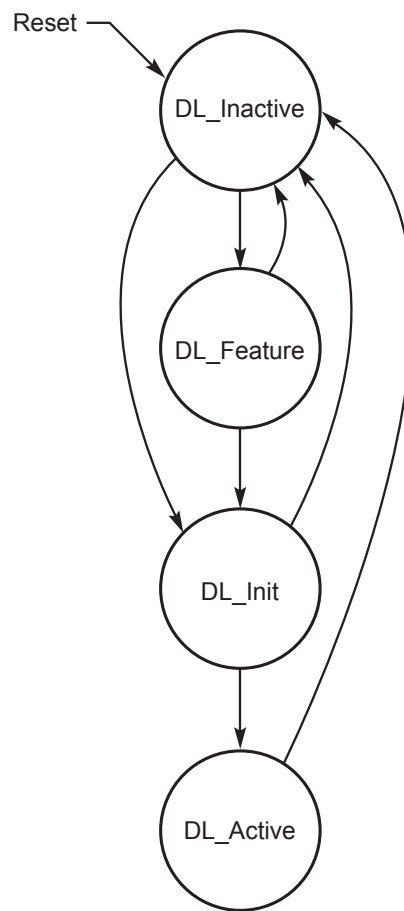

The Data Link Layer tracks the state of the Link. It communicates Link status with the Transaction and Physical Layers, and performs Link management through the Physical Layer. The Data Link Layer contains the Data Link Control and Management State Machine (DLCMSM) to perform these tasks. The states for this machine are described below, and are shown in § Figure 3-2.

States:

- DL_Inactive - Physical Layer reporting Link is non-operational or nothing is connected to the Port
- DL_Feature (optional) - Physical Layer reporting Link is operational, perform the Data Link Feature Exchange
- DL_Init - Physical Layer reporting Link is operational, initialize Flow Control for the default Virtual Channel
- DL_Active - Normal operation mode

Status Outputs:

- **DL_Down** - The Data Link Layer is not communicating with the component on the other side of the Link.
- **DL_Up** - The Data Link Layer is communicating with the component on the other side of the Link.

OM13779A

Figure 3-2 Data Link Control and Management State Machine §

3.2.1 Data Link Control and Management State Machine Rules §

Rules per state:

- **DL_Inactive**
 - Initial state following PCI Express Hot, Warm, or Cold Reset (see § Section 6.6). Note that DL states are unaffected by an FLR (see § Section 6.6).

- Upon entry to DL_Inactive
 - Reset all Data Link Layer state information to default values
 - If the Port supports the optional Data Link Feature Exchange, the Remote Data Link Feature Supported, and Remote Data Link Feature Supported Valid fields must be cleared.
 - Discard the contents of the Data Link Layer Retry Buffer (see § Section 3.6)
- While in DL_Inactive:
 - Report DL_Down status to the Transaction Layer as well as to the rest of the Data Link Layer

Note: This will cause the Transaction Layer to discard any outstanding transactions and to terminate internally any attempts to transmit a TLP. For a Downstream Port, this is equivalent to a Hot-Remove. For an Upstream Port, having the Link go down is equivalent to a hot reset (see § Section 2.9).
 - Discard TLP information from the Transaction and Physical Layers
 - Do not generate or accept DLLPs
- Exit to DL_Feature if all of the following conditions are satisfied:
 - the Port supports Data Link Feature Exchange
 - either the Data Link Feature Exchange is Enabled bit in the Data Link Feature Extended Capability is Set or the Data Link Feature Extended Capability is not implemented
 - the Transaction Layer indicates that the Link is not disabled by software
 - the Physical Layer reports Physical LinkUp = 1b
- Exit to DL_Init if:
 - The Port does not support the optional Data Link Feature Exchange, the Transaction Layer indicates that the Link is not disabled by software, and the Physical Layer reports Physical LinkUp = 1b
or
 - The Port supports the optional Data Link Feature Exchange, the Data Link Feature Exchange is Enabled bit is Clear, the Transaction Layer indicates that the Link is not disabled by software, and the Physical Layer reports Physical LinkUp = 1b
- **DL_Feature**
 - While in DL_Feature:
 - Perform the Data Link Feature Exchange protocol as described in § Section 3.3
 - Report DL_Down status
 - The Data Link Layer of a Port with DL_Down status is permitted to discard any received TLPs provided that it does not acknowledge those TLPs by sending one or more Ack DLLPs
 - Exit to DL_Init if:
 - Data Link Feature Exchange completes successfully, and the Physical Layer continues to report Physical LinkUp = 1b,
or
 - Data Link Feature Exchange determines that the remote Data Link Layer does not support the optional Data Link Feature Exchange protocol, and the Physical Layer continues to report Physical LinkUp = 1b
 - Terminate the Data Link Feature Exchange protocol and exit to DL_Inactive if:
 - Physical Layer reports Physical LinkUp = 0b

- **DL_Init**

- While in DL_Init:
 - Initialize Flow Control for the default Virtual Channel, VC0, following the Flow Control initialization protocol described in § Section 3.4
 - Report DL_Down status while in state FC_INIT1; DL_Up status while in state FC_INIT2
 - The Data Link Layer of a Port with DL_Down status is permitted to discard any received TLPs provided that it does not acknowledge those TLPs by sending one or more Ack DLLPs
- Exit to DL_Active if:
 - Flow Control initialization completes successfully, and the Physical Layer continues to report Physical LinkUp = 1b
- Terminate attempt to initialize Flow Control for VC0 and exit to DL_Inactive if:
 - Physical Layer reports Physical LinkUp = 0b

- **DL_Active**

- DL_Active is referred to as the normal operating state
- While in DL_Active:
 - Accept and transfer TLP information with the Transaction and Physical Layers as specified in this chapter
 - Generate and accept DLLPs as specified in this chapter
 - Report DL_Up status to the Transaction and Data Link Layers
- Exit to DL_Inactive if:
 - Physical Layer reports Physical LinkUp = 0b
 - Downstream Ports that are Surprise Down Error Reporting Capable (see § Section 7.5.3.6) must treat this transition from DL_Active to DL_Inactive as a Surprise Down error, except in the following cases where this error detection is blocked:
 - If the Secondary Bus Reset bit in the Bridge Control Register has been Set by software, then the subsequent transition to DL_Inactive must not be considered an error.
 - If the Link Disable bit has been Set by software or if DPC has been triggered, then the subsequent transition to DL_Inactive must not be considered an error.
 - If a Switch Downstream Port transitions to DL_Inactive due to an event above that Port, that transition to DL_Inactive must not be considered an error. Example events include the Switch Upstream Port propagating Hot Reset, the Switch Upstream Link transitioning to DL_Down, and the Secondary Bus Reset bit in the Switch Upstream Port being Set.
 - If a PME_Turn_Off Message has been sent through this Port, then the subsequent transition to DL_Inactive must not be considered an error.
 - Note that the DL_Inactive transition for this condition will not occur until a power off, a reset, or a request to restore the Link is sent to the Physical Layer.
 - Note also that in the case where the PME_Turn_Off/PME_TO_Ack handshake fails to complete successfully, a Surprise Down error may be detected.
 - If the Port is associated with a hot-pluggable slot (the Hot-Plug Capable bit in the Slot Capabilities register Set), and the Hot-Plug Surprise bit in the Slot Capabilities register is Set, then any transition to DL_Inactive must not be considered an error.

- If the Port is associated with a hot-pluggable slot (Hot-Plug Capable bit in the Slot Capabilities register Set), and Power Controller Control bit in Slot Control register is Set (Power-Off), then any transition to DL_Inactive must not be considered an error.

Error blocking initiated by one or more of the above cases must remain in effect until the Port exits DL_Active and subsequently returns to DL_Active with none of the blocking cases in effect at the time of the return to DL_Active.

Note that the transition out of DL_Active is simply the expected transition as anticipated per the error detection blocking condition.

If implemented, this is a reported error associated with the detecting Port (see § Section 6.2).

IMPLEMENTATION NOTE: PHYSICAL LAYER THROTTLING §

Note that there are conditions where the Physical Layer may be temporarily unable to accept TLPs and DLLPs from the Data Link Layer. The Data Link Layer must comprehend this by providing mechanisms for the Physical Layer to communicate this condition, and for TLPs and DLLPs to be temporarily blocked by the condition.

3.3 Data Link Feature Exchange §

The Data Link Feature Exchange protocol is required for Ports that support Flit Mode and for Ports that support 16.0 GT/s and higher data rates. It is optional for other Ports. Downstream Ports that implement this protocol must contain the Data Link Feature Extended Capability (see § Section 7.7.4). Upstream Ports that implement this protocol are optionally permitted to include the Data Link Feature Extended Capability. This capability contains four fields:

- The Local Data Link Feature Supported field indicates the Data Link Features supported by the local Port
- The Remote Data Link Feature Supported field indicates the Data Link Features supported by the remote Port
- The Remote Data Link Feature Supported Valid bit indicates that the Remote Data Link Feature Supported field contains valid data
- The Data Link Feature Exchange is Enabled field permits systems to disable the Data Link Feature Exchange. This can be used to work around legacy hardware that does not correctly ignore the DLLP.

The Data Link Feature Exchange protocol transmits a Port's Local Feature Supported information to the Remote Port and captures that Remote Port's Feature Supported information.

Rules for this protocol are:

- On entry to DL_Feature:
 - It is permitted to Clear the Remote Data Link Feature Supported and Remote Data Link Feature Supported Valid fields
- While in DL_Feature:
 - Transaction Layer must block transmission of TLPs
 - Transmit the Data Link Feature DLLP

- The transmitted Feature Supported field must use the value in the Local Data Link Feature Supported field.
- The transmitted Feature Ack bit must use the value in the Remote Data Link Feature Supported Valid bit.
- The Data Link Feature DLLP must be transmitted at least once every 34 μ s. Time spent in the Recovery or Configuration LTSSM states does not contribute to this limit.
- Process received Data Link Feature DLLPs:
 - If the Remote Data Link Feature Supported Valid bit is Clear, record the Feature Supported field from the received Data Link Feature DLLP in the Remote Data Link Feature Supported field and Set the Remote Data Link Feature Supported Valid bit.
- Exit DL_Feature if:
 - An InitFC1 DLLP has been received.
 - An MR-IOV MRInit DLLP (encoding 0000 0001b) has been received. MR-IOV is deprecated so this clause has no effect in new designs.
 - or
 - While in DL_Feature, at least one Data Link Feature DLLP has been received with the Feature Ack bit Set.

A **Data Link Feature** is a field representing a protocol feature. Protocol features are either activated, not activated, or not supported. A Data Link Feature is activated when Remote Data Link Feature Supported Valid is Set and when the associated Feature Supported bit is Set in both the Local Data Link Feature Supported and Remote Data Link Feature Supported fields.

A **Data Link Parameter** is a field that communicates a value across the interface. Data Link Parameters have a parameter-specific mechanism for software to determine when the field value is meaningful. For example, the field might be meaningful if its value is non-zero or the field might be meaningful if some other field(s) have specific values.

Data Link Features and their corresponding bit locations are shown in § Table 3-1.

Table 3-1 Data Link Feature Supported Bit Definition §

Bit Location	Description	Type
0	<p><u>Scaled Flow Control</u> – indicates support for Scaled Flow Control.</p> <p>Must be Set in Ports that support 16.0 GT/s or higher data rates.</p> <p>Must be Set if Flit Mode is enabled.</p>	<u>Data Link Feature</u>
1	<p><u>Immediate Readiness</u> – indicates that all non-Virtual Functions in the sending Port have <u>Immediate Readiness Set</u> (see § <u>Section 7.5.1.1.4</u>).</p> <p>In Flit Mode, this bit is always meaningful. In Non-Flit Mode, this bit is meaningful when Set, but when Clear indicates either that some non-Virtual Function has <u>Immediate Readiness Clear</u> or that the sending Port is not providing this information.</p>	<u>Data Link Parameter</u>
4:2	<p><u>Extended VC Count</u> – This field indicates the number of VC Resources supported by the sending Port. This is the value of the <u>Extended VC Count</u> field in either the <u>Multi-Function Virtual Channel Extended Capability</u> or the <u>Virtual Channel Extended Capability</u> (with Capability ID <u>0002h</u>).</p> <p>This field is meaningful in Flit Mode. In Non-Flit Mode, this field must be zero.</p>	<u>Data Link Parameter</u>

Bit Location	Description	Type																
7:5	<p>L0p Exit Latency - This field indicates sending Port's L0p Exit Latency. The value reported indicates the length of time the sending Port requires to complete widening a link using L0p. If the sending Port does not support L0p, this field must contain 000b.</p> <p>Defined encodings are:</p> <table> <tr> <td>000b</td> <td>Less than 1µs</td> </tr> <tr> <td>001b</td> <td>1 µs to less than 2 µs</td> </tr> <tr> <td>010b</td> <td>2 µs to less than 4 µs</td> </tr> <tr> <td>011b</td> <td>4 µs to less than 8 µs</td> </tr> <tr> <td>100b</td> <td>8 µs to less than 16 µs</td> </tr> <tr> <td>101b</td> <td>16 µs to less than 32 µs</td> </tr> <tr> <td>110b</td> <td>32 µs-64 µs</td> </tr> <tr> <td>111b</td> <td>More than 64 µs</td> </tr> </table> <p>This field is meaningful in Flit Mode. In Non-Flit Mode, this field must be zero.</p>	000b	Less than 1µs	001b	1 µs to less than 2 µs	010b	2 µs to less than 4 µs	011b	4 µs to less than 8 µs	100b	8 µs to less than 16 µs	101b	16 µs to less than 32 µs	110b	32 µs-64 µs	111b	More than 64 µs	Data Link Parameter
000b	Less than 1µs																	
001b	1 µs to less than 2 µs																	
010b	2 µs to less than 4 µs																	
011b	4 µs to less than 8 µs																	
100b	8 µs to less than 16 µs																	
101b	16 µs to less than 32 µs																	
110b	32 µs-64 µs																	
111b	More than 64 µs																	
22:8	Reserved																	

3.4 Flow Control Initialization Protocol §

Before starting normal operation following power-up or interconnect reset, it is necessary to initialize Flow Control for the default Virtual Channel, VC0 (see § Section 6.6). In addition, when additional Virtual Channels (VCs) are enabled, the Flow Control initialization process must be completed for each newly enabled VC before it can be used (see § Section 2.6.1). This section describes the initialization process that is used for all VCs. Note that since VC0 is enabled before all other VCs, no TLP traffic of any kind will be active prior to initialization of VC0. However, when additional VCs are being initialized there will typically be TLP traffic flowing on other, already enabled, VCs. Such traffic has no direct effect on the initialization process for the additional VC(s).

Shared Flow Control is enabled in Flit Mode. Shared Flow Control is disabled in Non-Flit Mode.

There are two states in the VC initialization process. These states are:

- FC_INIT1
- FC_INIT2

The rules for this process are given in the following section.

3.4.1 Flow Control Initialization State Machine Rules §

- If at any time during initialization for VCs 1-7 the VC is disabled, the flow control initialization process for the VC is terminated
- Rules for state **FC_INIT1**:
 - Entered when initialization of a VC (VCx) is required
 - When the DL_Init state is entered (VCx = VC0)
 - When VC (VCx = VC1-7) is enabled by software (see § Section 7.9.1 and § Section 7.9.2)

- While in FC_INIT1:
 - Transaction Layer must block transmission of TLPs using VCx
 - In Non-Flit Mode, transmit the following three InitFC1 DLLPs for VCx in the following relative order:
 - InitFC1-P [Dedicated] (first)
 - InitFC1-NP [Dedicated] (second)
 - InitFC1-Cpl [Dedicated] (third)
 - In Flit Mode, transmit the following six InitFC1 DLLPs for VCx in the following relative order:
 - InitFC1-P [Dedicated] (first)
 - InitFC1-NP [Dedicated] (second)
 - InitFC1-Cpl [Dedicated] (third)
 - InitFC1-P [Shared] (fourth)
 - InitFC1-NP [Shared] (fifth)
 - InitFC1-Cpl [Shared] (sixth)
 - The three (or six) InitFC1 DLLPs must be transmitted at least once every 34 μ s.
 - Time spent in the Recovery or Configuration LTSSM states does not contribute to this limit.
 - It is strongly encouraged that the InitFC1 DLLP transmissions are repeated frequently, particularly when there are no other TLPs or DLLPs available for transmission.
 - Set DataFC, DataScale, HdrFC, and HdrScale as shown in § Table 3-2 and § Table 3-3
 - When DataFC or HdrFC is 0, the following encodings of DataScale and HdrScale are used:
 - Non-Flit Mode, no Scaled FC:
 - [Infinite.1]**
DataScale/HdrScale = 00b
 - [Reserved]**
DataScale/HdrScale = 01b, 10b, or 11b
 - Non-Flit Mode, Scaled FC:
 - [Infinite.2]**
DataScale/HdrScale = 01b, 10b, or 11b
 - [Reserved]**
DataScale/HdrScale = 00b
 - Flit Mode:
 - [Infinite.3]**
DataScale/HdrScale = 00b
 - [Zero]**
DataScale/HdrScale = 01b
 - [Merged]**
DataScale/HdrScale = 10b
 - [Reserved]**
DataScale/HdrScale = 11b

Table 3-2 InitFC1 / InitFC2 Options – Non-Flit Mode ⁵

Row	Scaled Flow Control Supported and Activated	Local and Remote Extended VC Count	Merged	InitFC Count	Dedicated / Shared	DataScale and HdrScale	DataFC and HdrFC	Notes
1	No Scaled FC	0 (Reserved)	Not Applicable	3	0b (Reserved)	[Infinite.1]	≠ 0	1
						00b		
2	Scaled FC	0 (Reserved)	Not Applicable	3	0b (Reserved)	[Infinite.2]	≠ 0	1, 2
						{ 01b 10b 11b }		

Notes:

- Backwards compatibility: In earlier versions of this specification, the DataScale and HdrScale bits are Reserved.
- Backwards compatibility: In earlier versions of this specification, any non-zero DataScale/ HdrScale means [Infinite.2].

Table 3-3 InitFC1 / InitFC2 Options – Flit Mode ⁵

Row	Local and Remote Extended VC Count	Merged	InitFC Count	Dedicated / Shared	Kind	DataScale and HdrScale	DataFC and HdrFC	Notes
3	Local = 0 OR optionally (Local ≠ 0 and Remote = 0)	Not Merged	6	0b (shared)	P, NP, Cpl	[Infinite.3]	≠ 0	5, 9
4				1b (dedicated)	P, NP, Cpl	[Zero]		
5	Local = 0 OR optionally (Local ≠ 0 and Remote = 0)	Merged	6	0b (shared)	P, NP	[Infinite.3]	≠ 0	8
6					Cpl	[Merged]		
7				1b (dedicated)	P, Cpl	[Infinite.3]	≠ 0	8, 10
8				NP	[Zero]			
9	Local ≠ 0	Not Merged	6	0b (shared)	P, NP, Cpl	[Infinite.3]	≠ 0	5, 6
						[Zero]		
						{ 01b 10b 11b }		

Row	Local and Remote Extended VC Count	Merged	InitFC Count	Dedicated / Shared	Kind	DataScale and HdrScale	DataFC and HdrFC	Notes
10				1b (dedicated)	P, NP, Cpl	[Infinite.3] { 01b 10b 11b }	≠ 0	5
11	Local ≠ 0	Merged	6	0b (shared)	P, NP	[Infinite.3]	≠ 0	6, 8
[Zero]								
12					Cpl	[Merged]	7, 8	
13				1b (dedicated)	P, NP, Cpl	[Infinite.3] { 01b 10b 11b }	≠ 0	8, 10

Notes:

- Since Extended VC Count is 0, only 1 VC is possible. [Zero] dedicated credits allocated. All credits are Shared.
- Since Extended VC Count is 0, only 1 VC is possible. [Zero] Non-Posted dedicated credits are allocated and all Non-Posted credits are Shared.
- When (Local ≠ 0 and Remote = 0), rows 3-4 are recommended but rows 9-10 are permitted.
- [Zero] shared credits indicates that no additional shared credits are being allocated. All shared credits are (were) allocated by other VCs (and are usable by this VC).

When more than one VC advertises shared credits with scale factor 01b, 10b, or 11b, that scale factor must be able to express all allocated shared credits, regardless of VC. For example, if VC0 and VC1 each advertise 120 header credits (i.e., a total of 240 credits), they must do so using a scale factor other than 1 (01b) since that scale factor is limited to 127 outstanding credits.

Use of [Infinite.3] shared credits must be consistent across VCs. If one VC uses [Infinite.3] shared credits for a given credit type (P/NP/Cpl, Hdr/Data), all VCs must also use [Infinite.3] shared credits for that credit type.

Use of scale values (HdrScale or DataScale) 01b, 10b, or 11b for shared credits must be consistent across VCs. If one VC uses scale value 01b, 10b, or 11b for a given credit type (P/NP/Cpl, Hdr/Data), all other VCs must either use the same scale value or must use [Zero] for that credit type.

When one VC uses [Zero] shared credits for a given credit type (P/NP/Cpl, Hdr/Data), at least one VC must use a scale value of 01b, 10b, or 11b for that credit type. For that credit type, shared credit UpdateFC DLLPs for all VCs must use this non-00b scale value, including VCs that advertised [Zero] during initialization.

It is permitted for all VCs to offer [Zero] shared credits resulting in only dedicated credits being available. Doing so means that every TLP will contain a Flit Mode Local TLP Prefix.

- [Merged] for Shared Completion credits indicates that Shared Completions and Shared Posted credits share a common pool of credits. [Merged] is not permitted on Shared Posted or Shared Non-Posted credits. Dedicated credits are never merged.

Use of [Merged] shared credits must be consistent across VCs. If one VC uses [Merged] shared credits, all VCs must also use [Merged] shared credits.

Row	Local and Remote Extended VC Count	Merged	InitFC Count	Dedicated / Shared	Kind	DataScale and HdrScale	DataFC and HdrFC	Notes
-----	--	--------	-----------------	-----------------------	------	---------------------------	------------------------	-------

Use of [Merged] shared credits must be consistent between Hdr and Data. If CplH uses [Merged] shared credits, CplD must also use [Merged] shared credits.

When [Merged] is used, and P Hdr shared credits are not [Infinite.3], UpdateFC DLLPs for CplH must use the same scale factor as PH.

When [Merged] is used, and P Data shared credits are not [Infinite.3], UpdateFC DLLPs for CplD must use the same scale factor as PD.

When [Merged], UpdateFC DLLPs and Optimized_Update_FCs return credits as if [Merged] was not enabled (i.e., based on the type of TLP being freed even though there is a single shared credit pool). Doing this provides the transmitter visibility into remote buffer occupancy (Posted vs Completion) and allows it to implement vendor specific mechanisms to manage that occupancy.

When [Merged] is used and P Hdr shared credits are not [Infinite.3], and at least one VC must use non [Zero] P Hdr shared credits.

When [Merged] is used and P Data shared credits are not [Infinite.3], and at least one VC must use non [Zero] P Data shared credits.

8. When (Local \neq 0 and Remote = 0), rows 5-8 are recommended, but rows 11-13 are permitted.
9. The Shared / Dedicated mechanism is defined so that shared credits are the common case. TLPs consuming dedicated credits use the Flit Mode Local TLP Prefix and thus consume an additional DW. In rows 3-4, all credits are shared.
10. To avoid deadlock, Posted and Completion credits must not be [Zero].

- Except as needed to ensure at least the required frequency of InitFC1 DLLP transmission, the Data Link Layer must not block other transmissions.
 - Note that this includes all Physical Layer initiated transmissions (e.g., Ordered Sets), Ack and Nak DLLPs (when applicable), and TLPs using VCs that have previously completed initialization (when applicable)
- Process received InitFC1 and InitFC2 DLLPs:
 - Record the indicated HdrFC and DataFC values
 - If the Receiver supports Scaled Flow Control, record the indicated HdrScale and DataScale values.
 - Set flag FI1 once FC unit values have been recorded for each of P, NP, and Cpl for VCx.
 - In Non-Flit Mode flag FI1 is Set when the three dedicated FC unit values have been recorded.
 - In Flit Mode, flag FI1 is Set when all six FC unit values have been recorded.
- Exit to FC_INIT2 if:
 - Flag FI1 has been Set indicating that FC unit values have been recorded for each of P, NP, and Cpl for VCx
- Rules for state **FC_INIT2**:
 - While in FC_INIT2:
 - Transaction Layer must block transmission of TLPs using VCx

- In non-Flit Mode, transmit the following three InitFC2 DLLPs for VCx in the following relative order:
 - InitFC2-P [Dedicated] (first)
 - InitFC2-NP [Dedicated] (second)
 - InitFC2-Cpl [Dedicated] (third)
- In Flit Mode, transmit the following six InitFC2 DLLPs for VCx in the following relative order:
 - InitFC2-P [Dedicated] (first)
 - InitFC2-NP [Dedicated] (second)
 - InitFC2-Cpl [Dedicated] (third)
 - InitFC2-P [Shared] (fourth)
 - InitFC2-NP [Shared] (fifth)
 - InitFC2-Cpl [Shared] (sixth)
- The three (six) InitFC2 DLLPs must be transmitted at least once every 34 μ s.
 - Time spent in the Recovery or Configuration LTSSM states does not contribute to this limit.
 - It is strongly encouraged that the InitFC2 DLLP transmissions are repeated frequently, particularly when there are no other TLPs or DLLPs available for transmission.
- Set DataFC, DataScale, HdrFC, and HdrScale as shown in [§ Table 3-2](#) and [§ Table 3-3](#)
- Except as needed to ensure at least the required frequency of InitFC2 DLLP transmission, the Data Link Layer must not block other transmissions
 - Note that this includes all Physical Layer initiated transmissions (for example, Ordered Sets), Ack and Nak DLLPs (when applicable), and TLPs using VCs that have previously completed initialization (when applicable)
- Process received InitFC1 and InitFC2 DLLPs:
 - Ignore the received HdrFC, HdrScale, DataFC, and DataScale values
 - Set flag FI2 on receipt of any InitFC2 DLLP for VCx
- Set flag FI2 on receipt of any TLP on VCx, any UpdateFC DLLP for VCx, or, in Flit Mode, any [Optimized_Update_FC](#)
- Signal completion and exit if:
 - Flag FI2 has been Set
 - If Scaled Flow Control is activated on the Link, the Transmitter must send 01b, 10b, or 11b for HdrScale and DataScale in all UpdateFC DLLPs for VCx.
 - If the Scaled Flow Control is not supported or if Scaled Flow Control is not activated on the Link, the Transmitter must send 00b for HdrScale and DataScale in all UpdateFC DLLPs for VCx.

IMPLEMENTATION NOTE: EXAMPLE OF FLOW CONTROL INITIALIZATION §

§ Figure 3-3 illustrates an example of the Flow Control initialization protocol for VC0 between a Switch and a Downstream component. In this example, each component advertises the minimum permitted values for each type of Flow Control credit. For both components the Rx_MPS_Limit is 1024 bytes, corresponding to a data payload credit advertisement of 040h. All DLLPs are shown as received without error.

Figure 3-3 VCO Flow Control Initialization Example with 8b/10b Encoding-based Framing 5

3.4.2 Scaled Flow Control §

Link performance can be affected when there are insufficient flow control credits available to account for the Link round trip time. This effect becomes more noticeable at higher Link speeds and the limitation of 127 header credits and 2047 data credits can limit performance. The Scaled Flow Control mechanism is designed to address this limitation.

All Ports are permitted to support Scaled Flow Control. Ports that support 16.0 GT/s and higher data rates must support Scaled Flow Control. Scaled Flow Control activation does not affect the ability to operate at 16.0 GT/s and higher data rates.

The following rules apply when Scaled Flow Control is not activated for the Link:

- The InitFC1, InitFC2, and UpdateFC DLLPs must contain 00b in the HdrScale and DataScale fields.
- The HdrFC counter is 8 bits wide and the HdrFC field includes all bits of the counter.
- The DataFC counter is 12 bits wide and the DataFC field includes all bits of the counter.

The following rules apply when Scaled Flow Control is activated for the Link:

- The InitFC1 and InitFC2 DLLPs that are transmitted must contain 01b, 10b, or 11b in the HdrScale field. The value is determined by the maximum number of header credits that will be outstanding of the indicated credit type as defined in § Table 3-4.
- The InitFC1 and InitFC2 DLLPs that are transmitted must contain 01b, 10b, or 11b in the DataScale field. The value is determined by the maximum number of data payload credits that will be outstanding of the indicated credit type as defined in § Table 3-4.

Table 3-4 Scaled Flow Control Scaling Factors §

Scale Factor	Scaled Flow Control Supported and Activated	Credit Type	Min Credits	Max Credits	Field Width	FC DLLP field	
						Transmitted	Received
00b	No	Hdr	1	127	8 bits	HdrFC	HdrFC
		Data	1	2,047	12 bits	DataFC	DataFC
01b	Yes	Hdr	1	127	8 bits	HdrFC	HdrFC
		Data	1	2,047	12 bits	DataFC	DataFC
10b	Yes	Hdr	4	508	10 bits	HdrFC >> 2	HdrFC << 2
		Data	4	8,188	14 bits	DataFC >> 2	DataFC << 2
11b	Yes	Hdr	16	2,032	12 bits	HdrFC >> 4	HdrFC << 4
		Data	16	32,752	16 bits	DataFC >> 4	DataFC << 4

3.5 Data Link Layer Packets (DLLPs) §

The following DLLPs are used to support Link operations:

- Data Link Feature DLLP: For negotiation of supported features

- Ack DLLP: TLP Sequence Number acknowledgement; used to indicate successful receipt of some number of TLPs (NFM only)
- Nak DLLP: TLP Sequence Number negative acknowledgement; used to initiate a Data Link Layer Retry (NFM only)
- InitFC1, InitFC2, and UpdateFC DLLPs; used for Flow Control
- DLLPs used for Power Management
- DLLPs used for Link Management (L0p)

3.5.1 Data Link Layer Packet Rules §

All DLLP fields marked Reserved (sometimes abbreviated as R) must be filled with all 0's when a DLLP is formed. Values in such fields must be ignored by Receivers. The handling of Reserved values in encoded fields is specified for each case.

In Non-Flit Mode, all DLLPs include the following fields:

- DLLP Type - Specifies the type of DLLP. The defined encodings are shown in § Table 3-5.
- 24 bits of DLLP Type specific information
- 16-bit CRC

In Flit Mode, DLLPs are transmitted in the DLP bytes of a Flit. They consist of:

- DLLP Type - Specifies the type of DLLP. The defined encodings are shown in § Table 3-5.
- 24 bits of DLLP Type specific information

See § Figure 3-4 and § Figure 3-5 below.

Figure 3-4 DLLP Type and CRC Fields (Non-Flit Mode) §

	Reserved (Flit Mode)		
All other encodings	Reserved		

1. The deprecated MR-IOV protocol uses this encoding for the MRInit negotiation. The MR-IOV protocol assumes that non-MR-IOV components will silently ignore these DLLPs.
2. The deprecated MR-IOV protocol uses these encodings only after the successful completion of MRInit negotiation.
3. Received DLLPs not supported by the receiver are silently ignored. See § Section 3.6.2.2 and § Section 3.6.2.3.

In § Figure 3-6 through § Figure 3-15 the 16-bit CRC is not shown. In Non-Flit Mode, the CRC is present as shown in § Figure 3-4.

- For Ack and Nak DLLPs (see § Figure 3-6):
 - The AckNak_Seq_Num field is used to indicate what TLPs are affected
 - Transmission and reception is handled by the Data Link Layer according to the rules provided in § Section 3.6.
 - These DLLPs are not used in Flit Mode. In Flit Mode, the Ack encoding is used for the NOP2.
- For InitFC1, InitFC2, and UpdateFC DLLPs:
 - The HdrFC field contains the credit value for headers of the indicated type (P, NP, or Cpl).
 - The DataFC field contains the credit value for data payload of the indicated type (P, NP, or Cpl).
 - When Scaled Flow Control is supported, the HdrScale field contains the scaling factor for headers of the indicated type. Encodings are defined in § Table 3-6.
 - When Scaled Flow Control is supported, the DataScale field contains the scaling factor for data payload of the indicated type. Encodings are defined in § Table 3-6.
 - When Scaled Flow Control is not supported, the HdrScale and Data Scale fields are Reserved.

- If Scaled Flow Control is activated, the HdrScale and DataScale fields must be set to 01b, 10b, or 11b in all InitFC1, InitFC2, and UpdateFC DLLPs transmitted.
- In UpdateFCs, a Transmitter is only permitted to send non-zero values in the HdrScale and DataScale fields if it supports Scaled Flow Control, Scaled Flow control is activated, and it received non-zero values for HdrScale and DataScale in the InitFC1s and InitFC2s it received for this VC. In Flit Mode, the Optimized_Update_FC mechanism is supported in addition to the UpdateFC DLLP. Optimized_Update_FCs do not contain HdrScale and DataScale fields, so the Transmitter and Receiver must treat the HdrFC and DataFC fields using corresponding HdrScale and DataScale fields advertised during initialization. For debug as well as ease of use by debug tools such as Logic Analyzers, devices must send at least one DLLP every 10 μ s with an Update_FC DLLP per VC with the scaled credit information. It is strongly recommended that a Transmitter cycles through the VCs with finite non-0 credits in the Optimized_Update_FC as long as there is a credit to be released in the corresponding VC.
- The packet formats are shown in § Figure 3-9, § Figure 3-10, and § Figure 3-11.
- Transmission is triggered by the Data Link Layer when initializing Flow Control for a Virtual Channel (see § Section 3.4), and following Flow Control initialization by the Transaction Layer according to the rules in § Section 2.6.
- Checked for integrity on reception by the Data Link Layer and if correct, the information content of the DLLP is passed to the Transaction Layer. If the check fails, the information must be discarded. Note: InitFC1 and InitFC2 DLLPs are used only for VC initialization

Table 3-6 HdrScale and DataScale Encodings §

HdrScale or DataScale Value	Scaled Flow Control Supported	Scaling Factor	HdrFC Field	DataFC Field
00b	No	1	HdrFC[7:0]	DataFC[11:0]
01b	Yes	1	HdrFC[7:0]	DataFC[11:0]
10b	Yes	4	HdrFC[9:2]	DataFC[13:2]
11b	Yes	16	HdrFC[11:4]	DataFC[15:4]

- For Power Management (PM) DLLPs (see § Figure 3-12):
 - Transmission is triggered by the component's power management logic according to the rules in § Chapter 5.
 - Checked for integrity on reception by the Data Link Layer, then passed to the component's power management logic
- For Vendor-Specific DLLPs (see § Figure 3-13)
 - It is recommended that receivers silently ignore Vendor-Specific DLLPs unless enabled by implementation specific mechanisms.
 - It is recommended that transmitters not send Vendor-Specific DLLPs unless enabled by implementation specific mechanisms.
- For NOP DLLPs (see § Figure 3-7) and NOP2 DLLPs (see § Figure 3-8).
 - Receivers shall discard this DLLP without action, unless otherwise specified, after checking it for data integrity.⁵⁶

56. This is a special case of the more general rule for unsupported DLLP Type encodings (see § Section 3.6.2.2 and § Section 3.6.2.3).

- For Data Link Feature DLLPs (see § Figure 3-14)
 - The Feature Ack bit is Set to 1b to indicate that the transmitting Port has received a Data Link Feature DLLP.
 - The Feature Supported field indicates the Data Link Features supported and/or attribute values for the transmitting Port. The individual bits of this field are defined in § Table 3-1.
- For Link Management DLLPs (see § Figure 3-15)
 - In Non-Flit Mode, receivers shall discard this DLLP without action after checking it for data integrity.⁵⁷

Figure 3-13 Data Link Layer Packet Format for Vendor-Specific §

Figure 3-14 Data Link Layer Packet Format for **Data Link Feature DLLP** §

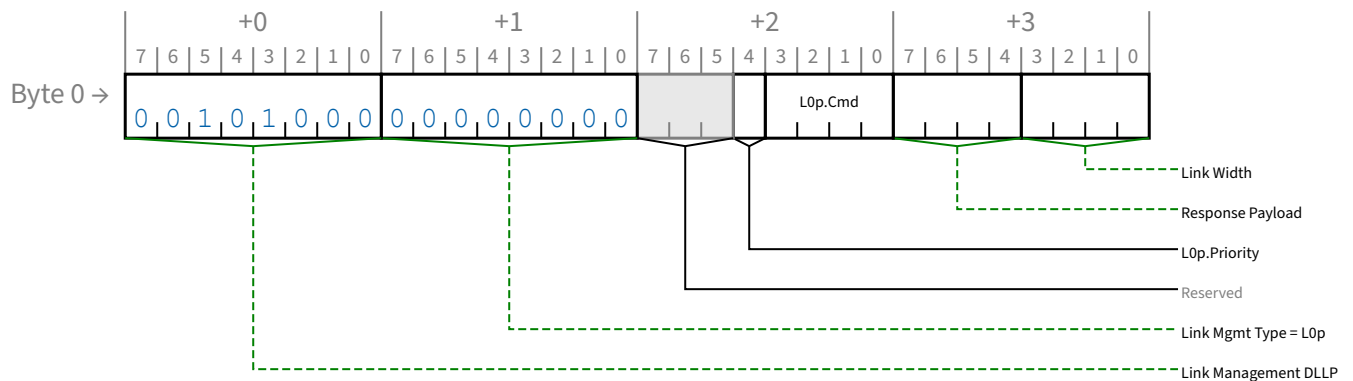

Figure 3-15 Data Link Packet Layer Format for **Link Management (Flit Mode)** §

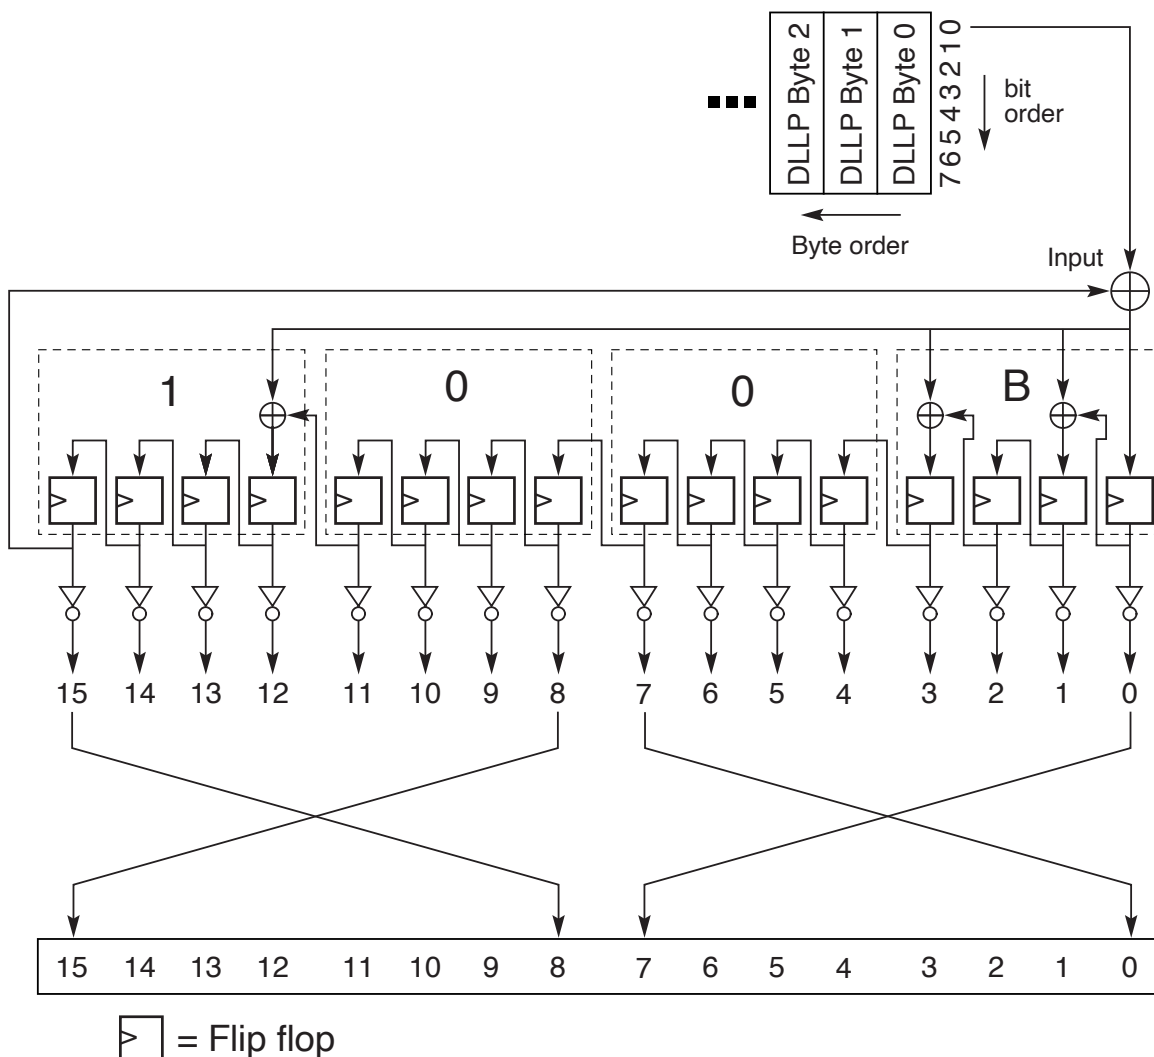

The following are the characteristics and rules associated with Data Link Layer Packets (DLLPs):

- DLLPs are differentiated from TLPs when they are presented to, or received from, the Physical Layer.
- DLLP data integrity is protected using a 16-bit CRC (NFM only)
- The CRC value is calculated using the following rules (see § Figure 3-16):
 - The polynomial used for CRC calculation has a coefficient expressed as 100Bh
 - The seed value (initial value for CRC storage registers) is FFFFh
 - CRC calculation starts with bit 0 of byte 0 and proceeds from bit 0 to bit 7 of each byte
 - Note that CRC calculation uses all bits of the DLLP, regardless of field type, including Reserved fields. The result of the calculation is complemented, then placed into the 16-bit CRC field of the DLLP as shown in § Table 3-7.

3.6 Data Integrity Mechanisms §

3.6.1 Introduction §

The Transaction Layer provides TLP boundary information to the Data Link Layer. This allows the Data Link Layer to apply a TLP Sequence Number and a Link CRC (LCRC) for error detection to the TLP. The Receive Data Link Layer validates received TLPs by checking the TLP Sequence Number, LCRC code and any error indications from the Receive Physical Layer. In case any of these errors are in a TLP, Data Link Layer Retry is used for recovery.

The format of a TLP with the TLP Sequence Number and LCRC code applied is shown in § Figure 3-17.

OM13786A

Figure 3-17 TLP with LCRC and TLP Sequence Number Applied - Non-Flit Mode §

On Ports that support Protocol Multiplexing, packets containing a non-zero value in Symbol +0, bits 7:4 are PMUX Packets. For TLPs, these bits must be 0000b. See § Appendix G. for details.

On Ports that do not support Protocol Multiplexing, Symbol +0, bits 7:4 are Reserved.

3.6.2 LCRC, Sequence Number, and Retry Management (TLP Transmitter) §

The TLP transmission path through the Data Link Layer (paths labeled 1 and 3 in § Figure 3-1) prepares each TLP for transmission by applying a sequence number, then calculating and appending a Link CRC (LCRC), which is used to ensure the integrity of TLPs during transmission across a Link from one component to another. TLPs are stored in a retry buffer, and are re-sent unless a positive acknowledgement of receipt is received from the other component. If repeated attempts to transmit a TLP are unsuccessful, the Transmitter will determine that the Link is not operating correctly, and will instruct the Physical Layer to retrain the Link (via the LTSSM Recovery state, § Section 4.2.7). If Link retraining fails, the Physical Layer will indicate that the Link is no longer up, causing the DLCMSM to move to the DL_Inactive state.

The mechanisms used to determine the TLP LCRC and the Sequence Number and to support Data Link Layer Retry are described in terms of conceptual counters and flags. This description does not imply nor require a particular implementation and is used only to clarify the requirements.

3.6.2.1 LCRC and Sequence Number Rules (TLP Transmitter) §

The following counters and timer are used to explain the remaining rules in this section:

- The following 12-bit counters are used:
 - NEXT_TRANSMIT_SEQ - Stores the packet sequence number applied to TLPs
 - Set to 000h in DL_Inactive state
 - ACKD_SEQ - Stores the sequence number acknowledged in the most recently received Ack or Nak DLLP.
 - Set to FFFh in DL_Inactive state
- The following 3-bit counter is used:
 - **REPLAY_NUM** - Counts the number of times the Retry Buffer has been re-transmitted

- Set to 000b in DL_Inactive state
- The following timer is used:
 - **REPLAY_TIMER** - Counts time that determines when a replay is required, according to the following rules:
 - Started at the last Symbol of any TLP transmission or retransmission, if not already running
 - For each replay, reset and restart REPLAY_TIMER when sending the last Symbol of the first TLP to be retransmitted
 - Resets and restarts for each Ack DLLP received while there are more unacknowledged TLPs outstanding, if, and only if, the received Ack DLLP acknowledges some TLP in the retry buffer.
 - Note: This ensures that REPLAY_TIMER is reset only when forward progress is being made
 - Reset and hold until restart conditions are met for each Nak received (except during a replay) or when the REPLAY_TIMER expires
 - Not advanced during Link retraining (holds its value when the LTSSM is in the Recovery or Configuration state). Refer to § Section 4.2.6.3 and § Section 4.2.6.4 .
 - If Protocol Multiplexing is supported, optionally not advanced during the reception of PMUX Packets (see § Appendix G.).
 - Resets and holds when there are no outstanding unacknowledged TLPs

The following rules describe how a TLP is prepared for transmission before being passed to the Physical Layer:

- The Transaction Layer indicates the start and end of the TLP to the Data Link Layer while transferring the TLP
 - The Data Link Layer treats the TLP as a “black box” and does not process or modify the contents of the TLP
- Each TLP is assigned a 12-bit sequence number when it is accepted from the Transmit side of the Transaction Layer
 - Upon acceptance of the TLP from the Transaction Layer, the packet sequence number is applied to the TLP by:
 - prepending the 12-bit value in NEXT_TRANSMIT_SEQ to the TLP
 - prepending 4 bits to the TLP, preceding the sequence number (see § Figure 3-18)
 - If the equation:

$$(\text{NEXT_TRANSMIT_SEQ} - \text{ACKD_SEQ}) \bmod 4096 \geq 2048$$

Equation 3-1 Tx SEQ Stall §

is true, the Transmitter must cease accepting TLPs from the Transaction Layer until the equation is no longer true

- Following the application of NEXT_TRANSMIT_SEQ to a TLP accepted from the Transmit side of the Transaction Layer, NEXT_TRANSMIT_SEQ is incremented (except in the case where the TLP is nullified):

$$\text{NEXT_TRANSMIT_SEQ} = (\text{NEXT_TRANSMIT_SEQ} + 1) \bmod 4096$$

Equation 3-2 Tx SEQ Update §

OM13787A

Figure 3-18 TLP Following Application of TLP Sequence Number and 4 Bits §

- TLP data integrity is protected during transfer between Data Link Layers using a 32-bit LCRC
- The LCRC value is calculated using the following mechanism (see § Figure 3-19):
 - The polynomial used has coefficients expressed as 04C1 1DB7h
 - The seed value (initial value for LCRC storage registers) is FFFF FFFFh
 - The LCRC is calculated using the TLP following sequence number application (see § Figure 3-18)
 - LCRC calculation starts with bit 0 of byte 0 (bit 8 of the TLP sequence number) and proceeds from bit 0 to bit 7 of each successive byte.
 - Note that LCRC calculation uses all bits of the TLP, regardless of field type, including Reserved fields
 - The remainder of the LCRC calculation is complemented, and the complemented result bits are mapped into the 32-bit LCRC field as shown in § Table 3-8.

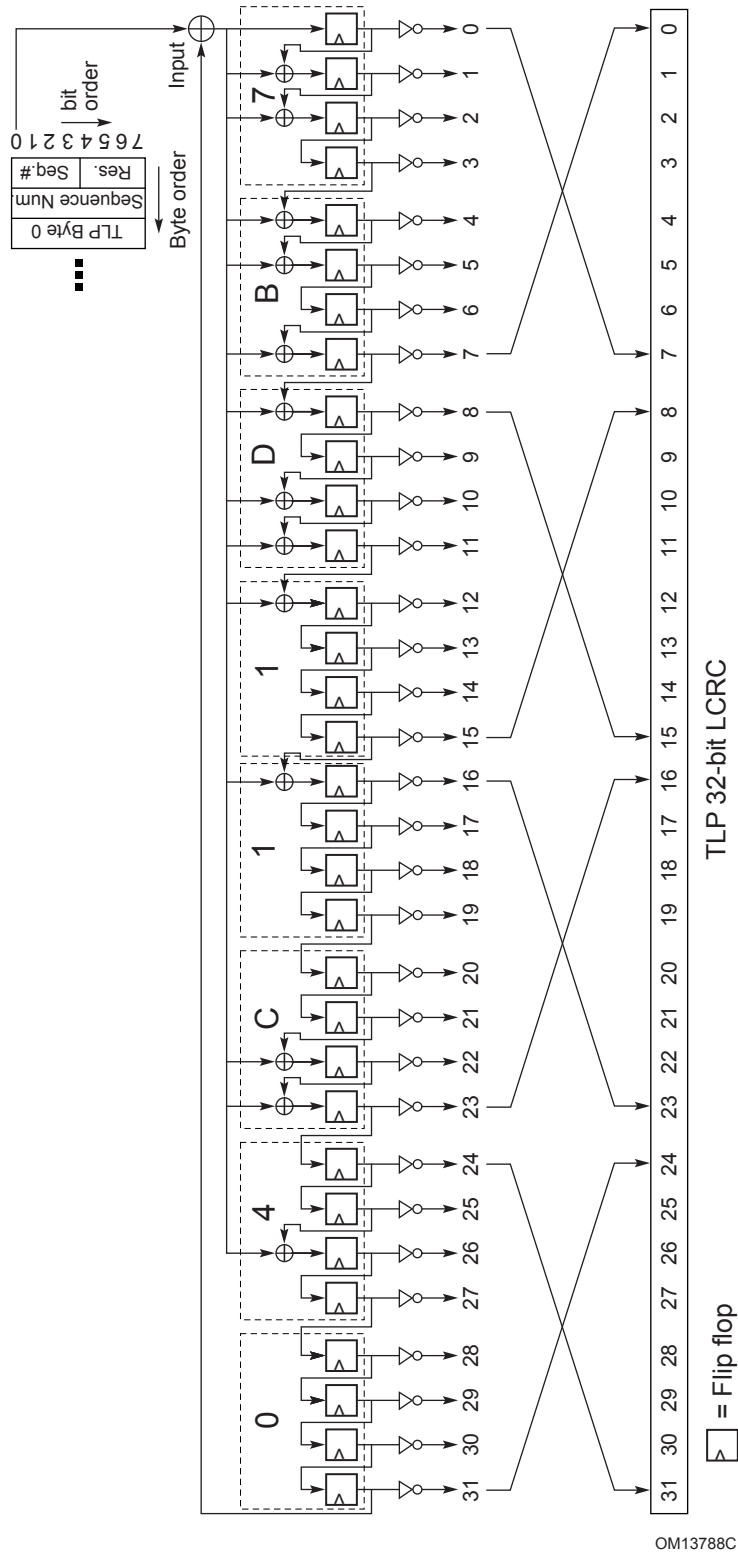

Figure 3-19 Calculation of LCRC §

The 32-bit LCRC field is appended to the TLP following the bytes received from the Transaction Layer (see § Figure 3-17).

To support cut-through routing of TLPs, a Transmitter is permitted to modify a transmitted TLP to indicate that the Receiver must ignore that TLP (“nullify” the TLP).

- A Transmitter is permitted to nullify a TLP being transmitted. To do this in a way that will robustly prevent misinterpretation or corruption, the Transmitter must do the following:
 - Transmit all DWs of the TLP when the Physical Layer is using 128b/130b encoding (see § Section 4.2.2.3.1)
 - Use the remainder of the calculated LCRC value without inversion (the logical inverse of the value normally used)
 - Indicate to the Transmit Physical Layer that the TLP is nullified
- When this is done, the Transmitter does not increment NEXT_TRANSMIT_SEQ

The following rules describe the operation of the Data Link Layer Retry Buffer, from which TLPs are re-transmitted when necessary:

- Copies of Transmitted TLPs must be stored in the Data Link Layer Retry Buffer, except for nullified TLPs.

When a replay is initiated, either due to reception of a Nak or due to REPLAY_TIMER expiration, the following rules describe the sequence of operations that must be followed:

- If all TLPs transmitted have been acknowledged (the Retry Buffer is empty), terminate replay, otherwise continue.

Note: In Flit Mode, Replay occurs at the Flit Level. See § Section 4.2.3.4.2.1.7 .
- Increment REPLAY_NUM by 2 when operating in Non-Flit Mode. If the Data Rate is 32.0 GT/s or lower, increment REPLAY_NUM by 2. When the replay is initiated by the reception of a Nak that acknowledged some TLPs in the retry buffer, REPLAY_NUM is reset. It is then permitted (but not required) to be incremented.
 - If REPLAY_NUM rolls over from 110b or 111b to either 000b or 001b, the Transmitter signals the Physical Layer to retrain the Link, and waits for the completion of retraining before proceeding with the replay. This is a reported error associated with the Port (see § Section 6.2).

Note that Data Link Layer state, including the contents of the Retry Buffer, are not reset by this action unless the Physical Layer reports Physical LinkUp = 0b (causing the Data Link Control and Management State Machine to transition to the DL_Inactive state).

 - If REPLAY_NUM does not roll over from 110b or 111b to either 000b or 001b, continue with the replay.
- Block acceptance of new TLPs from the Transmit Transaction Layer.
- Complete transmission of any TLP currently being transmitted.
- Retransmit unacknowledged TLPs, starting with the oldest unacknowledged TLP and continuing in original transmission order
 - Reset and restart REPLAY_TIMER when sending the last Symbol of the first TLP to be retransmitted
 - Once all unacknowledged TLPs have been re-transmitted, return to normal operation.
 - If any Ack or Nak DLLPs are received during a replay, the Transmitter is permitted to complete the replay without regard to the Ack or Nak DLLP(s), or to skip retransmission of any newly acknowledged TLPs.
 - Once the Transmitter has started to resend a TLP, it must complete transmission of that TLP in all cases.
 - Ack and Nak DLLPs received during a replay must be processed, and may be collapsed

- Example: If multiple Acks are received, only the one specifying the latest Sequence Number value must be considered - Acks specifying earlier Sequence Number values are effectively “collapsed” into this one
- Example: During a replay, Nak is received, followed by an Ack specifying a later Sequence Number - the Ack supersedes the Nak, and the Nak is ignored.
Note: Since all entries in the Retry Buffer have already been allocated space in the Receiver by the Transmitter's Flow Control gating logic, no further flow control synchronization is necessary.
- Re-enable acceptance of new TLPs from the Transmit Transaction Layer.

A replay can be initiated by the expiration of REPLAY_TIMER, or by the receipt of a Nak. The following rule covers the expiration of REPLAY_TIMER:

- If the Transmit Retry Buffer contains TLPs for which no Ack or Nak DLLP has been received, and (as indicated by REPLAY_TIMER) no Ack or Nak DLLP has been received for a period exceeding the applicable REPLAY_TIMER Limit, the Transmitter initiates a replay.
 - Simplified REPLAY_TIMER Limits are:
 - A value from 24,000 to 31,000 (inclusive) Symbol Times (-0%/+0%) when the Extended Synch bit is Clear.
 - A value from 80,000 to 100,000 (inclusive) Symbol Times (-0%/+0%) when the Extended Synch bit is Set.
 - If the Extended Synch bit changes state while unacknowledged TLPs are outstanding, implementations are permitted to adjust their REPLAY_TIMER Limit when the Extended Synch bit changes state or the next time the REPLAY_TIMER is reset.
 - Implementations that support 16.0 GT/s or higher data rates must use the Simplified REPLAY_TIMER Limits for operation at all data rates when operating in Non-Flit Mode.
 - Implementations that only support data rates less than 16.0 GT/s are strongly recommended to use the Simplified REPLAY_TIMER Limits for operation at all data rates when operating in Non-Flit Mode, but they are permitted to use the REPLAY_TIMER Limits described in the [PCIe-3.1].
 - The Replay Timeout rules defined in Replay Schedule Rule 0 in § Section 4.2.3.4.2.1.6 must be used for operation at all data rates in Flit Mode.

This is a Replay Timer Timeout error and it is a reported error associated with the Port (see § Section 6.2).

IMPLEMENTATION NOTE: DETERMINING REPLAY_TIMER LIMIT VALUES §

Replays are initiated primarily with a Nak DLLP, and the REPLAY_TIMER serves as a secondary mechanism. Since it is a secondary mechanism, the REPLAY_TIMER Limit has a relatively small effect on the average time required to convey a TLP across a Link. The Simplified REPLAY_TIMER Limits have been defined so that no adjustments are required for ASPM L0s, Retimers, or other items as in previous revisions of this specification.

TLP Transmitters and compliance tests must base replay timing as measured at the Port of the TLP Transmitter. Timing starts with either the last Symbol of a transmitted TLP, or else the last Symbol of a received Ack DLLP, whichever determines the oldest unacknowledged TLP. Timing ends with the First Symbol of TLP retransmission.

When measuring replay timing to the point when TLP retransmission begins, compliance tests must allow for any other TLP or DLLP transmission already in progress in that direction (thus preventing the TLP retransmission).

IMPLEMENTATION NOTE: RECOMMENDED PRIORITY OF SCHEDULED TRANSMISSIONS §

When multiple DLLPs of the same type are scheduled for transmission but have not yet been transmitted, it is possible in many cases to “collapse” them into a single DLLP. For example, if a scheduled Ack DLLP transmission is stalled waiting for another transmission to complete, and during this time another Ack is scheduled for transmission, it is only necessary to transmit the second Ack, since the information it provides will supersede the information in the first Ack.

In addition to any TLP from the Transaction Layer (or the Retry Buffer, if a replay is in progress), multiple DLLPs of different types may be scheduled for transmission at the same time, and must be prioritized for transmission. The following list shows the preferred priority order for selecting information for transmission. Note that the priority of the NOP DLLP and the Vendor-Specific DLLP is not listed, as usage of these DLLPs is completely implementation specific, and there is no recommended priority. Note that this priority order is a guideline, and that in all cases a fairness mechanism is strongly recommended to ensure that no type of traffic is blocked for an extended or indefinite period of time by any other type of traffic. Note that the Ack Latency Limit value and REPLAY_TIMER Limit specify requirements measured at the Port of the component, and the internal arbitration policy of the component must ensure that these externally measured requirements are met.

In Flit Mode, DLP information is contained in every Flit and can contain either a DLLP, Optimized_Update_FC, or a Flit_Marker. Currently defined Flit_Markers are related to a specific TLP and have the highest priority. Future Flit_Markers may have lower priorities.

Recommended Priority	Non-Flit Mode	Flit Mode
1	Completion of any transmission (TLP or DLLP) currently in progress (highest priority).	<i>n/a: DLP information is independent of TLPs</i>
2	<i>n/a: Poison and Nullify use TLP Framing</i>	Poisoned TLP and Nullified TLP <u>Flit_Markers</u>
3	Nak DLLP Transmissions	<i>n/a: Ack and Nak use dedicated DLP Symbols, not DLLPs</i>
4	Ack DLLP transmissions scheduled for transmission as soon as possible due to: receipt of a duplicate TLP -OR- expiration of the Ack latency timer (see § Section 3.6.3.1).	
5	Flow Control required to satisfy § Section 2.6 : UpdateFC DLLPs	Flow Control required to satisfy § Section 2.6 : UpdateFC DLLPs and/or <u>Optimized_Update_FC</u>
6	Retry Buffer re-transmissions	<i>n/a: DLP information is independent of TLPs</i>
7	TLPs from the Transaction Layer	
8	Flow Control other than that required to satisfy § Section 2.6 : UpdateFC DLLPs	Flow Control other than that required to satisfy § Section 2.6 : <u>Optimized_Update_FC</u> and/or UpdateFC DLLPs
9	All other DLLP transmissions (lowest priority)	

3.6.2.2 Handling of Received DLLPs (Non-Flit Mode) §

Since Ack/Nak and Flow Control DLLPs affect TLPs flowing in the opposite direction across the Link, the TLP transmission mechanisms in the Data Link Layer are also responsible for Ack/Nak and Flow Control DLLPs received from the other component on the Link. These DLLPs are processed according to the following rules (see § Figure 3-20):

- If the Physical Layer indicates a Receiver Error, discard any DLLP currently being received and free any storage allocated for the DLLP. Note that reporting such errors to software is done by the Physical Layer (and, therefore, are not reported by the Data Link Layer).
- For all received DLLPs, the CRC value is checked by:
 - Applying the same algorithm used for calculation of transmitted DLLPs to the received DLLP, not including the 16-bit CRC field of the received DLLP
 - Comparing the calculated result with the value in the CRC field of the received DLLP
 - If not equal, the DLLP is corrupt
 - A corrupt received DLLP is discarded. This is a Bad DLLP error and is a reported error associated with the Port (see § Section 6.2).
- A received DLLP that is not corrupt, but that uses unsupported DLLP Type encodings is discarded without further action. This is not considered an error.
- Values in Reserved fields are ignored.
- Receivers must process all DLLPs received at the rate they are received

Figure 3-20 Received DLLP Error Check Flowchart §

- Received NOP DLLPs are discarded
 - Note: NOP2 DLLPs do not exist in Non-Flit Mode, as that encoding encoding is used for the Ack DLLP.
- Received FC DLLPs are passed to the Transaction Layer
- Received PM DLLPs are passed to the component's power management control logic
- For Ack and Nak DLLPs, the following steps are followed (see § Figure 3-21):
 - If the Sequence Number specified by the AckNak_Seq_Num does not correspond to an unacknowledged TLP, or to the value in ACKD_SEQ, the DLLP is discarded
 - This is a Data Link Protocol Error, which is a reported error associated with the Port (see § Section 6.2).

Note that it is not an error to receive an Ack DLLP when there are no outstanding unacknowledged TLPs, including the time between reset and the first TLP transmission, as long as the specified Sequence Number matches the value in ACKD_SEQ.

- If the AckNak_Seq_Num does not specify the Sequence Number of the most recently acknowledged TLP, then the DLLP acknowledges some TLPs in the retry buffer:
 - Purge from the retry buffer all TLPs from the oldest to the one corresponding to the AckNak_Seq_Num
 - Load ACKD_SEQ with the value in the AckNak_Seq_Num field
 - Reset REPLAY_NUM and REPLAY_TIMER
- If the DLLP is a Nak, initiate a replay (see above)

Note: Receipt of a Nak is not a reported error.

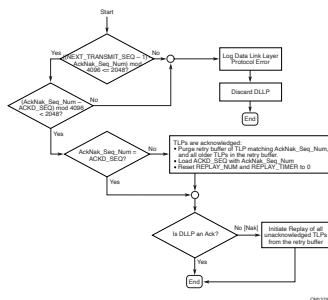

Figure 3-21 Ack/Nak DLLP Processing Flowchart §

The following rules describe the operation of the Data Link Layer Retry Buffer, from which TLPs are re-transmitted when necessary:

- Copies of Transmitted TLPs must be stored in the Data Link Layer Retry Buffer

3.6.2.3 Handling of Received DLLPs (Flit Mode) §

Since Flow Control DLLPs affect TLPs flowing in the opposite direction across the Link, the TLP transmission mechanisms in the Data Link Layer are also responsible for Flow Control DLLPs received from the other component on the Link. These DLLPs are processed according to the following rules:

- In Flit Mode, detection of corrupt DLLPs occurs at the Flit level and there is no corruption check for DLLPs in the Data Link Layer.
- In Flit Mode, replay occurs at the Flit level and the Ack and Nak DLLPs are not used.
- DLLPs and Optimized_Update_FCs are not stored in the Replay Buffer.
 - When a Flit is replayed, the DLP information is likely to be different from the original value.
 - Flit_Markers are associated with the TLP payload and are stored in the Replay Buffer.
- A received DLLP that uses unsupported DLLP Type encodings is discarded without further action. This is not considered an error.
- Non-zero values in Reserved fields are ignored.
- Receivers must process all DLLPs received at the rate they are received
- Received NOP DLLPs and NOP2 DLLPs are discarded
- Received FC DLLPs are passed to the Transaction Layer

- Received Optimized_Update_FCs are passed to the Transaction Layer
- Received PM DLLPs are passed to the component's power management control logic
- Received Link Management DLLPs are passed to the component's L0p control logic

3.6.3 LCRC and Sequence Number (TLP Receiver) (Non-Flit Mode) §

The TLP Receive path through the Data Link Layer (paths labeled 2 and 4 in § Figure 3-1) processes TLPs received by the Physical Layer by checking the LCRC and sequence number, passing the TLP to the Receive Transaction Layer if OK and requesting a replay if corrupted.

The mechanisms used to check the TLP LCRC and the Sequence Number and to support Data Link Layer Retry are described in terms of conceptual counters and flags. This description does not imply or require a particular implementation and is used only to clarify the requirements.

3.6.3.1 LCRC and Sequence Number Rules (TLP Receiver) §

The following counter, flag, and timer are used to explain the remaining rules in this section:

- The following 12-bit counter is used:
 - **NEXT_RCV_SEQ** - Stores the expected Sequence Number for the next TLP
 - Set to 000h in DL_Inactive state
- The following flag is used:
 - **NAK_SCHEDULED**
 - Cleared when in DL_Inactive state
- The following timer is used:
 - **AckNak_LATENCY_TIMER** - Counts time that determines when an Ack DLLP becomes scheduled for transmission, according to the following rules:
 - Set to 0 in DL_Inactive state
 - Restart from 0 each time an Ack or Nak DLLP is scheduled for transmission; Reset to 0 when all TLPs received have been acknowledged with an Ack DLLP
 - If there are initially no unacknowledged TLPs and a TLP is then received, the AckNak_LATENCY_TIMER starts counting only when the TLP has been forwarded to the Receive Transaction Layer

The following rules are applied in sequence to describe how received TLPs are processed, and what events trigger the transmission of Ack and Nak DLLPs (see § Figure 3-22):

- If the Physical Layer indicates a Receiver Error, discard any TLP currently being received and free any storage allocated for the TLP. Note that reporting such errors to software is done by the Physical Layer (and so are not reported by the Data Link Layer).
 - If a TLP was being received at the time the Receiver Error was indicated and the NAK_SCHEDULED flag is clear,
 - Schedule a Nak DLLP for transmission immediately
 - Set the NAK_SCHEDULED flag
- If the Physical Layer reports that the received TLP was nullified, and the LCRC is the logical NOT of the calculated value, discard the TLP and free any storage allocated for the TLP. This is not considered an error.

- If TLP was nullified but the LCRC does not match the logical NOT of the calculated value, the TLP is corrupt - discard the TLP and free any storage allocated for the TLP.
 - If the NAK_SCHEDULED flag is clear,
 - Schedule a Nak DLLP for transmission immediately
 - Set the NAK_SCHEDULED flag

This is a Bad TLP error and is a reported error associated with the Port (see § Section 6.2).

- The LCRC value is checked by:
 - Applying the same algorithm used for calculation (above) to the received TLP, not including the 32-bit LCRC field of the received TLP
 - Comparing the calculated result with the value in the LCRC field of the received TLP
 - if not equal, the TLP is corrupt - discard the TLP and free any storage allocated for the TLP
 - If the NAK_SCHEDULED flag is clear,
 - schedule a Nak DLLP for transmission immediately
 - set the NAK_SCHEDULED flag

This is a Bad TLP error and is a reported error associated with the Port (see § Section 6.2).

- If the TLP Sequence Number is not equal to the expected value, stored in NEXT_RCV_SEQ:
 - Discard the TLP and free any storage allocated for the TLP
 - If the TLP Sequence Number satisfies the following equation:
 $(\text{NEXT_RCV_SEQ} - \text{TLP Sequence Number}) \bmod 4096 \leq 2048$
 the TLP is a duplicate, and an Ack DLLP is scheduled for transmission (per transmission priority rules)
 - Otherwise, the TLP is out of sequence (indicating one or more lost TLPs):
 - if the NAK_SCHEDULED flag is clear,
 - schedule a Nak DLLP for transmission immediately
 - set the NAK_SCHEDULED flag
 - This is a Bad TLP error and is a reported error associated with the Port (see § Section 6.2).
 - if the NAK_SCHEDULED flag is Set, the Port is permitted to, but is not recommended to, report a Bad TLP error associated with the Port (see § Section 6.2) and this permission is shown in § Figure 3-20.
- If the TLP Sequence Number is equal to the expected value stored in NEXT_RCV_SEQ:
 - The four bits, TLP Sequence Number, and LCRC (see § Figure 3-17) are removed and the remainder of the TLP is forwarded to the Receive Transaction Layer
 - The Data Link Layer indicates the start and end of the TLP to the Transaction Layer while transferring the TLP
 - The Data Link Layer treats the TLP as a “black box” and does not process or modify the contents of the TLP
 - Note that the Receiver Flow Control mechanisms do not account for any received TLPs until the TLP(s) are forwarded to the Receive Transaction Layer
 - NEXT_RCV_SEQ is incremented
 - If Set, the NAK_SCHEDULED flag is cleared

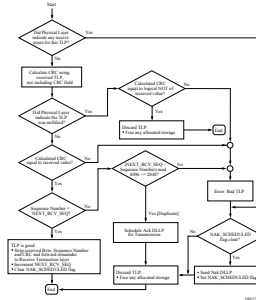

Figure 3-22 Receive Data Link Layer Handling of TLPs Flowchart §

- A TLP Receiver must schedule an Ack DLLP such that it will be transmitted no later than when all of the following conditions are true:
 - The Data Link Control and Management State Machine is in the DL_Active state
 - TLPs have been forwarded to the Receive Transaction Layer, but not yet acknowledged by sending an Ack DLLP
 - The AckNak_LATENCY_TIMER reaches or exceeds the value specified in § Table 3-10 for 2.5 GT/s operation, § Table 3-11 for 5.0 GT/s operation, § Table 3-12 for 8.0 GT/s and higher operation
 - The Link used for Ack DLLP transmission is already in L0 or has transitioned to L0
 - Note: if not already in L0, the Link must transition to L0 in order to transmit the Ack DLLP
 - Another TLP or DLLP is not currently being transmitted on the Link used for Ack DLLP transmission
 - The NAK_SCHEDULED flag is clear
 - Note: The AckNak_LATENCY_TIMER must be restarted from 0 each time an Ack or Nak DLLP is scheduled for transmission
- Data Link Layer Ack DLLPs may be scheduled for transmission more frequently than required
- Data Link Layer Ack and Nak DLLPs specify the value (NEXT_RCV_SEQ - 1) in the AckNak_Seq_Num field

§ Table 3-10, § Table 3-11, and § Table 3-12 define the threshold values for the AckNak_LATENCY_TIMER, which for any specific case is called the Ack Latency Limit.

TLP Receivers and compliance tests must base Ack Latency timing as measured at the Port of the TLP Receiver, starting with the time the last Symbol of a TLP is received to the first Symbol of the Ack DLLP being transmitted.

When measuring until the Ack DLLP is transmitted, compliance tests must allow for any TLP or other DLLP transmission already in progress in that direction (thus preventing the Ack DLLP transmission). If L0s is enabled, compliance tests must allow for the L0s exit latency of the Link in the direction that the Ack DLLP is being transmitted. If the Extended Synch bit is Set, compliance tests must also allow for its effect on L0s exit latency.

TLP Receivers are not required to adjust their Ack DLLP scheduling based upon L0s exit latency or the value of the Extended Synch bit.

For a Multi-Function Device where different Functions have different Rx_MPS_Limit values, it is strongly recommended that the smallest Rx_MPS_Limit value across all Functions be used.

*Table 3-10 Maximum Ack Latency Limits for 2.5 GT/s
(Symbol Times) (-0%/+0%) §*

IMPLEMENTATION NOTE: RETRY BUFFER SIZING §

The Retry Buffer should be large enough to ensure that under normal operating conditions, transmission is never throttled because the retry buffer is full. In determining the optimal buffer size, one must consider the Ack Latency value, Ack delay caused by the Receiver already transmitting another TLP or DLLP, the delays caused by the physical Link interconnect, and the time required to process the received Ack DLLP.

Given two components A and B, the L0s exit latency required by A's Receiver should be accounted for when sizing A's transmit retry buffer, as is demonstrated in the following example:

- A exits L0s on its Transmit path to B and starts transmitting a long burst of write Requests to B
- B initiates L0s exit on its Transmit path to A, but the L0s exit time required by A's Receiver is large
- Meanwhile, B is unable to send Ack DLLPs to A, and A stalls due to lack of Retry Buffer space
- The Transmit path from B to A returns to L0, B transmits an Ack DLLP to A, and the stall is resolved

This stall can be avoided by matching the size of a component's Transmitter Retry Buffer to the L0s exit latency required by the component's Receiver, or, conversely, by matching the Receiver L0s exit latency to the desired size of the Retry Buffer.

Ack Latency Limit values were chosen to allow implementations to achieve good performance without requiring an uneconomically large retry buffer. To enable consistent performance across a general purpose interconnect with differing implementations and applications, it is necessary to set the same requirements for all components without regard to the application space of any specific component. If a component does not require the full transmission bandwidth of the Link, it may reduce the size of its retry buffer below the minimum size required to maintain available retry buffer space with the Ack Latency Limit values specified.

Note that the Ack Latency Limit values specified ensure that the range of permitted outstanding TLP Sequence Numbers will never be the limiting factor causing transmission stalls.

Retimers add latency (see § Section 4.3.8) and operating in SRIS can add latency. Implementations are strongly encouraged to consider these effects when determining the optimal buffer size.

4. Physical Layer Logical Block §

4.1 Introduction §

The Physical Layer isolates the Transaction and Data Link Layers from the signaling technology used for Link data interchange. The Physical Layer is divided into the logical and electrical sub-blocks (see § Figure 4-1).

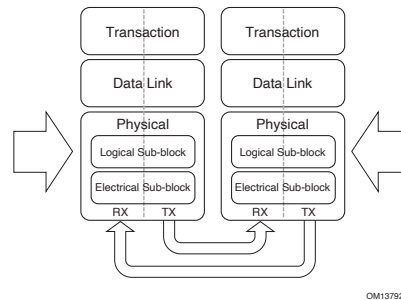

Figure 4-1 Layering Diagram Highlighting Physical Layer §

§ Chapter 4. describes the logical sub-block and § Chapter 8. describes the electrical sub-block.⁵⁸

4.2 Logical Sub-block §

The logical sub-block has two main sections: a Transmit section that prepares outgoing information passed from the Data Link Layer for transmission by the electrical sub-block, and a Receiver section that identifies and prepares received information before passing it to the Data Link Layer.

The logical sub-block and electrical sub-block coordinate the state of each Transceiver through a status and control register interface or functional equivalent. The logical sub-block directs control and management functions of the Physical Layer.

PCI Express uses three types of encoding (8b/10b, 128b/130b, and 1b/1b) and two Data Stream modes (Flit Mode and Non-Flit Mode). A Data Stream in the Non-Flit Mode is defined as a contiguous collection of TLPs, DLLPs, and Logical Idle/IDL Token, starting at the end of an Ordered Set and ending with another Ordered Set or a Link Electrical Idle. A Data Stream in Flit Mode is defined as a set of Flits (see § Section 4.2.3), starting at the end of the first SKP Ordered Set after an SDS Ordered Set, and ending with the last Flit prior to an Ordered Set other than SKP Ordered Set that causes the Link to exit out of L0 state or if the Link enters Electrical Idle. The encoding is determined by the Data Rate of the Link. The Data Stream mode is determined during initial Link training. If not disabled (see Flit Mode Disable) and if both the Ports (and all Pseudo-Ports, if any) support it, (see Flit Mode Supported), Flit Mode is chosen. Otherwise, Non-Flit Mode is chosen. See § Table 4-1 for valid encoding and symbol placement mode combinations.

58. Prior to [PCIe-4.0] § Chapter 4. described both logical and electrical sub-blocks. With [PCIe-4.0], the electrical section was moved to a new § Chapter 8. and a new Retimer section was added.

Table 4-1 Valid Encoding and Data Stream Mode Combinations §

Current Data Rate	Flit Mode Negotiated during Configuration when LinkUp=0b	Encoding	Data Stream
2.5 GT/s, 5.0 GT/s	No	8b/10b	Non-Flit Mode
2.5 GT/s, 5.0 GT/s	Yes	8b/10b	Flit Mode
8.0 GT/s, 16.0 GT/s, 32.0 GT/s	No	128b/130b	Non-Flit Mode
8.0 GT/s, 16.0 GT/s, 32.0 GT/s	Yes	128b/130b	Flit Mode
64.0 GT/s	Yes (mandatory)	1b/1b	Flit Mode

The Ordered Set encoding follows the 8b/10b, 128b/130b, and 1b/1b encoding as defined in § Table 4-2.

Table 4-2 Valid Encoding for Ordered Sets §

Current Data Rate	Flit Mode Negotiated during Configuration when LinkUp=0b	Encoding	Comments
2.5 GT/s, 5.0 GT/s	Yes / No	8b/10b	Same Ordered Sets are used in Flit Mode as well as Non-Flit Mode.
8.0 GT/s	No	128b/130b	Only Standard SKP Ordered Set sent when SKP OS needs to be sent. Rest of the Ordered Sets are identical for Non-Flit Mode and Flit Mode in 8.0 GT/s.
16.0 GT/s, 32.0 GT/s	No	128b/130b	Alternates between Standard SKP OS and Control SKP OS, when SKP OS needs to be sent. Rest of the Ordered Sets are identical for Non-Flit Mode and Flit Mode in the corresponding Data Rate.
8.0 GT/s, 16.0 GT/s, 32.0 GT/s	Yes	128b/130b	Alternates between Standard SKP OS and Control SKP OS, when SKP OS needs to be sent. Rest of the Ordered Sets are identical for Non-Flit Mode and Flit Mode in the corresponding Data Rate.
64.0 GT/s	Yes (mandatory)	1b/1b	All Ordered Sets follow 1b/1b encoding at 64.0 GT/s with PAM4 signaling. Only Control SKP OS sent when SKP OS needs to be sent.

IMPLEMENTATION NOTE:

FLIT MODE IDENTIFICATION THROUGHOUT THE DOCUMENT §

Support for Flit Mode behavior is referenced five times in the specification through the use of the following fields/variables:

Flit Mode Supported bit

Bit 0 of the Data Rate Identifier Symbol of 8b/10b and 128b/130b encoded TS1s and TS2s. This bit is Set when the Flit Mode Supported bit in the PCI Express Capabilities Register is Set and the Flit Mode Disable bit in the Link Control Register is Clear. See § Table 4-25, § Table 4-26, and § Table 4-27.

Flit_Mode_Enabled

Variable that indicates whether or not Flit Mode has been successfully negotiated. See § Section 4.2.7.1.1 and § Section 4.2.7.3.2 .

Flit Mode Supported

Field in the PCI Express Capabilities Register. Flit Mode is supported when this bit is Set. See § Section 7.5.3.2 .

Flit Mode Disable

Field in the Link Control Register. This bit used to disable Flit Mode. This bit is most useful in Downstream Ports but is also defined for Upstream Ports (useful for crosslinks or by device firmware). See § Section 7.5.3.7 . Setting this bit may be useful to workaround faulty hardware.

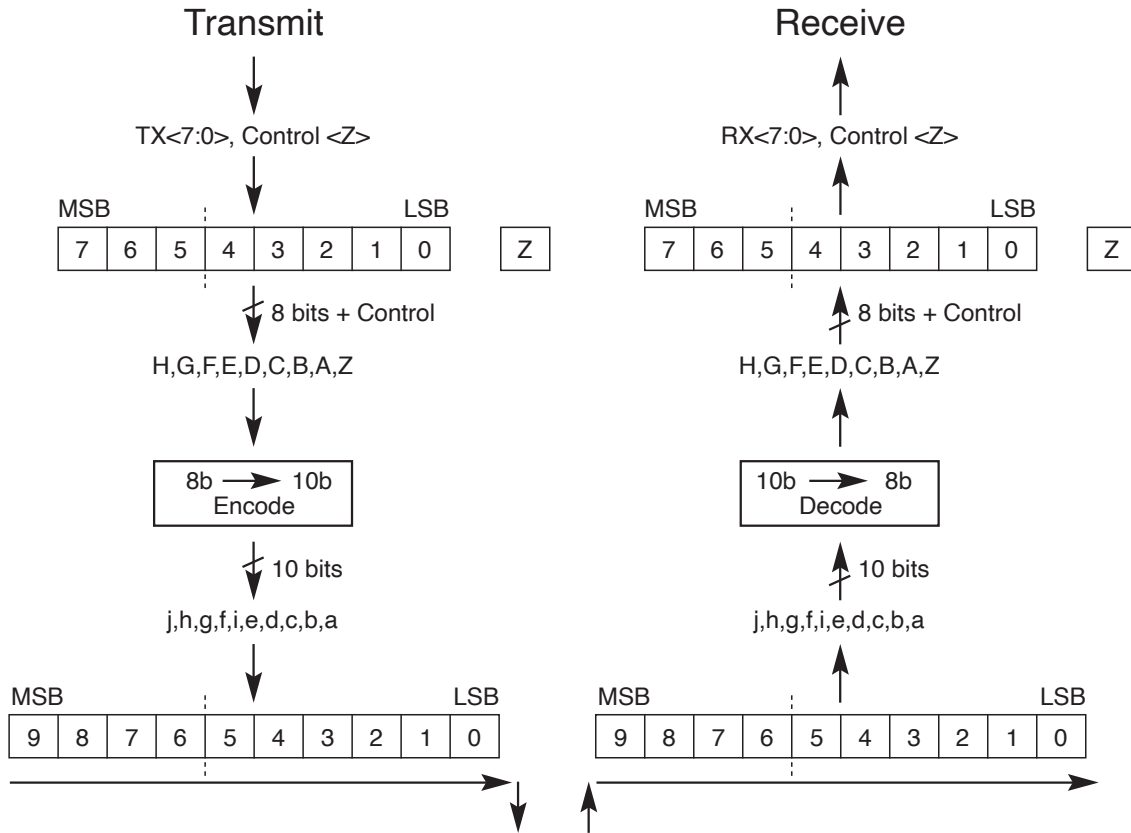

Flit Mode Status

Field in the Link Status 2 Register. Indicates that that the Link is or will be operating in Flit Mode. Should match the Flit_Mode_Enabled variable. See § Section 7.5.3.20 .

4.2.1 8b/10b Encoding for 2.5 GT/s and 5.0 GT/s Data Rates §

4.2.1.1 Symbol Encoding §

At 2.5 and 5.0 GT/s, PCI Express uses an 8b/10b transmission code. The definition of this transmission code is identical to that specified in ANSI X3.230-1994, clause 11 (and also IEEE 802.3z, 36.2.4). Using this scheme, 8-bit data characters are treated as 3 bits and 5 bits mapped onto a 4-bit code group and a 6-bit code group, respectively. The control bit in conjunction with the data character is used to identify when to encode one of the 12 Special Symbols included in the 8b/10b transmission code. These code groups are concatenated to form a 10-bit Symbol. As shown in § Figure 4-2, ABCDE maps to abcdei and FGH maps to fghj.

OM13793

Figure 4-2 Character to Symbol Mapping §

4.2.1.1.1 Serialization and De-serialization of Data §

The bits of a Symbol are placed on a Lane starting with bit “a” and ending with bit “j”. Examples are shown in § Figure 4-3 and § Figure 4-4.

OM13808

Figure 4-3 Bit Transmission Order on Physical Lanes - x1 Example §

OM13809

Figure 4-4 Bit Transmission Order on Physical Lanes - x4 Example §

4.2.1.1.2 Special Symbols for Framing and Link Management (K Codes) §

The 8b/10b encoding scheme provides Special Symbols that are distinct from the Data Symbols used to represent Characters. These Special Symbols are used for various Link Management mechanisms described later in this chapter. Special Symbols are also used to frame DLLPs and TLPs⁵⁹ in Non-Flit Mode, using distinct Special Symbols to allow these two types of Packets to be quickly and easily distinguished. When Flit Mode is enabled, each Symbol (Byte) of the Data Stream is still encoded with 8b/10b encoding without the Framing described. The Flit Mode operation is described in § Section 4.2.3.1. Even when Flit Mode is enabled, the Ordered Sets follow the description provided in § Section 4.2.1, when operating in 2.5 GT/s or 5.0 GT/s Data Rates.

§ Table 4-3 shows the Special Symbols used for PCI Express and provides a brief description for each. These Symbols will be discussed in greater detail in following sections. Each of these Special Symbols, as well as the data Symbols, must be interpreted by looking at the 10-bit Symbol in its entirety.

Table 4-3 Special Symbols in 8b/10b Encoding §

Encoding	Symbol	Name	Description
K28.5	COM	Comma	Used for Lane and Link initialization and management

59. In § Chapter 4, PMUX packets follow the TLP framing rules for Non-Flit Mode. PMUX is not supported in Flit Mode.

Encoding	Symbol	Name	Description
			Used identically in Flit Mode and Non-Flit Mode
K27.7	STP	Start TLP	Marks the start of a Transaction Layer Packet in Non-Flit Mode. Reserved in Flit Mode.
K28.2	SDP	Start DLLP	Marks the start of a Data Link Layer Packet in Non-Flit Mode. Reserved in Flit Mode.
K29.7	END	End	Marks the end of a Transaction Layer Packet or a Data Link Layer Packet in Non-Flit Mode. Reserved in Flit Mode.
K30.7	EDB	End Bad	Marks the end of a nullified TLP in Non-Flit Mode. Reserved in Flit Mode.
K23.7	PAD	Pad	Used in Framing in Non-Flit Mode only. It is also used in Link Width and Lane ordering negotiations in both Non-Flit Mode and Flit Mode.
K28.0	SKP	Skip	Used for compensating for different bit rates for two communicating Ports. Used identically in Flit Mode and Non-Flit Mode.
K28.1	<u>FTS</u>	<u>Fast Training Sequence</u>	Used within an Ordered Set to exit from <u>L0s</u> to <u>L0</u> in Non-Flit Mode. No usage for this Encoding is defined in Flit Mode.
K28.3	IDL	Idle	Used in the <u>Electrical Idle Ordered Set (EIOS)</u> Used identically in Flit Mode and Non-Flit Mode.
K28.4			Reserved
K28.6			Reserved
K28.7	EIE	Electrical Idle Exit	Reserved in 2.5 GT/s Used in the <u>Electrical Idle Exit Ordered Set (EIEOS)</u> and sent prior to sending <u>FTS</u> at data rates other than 2.5 GT/s

4.2.1.1.3 8b/10b Decode Rules §

The Symbol tables for the valid 8b/10b codes are given in Appendix B. These tables have one column for the positive disparity and one column for the negative disparity.

A Transmitter is permitted to pick any disparity, unless otherwise required, when first transmitting differential data after being in an Electrical Idle state. The Transmitter must then follow proper 8b/10b encoding rules until the next Electrical Idle state is entered.

The initial disparity for a Receiver that detects an exit from Electrical Idle is set to the disparity of the first Symbol used to obtain Symbol lock. Disparity may also be re-initialized if Symbol lock is lost and regained during the transmission of differential information due to an implementation specific number of errors. All following received Symbols after the initial disparity is set must be found in the proper column corresponding to the current running disparity.

If a received Symbol is found in the column corresponding to the incorrect running disparity or if the Symbol does not correspond to either column, the Physical Layer must notify the Data Link Layer that the received Symbol is invalid. This is a Receiver Error, and is a reported error associated with the Port (see § Section 6.2) in Non-Flit Mode. In Flit Mode, the Symbol in error is passed to the FEC logic to correct; the Receiver is permitted to send any 8-bit value to the FEC logic if an 8b/10b error or k-char is detected inside the Flit boundary.

4.2.1.2 Framing and Application of Symbols to Lanes §

There are two classes of framing and application of Symbols to Lanes. The first class consists of the Ordered Sets. The second class consists of TLPs and DLLPs in the Data Stream. Ordered Sets are always transmitted serially on each Lane, such that a full Ordered Set appears simultaneously on all Lanes of a multi-Lane Link. The Non-Flit Mode of Data Stream is described below. The Flit Mode description for Data Stream is described in § Section 4.2.3.2 and § Section 4.2.3.3 . There are no defined framing-related errors while using 8b/10b encoding in Flit Mode.

4.2.1.2.1 Framing and Application of Symbols to Lanes for TLPs and DLLPs in Non-Flit Mode §

The Framing mechanism uses Special Symbol K28.2 “SDP” to start a DLLP and Special Symbol K27.7 “STP” to start a TLP. The Special Symbol K29.7 “END” is used to mark the end of either a TLP or a DLLP.

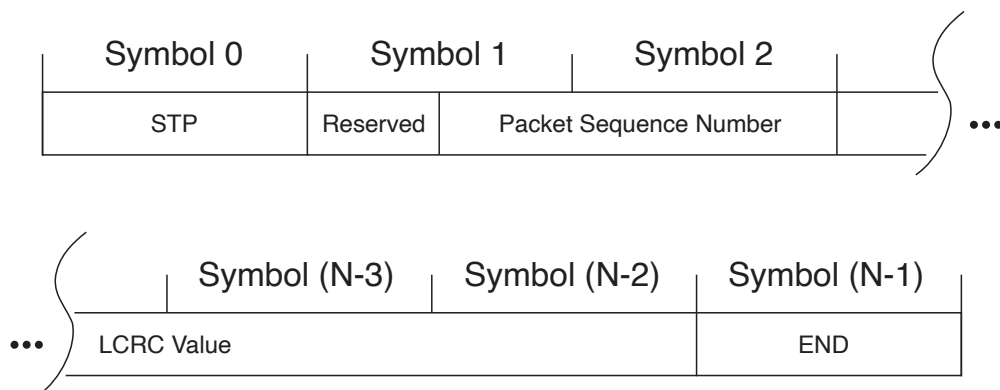

The conceptual stream of Symbols must be mapped from its internal representation, which is implementation dependent, onto the external Lanes. The Symbols are mapped onto the Lanes such that the first Symbol (representing Character 0) is placed onto Lane 0; the second is placed onto Lane 1; etc. The x1 Link represents a degenerate case and the mapping is trivial, with all Symbols placed onto the single Lane in order.

When no packet information or special Ordered Sets are being transmitted, the Transmitter is in the Logical Idle state. During this time idle data must be transmitted. The idle data must consist of the data byte 0 (00h), scrambled according to the rules of § Section 4.2.1.3 and 8b/10b encoded according to the rules of § Section 4.2.1.1 , in the same way that TLP and DLLP Data Symbols are scrambled and encoded. Likewise, when the Receiver is not receiving any packet information or special Ordered Sets, the Receiver is in Logical Idle and shall receive idle data as described above. During transmission of the idle data, the SKP Ordered Set must continue to be transmitted as specified in § Section 4.2.8 .

For the following rules, “placed” is defined to mean a requirement on the Transmitter to put the Symbol into the proper Lane of a Link.

- TLPs must be framed by placing an STP Symbol at the start of the TLP and an END Symbol or EDB Symbol at the end of the TLP (see § Figure 4-5).
- A properly formed TLP contains a minimum of 18 symbols between the STP and END or EDB Symbols. If a received sequence has less than 18 symbols between the STP and END or EDB symbols, the receiver is permitted to treat this as a Receiver Error.
 - If checked, this is a reported error associated with the Receiving Port (see § Section 6.2).
- DLLPs must be framed by placing an SDP Symbol at the start of the DLLP and an END Symbol at the end of the DLLP (see § Figure 4-6).

- Logical Idle is defined to be a period of one or more Symbol Times when no information: TLPs, DLLPs or any type of Special Symbol is being Transmitted/Received. Unlike Electrical Idle, during Logical Idle the Idle data Symbol (00h) is being transmitted and received.
 - When the Transmitter is in Logical Idle, the Idle data Symbol (00h) shall be transmitted on all Lanes. This is scrambled according to the rules in § Section 4.2.1.3 .
 - Receivers must ignore incoming Idle data Symbols, and must not have any dependency other than scramble sequencing on any specific data patterns.
- For Links wider than x1, the STP Symbol (representing the start of a TLP) must be placed in Lane 0 when starting Transmission of a TLP from a Logical Idle Link condition.
- For Links wider than x1, the SDP Symbol (representing the start of a DLLP) must be placed in Lane 0 when starting Transmission of a DLLP from a Logical Idle Link condition.
- The STP Symbol must not be placed on the Link more frequently than once per Symbol Time.
- The SDP Symbol must not be placed on the Link more frequently than once per Symbol Time.
- As long as the above rules are satisfied, TLP and DLLP Transmissions are permitted to follow each other successively.
- One STP Symbol and one SDP Symbol may be placed on the Link in the same Symbol Time.
 - Links wider than x4 can have STP and SDP Symbols placed in Lane $4*N$, where N is a positive integer. For example, for x8, STP and SDP Symbols can be placed in Lanes 0 and 4; and for x16, STP and SDP Symbols can be placed in Lanes 0, 4, 8, or 12.
- For xN Links where N is 8 or more, if an END or EDB Symbol is placed in a Lane K, where K does not equal N-1, and is not followed by an STP or SDP Symbol in Lane K+1 (i.e., there is no TLP or DLLP immediately following), then PAD Symbols must be placed in Lanes K+1 to Lane N-1.
 - For example, on a x8 Link, if END or EDB is placed in Lane 3, PAD must be placed in Lanes 4 to 7, when not followed by STP or SDP.
- The EDB Symbol is used to mark the end of a nullified TLP. Refer to § Section 3.6.2.1 for information on the usage of EDB.
- Receivers may optionally check for violations of the rules of this section. These checks are independently optional (see § Section 6.2.3.4). If checked, violations are Receiver Errors, and are reported errors associated with the Port (see § Section 6.2).

4.2.1.3 Data Scrambling §

In order to improve electrical characteristics of a Link, data is typically scrambled. This is applicable for both the Flit Mode as well as Non-Flit Mode at 2.5 GT/s and 5.0 GT/s Data Rates. This involves XORing the data stream with a pattern generated by a Linear Feedback Shift Register (LFSR). On the Transmit side, scrambling is applied to characters prior to the 8b/10b encoding. On the Receive side, de-scrambling is applied to characters after 8b/10b decoding.

On a multi-Lane Link, the scrambling function can be implemented with one or many LFSRs. When there is more than one Transmit LFSR per Link, these must operate in concert, maintaining the same simultaneous (Lane-to-Lane Output Skew) value in each LFSR. When there is more than one Receive LFSR per Link, these must operate in concert, maintaining the same simultaneous (Lane-to-Lane Skew) value in each LFSR. Regardless of how they are implemented, LFSRs must interact with data on a Lane-by-Lane basis as if there was a separate LFSR as described here for each Lane within that Link.

The LFSR is graphically represented in § Figure 4-10. Scrambling or unscrambling is performed by serially XORing the 8-bit (D0-D7) character with the 16-bit (D0-D15) output of the LFSR. An output of the LFSR, D15, is XORed with D0 of the data to be processed. The LFSR and data register are then serially advanced and the output processing is repeated for D1 through D7. The LFSR is advanced after the data is XORed. The LFSR implements the polynomial:

$$G(X)=X^{16}+X^5+X^4+X^3+1$$

The mechanism(s) and/or interface(s) utilized by the Data Link Layer to notify the Physical Layer to disable scrambling is implementation specific and beyond the scope of this specification.

The data scrambling rules are the following:

- The COM Symbol initializes the LFSR.
- The LFSR value is advanced eight serial shifts for each Symbol except the SKP.
- All data Symbols (D codes) except those within Ordered Sets (e.g., TS1, TS2, EIEOS), the Compliance Pattern (see § Section 4.2.9), and the Modified Compliance Pattern (see § Section 4.2.10) are scrambled.
- All special Symbols (K codes) are not scrambled.
- The initialized value of an LFSR seed (D0-D15) is FFFFh. Immediately after a COM exits the Transmit LFSR, the LFSR on the Transmit side is initialized. Every time a COM enters the Receive LFSR on any Lane of that Link, the LFSR on the Receive side is initialized.
- Scrambling can only be disabled at the end of Configuration (see § Section 4.2.7.3.5).
- Scrambling does not apply to a Loopback Follower.
- Scrambling is always enabled in Detect by default.

IMPLEMENTATION NOTE: DISABLING SCRAMBLING §

Disabling scrambling is intended to help simplify test and debug equipment. Control of the exact data patterns is useful in a test and debug environment. Since scrambling is reset at the Physical Layer there is no reasonable way to reliably control the state of the data transitions through software. Thus, the Disable Scrambling bit in the TS1 and TS2 Ordered Sets is provided for these purposes.

The mechanism(s) and/or interface(s) utilized by the Data Link Layer to notify the Physical Layer to disable scrambling is implementation specific and beyond the scope of this specification.

For more information on scrambling, see § Appendix C. .

Figure 4-10 LFSR with 8b/10b Scrambling Polynomial §

4.2.2 128b/130b Encoding for 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s Data Rates §

When a PCI Express Link is operating at a data rate of 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s, it uses the 128b/130b encoding rules described in this section. For backwards compatibility, the Link initially trains to L0 at the 2.5 GT/s data rate using 8b/10b encoding as described in § Section 4.2.1, then when the data rate is changed to 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s, 128b/130b encoding is used. 128b/130b encoding uses a Link-wide packetization mechanism in Non-Flit Mode and a

per-Lane block code with scrambling in both Flit Mode and Non-Flit Modes. In the Flit Mode, the Data Stream follows the same mechanism described in § Section 4.2.3.1 , for the 128b payload inside the 128b/130b Data Block(s).

The basic entity of data transmission is an 8-bit data character, referred to as a Symbol, as shown in § Figure 4-11 and § Figure 4-12.

IMPLEMENTATION NOTE: SYMBOL IN 128B/130B ENCODING SCHEME §

In the 128b/130b encoding scheme, the Symbol is one byte long, similar to the 10-bit Symbol of 8b/10b encoding.

4.2.2.1 Lane Level Encoding §

The Physical Layer uses a per-Lane block code. Each Block consists of a 2-bit Sync Header and a payload. There are two valid Sync Header encodings: 10b and 01b. The Sync Header defines the type of payload that the Block contains.

A Sync Header of 10b indicates a Data Block. Each Data Block has a 128 bit payload, resulting in a Block size of 130 bits. The payload is a Data Stream described in § Section 4.2.2.3 .

A Sync Header of 01b indicates an Ordered Set Block. Each Ordered Set Block has a 128 bit payload, resulting in a Block size of 130 bits except for the SKP Ordered Set which can be of variable length.

All Lanes of a multi-Lane Link must transmit Blocks with the same Sync Header simultaneously, except when transmitting Jitter Measurement Pattern in Polling.Compliance.

The bit transmission order is as follows. A Sync Header represented as ‘H₀H₁’ is placed on a Lane starting with ‘H₀’ and ending with ‘H₁’. A Symbol, represented as ‘S₇S₆S₅S₄S₃S₂S₁S₀’, is placed on a Lane starting with ‘S₀’ and ending with ‘S₇’. In the diagrams that show a time scale, bits represent the transmission order. In layout diagrams, bits are arranged in little-endian format, consistent with packet layout diagrams in other chapters of this specification.

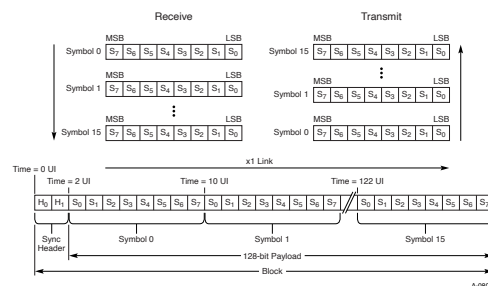

Figure 4-11 Example of Bit Transmission Order in a x1 Link Showing 130 Bits of a Block §

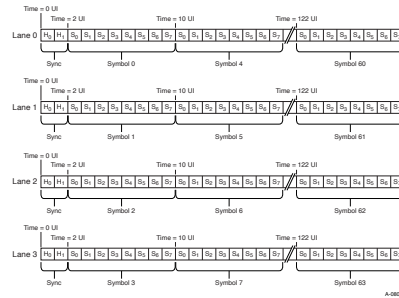

Figure 4-12 Example of Bit Placement in a x4 Link with One Block per Lane §

4.2.2.2 Ordered Set Blocks §

An Ordered Set Block contains a Sync Header followed by one Ordered Set. All Lanes of a multi-Lane Link must transmit the same Ordered Set type simultaneously. The first Symbol of the Ordered Set defines the type of Ordered Set. Subsequent symbols of the Ordered Set are defined by the Ordered Set type and need not be identical across lanes of a multi-Lane Link. The Ordered Sets are described in detail in § Section 4.2.5 and § Section 4.2.8. Ordered Set Blocks are the same for both Flit Mode and Non-Flit Mode except for the use and frequency of SKP Ordered Set. In Flit Mode at 8.0 GT/s, both Standard SKP Ordered Sets and Control SKP Ordered Sets are used.

4.2.2.2.1 Block Alignment §

During Link training, the 130 bits of the Electrical Idle Exit Ordered Set (EIEOS) are a unique bit pattern that Receivers use to determine the location of the Block Sync Headers in the received bit stream. Conceptually, Receivers can be in three different phases of Block alignment: Unaligned, Aligned, and Locked. These phases are defined to illustrate the required behavior, but are not meant to specify a required implementation.

Unaligned Phase

Receivers enter this phase after a period of Electrical Idle, such as when the data rate is changed to one that uses 128b/130b encoding or when they exit a low-power Link state, or if directed (by an implementation specific method). In this phase, Receivers monitor the received bit stream for the EIEOS bit pattern. When one is detected, they adjust their alignment to it and proceed to the Aligned phase.

Aligned Phase

Receivers monitor the received bit stream for the EIEOS bit pattern and the received Blocks for a Start of Data Stream (SDS) Ordered Set. If an EIEOS bit pattern is detected on an alignment that does not match the current alignment, Receivers must adjust their alignment to the newly received EIEOS bit pattern. If an SDS Ordered Set is received, Receivers proceed to the Locked phase. Receivers are permitted to return to the Unaligned phase if an undefined Sync Header (00b or 11b) is received.

Locked Phase

Receivers must not adjust their Block alignment while in this phase. The Data Stream starts after an SDS Ordered Set, and adjusting the Block alignment would interfere with the processing of these Blocks. Receivers must return to the Unaligned or Aligned phase if an undefined Sync Header is received.

IMPLEMENTATION NOTE:

DETECTION OF LOSS OF BLOCK ALIGNMENT §

The sequence of EIEOS and TS Ordered Sets transmitted during training sequences will cause misaligned Receivers to detect an undefined Sync Header.

Additional Requirements:

- While in the Aligned or Locked phase, Receivers must adjust their alignment as necessary when a SKP Ordered Set is received. See § Section 4.2.8 for more information on SKP Ordered Sets.
- After any LTSSM transition to Recovery, Receivers must ignore all received TS Ordered Sets until they receive an EIEOS. Conceptually, receiving an EIEOS validates the Receiver's alignment and allows TS Ordered Set processing to proceed. If a received EIEOS initiates an LTSSM transition from L0 to Recovery, Receivers are permitted to process any TS Ordered Sets that follow the EIEOS or ignore them until another EIEOS is received after entering Recovery.
- Receivers are permitted to transition from the Locked phase to the Unaligned or Aligned phase as long as Data Stream processing is stopped. See § Section 4.2.2.3 for more information on Data Stream requirements.
- Loopback Leads: While in Loopback.Entry, Leads must be capable of adjusting their Receiver's Block alignment to received EIEOS bit patterns. While in Loopback.Active, Leads are permitted to transmit an EIEOS and adjust their Receiver's Block alignment to the looped back bit stream.
- Loopback Followers: While in Loopback.Entry, Followers must be capable of adjusting their Receiver's Block alignment to received EIEOS bit patterns. While in Loopback.Active, Followers must not adjust their Receiver's Block alignment. Conceptually, the Receiver is directed to the Locked phase when the Follower starts to loop back the received bit stream.

4.2.2.3 Data Blocks §

The payload of Data Blocks is a stream of Symbols defined as a "Data Stream". In Non-Flit Mode, the Data Stream consists of Framing Tokens, TLPs, and DLLPs. In Flit Mode, the Data Stream is described in § Section 4.2.3.1. Each Symbol of the Data Stream is placed on a single Lane of the Link, and the stream of Symbols is striped across all Lanes of the Link and spans Block boundaries.

A Data Stream starts with the first Symbol of the Data Block that follows an SDS Ordered Set. It ends either when a Framing Error is detected or with the last Symbol of the Data Block that precedes an Ordered Set other than a SKP Ordered Set. SKP Ordered Sets that occur within a Data Stream have specific requirements as described in the following sections.

4.2.2.3.1 Framing Tokens in Non-Flit-Mode §

The Framing Tokens used by the Physical Layer in Non-Flit Mode are shown in § Table 4-4. Each Framing Token specifies or implies the number of Symbols associated with the Token and therefore the location of the next Framing Token. § Figure 4-15 shows an example of TLPs, DLLPs, and IDLs transmitted on a x8 link.

The first Framing Token of a Data Stream is always located in Symbol 0 of Lane 0 of the first Data Block of the Data Stream. For the rest of this chapter, the terms Framing Token and Token are used interchangeably.

Table 4-4 Framing Token Encoding §

Framing Token Type	Description
IDL	Logical Idle. The Framing Token is 1 Symbol. This Token is transmitted when no TLPs or DLLPs or other Framing Tokens are being transmitted.
SDP	Start of DLLP. The Framing Token is 2 Symbols long and is followed by the DLLP information.
STP	Start of TLP. The Framing Token is 4 Symbols long and includes the 12-bit TLP Sequence Number. It is followed by the TLP information.
EDB	EnD Bad. The Framing Token is 4 Symbols long and is used to confirm that the previous TLP was nullified.
EDS	End of Data Stream. The Framing Token is four Symbols long and indicates that the next Block will be an Ordered Set Block.

STP Token

EDS Token

EDB Token

SDP Token

IDL Token

A-0802

Figure 4-13 Layout of Framing Tokens §

The Physical Layer DLLP layout is shown in § Figure 4-14. Symbols 0 and 1 are the SDP Token, and Symbols 2 through 7 are the Data Link Layer DLLP information.

The Physical Layer TLP layout is shown in § Figure 4-14. Details of the STP Framing Token are shown in § Figure 4-13. The length of the TLP (in DWs) being transmitted is specified by an 11-bit field called TLP Length. The TLP Length field is the total amount of information transferred, including the Framing Token, TLP Prefixes (if any), TLP Header, TLP data payload (if any), TLP digest (if any), TLP PCRC (if any), TLP MAC (if any), and TLP LCRC. For example, if a TLP has a 3 DW header, a 1 DW data payload, and does not include a TLP digest, the TLP Length field value is 6: 1 (Framing Token) + 0 (TLP Prefixes) + 3 (TLP header) + 1 (TLP data payload) + 0 (TLP digest) + 1 (TLP LCRC). If the same TLP included a TLP digest, the TLP Length field value would be 7. When a TLP is nullified, the EDB Token is considered an extension of the TLP but is not included in the calculation of the TLP Length field.

The TLP Length field is protected by a 4-bit CRC (Frame CRC), and an even parity bit (Frame Parity) protects both the TLP Length and Frame CRC fields. The Frame CRC and Frame Parity are calculated as follows:

$$C[0] = L[10] \wedge L[7] \wedge L[6] \wedge L[4] \wedge L[2] \wedge L[1] \wedge L[0]$$

$$C[1] = L[10] \wedge L[9] \wedge L[7] \wedge L[5] \wedge L[4] \wedge L[3] \wedge L[2]$$

$$C[2] = L[9] \wedge L[8] \wedge L[6] \wedge L[4] \wedge L[3] \wedge L[2] \wedge L[1]$$

$$C[3] = L[8] \wedge L[7] \wedge L[5] \wedge L[3] \wedge L[2] \wedge L[1] \wedge L[0]$$

$$P = L[10] \wedge L[9] \wedge L[8] \wedge L[7] \wedge L[6] \wedge L[5] \wedge L[4] \wedge L[3] \wedge L[2] \wedge L[1] \wedge L[0] \wedge C[3] \wedge C[2] \wedge C[1] \wedge C[0]$$

The Frame Parity reduces to $P = L[10] \wedge L[9] \wedge L[8] \wedge L[6] \wedge L[5] \wedge L[2] \wedge L[0]$

The TLP Length field is represented in the above equations as $L[10:0]$, where $L[0]$ is the least significant bit and $L[10]$ is the most significant bit. Transmitters calculate the Frame CRC and Frame Parity before transmission. Receivers must calculate the Frame CRC and Frame Parity using the same algorithm as the transmitter and then compare the calculated values to the received values.

STP Tokens do not have a TLP Length field value of 1. If a received sequence of Symbols matches the format of an STP Token with a TLP Length field value of 1, the Symbols are evaluated to determine whether they match the EDS Token.

IMPLEMENTATION NOTE: FRAME CRC AND FRAME PARITY §

The Frame CRC bits are effectively calculated as $(L[0]X^{14} + L[1]X^{13} + \dots + L[9]X^5 + L[10]X^4) \bmod (X^4 + X + 1)$. It should be noted that $X^4 + X + 1$ is a primitive polynomial and the CRC can detect two bit errors. The Frame Parity bit can detect an odd number of bit errors. Thus, the Frame CRC and Frame Parity together guarantee three bit error detection for the TLP Length field. It must be noted that even though in the reduced Frame Parity equation all terms are not present, it still maintains the property of detecting odd bit errors. Only those TLP Length field bits which are present in an even number of CRC terms are used in the calculation.

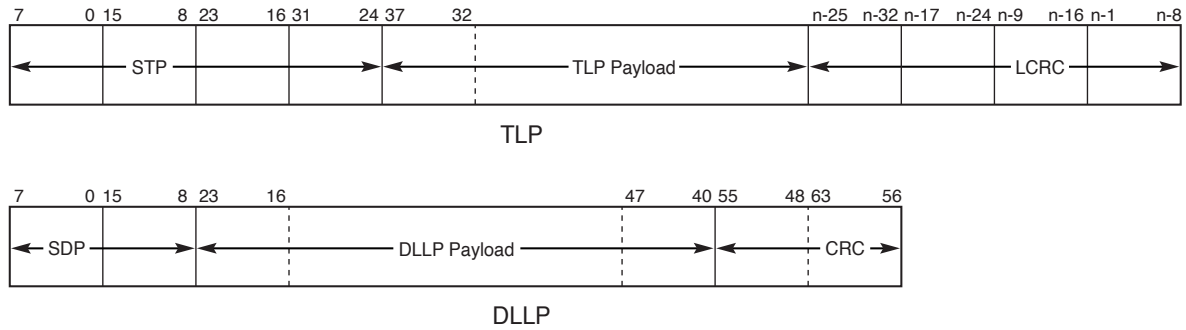

Note that, for TLPs, the Data Link Layer prepends 4 Reserved bits (0000b) to the TLP Sequence Number field before it calculates the LCRC. These Reserved bits are not explicitly transmitted when using 128b/130b encoding, and Receivers assume that the 4 bits received are 0000b when calculating the LCRC.

Packets containing a TLP Length field that is greater than 1535 are PMUX Packets. For such packets, the actual packet length is computed differently, the TLP Sequence Number field in the STP Token contains other information, and the Link CRC is computed using different rules. See § Appendix G. for details.

Packets containing a TLP Length field that is between 1152 and 1535 (inclusive) are reserved for future standardization.

Transmitters must transmit all DWs of a TLP specified by the TLP Length field of the STP Framing Token. TLPs are never truncated when using 128b/130b encoding - even when nullified. § Figure 4-16 shows an example of a nullified 23 DW TLP.

§ Figure 4-17 shows an example of TLPs, DLLPs, IDLs, and an EDS Token followed by a SKP Ordered Set. SKP Ordered Sets are defined in § Section 4.2.8.2 .

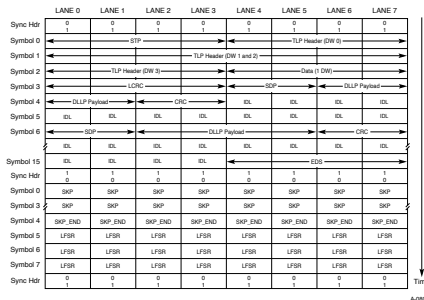

Figure 4-17 SKP Ordered Set of Length 66-bit in a x8 Link §

4.2.2.3.2 Transmitter Framing Requirements in Non-Flit Mode §

The following requirements apply to the transmitted Data Stream.

- To Transmit a TLP:
 - Transmit an STP Token immediately followed by the complete TLP information provided by the Data Link Layer.
 - All DWs of the TLP, as specified by the TLP Length field of the STP Token, must be transmitted, even if the TLP is nullified.
 - If the TLP is nullified, an EDB Token must be transmitted immediately following the TLP. There must be no Symbols between the last Symbol of the TLP and the first Symbol of the EDB Token. The value of the TLP Length field of a nullified TLP's STP Token is not adjusted to account for the EDB Token.
 - The STP Token must not be transmitted more frequently than once per Symbol Time.
- To Transmit a DLLP:
 - Transmit an SDP Token immediately followed by the complete DLLP information provided by the Data Link Layer.
 - All 6 Symbols of the DLLP must be transmitted.
 - The SDP Token must not be transmitted more frequently than once per Symbol Time.
- To Transmit a SKP Ordered Set within a Data Stream:
 - Transmit an EDS Token in the last DW of the current Data Block. For example, the Token is transmitted on Lane 0 in Symbol Times 12-15 of the Block for a x1 Link, and on Lanes 12-15 of Symbol Time 15 of the Block for a x16 Link.
 - Transmit the SKP Ordered Set following the current Data Block.
 - Transmit a Data Block following the SKP Ordered Set. The Data Stream resumes with the first Symbol of the Data Block. If multiple SKP Ordered Sets are scheduled for transmission, each SKP Ordered Set must be preceded by a Data Block with an EDS Token.
- To end a Data Stream:
 - Transmit an EDS Token in the last DW of the current Data Block, followed in the next block by an EIOS or an EIEOS. An EIOS is transmitted for LTSSM power management state transitions, and an EIEOS is transmitted for all other cases. For example, the Token is transmitted on Lane 0 in Symbol Times 12-15 of the Block for a x1 Link, and on Lanes 12-15 of Symbol Time 15 of the Block for a x16 Link.
- The IDL Token must be transmitted on all Lanes when not transmitting a TLP, DLLP, or other Framing Token.
- Multi-Lane Links:

- After transmitting an IDL Token, the first Symbol of the next STP or SDP Token must be transmitted in Lane 0 of a future Symbol Time. An EDS Token can be transmitted after an IDL Token in the same Symbol Time, since it must be transmitted in the last DW of a Block.
- For xN Links where N is 8 or more, if an EDB Token, TLP, or DLLP ends in a Lane K, where K does not equal N-1, and it is not followed by the first Symbol of an STP, SDP, or EDB Token in Lane K+1, then IDL Tokens must be placed in Lanes K+1 to N-1. For example, on a x8 Link, if a TLP or DLLP ends in Lane 3, IDL Tokens must be placed in Lanes 4 to 7. The EDS Token is an exception to this requirement, and can be transmitted following IDL Tokens.
- Tokens, TLPs, and DLLPs are permitted to follow each other successively such that more than one Token may be transmitted in the same Symbol Time as long as their transmission conforms with the other requirements stated in this section.
 - Links wider than x4 can have Tokens placed starting on Lane $4*N$, where N is a positive integer. For example, Tokens can be placed in Lanes 0 and 4 of a x8 Link, and Tokens can be placed in Lanes 0, 4, 8, or 12 of a x16 Link.

4.2.2.3.3 Receiver Framing Requirements in Non-Flit Mode §

The following requirements apply to the received Data Stream and the Block type transitions that occur at the beginning and end of the Data Stream.

- When processing Symbols that are expected to be a Framing Token, receiving a Symbol or sequence of Symbols that does not match the definition of a Framing Token is a Framing Error. It is strongly recommended that Receivers of a multi-Lane Link report an error in the Lane Error Status Register for the Lane that receives the first Symbol of an expected Framing Token when that Symbol does not match Symbol +0 of an STP (bits [3:0] only), IDL, SDP, EDB, or EDS Token (see § Figure 4-13).
- All optional error checks and error reports in this section are independently optional (see § Section 6.2.3.4).
- When an STP Token is received:
 - Receivers must calculate the Frame CRC and Frame Parity of the received TLP Length field and compare the results to the received Frame CRC and Frame Parity fields. A Frame CRC or Frame Parity mismatch is a Framing Error.
 - An STP Token with Framing Error is not considered part of a TLP for the purpose of reporting to the Data Link Layer.
 - If the TLP Length field is 1, the Symbols are not an STP Token and are instead evaluated to determine whether they are an EDS Token.
 - Receivers are permitted to check whether the TLP Length field has a value of 0. If checked, receiving a TLP Length field of 0 is a Framing Error.
 - Receivers are permitted to check whether the TLP Length field has a value of 2, 3, or 4. If checked, receiving such a TLP Length field is a Framing Error.
 - Receivers are permitted to check whether the TLP Length field has a value between 1152 and 1535 (inclusive). If checked, receiving such a TLP Length field is a Framing Error.
 - Receivers on Ports that do not support Protocol Multiplexing are permitted to check whether the TLP Length field has a value greater than 1535. If checked, receiving such a TLP Length field is a Framing Error.
 - Receivers on Ports that support Protocol Multiplexing, shall process STP Tokens with a TLP Length field that is greater than 1535 as the start of a PMUX Packet as defined in § Appendix G. .

- The next Token to be processed begins with the Symbol immediately following the last DW of the TLP, as determined by the TLP Length field.
 - Receivers must evaluate this Symbol and determine whether it is the first Symbol of an EDB Token and therefore whether the TLP is nullified. See the EDB Token requirements.
- Receivers are permitted to check whether more than one STP Token is received in a single Symbol Time. If checked, receiving more than one STP Token in a single Symbol Time is a Framing Error
- When an EDB Token is received:
 - If an EDB Token is received immediately following a TLP (there are no Symbols between the last Symbol of the TLP and the first Symbol of the EDB Token), receivers must inform the Data Link Layer that an EDB Token has been received. Receivers are permitted to inform the Data Link Layer that an EDB Token has been received after processing the first Symbol of the EDB Token or after processing any or all of the remaining Symbols of the EDB Token. Regardless of when they inform the Data Link Layer of a received EDB Token, Receivers must check all Symbols of the EDB Token. Receiving a Symbol that does not match the definition of an EDB Token is a Framing Error.
 - Receiving an EDB Token at any time other than immediately following a TLP is a Framing Error.
 - The next Token to be processed begins with the Symbol immediately following the EDB Token.
- When an EDS Token is received in the last four Symbols of the Data Block across the Link:
 - Receivers must stop processing the Data Stream.
 - Receiving an Ordered Set other than SKP, EIOS, or EIEOS in the Block following the EDS Token is a Framing Error.
 - If a SKP Ordered Set is received in the Block following the EDS Token, Receivers resume Data Stream processing with the first Symbol of the Data Block that follows the SKP Ordered Set unless a Framing Error has been detected.
- When an SDP Token is received:
 - The next Token to be processed begins with the Symbol immediately following the last Symbol of the DLLP.
 - Receivers are permitted to check whether more than one SDP Token is received in a single Symbol Time. If checked, receiving more than one SDP Token in a single Symbol Time is a Framing Error.
- When an IDL Token is received:
 - For a x1 Link, the next Token to be processed begins with the next Symbol received.
 - For a x2 Link, the next Token to be processed begins with the Symbol received in Lane 0 of the next Symbol Time. It is strongly recommended that Receivers check whether the Symbol received in Lane 1, if it did not receive IDL, after an IDL Token was received in Lane 0 is also IDL and report an error for Lane 1 in the Lane Error Status Register. If checked, receiving a Symbol other than IDL is a Framing Error.
 - For a x4 Link, the next Token to be processed begins with the Symbol received in Lane 0 of the next Symbol Time. It is strongly recommended that Receivers check whether the Symbols received in Lanes 1-3, after an IDL Token was received in Lane 0 are also IDL and report an error for the Lane(s) that did not receive IDL, in the Lane Error Status Register. If checked, receiving a Symbol other than IDL is a Framing Error.
 - For x8 and x16 Links, the next Token to be processed begins with the Symbol received in the next DW aligned Lane following the IDL Token. For example, if an IDL Token is received in Lane 4 of a x16 Link, the next Token location begins with Lane 8 of the same Symbol Time. However, if an IDL Token is received on Lane 4 of a x8 Link, the next Token location begins with Lane 0 of the following Symbol Time. It is strongly recommended that Receivers check whether the Symbols received between the IDL Token and the next Token location are also IDL and report an error for the Lane(s) that did not

receive IDL, in the Lane Error Status Register. If checked, receiving a Symbol other than IDL is a Framing Error.

Note: The only Tokens expected to be received in the same Symbol Time following an IDL Token are additional IDL Tokens or an EDS Token.

- While processing the Data Stream, Receivers must also check the Block type received by each Lane, after accounting for Lane-to-Lane de-skew, for the following conditions:
 - Receiving an Ordered Set Block on any Lane immediately following an SDS Ordered Set is a Framing Error.
 - Receiving a Block with an undefined Block type (a Sync Header of 11b or 00b) is a Framing Error. It is strongly recommended that Receivers of a multi-Lane Link report an error for any Lane that received the undefined Block type in the Lane Error Status register.
 - Receiving an Ordered Set Block on any Lane without receiving an EDS Token in the preceding Block is a Framing Error. For example, receiving a SKP Ordered Set without a preceding EDS Token is a Framing Error. In addition, receiving a SKP Ordered Set followed immediately by another Ordered Set Block (including another SKP Ordered Set) within a Data Stream is a Framing Error. It is strongly recommended that if the first Symbol of the Ordered Set is SKP, Receivers of a multi-Lane Link report an error for the Lane(s) in the Lane Error Status register if the received Symbol number 1 through 4N does not match the corresponding Symbol in § Table 4-52 or § Table 4-53.
 - Receiving a Data Block on any Lane when the previous block contained an EDS Token is a Framing Error. It is strongly recommended that Receivers of a multi-Lane Link report an error for the Lane(s) that received the Data Block in the Lane Error Status register.
 - Receivers are permitted to check for different Ordered Sets on different Lanes. If checked, receiving different Ordered Sets is a Framing Error. For example, if Lane 0 receives a SKP Ordered Set and Lane 1 receives an EIOS, it would be a Framing Error.

4.2.2.3.4 Receiver Framing Requirements in Flit Mode §

While processing the Data Stream, Receivers must check the Block type received by each Lane, after accounting for Lane-to-Lane de-skew, for the following conditions:

- Not receiving a SKP Ordered Set followed by a Data Block on any Lane immediately following an SDS Ordered Set is a Framing Error.
- Receiving a Block with an undefined Block type (a Sync Header of 11b or 00b) is a Framing Error. It is strongly recommended that Receivers of a multi-Lane Link report an error for any Lane that received the undefined Block type in the Lane Error Status register.
- For Lanes that are not entering or exiting the electrical idle state as part of L0p state, the following conditions result in a Framing Error. It is strongly recommended that Receivers of a multi-Lane Link report an error for any Lane that caused the Framing Error in the Lane Error Status register.
 - Receiving an Ordered Set Block on any Lane in an unscheduled Block boundary, as defined in § Section 4.2.3.1
 - Not receiving one of these three Ordered Sets of the appropriate length at the scheduled Block boundary: EIEOS, SKP Ordered Set, or EIOS
 - Receivers are permitted to check for different Ordered Sets on different Lanes, except as permitted for an L0p width transition. If checked, receiving different Ordered Sets is a Framing Error. For example, if Lane 0 receives a SKP Ordered Set and Lane 1 receives an EIOS and no L0p transition is expected, it would be a Framing Error.

4.2.2.3.5 Recovery from Framing Errors in Non-Flit Mode and Flit Mode §

If a Receiver detects a Framing Error while processing the Data Stream, it must:

- Report a Receiver Error as described in § Section 4.2.5.8 .
- Stop processing the Data Stream. Processing of a new Data Stream is initiated when the next SDS Ordered Set is received as previously described.
- Initiate the error recovery process as described in § Section 4.2.5.8 . If the LTSSM state is L0, direct the LTSSM to Recovery. If the LTSSM state is Configuration.Complete or Configuration.Idle when the Framing Error is detected, the error recovery process is satisfied by either a transition from Configuration.Idle to Recovery.RcvrLock due to the specified timeout, or a transition to Recovery through L0. If the LTSSM state is Recovery.RcvrCfg or Recovery.Idle when the Framing Error is detected, the error recovery process is satisfied by either a transition from Recovery.Idle to Recovery.RcvrLock due to the specified timeout, or a directed transition from L0 to Recovery. If the LTSSM substate is either Recovery.RcvrLock or Configuration.Linkwidth.Start, the error recovery process is satisfied upon exit from these substates and no direction of the LTSSM to Recovery is required.
 - Note: The framing error recovery mechanism is not expected to directly cause any Data Link Layer initiated recovery action such as NAK.

IMPLEMENTATION NOTE: TIME SPENT IN RECOVERY DUE TO DETECTION OF A FRAMING ERROR §

When using 128b/130b encoding, all Framing Errors require Link recovery. It is expected that implementations will require less than 1 microsecond to recover from a Framing Error as measured from the time that both Ports have entered the Recovery state.

4.2.2.4 Scrambling in Non-Flit Mode and Flit Mode §

Each Lane of the transmitter in a multi-Lane Link may implement a separate LFSR for scrambling. Each Lane of the receiver in a multi-Lane Link may implement a separate LFSR for descrambling. Implementations may choose to implement fewer LFSRs but must achieve the same functionality as independent LFSRs.

The LFSR uses the following polynomial: $G(X) = X^{23} + X^{21} + X^{16} + X^8 + X^5 + X^2 + 1$ and is demonstrated in § Figure 4-18.

The scrambling rules are as follows:

- The two bits of the Sync Header used in 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s Data Rate are not scrambled and do not advance the LFSR.
- All 16 Symbols of an Electrical Idle Exit Ordered Set (EIEOS) bypass scrambling. Except during L0p, the scrambling LFSR is initialized after the last Symbol of an EIEOS is transmitted, and the descrambling LFSR is initialized after the last Symbol of an EIEOS is received.
- TS1 and TS2 Ordered Sets for 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s Data Rate:
 - Symbol 0 of a TS1 or TS2 Ordered Set bypasses scrambling.
 - Symbols 1-13 are scrambled.

- Symbols 14 and 15 bypass scrambling if required for DC Balance, but they are scrambled if not required for DC Balance.
- All 16 Symbols of a Fast Training Sequence (FTS) Ordered Set used in 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s bypass scrambling.
- All 16 Symbols of a Start of Data Stream (SDS) Ordered Set bypass scrambling.
- All 16 Symbols of an Electrical Idle Ordered Set (EIOS) bypass scrambling.
- All Symbols of a SKP Ordered Set bypass scrambling.
- Transmitters advance their LFSR for all Symbols of all Ordered Sets except for the SKP Ordered Set. The LFSR is not advanced for any Symbols of a SKP Ordered Set.
- Receivers evaluate Ordered Sets to determine whether to advance their LFSR. If the Ordered Set is a SKP Ordered Set (see § Section 4.2.8), or an EIOS with L0p in the midst of a data stream then the LFSR is not advanced for any Symbol of the Ordered Set. Otherwise, the LFSR is advanced for all Symbols of the Ordered Set.
- In L0p, the scrambler on the Transmit and Receive sides associated with all the Lanes must advance whenever the scrambler associated with Lane 0 advances and does not advance whenever the scrambler associated Lane 0 does not advance. As a result, in L0p, the transmit or receipt of an EIEOS does not reset the scrambler associated with the Lane, if it is not Lane 0.

IMPLEMENTATION NOTE: ELASTIC BUFFER AND L0P §

For implementations that descramble prior to putting entries into the elastic buffer, one way to handle the scramblers advancing in the idle lane during L0p is as follows:

- The Lane which goes to electrical idle will tie its decision to advance the scrambler, accounting for sync hdr, if any, and SKP Ordered Set to Lane 0. Since the EIOS in the Lane coincides with SKP OS in Lane 0, the scrambler in the idle Lane should be synchronized with the Lane 0 on receipt of EIOS
- The TS1/TS2 Ordered Sets exchanged when trying to upsize the Link on L0p will be scrambled using the continually running LFSR.
- Depending on the implementation, any differences in scrambler synchronization on the receive side for lanes which have recently become active can be determined on the SKP Ordered Set boundary following block alignment and adjusted accordingly.
- The special scrambler rules for L0p above apply only to 128b/130b and 1b/1b encoding since the Ordered Sets are scrambled, and different Lanes can have different seeds/ taps which must run continuously without being reset during the data stream. In contrast, 8b/10b encoding does not scramble Ordered Sets and all the scramblers across all Lanes will be reset during SKP Ordered Sets during the link width up-size.

- All 16 Symbols of a Data Block are scrambled and advance the scrambler.
- For Symbols that need to be scrambled, the least significant bit is scrambled first and the most significant bit is scrambled last.
- The seed value of the LFSR is dependent on the Lane number Default Lane numbers are assigned in an implementation specific manner which is invariant to Link width and Lane reversal negotiation. These default numbers must be unique. For example, each Lane of a x16 Link must be assigned a unique Lane number from 0

to 15. These default Lane numbers are reassigned to the Lane when the Link first enters Configuration.Idle (i.e., having gone through Polling from Detect with LinkUp = 0b).

- The seed values for Lane number modulo 8 are:

Lane	Seed
0	1DBFBCh
1	0607BBh
2	1EC760h
3	18C0DBh
4	010F12h
5	19CFC9h
6	0277CEh
7	1BB807h

IMPLEMENTATION NOTE: SCRAMBLING PSEUDO-CODE §

The pseudo-code for the scrambler along with examples are provided in § Section C.2 of § Appendix C.

- The seed value of the LFSR does not change while LinkUp=1. Link reconfiguration through the LTSSM Configuration state does not modify the initial Lane number assignment as long as LinkUp remains 1 (even though the Lane assignment may change during Configuration).
- Scrambling cannot be disabled in Configuration.Complete when using 128b/130b encoding.
- A Loopback Follower must not descramble or scramble the looped-back bit stream.

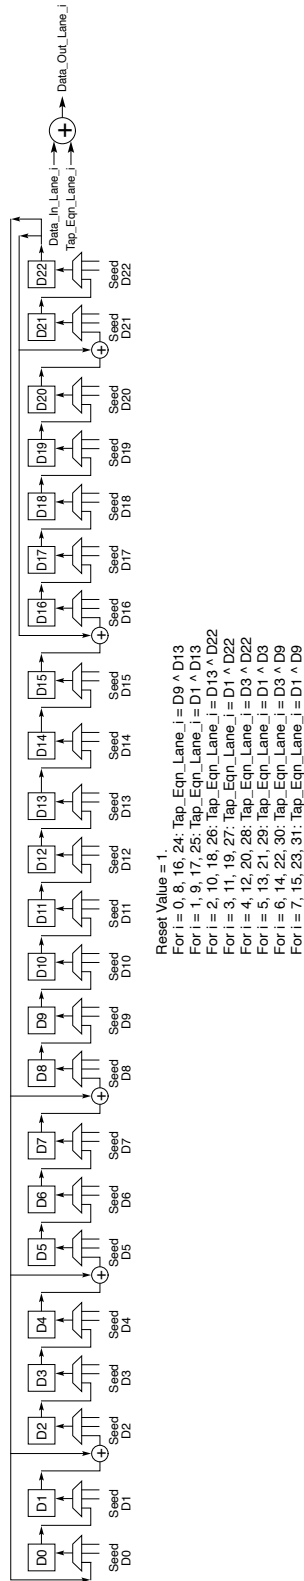

Figure 4-18 LFSR with Scrambling Polynomial in 8.0 GT/s and Above Data Rate 5

IMPLEMENTATION NOTE: LFSR IMPLEMENTATION WITH A SHARED LFSR §

Implementations may choose to implement one LFSR and take different tap points as shown in § Figure 4-19, which is equivalent to the individual LFSR per-lane with different seeds, as shown in § Figure 4-18. It should also be noted that the tap equations of four Lanes are the XOR of the tap equations of two neighboring Lanes. For example, Lane 0 can be obtained by XORing the output of Lanes 1 and 7; Lane 2 is the XOR of Lanes 1 and 3; Lane 4 is the XOR of Lanes 3 and 5; and Lane 6 is the XOR of Lanes 5 and 7. This can be used to help reduce the gate count at the expense of potential delay due to the XOR results of the two Lanes.

A-0808

Figure 4-19 Alternate Implementation of the LFSR for Descrambling §

4.2.2.5 Precoding §

A Receiver may request precoding from its transmitter for operating at data rates of 32.0 GT/s and higher. Precoding, when enabled at a Data Rate, applies to both Flit Mode and Non-Flit Mode at that data rate. The precoding rules are as follows:

- A Port or Pseudo-Port must request precoding on all configured Lanes of the Link. Behavior is undefined if precoding is requested on some Lanes but not others by a Port or Pseudo-Port.
- A Port or Pseudo-Port may request precoding independent of other Ports or Pseudo-Ports. For example, it is possible that precoding may be turned on only in the Upstream Port in the case with no Retimers in § Figure 4-61, or on all the Lanes in Tx(A) and Tx(E) in the two Retimer example in § Figure 4-61.
- Precoding is turned off for all data rates when the LTSSM is in the Detect state.
- If a precoding request for a data rate is to be made, it must be made prior to entering that data rate. A precoding request is made by setting the Transmitter Precode Request bit in the EQ TS2 or the 128b/130b EQ TS2 Ordered Sets prior to the transition to Recovery.Speed for the data rate at which the precoding will be turned on. Prior to the first Link speed negotiation to 32.0 GT/s since exiting Detect, the Transmitter Precode Request bit represents the precoding request for 32.0 GT/s when the Supported Link Speeds field in the EQ TS2 or the 128b/130b EQ TS2 Ordered sets is 32.0 GT/s or above. If the Link speed has been negotiated to 32.0 GT/s since exiting Detect, the Transmitter Precode Request bit represents the precoding request for the same data rate that the values in the Transmitter Preset field apply to. For each data rate of 32.0 GT/s or higher, the precoding request must be made independently.
- Each (pseudo) Port must store the precoding request along with the Tx Eq values from the most recent equalization procedure in each Lane. If the Link operates at 32.0 GT/s or higher data rate without performing equalization through the No Equalization Needed mechanism it negotiated in the TS1/TS2 Ordered Sets or modified TS1/TS2 Ordered Sets or the Link operates at the 32.0 GT/s or higher data rate in Polling.Compliance or Loopback, the precoding requests from the last equalization results that are being used must be enforced. If no equalization has ever been performed on the Link (prior to the current Link up), then precoding will not be turned on.
- If the Transmitter Precode Request bit is Set to 1b in each of the received eight consecutive EQ TS2 or 128b/130b EQ TS2 Ordered Sets during Recovery.RcvrCfg prior to entry to Recovery.Speed, the Transmitter must turn on the precoding for the data rate at which the Link will operate on exit from Recovery.Speed if the data rate is 32.0 GT/s or higher and the precoding request was intended for the data rate of operation. If the precoding request applies to a speed other than the data rate at which the Link will operate on exit from Recovery.Speed, the received Transmitter Precode Request bit must be ignored and the Precoding setting must not be updated for any data rate. Once turned on, precoding will be in effect for that data rate until the Transmitter receives another set of eight consecutive EQ TS2 or 128b/130b EQ TS2 Ordered Sets with Transmitter Precode Request set to 0b during Recovery.RcvrCfg prior to entry to Recovery.Speed for the same data rate.
- A Transmitter must not turn on precoding for any data rates lower than 32.0 GT/s.
- In data rates of 32.0 GT/s or higher, a Transmitter must set the Transmitter Precoding On bit to 1b in the TS1 Ordered Sets that it transmits in Recovery if its precoding is on for the current data rate; else the bit must be set to 0b.
- A Transmitter that has turned on precoding for the 32.0 GT/s data rate on Lane 0 must set the 32.0 GT/s Transmitter Precoding On bit to 1b in the 32.0 GT/s Status Register; else, it must set the bit to 0b. A Receiver that has requested, or will request, its link partner to turn on precoding at the 32.0 GT/s data rate must set the 32.0 GT/s Transmitter Precode Request to 1b in the 32.0 GT/s Status Register; else it must set the bit to 0b.
- A Transmitter that has turned on precoding for the 64.0 GT/s data rate on Lane 0 must set the 64.0 GT/s Transmitter Precoding On bit to 1b in the 64.0 GT/s Status Register; else it must set the bit to 0b. A Receiver that

has requested, or will request, its link partner to turn on precoding at the 64.0 GT/s data rate must set the 64.0 GT/s Transmitter Precode Request to 1b in the 64.0 GT/s Status Register; else it must set the bit to 0b.

- See § Section 4.2.2.5.1 for 32.0 GT/s precoding requirements. See § Section 4.2.3.1.4 for 64.0 GT/s and above data rate precoding requirements.

4.2.2.5.1 Precoding at 32.0 GT/s Data Rate §

When precoding is on at 32.0 GT/s, the following rules apply (see § Figure 4-20):

- Only scrambled bits are precoded.
- The “previous bit” used for precoding is set to 1b on every block boundary and gets updated by the last scrambled and precoded bit transmitted within the current block boundary.
- For symbols that are scrambled, Receivers must first decode the precoded bits before sending them to the descrambler.

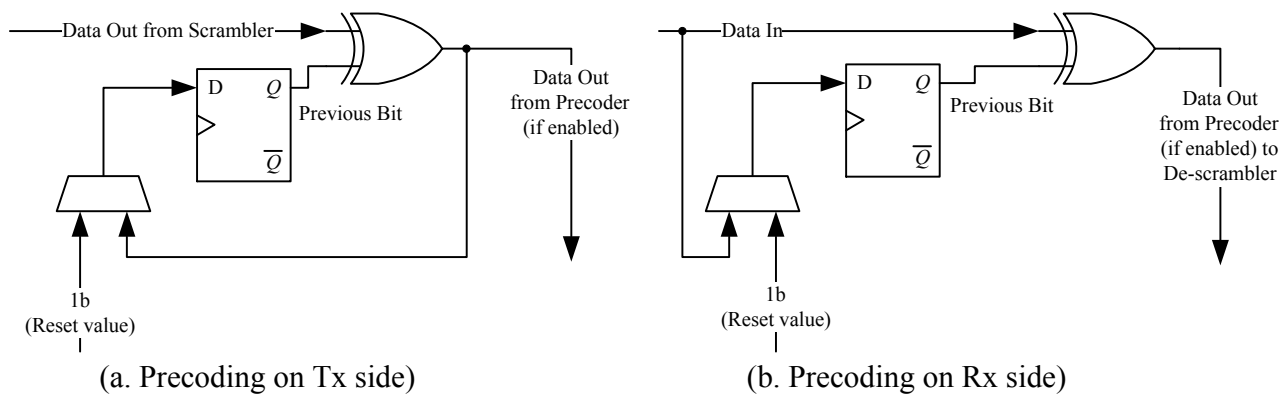

Figure 4-20 Precoding working the scrambler/ de-scrambler §

IMPLEMENTATION NOTE: PARITY IN THE SKP ORDERED SET WHEN PRECODING IS TURNED ON §

As per the rules of § Section 4.2.5.1 and § Section 4.2.8.2 , when precoding is turned on, the parity in the SKP Ordered Sets should be calculated before precoding is applied on the Transmitter side. Thus, the order in the Transmitter is:

1. scrambling,
2. followed by parity bit calculation,
3. followed by precoding for the scrambled bits.

Accordingly, in the Receiver, the order is:

1. precoding (if turned on by the Transmitter),
2. followed by parity bit calculation,
3. followed by descrambling.

The rationale for this order is that in a Link with one or two Retimers, different Link segments may have the precoding on or off. Let us consider an example system with one retimer between the Root Port and End Point to illustrate this. In the upstream direction, the End Point has precoding on in its Transmitter Lanes since the Retimer Receiver needs it but the Retimer to Root Port Link segment has the precoding off since the Root Port does not need precoding at its Receiver. Since the Retimer does not change the parity bit, the Root Port would get a parity error if the parity calculation was done by the Transmitter (of the End Point) after precoding.

IMPLEMENTATION NOTE: LOOPBACK LEAD'S BEHAVIOR IF PRECODING IS ON IN ANY LINK SEGMENT §

As per the rules of precoding mentioned in this section and § Section 4.2.7.4 , a Loopback Lead operating at a data rate of 32.0 GT/s or higher should account for precoding to be on some link segments and off in other link segments. This is particularly relevant when the Loopback Follower transitions from sending TS1 Ordered Sets to looping back the bits. This is where the precoding on the receiver of the Loopback Lead may switch (between precoding on and off). The Loopback Lead is permitted to use implementation specific mechanisms to handle this scenario.

IMPLEMENTATION NOTE: TS1/TS2 ORDERED SETS WHEN PRECODING IS TURNED ON §

As per the rules in this section, when precoding is turned on, the 'previous bit' used for precoding is 1b for the first bit of Symbol 1 since Symbol 0 is not scrambled and the 'previous bit' gets set to 1b at the block boundary.

4.2.2.6 Loopback with 128b/130b Code in Non-Flit Mode and Flit Mode §

When using 128b/130b encoding, Loopback Leads must transmit Blocks with the defined 01b and 10b Sync Headers. However, they are not required to transmit an SDS Ordered Set when transitioning from Ordered Set Blocks to Data Blocks, nor are they required to transmit an EDS Token when transitioning from Data Blocks to Ordered Set Blocks. Leads must transmit SKP Ordered Sets periodically as defined in § Section 4.2.8, and they must be capable of processing received (looped-back) SKP Ordered Sets of varying length. Leads are permitted to transmit Electrical Idle Exit Ordered Sets (EIEOS) as defined in § Section 4.2.2.2.1. Leads are permitted to transmit any payload in Data Blocks and Ordered Set Blocks that they expect to be looped-back. If the Loopback Lead transmits an Ordered Set Block whose first symbol matches the first symbol of SKP OS, EIEOS, or EIOS, that Ordered Set Block must be a complete and valid SKP OS, EIEOS, or EIOS.

When using 128b/130b encoding, Loopback Followers must retransmit all bits received without modification, except for SKP Ordered Sets which can be adjusted as needed for clock compensation. If clock compensation is required, Followers must add or remove 4 SKP Symbols per Ordered Set. The modified SKP Ordered Set must meet the definition of § Section 4.2.8.2 (i.e., it must have between 4 to 20 SKP Symbols followed by the SKP_END Symbol and the three Symbols that follow it as transmitted by the Loopback Leads. If a Follower is unable to obtain Block alignment or it is misaligned, it may be unable to perform clock compensation and therefore unable to loop-back all bits received. In this case, it is permitted to add or remove Symbols as necessary to continue operation. Followers must not check for a received SDS Ordered Set when a transition from Ordered Set Blocks to Data Blocks is detected, and they must not check for a received EDS Token when a transition from Data Blocks to Ordered Set Blocks is detected.

4.2.3 Flit Mode Operation §

Flit definition and Symbol placement is specified in this section.

Flits encoded with 8b/10b encoding follow the rules in § Section 4.2.1 with the following exception:

- Since the Flit Mode has its fixed TLP and DLP placement, the packet markers such as STP, SDP, END, EDB are not used.

Flits Encoded with 128b/130b encoding follow the rules in § Section 4.2.2 with the following exceptions:

- Since the Flit Mode has its fixed TLP and DLP placement, the Framing Tokens are not used.

1b/1b encoding is specified in Section 4.2.3.1.

4.2.3.1 1b/1b Encoding for 64.0 GT/s and higher Data Rates §

When the PCI Express Link is operating at 64.0 GT/s or higher Data Rates, it uses Flit Mode. A Symbol (8 bits) is the basic unit of transfer per Lane. PAM4 signaling is used for all Symbols, whether it belongs to a Data Stream or an Ordered Set. PAM4 operates on 2-bit aligned boundaries. A Symbol, represented as 'S₇S₆S₅S₄S₃S₂S₁S₀', is placed on a Lane starting with the voltage encoding of 'S₁S₀' and ending with 'S₇S₆'. An example placement of Flits (described later) or Ordered Set on a x4 Link is shown in § Figure 4-21 below.

Figure 4-21 Example of Symbol placement in a x4 Link with 1b/1b encoding §

A conceptual diagram of the Transmit side and Receive side is shown in § Figure 4-22 and § Figure 4-23 respectively. These diagrams are provided to explain the order of operations that must be performed on the Transmit and Receive side. An implementation may choose to operate on different widths depending on the design goals and constraints.

At a Flit level, on the Transmit side, CRC is first applied followed by FEC generation. After that, each Lane is allotted its Symbol in the byte interleaved fashion for the Flit. On a per Lane basis, Scrambling is performed, if required, followed by Gray Coding at a 2-bit aligned boundary, after which Precoding is performed at 2-bit aligned UI level, if enabled and required. Thus, in the Symbol above, Gray Coding and Precoding will be applied for the bits corresponding to ‘S₁S₀’, ‘S₃S₂’, ..., ‘S₇S₆’. As shown in the diagram below, the scrambled symbols of the TS1/TS2 Ordered sets also undergo the precoding logic (including bypass). All Symbols, whether they belong to a Flit (Data Stream) or scrambled Symbols of an Ordered Set or any pattern where explicitly mentioned (e.g., scrambled part of modified compliance pattern) undergo the Gray Coding and PAM4 encoding, whereas unscrambled Symbols of an Ordered Set or any pattern only undergo the PAM4 encoding (the gray coding and DC-balance is effectively taken care of through the bit definition). For the cases where parts of a pattern may be expressed as a repeated sequence of UIs, the Symbol here refers to the aligned 4 UI interval of that pattern.

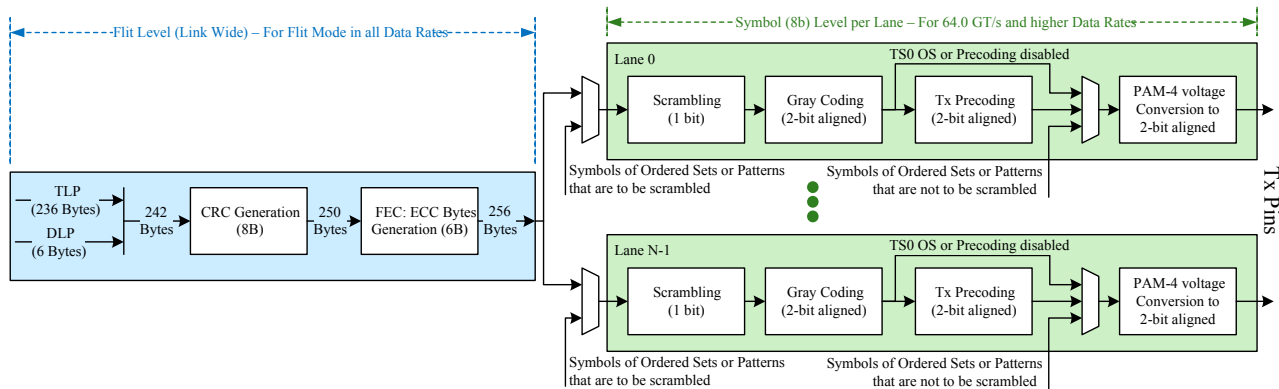

Figure 4-22 Transmit side at 64.0 GT/s §

The Receive side is similar to the Transmit side in the opposite direction. After the PAM4 voltage is converted to a 2-bit aligned quantity, it undergoes the Receive side precoding if applicable followed by the decoding of the Gray code, followed by descrambling on a single bit level, if applicable. The Data Stream (Flit) is aggregated across all Lanes and undergoes the FEC decode and correction followed by the CRC check before sending up the Transactions and Data Link Payload.

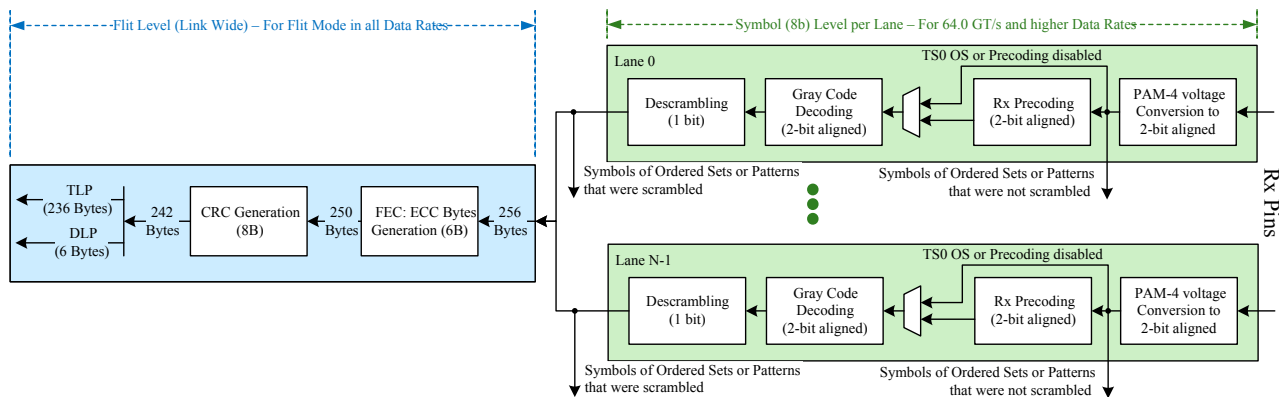

Figure 4-23 Receive side at 64.0 GT/s §

4.2.3.1.1 PAM4 Signaling §

PAM4 stands for Pulse Amplitude Modulation 4-levels. It is a signaling mechanism where 4 levels (2 bits) are encoded in same Unit Interval (UI) resulting in 3 eyes, as shown in § Figure 4-24. It is deployed only for 64.0 GT/s or higher Data Rates. As described in § Chapter 8, , PAM4 helps with the channel loss as it has the same Nyquist frequency as 32.0 GT/s for 64.0 GT/s Data Rate. The four voltage levels 0, 1, 2, and 3, nominally map to -400 mV, -133 mV, +133 mV and +400 mV respectively, and the Gray code encoded values of 00b, 01b, 11b, and 10b respectively, with the little-endian bit order, as shown in § Figure 4-24. The corresponding DC Balance values to be used when designing Ordered Sets to meet the DC

balance needs is also shown in § Figure 4-24. The Reduced voltage levels (eye height or EH) and eye width (EW) increases susceptibility to errors. Gray coding is used to help minimize errors within a UI for the voltage levels.

Scrambled 2-bit aligned value		Unscrambled 2-bit as well as TS0 Ordered Sets	Voltage Level	DC-balance Values
Prior to Gray Coding	After Gray Coding			
10	11	11	3	+3
11	10	10	2	+1
01	01	01	1	-1
00	00	00	0	-3

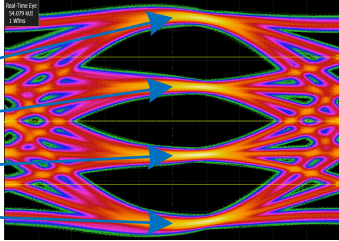

Figure 4-24 PAM4 Signaling at UI level: Voltage levels, 2-bit encoding, and their corresponding DC balance values §

With PAM4 encoding, the bit error rate (BER) is expected to be significantly worse than the 10^{-12} BER target of the lower data rates (2.5, 5.0, 8.0, 16.0, and 32.0 GT/s). In addition, errors are expected to occur in bursts in a Lane and some amount of Lane to Lane correlation is also expected. The electrical spec parameters along with FBER (First Bit Error Rate) $< 10^{-6}$ described in § Chapter 8, must be met to ensure probability of a Flit error after FEC to be less than 3×10^{-5} .

A **Forward Error Correction (FEC)** mechanism is used to deal with the high FBER in the Data Stream. Since FEC works on fixed sized code words, Flit (flow control unit) will be used for sending/ receiving TLPs and DLLPs in a data stream. A low-overhead FEC will be used to keep the latency low. This will be augmented with a strong CRC at Flit level for high reliability. Link level retry will be deployed at the Flit level in Flit Mode. Ordered Sets will be protected through replication for Data Rates of 64.0 GT/s and above. Additionally, the precoding mechanism described below will be used for all scrambled bits to help minimize the number of errors in an error burst within a Lane.

4.2.3.1.2 1b/1b Scrambling §

The scrambling mechanism in the 64.0 GT/s Data Rate is identical to that for the 8.0, 16.0, and 32.0 GT/s Data Rates and is already covered in § Section 4.2.2.4, except for the TS0 / TS1 / TS2 / SKP Ordered Set rules defined below. § Figure 4-25 demonstrates the scrambler on the Transmitter side. All Data Stream bits as well as some Ordered Set bits are scrambled.

- TS1 and TS2 Ordered Sets:
 - Symbols 0 and 8 bypass scrambling.
 - Symbols 1 through 6 and Symbols 9 through 14 are scrambled.
 - Symbols 7 and 15 bypass scrambling if required for DC Balance, but they are scrambled if not required for DC Balance.
- TS0 Ordered Sets:
 - Symbols 0 and 8 bypass scrambling
 - Symbols 1 through 6 and Symbols 9 through 14 use NRZ-based scrambling
 - NRZ-based scrambling consists of scrambling all 8 bits and then, in place of gray-coding, forcing the even bit $2i$ to be identical to the odd bit $(2i+1)$ [where $0 \leq i \leq 3$]. This ensures that only voltage levels 0 and 3 are sent.

- Symbols 7 and 15 bypass scrambling if required for DC Balance; else they carry even parity of Symbols 1 through 6 and Symbols 9 through 14 respectively with NRZ-scrambling
- All Symbols in TS0 are NRZ-based (i.e., each UI maps to voltage levels 0 or 3, encoded as 00b or 10b). Only TS0 Ordered Set is designed to be NRZ-based in 64.0 GT/s Data Rate.
- SKP Ordered Sets:
 - When processing Ordered Sets outside of a Data Stream, receivers use the 1b/1b SKP decode rules in § Section 4.2.3.1.5 . When processing Ordered Sets inside a Data Stream, receivers use the 1b/1b SKP decode rules in § Section 4.2.3.2 . If it is determined by the Receiver that the Ordered Set is a SKP Ordered Set, then the LFSR is not advanced for any Symbol of the Block, as specified in § Section 4.2.2.4 .

IMPLEMENTATION NOTE: NRZ-BASED SCRAMBLING §

During NRZ-based scrambling, forcing the even bit $2i$ to be identical to the odd bit $(2i+1)$ [where $0 \leq i \leq 3$] can be performed after gray-coding or instead of gray-coding. The result will be the same either way.

4.2.3.1.3 Gray Coding at 64.0 GT/s and Higher Data Rates §

Only scrambled bits on a 2-bit aligned boundary are Gray coded, when both bits are scrambled. All bits in the Data Stream are scrambled and Gray coded. Only some Symbols of the TS1/TS2 Ordered Sets are scrambled – those are Gray coded, while the unscrambled symbols are not Gray coded. All TS0 Ordered Set Symbols to be Half Scrambled undergo NRZ-based scrambling, as described in § Section 4.2.3.1.2 . § Figure 4-25 represents the sequence of Gray Coding, which is followed by Tx Precoding, when enabled, followed by the PAM4 voltage translation on the Tx side as well as the Rx side, considering an error E_n that may affect the n th 2-bit quantity on the channel.

Gray Coding is only enabled in the PAM4 mode (at 64.0 GT/s and above Data Rates). Gray-coding works on aligned 2-bit quantities on a per-Lane basis. On the Transmit side, input G_n ($G_{n1}G_{n0}$) is transformed to output P_n ($P_{n1}P_{n0}$), using the Gray code encoding where the input 00b, 01b, 10b, 11b becomes 00b, 01b, 11b, and 10b respectively in the output. This can be represented by the equations: $P_{n1} = G_{n1}$ and $P_{n0} = G_{n1} \oplus G_{n0}$. The Receive side is identical and can be represented as: $G'_{n1} = P'_{n1}$ and $G'_{n0} = P'_{n1} \oplus P'_{n0}$. § Table 4-6 demonstrates how a likely error of ± 1 on voltage level at most affects one bit with Gray Coding.

Figure 4-25 The Sequence of Gray Coding, Precoding, and PAM4 voltage translation on an aligned 2-bit boundary on a per Lane §

Table 4-6 Effect of +/-1 voltage level error on the wire for various PAM4 voltage levels – at most one bit flips with an error on a UI §

Voltage Level	Resulting Voltage Level	
	Error of +1	Error of -1
0	1	0 (no error)
1	2	0
2	3	1
3	3 (no error)	2

4.2.3.1.4 Precoding at 64.0 GT/s and Higher Data Rates §

Only scrambled bits on a 2-bit aligned boundary are precoded, when both bits are scrambled and precoding is enabled. Precoding is bypassed for all Symbols of TS0 Ordered Sets. Other than the precoding mechanism described here, all the precoding rules in § Section 4.2.2.5 apply to 1b/1b encoding with the exception of TS0 Ordered Set. § Figure 4-25 represents the Precoding on the Transmit as well as Receive side. On the Transmit side, the input is P_n and the output is T_n . T_{n-1} represents the output from the precoder in the previous UI. When the prior UI was unscrambled and precoding is enabled, T_{n-1} is set to 00b. The output T_n will be converted to the PAM4 voltage levels described above, when precoding is enabled. The channel may inject an error E_n (no error means $E_n = 00b$). On the Receive side, $R_n = T_n + E_n$. The input to the Precoding logic is R'_n ($R_n = T_n + e_n$), where e_n is inclusive of the error on the wire E_n as well as any internal DFE propagated error. The output of the precoding logic is P'_n , when precoding is enabled. The Truth Table for the Precoding function for the Transmit and Receive side is shown in § Table 4-7 and § Table 4-8. Precoding can help mitigate the number of errors in a burst.

Table 4-7 Truth Table for Precoding on the Transmit side §

		T_n			
		T_{n-1}			
P_n		00	01	11	10

00		00	01	11	10
01		01	10	00	11
11		11	00	10	01
10		10	11	01	00

IMPLEMENTATION NOTE: HOW DOES PRECODING HELP REDUCE THE NUMBER OF ERRORS? §

Precoding is effective with Gray coding on certain channels to reduce the impact of errors in the presence of DFE. It works similar to the precoding in 32.0 GT/s, except here it works on 2-bit aligned quantities with PAM4 encoding. The most likely error scenario is +/-1 on the voltage level over one UI with PAM4 signaling. § Table 4-6 demonstrates the resulting voltage level under this error scenario and the resulting bit error with Gray code encoding. Gray Coding results in at most a single bit flip within that UI. Error propagation due to DFE will most likely occur in consecutive UIs. Under these assumptions, precoding ensures that the error appears in two bits within a wire: when the error gets introduced in the wire and the UI after the DFE burst stops. For cases such as error voltage magnitude is > +1 or < -1 or for cases where the DFE introduces errors in non-contiguous UI's, precoding may not be effective.

The precoding equation on Transmit side, based on the Truth Table in § Table 4-7 is: $T_n = (P_n - T_{n-1}) \bmod 4$, which is equivalent to $P_n = (T_n + T_{n-1}) \bmod 4$. The precoding equation on the Receive side, based on the Truth Table in § Table 4-8 is: $P'_n = (R_n + R_{n-1}) \bmod 4$. This can be simplified as: $P'_n = (T_n + e_n + T_{n-1} + e_{n-1}) \bmod 4 = (P_n + e_n + e_{n-1}) \bmod 4$. When we have the first error burst on the wire, $E_n = +/-1$ which will translate to $e_n = E_n (+/-1)$. So, with FBER, one bit gets affected in the UI where the external error happened. In the subsequent UIs, in the absence of any additional external errors, $e_n = -e_{n-1}$ or 0 (0 when DFE stops propagating the error, when it does propagate the magnitude is negative of the earlier error since the corresponding tap has a negative weight). If the error propagates due to DFE, $e_n + e_{n-1} = 0$. If it stops propagating, e_n becomes +/- 1. So only two bit errors will be observed when precoding is effective: first bit error in the UI where the first error occurred in the wire and the UI following when DFE stopped propagating the error burst.

§ Table 4-9 illustrates the concept with an error in the channel and subsequent DFE error propagations. The bits after scrambling to be sent across the Link across successive UIs are in the first row, represented as G_n (pre-gray coding). The different stages are represented in subsequent rows in the table. It must be noted that after gray coding (starting with T_n) until we decode with the gray-coding at the receiver (G'_n), we are dealing with voltage levels of 0, 1, 2, 3. The channel error occurs with the PAM-4 Symbol in UI #1 of magnitude -1, which causes only one error of magnitude in the receiver pin (R_n). However, due to DFE burst, the error propagates in the receiver circuits from UI# 1 through 5 (R'_n). Once we precode in the Receiver, these errors occur in two places, UI #1 and 6, as shown in P'_n , which then translates to two bit errors, one each in UI #1 and 6, as shown in G'_n .

Table 4-9 Example of precoding with an error in the channel and DFE error propagation at the Receiver §

		0	1	2	3	4	5	6	7
Voltage Level Domain)	G_n	10	11	10	11	00	01	00	01
	P_n	11	10	11	10	00	01	00	01
	$T_n^{+(P_n - T_{n-1}) \bmod 4}$	3	3	0	2	2	3	1	0
	E_n (Channel Error)	0	-1	0	0	0	0	0	0
	R_n	3	2	0	2	2	3	1	0

R'_n (Difference from T_n is an error)	3	2	1	1	3	2	1	0
P'_n ($+(R_n - R_{n-1}) \bmod 4$)	3	1	3	2	0	1	3	1
G'_n (Difference from G_n is an error)	10	01	10	11	00	01	10	01

4.2.3.1.5 Ordered Set Blocks at 64.0 GT/s and Higher Data Rates §

All Ordered Sets with the exception SKP Ordered Sets (i.e., TS0, TS1, TS2, EIOS, EIEOS and SDS) are 16 Bytes long on both the Transmit and the Receive side. SKP Ordered Sets are 40 Bytes long on the Transmit side and can be 24, 32, 40, 48 or 56 bytes long on the Receive side. Ordered Sets exhibit a greater degree of redundancy than the corresponding Ordered Sets at Data Rates lower than 64.0 GT/s. The redundancy is required due to the high FBER with correlated errors with PAM4 signaling. The Ordered Sets are described in detail in § Section 4.2.5.1, § Section 4.2.5.3, § Section 4.2.5.7, and § Section 4.2.8.3.

While processing Ordered Sets outside of a Data Stream, the following rules apply for the EIEOS, SKP OS, and EIOS, after obtaining Block alignment:

- An EIEOS is considered to be received under the following conditions:
 - any 5 or more aligned and consecutive bytes in each of the first and last 8 bytes of a Block match the corresponding bytes of an EIEOS and
 - either Symbol 0 or Symbol 8 of the Block matches the corresponding byte of an EIEOS. A Receiver is permitted to ignore up to one bit mismatch for this comparison

While in Aligned phase, a Receiver must switch the block boundary by > 1 UI on an EIEOS Ordered Set or should shift the Block boundary by ≤ 1 UI only if it receives an EIEOS followed by a valid first symbol of an expected Ordered Set.

While searching for an EIEOS, the 8-byte boundary can begin in any aligned UI and the bits must be looked at prior to performing gray coding, precoding, or descrambling in the Receiver side.

- An EIOS is considered to be received under the following conditions:
 - any 5 or more aligned bytes of the first 8 bytes of a Block match the corresponding bytes of an EIOS and
 - either Symbol 0 or Symbol 8 of the Block matches the corresponding byte of an EIOS. When an EIOS is received, the Lane is ready to enter Electrical Idle irrespective of what is received in the last 7 Bytes of the Block.
- A SKP OS is considered to begin under the following conditions: (i) any 5 or more aligned bytes of the first 8 bytes of a Block match a SKP, and (ii) either Symbol 0 is a SKP or Symbol 8 of the Block is either a SKP or a SKP_END. It looks at each subsequent aligned 8 byte chunks and applies the following rules:

- If any 5 or more aligned bytes match SKP_END or the current chunk is the fifth 8 byte chunk after the start of the SKP OS (i.e., current set is bytes 40 through 47 from the start of the SKP OS), the SKP OS will terminate after the next aligned 8 byte chunk.

IMPLEMENTATION NOTE: INFERRING ORDERED SETS WITHIN AND OUTSIDE OF DATA STREAMS §

Since most bytes of TS0/TS1/TS2 Ordered Sets are scrambled (except Symbols 0 and 8), one has to get an exact match in at least Symbol 0 or 8, in addition to the match in 5 Byte positions to infer the EIEOS, EIOS, or SKP OS, while not in a Data Stream. The rules for detection of TS0, TS1, TS2, and SDS Ordered Set appears with the description of the Ordered Set. Since SKP, EIEOS, and EIOS can appear within a Data Stream, there are slightly different rules for inferring those in a Data Stream than while not in a Data Stream, taking advantage of the fact that none of these Ordered Sets have any scrambling, to ensure higher fault tolerance during a Data Stream. Hence the rules for detection of EIOS, EIEOS and SKP OS are specified twice; in this section as well as in § Section 4.2.8.3.

4.2.3.1.6 Alignment at Block/ Flit Level for 1b/1b Encoding §

With 1b/1b encoding, Block alignment aligns with the Ordered Set boundary on a per-Lane basis. Once this is accomplished, the Flit-level alignment at the Link level occurs automatically with the Data Stream that starts at the end of the Control SKP Ordered Set that immediately follows the SDS Ordered Set sequence. Once the Flit alignment starts, it adjusts to the Flit boundary. When an Ordered Set is scheduled to be received and the received Ordered Set is a Control SKP Ordered Set, the Flit boundary is automatically adjusted to start at the conclusion of the Ordered Set.

The Block level alignment occurs with the EIEOS Ordered Set in Configuration or Recovery states. The EIEOS is a unique pattern that Receivers use to determine the start/ end of the Ordered Set boundary in the received bit stream. Conceptually, Receivers can be in three different phases of alignment: Unaligned, Aligned, and Locked. These phases are defined to illustrate the required behavior, but are not meant to specify a required implementation.

Unaligned Phase

Receivers enter this phase after a period of Electrical Idle, such as when the data rate is changed to one that uses 1b/1b encoding or when they exit a low-power Link state, or if directed (by an implementation specific method). In this phase, Receivers monitor the received bit stream for a match against all 128 bits of the EIEOS bit pattern. When one is detected, they adjust their alignment to it and proceed to the Aligned Phase.

Aligned Phase

Receivers monitor the received bit stream for the EIEOS OS and the received Blocks for a Start of Data Stream (SDS) Ordered Set. If an EIEOS bit pattern is detected on an alignment that does not match the current alignment and the LTSSM is in the Recovery.RcvrLock state, Receivers must adjust their alignment to the newly received EIEOS bit pattern. If an EIEOS bit pattern is detected on an alignment that does not match the current alignment, the LTSSM is in the Recovery.RcvrCfg state, and the subsequent Symbol matches the first Symbol of an expected Ordered Set, Receivers must adjust their alignment to the newly received EIEOS bit pattern. If an SDS Ordered Set is received, Receivers proceed to the Locked phase. The Data Stream starts after the SDS Ordered Set sequence is received, though Flits start after the Control SKP Ordered Set immediately succeeding the SDS Ordered Set sequence. The conclusion of the SKP Ordered Set immediately following an SDS Ordered Set sequence marks the start of the Flit boundary at the end of the Control SKP Ordered Set.

Locked Phase

Receivers must not adjust their Block or Flit alignment while in this phase. Data Blocks are expected to be received after the Control SKP Ordered Set following the SDS Ordered Set sequence, and adjusting the Block alignment would interfere with the processing of these Blocks. Receivers must return to the Unaligned or Aligned Phase if the Data Stream is terminated by the Link entering Recovery and/or a Framing Error is detected.

Additional Requirements:

- While in the Aligned Phase, Receivers must adjust their Block alignment, as necessary, when a Control SKP Ordered Set is received. See § Section 4.2.8 for more information on SKP Ordered Sets.
- While in the Locked phase, Receivers must adjust their Block and Flit alignment, as necessary, when a Control SKP Ordered Set is received.
- After any LTSSM transition to Recovery, Receivers must ignore all received TS Ordered Sets until they receive an EIEOS. Conceptually, receiving an EIEOS validates the Receiver's alignment and allows TS Ordered Set processing to proceed. If a received EIEOS initiates an LTSSM transition from L0 to Recovery, Receivers are permitted to process any TS Ordered Sets that follow the EIEOS or ignore them until another EIEOS is received after entering Recovery.
- Receivers are permitted to transition from the Locked phase to the Unaligned or Aligned phase as long as Data Stream processing is stopped.
- Loopback Leads: While in Loopback.Entry, Leads must be capable of adjusting their Receiver's Block / Flit alignment to received EIEOS bit patterns. While in Loopback.Active, Leads are permitted to transmit an EIEOS and adjust their Receiver's Block alignment to the looped back bit stream.
- Loopback Followers: While in Loopback.Entry, Followers must be capable of adjusting their Receiver's Block alignment to received EIEOS bit patterns. While in Loopback.Active, Followers must not adjust their Receiver's Block alignment, except at the scheduled Control SKP Ordered Set boundary. Conceptually, the Receiver is directed to the Locked phase when the Follower starts to loop back the received bit stream.

4.2.3.2 Processing of Ordered Sets During Flit Mode Data Stream §

Flit Mode does not employ the EDS ('End of Data Stream') token. Instead, a Data Stream can be terminated by either an EIOS (prior to entering a low power state, such as L1) or an EIEOS (upon entry into Recovery). SKP Ordered Sets appear at periodic intervals during the Data Stream (as defined in § Table 4-21. When necessary, the EIOS or EIEOS must be transmitted in place of the SKP Ordered Set, as defined in § Section 4.2.3.4.5. Therefore, these three Ordered Sets are defined such that one cannot alias to another even with a burst error.

Ordered Set processing during or at the end of a Data Stream must be performed as follows by the Receiver for 64.0 GT/s or higher Data Rates:

- Receiver checks the first 8 bytes of the Ordered Set in the place where an Ordered Set is expected to appear.
- Any 5 or more aligned bytes of the first aligned 8 byte chunk matches the corresponding bytes of either a SKP, EIOS, or EIEOS for the corresponding Ordered Set to be considered valid in each of the active Lanes. Failure to meet this requirement is considered a framing error and the Link must enter Recovery.
- If a SKP Ordered Set is inferred from the first 8 bytes, the Receiver looks at each subsequent aligned 8 byte chunks and applies the following rules:
 - If at least each of any 5 aligned bytes matches SKP_END or the current chunk is the fifth 8 byte chunk after the start of the SKP OS (i.e., current set is bytes 40 through 47), the SKP OS will terminate after the next aligned 8 byte chunk. At the conclusion of the SKP OS the Data Stream resumes, if the SKP OS terminated with the receipt of 5 aligned bytes of SKP_END. If the SKP OS is being terminated without receipt of 5 aligned bytes of SKP_END, a Framing Error occurs.

- Any of the following conditions are Framing Error even with the receipt of a proper OS on each of active Lanes and the Link must enter Recovery:
 - Receiving any combination of these ordered sets simultaneously on any two active Lanes: EIEOS and EIOS or EIEOS and SKP OS,
 - Receiving a SKP OS of unequal lengths across all Lanes
 - Receiving a combination of EIOS and SKP OS and any of the following conditions is true:
 - L0p has not been enabled in the Link
 - The set of Lanes receiving EIOS are not contiguous
 - The set of Lanes receiving SKP OS are not contiguous
 - The number of Lanes receiving SKP OS is not a valid link width (1, 2, 4, or 8)
 - Any of these Lanes is receiving neither SKP OS nor EIOS.
- If an EIEOS is inferred from the first 8 bytes on any active Lane, the Data Stream ends with the receipt of the EIEOS and the Link must enter Recovery when permitted by the LTSSM.
- If an EIOS is inferred from the first 8 bytes across any active Lanes, the Link prepares to enter the low-power state for which the negotiation has occurred (L0p or L1 or L2).
- Data stream continues on a reduced set of Lanes at the conclusion of the OS if all of the following conditions are true:
 - An EIOS is inferred from the first 8 bytes on some active Lanes,
 - The remaining active Lanes received the SKP OS on 1, 2, 4 or 8 Lanes, and
 - L0p has been enabled in the Link

IMPLEMENTATION NOTE:

64.0 GT/S DATA STREAM ORDERED SET PROCESSING §

A Flow chart depicting part of the above flow is illustrated in § Figure 4-26. This flow chart is not meant to specify all the rules but illustrate some of the rules for illustration purposes.

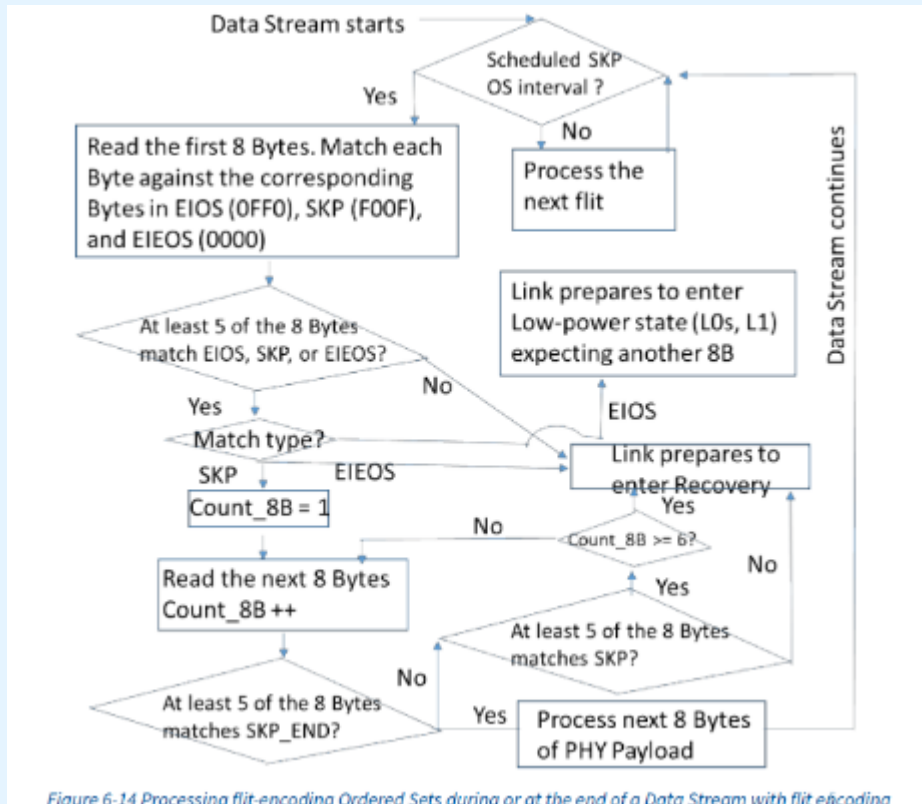

Figure 6-14 Processing flit-encoding Ordered Sets during or at the end of a Data Stream with flit encoding

Figure 4-26 Processing of Ordered Sets during or at the end of a Data Stream in Flit mode at 64.0 GT/s Data Rate §

4.2.3.3 Data Stream in Flit Mode §

The flit size is 256 Bytes, allocated as follows:

- 236 Bytes for TLPs (Bytes 0 through 235 in the Flit, as shown in § Table 4-10 through § Table 4-14)
- 6 Bytes for Data Link Layer Payload (DLP in Bytes 236 through 241 in the Flit, shown as DLP0..6 in § Table 4-10 through § Table 4-14)
- 8 Bytes for CRC (Bytes 242 through 249 in the Flit, shown as CRC0..7 in § Table 4-10 through § Table 4-14), and
- 6 Bytes for ECC (Bytes 250 through 255 arranged as 3 groups of ECC0[0:1], ECC1[0:1], ECC2[0:1], as shown in § Table 4-10 through § Table 4-14).

A flit is interleaved across the Lanes in the Link in a Byte aligned fashion, as shown in § Table 4-10 through § Table 4-14. Each Byte corresponds to a Symbol in the 64.0 GT/s and above Data Rates, a Symbol within the Data Block with 128b/130b encoding, for 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s; and gets converted to a 10b Symbol using the 8b/10b encoding for

2.5 GT/s and 5.0 GT/s Data Rates. Since the TLP and DLP have fixed allocation of bytes within each flit, the Port will schedule the packets of each type accordingly. The 8 Bytes of CRC protects the TLP and DLLP Bytes (and not the ECC bytes). The 6 Bytes of ECC protects the entire flit, including the CRC. Even though the ECC protection is needed only with the high FBER with the PAM4 signaling at 64.0 GT/s and higher Data Rates, it will be deployed for the lower Data Rates for consistency.

On a Link layer retry, only the TLPs will be replayed, and not the DLP. Thus, the link layer payload in each flit (DLP) does not enter the Link Layer Retry Buffer (LLRB) at the Transmitter. The DLP fields in the retried flits will reflect the latest Data Link Layer Payload. Thus, a DLP can be lost and the same mechanism of replication/ aggregation for DLLPs ensures that the data link layer messages gets delivered to the Link partner.

The FEC is a 3-way interleaved ECC, with each ECC code capable of correcting a single Byte error. The interleaving is done so that a burst error of up to 16 bits in any Lane does not impact more than a Byte in each interleaved ECC code word. Each of the interleaved ECC has a different color. Thus, all blue colored Bytes [e.g., 0, 3, 6, 9, ..., 231, 234, DLP1, DLP4, CRC1, CRC4, and CRC7] are part of ECC Group 0 and are covered by the 2 blue colored ECC0[0] and ECC0[1] bytes (which are placed in the last Symbol of the flit in Lanes 12 and 15 respectively).

A conceptual representation of the processing of Symbols in the Flit Mode for the 64.0 GT/s Data Rate on the Transmit and the Receive side is demonstrated in § Figure 4-21, § Figure 4-22, and § Figure 4-25. A conceptual representation of the Flit Mode and Non-Flit Mode processing with 8b/10b encoding for 2.5 GT/s and 5.0 GT/s as well as with 128b/130b encoding for 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s for the Transmit and Receive side is shown in and respectively.

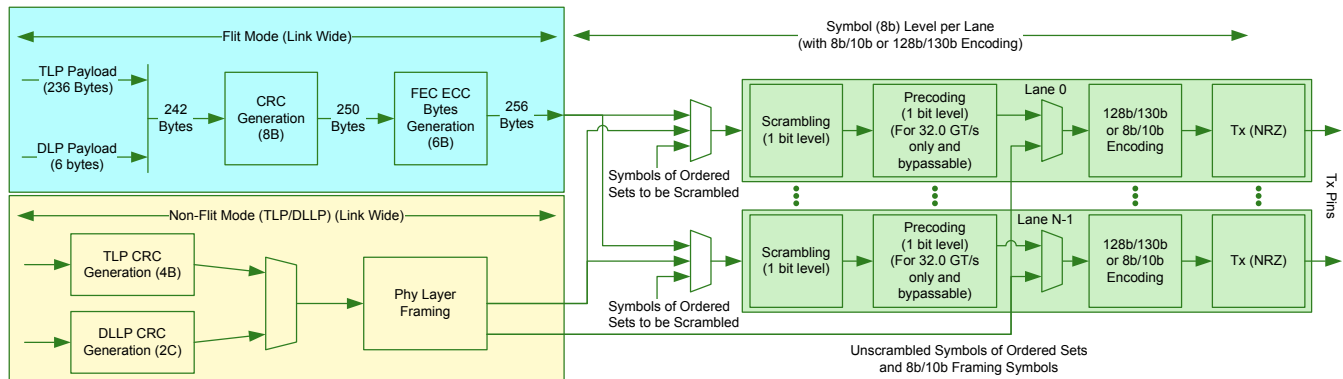

Figure 4-27 Flit Mode and Non-Flit Mode processing with 8b/10b and 128b/130b encoding on the Transmit side §

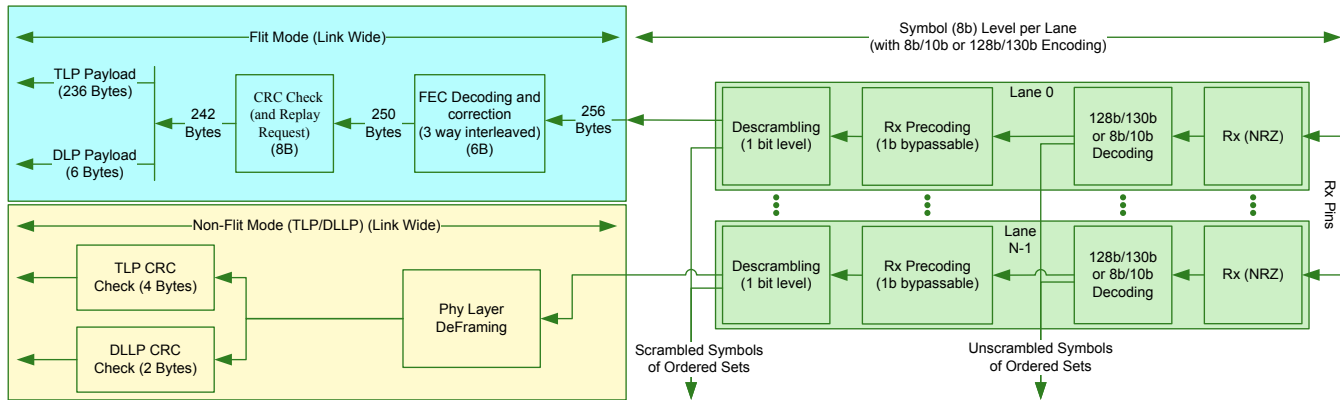

Figure 4-28 Flit Mode and Non-Flit Mode processing with 8b/10b and 128b/130b encoding on the Receive side §

4.2.3.4 Bytes in Flit Layout §

4.2.3.4.1 TLP Bytes in Flit §

The TLP Bytes in the flit carry Transaction Layer TLPs. Since the Flit Mode does not support STP tokens, these TLP bytes must be populated by the Transaction Layer, irrespective of whether it has a TLP to send or not. A TLP may span across multiple flits depending on its length and placement. The following rules must be observed:

- When the transaction layer does not have a TLP to send, it sends a NOP TLP (1DW). Once a NOP TLP is scheduled to be sent, NOP TLPs must be scheduled till the next 4DW aligned boundary within the Flit or the Flit boundary, whichever is earlier.
- NOP TLPs do not consume any credits.
- The TLPs in Flit Mode have information in predetermined position to determine the length of the TLPs, including the case where TLP prefix is used. See § Chapter 2. for details.
- The following rules apply for the non-NOP TLPs in bytes 0 through 127 of the Flit (i.e., the TLP bytes within the first Flit half) and bytes 128 through 235 of the Flit (i.e., the TLP bytes within the second Flit half):
 - No more than 8 TLPs, including partial TLPs. Receivers are permitted to check this rule.
 - If checked, this is logged as a Data Link Protocol Error in the receiving Port (see § Section 6.2).
- If a TLP at the end of a Flit gets poisoned or nullified through Flit_Status, and if that TLP extends to subsequent Flits, each of those Flits must also be poisoned or nullified through Flit_Status so that the poisoned or nullified Flit_Status is set in the Flit where the TLP ends. A Receiver is permitted to only look at the poison bit in the Flit where the TLP ends.
- A TLP that gets nullified through the Flit_Status field in the DLP Bytes described below is ignored by the Receiver if the Flit is valid, but the credits must be released.
- A TLP that gets EDB'ed or Poisoned through the Flit_Status field in the DLP Bytes described below must be succeeded by only NOP TLPs through the end of the Flit.

IMPLEMENTATION NOTE: HANDLING TLPS SPANNING MULTIPLE FLITS §

When a TLP spans multiple Flits, it may be interrupted by SKPs, NOP Flits, transitions through Recovery and/or other unavoidable scenarios. Transmitters should attempt to avoid this interruption whenever possible for optimal bandwidth and latency and Receivers must be able to deal with scenarios where the TLP may be interrupted.

Example: § Table 4-15 shows an example of TLP placement in the Flit Mode for a x16 Link. For narrower Link widths, similar arrangements will exist subject to the rules mentioned above.

- This flit starts with a continuation of the remaining 2 DWs from TLP 19 (the 3rd DW of Hdr and 1 DW of Data).
- TLP 20 (4DW Hdr and 1DW Data) immediately starts in Lane 8 and ends in Lane 11 in the following Symbol.
- Since the Transmitter has nothing to send, it sends NOP sending till the 4DW aligned boundary, which is in Lane 15.
- TLPs 22, and 23 are scheduled without any intervening NOP.
- After TLP 23, the Transmitter did not have anything to send and sends 7 NOPs, aligned to a 4DW boundary till TLP 24 is ready, which continues till the flit boundary for TLP Bytes.
- After that we have 6 Bytes of DLP, 8 Bytes of CRC covering the 236 Bytes of TLP and 6 Bytes of DLP in the flit.
- Then we have the 3 sets of interleaved ECC, 2 bytes each, covering the entire 256B flit.

It should be noted that every Byte of each TLP as well the DLP is covered by one of the 3 ECC groups and each TLP/DLP is a member of all 3 ECC groups, and as indicated in the color code.

Table 4-15 Example TLP Placement in Flit Mode on a x16 Link ⁵

4.2.3.4.2 DLP Bytes in Flit §

In every flit, 6 bytes are allotted to carry the information carried by the Data Link Layer Packets (DLLPs) described in § Chapter 3. . While the DLP bytes are designed to reuse the DLLP mechanism and formats for the most part, some optimizations have been made to effectively carry the Ack/Nak flit along with an optimized credit release (Optimized_Update_FC, defined below) or a traditional DLLP. An encoding has been added in the DLP to provide Update_FC credits for PRH, PRD, and NPRH within one 32 bit payload of DLP. The following table summarizes the DLP encodings.

Three Flit Types have been defined in § Table 4-16, along with their intended usages. They all have the same CRC and FEC mechanism. The distinction is made for ease of reference based on the TLP and DLP Bytes they carry. An IDLE Flit uses the sequence number of 0 along with the appropriate Replay Command (00b) as described in § Table 4-16. IDLE Flits are only sent after the Control SKP Ordered Set following the SDS Ordered Set Sequence with 128b/130b and 1b/1b encoding. For 8b/10b encoding, an IDLE Flit will be sent at the conclusion of the TS2 Ordered Set (or after a SKP OS following the last TS2 Ordered Set, depending on the SKP insertion interval). With 8b/10b encoding, an Ordered Set vs. a Flit is distinguished the lack of a COM at the end of a SKP OS. IDLE Flits continue to be sent until a Flit other than an IDLE Flit must be sent. Devices that advertise infinite credits across all FC/VC are permitted to send NOP DLLP if there is no DLLP to be sent in dlp 2, 3, 4, and 5.

A valid Flit is one that passes the CRC check after performing the FEC correction, if required, and none of the ECC groups in the FEC are reporting an uncorrectable error (by ECC), as described in § Section 4.2.3.4.4 , and the Flit Usage as well as the Flit Status fields do not have a Reserved encoding defined below.

An FEC-correctable Flit is a valid Flit that passes the CRC check after performing the FEC correction.

An FEC uncorrectable error is an error in a Flit that is detected by the CRC after FEC correction or ‘uncorrectable error’ reported by an ECC group in the FEC which may result in a NAK and a replay.

An invalid Flit is a Flit that is not a valid Flit.

A valid non-IDLE Flit is a valid Flit that is either a NOP Flit or a Payload Flit. All subsequent Flits after the first valid non-IDLE Flit are non-IDLE Flits while the Link is in L0.

Figure 4-29 DLP Byte to Bit Number Assignment §

Figure 4-30 DLP Bit usage §

Table 4-16 Flit Types §

Flit Type	TLP Bytes	DLP Bytes 0,1	DLP Bytes 2..5
IDLE Flit	Transmitters must place 00h in all 236 bytes.	Transmitters must place 00h in both bytes.	NOP2 DLLP (see § Figure 3-8)
NOP Flit	All 236 bytes are Reserved.	Flit Usage = 00b Flit Sequence Number ⁶⁰ = NEXT_TX_FLIT_SEQ_NUM - 1 if Replay Command is 00b Other Fields = Any valid encoding	Any valid encoding
Payload Flit	TLP content, packed per rules described in § Section 4.2.3.4.1 . A portion of at least one non-NOP TLP in the 236 Bytes	Flit Usage = 01b Flit Sequence Number != 00b if Replay Command is 00b Other Fields = Any valid encoding	Any valid encoding

Table 4-17 DLP Bytes in the Flit §

Field	Location	Encoding
Flit Usage	DLP0: Bits 7:6	00b IDLE Flit or NOP Flit 01b Payload Flit Others Reserved
Prior Flit was Payload	DLP0: Bit 5	0b Prior flit was a NOP Flit or IDLE Flit 1b Prior flit was a Payload Flit
Type of DLLP Payload	DLP0: Bit 4	0b DLLP Payload in DLP 2..5 1b Optimized_Update_FC or Flit_Marker in DLP 2..5
Replay Command [1:0]	DLP0: Bits 3:2	00b The Flit Sequence Number included in the Flit is an Explicit Flit Sequence Number of the transmitted Flit.

60. A NOP Flit does not consume a Flit Sequence Number.

Field	Location	Encoding
		<p>01b Ack of <u>Flit Sequence Number</u> from Receiver. The included <u>Flit Sequence Number</u> indicates the <u>Flit Sequence Number</u> of the last valid Flit received.</p> <p>10b Nak requesting a Replay of all unacknowledged Flits. The included <u>Flit Sequence Number</u> indicates the <u>Flit Sequence Number</u> of the last valid Flit received.</p> <p>11b Nak requesting a Replay of a single Flit (<u>Flit Sequence Number</u> + 1). The included <u>Flit Sequence Number</u> indicates the <u>Flit Sequence Number</u> of the last valid Flit received.</p>
Flit Sequence Number [9:0]	{ DLP0: Bits 1:0, DLP1: Bits 7:0 }	10-bit sequence number applied to Flits. See Flit Sequence Number Rules. DLP0[1:0] contains <u>Flit Sequence Number</u> [9:8] and DLP1[7:0] has <u>Flit Sequence Number</u> [7:0].
DLLP Payload	{ DLP2, DLP3, DLP4, DLP5 }	Type of DLLP Payload is 0b Regular DLLP Payload (see § Chapter 3.)
<u>Optimized_Update_FC</u>	Bits 31:0	Type of DLLP Payload is 1b and bit 31 = 0b (see § Table 4-18)
<u>Flit_Marker</u>	DLP2 is 31:24 DLP3 is 23:16 DLP4 is 15:8 DLP5 is 7:0	Type of DLLP Payload is 1b and bit 31 = 1b (see § Table 4-19)

In the Table above, a Transmitter must not use the Reserved encodings.

31	Flit_Marker Indicator Must be "1"
30:29	<p>Flit_Status - Indicates the validity of the Last TLP in this Flit. Encoding is:</p> <p>00b No special information - No TLPs that end in this Flit are Nullified or Poisoned. TLPs that starts in this Flit and ends in a subsequent Flit are marked in that Flit.</p> <p>01b Last TLP Nullified - Last TLP ending in current Flit is Nullified This mechanism replaces the EDB Mechanism in Non-Flit Mode framing.</p> <p>10b Last TLP Poisoned - Last TLP ending in the current Flit is Poisoned See § Section 2.7.2 regarding how this mechanism relates to the Transaction Layer EP bit mechanism.</p> <p>11b Reserved</p>
28	<p>PTM Message contained in this Flit - In Flit Mode, timestamps for Precision Time Measurement messages are measured at the Flit level rather than at the TLP level. This bit indicates that this Flit contains the last symbol of a non-nullified PTM Message.</p> <p>Nullified PTM Messages do not set this bit.</p> <p>Poisoned PTM Messages are not permitted.</p>

For the DLLP Payload in the above table, the Optimized_Update_FC is used to transmit performance critical NPRH, PRH, and PRD credits in 4 Bytes. For debug as well as ease of use by debug tools such as Logic Analyzers, devices must send at least one DLLP every 10 μ s with an Update_FC DLLP per VC with the scaled credit information. It is strongly recommended that a Transmitter cycles through the VCs with finite non-0 credits in the Optimized_Update_FC as long as there is a credit to be released in the corresponding VC.

Receivers are permitted to check for the following Flit errors:

- Reserved value of Flit Usage
- Reserved encoding of Flit_Status field in a Flit_Marker
- Invalid sequence number (see § Section 4.2.3.4.2.1.4).
- Violations of the TLP packing rules as defined in § Section 4.2.3.4.1

If checked, these Flit errors are logged as a Data Link Protocol Error in the receiving Port (see § Section 6.2).

4.2.3.4.2.1 Flit Sequence Number and Retry Mechanism §

Term Definitions

Explicit Sequence Number Flit

A Payload Flit or NOP Flit with Replay Command 00b.

Ack Flit

A Flit with Replay Command 01b.

Standard Nak Flit

A Flit with Replay Command 10b.

Selective Nak Flit

A Flit with Replay Command 11b.

Nak Flit

A Flit with either Replay Command 10b or 11b.

Standard Nak

A Nak that requests a Replay of all unacknowledged Flits.

Selective Nak

A Nak that requests a Replay of a specific Flit.

Standard Replay

A Replay of all unacknowledged Flits in the TX Retry Buffer.

Selective Replay

A Replay of a specific Flit from the TX Retry Buffer.

TX Retry Buffer

The buffer which stores information for transmitted Flits until the Flit has been acknowledged by the Link partner.⁶¹

RX Retry Buffer

The buffer which stores information for received Flits until the Flit has been consumed by the Receiver.⁶²

Nak Ignore Window

A time window in which received Nak Flits are ignored for a specific Flit Sequence Number.

- The Nak Ignore Window is started when a Payload Explicit Sequence Number Flit is sent with Flit Sequence Number = NAK_IGNORE_FLIT_SEQ_NUM + 1 and NAK_IGNORE_FLIT_SEQ_NUM != 0.

⁶³

Flags and Counters

NEXT_TX_FLIT_SEQ_NUM

10-bit unsigned counter that tracks the Flit Sequence Number for transmitted Flits.

- Set to 001h in DL_Inactive state.
- Behavior defined in NEXT_TX_FLIT_SEQ_NUM Rules.
- Usage defined in § Section 4.2.3.4.2.1.2 , § Section 4.2.3.4.2.1.3 , § Section 4.2.3.4.2.1.4 , and § Section 4.2.3.4.2.1.6 .

TX_ACKNAK_FLIT_SEQ_NUM

Stores the 10-bit Sequence Number to be transmitted in the next Ack Flit or Nak Flit.

61. The Link Speed and Link Width that a Device supports should be taken into consideration when sizing the TX Retry Buffer.

62. Expected Nak latency should be considered when sizing the RX Retry Buffer to avoid overflow when using the Selective Replay mechanism.

63. The Nak Ignore Window is used in the two specific scenarios: 1) A Replay is started due to a received Nak Flit. 2) A Payload Explicit Sequence Number Flit with Flit Sequence Number = NEXT_TX_FLIT_SEQ_NUM is sent after having received a Nak with Flit Sequence Number = NEXT_TX_FLIT_SEQ_NUM - 1.

- Set to 1023 in DL_Inactive state.
- Usage defined in § Section 4.2.3.4.2.1.2 , § Section 4.2.3.4.2.1.3 , and § Section 4.2.3.4.2.1.5 .

CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS

2-bit unsigned counter which tracks how many consecutive Explicit Sequence Number Flits have been sent by the Transmitter.

- Set to 00b IDLE Flit Handshake Phase.
- Behavior defined in CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS Rules
- Usage defined in § Section 4.2.3.4.2.1.2 and § Section 4.2.3.4.2.1.3 .

CONSECUTIVE_TX_NAK_FLITS

3-bit unsigned counter which tracks how many consecutive Nak Flits have been sent by the Transmitter.

- Set to 000b in the IDLE Flit Handshake Phase.
- This counter saturates at 111b and does not roll over to 000b.
- Behavior defined in CONSECUTIVE_TX_NAK_FLITS Rules.
- Usage defined in § Section 4.2.3.4.2.1.3 and § Section 4.2.3.4.2.1.7 .

NEXT_EXPECTED_RX_FLIT_SEQ_NUM

10-bit unsigned counter that stores the expected Flit Sequence Number of the next valid non-IDLE non-duplicate Flit to be received.

- Set to 001h in DL_Inactive state.
- Behavior and usage defined in § Section 4.2.3.4.2.1.5 .

IMPLICIT_RX_FLIT_SEQ_NUM

10-bit unsigned counter that tracks the implicit Flit Sequence Number of received Flits.

- Set to 000h in DL_Inactive state.
- Behavior defined in IMPLICIT_RX_FLIT_SEQ_NUM Rules.
- Usage defined in § Section 4.2.3.4.2.1.5 .

ACKD_FLIT_SEQ_NUM

Stores the 10-bit Flit Sequence Number received in the most recently processed valid Ack Flit or Nak Flit.

- Set to 3FFh in DL_Inactive state.
- Behavior defined in § Section 4.2.3.4.2.1.4 .
- Usage defined in § Section 4.2.3.4.2.1.4 and § Section 4.2.3.4.2.1.6 .

NON_IDLE_EXPLICIT_SEQ_NUM_FLIT_RCVD

Flag to indicate that a Non-IDLE Explicit Sequence Number Flit has been received since the last entry to IDLE Flit Handshake Phase.

- Set to 1 when first Non-IDLE Explicit Sequence Number Flit is received after last entry to IDLE Flit Handshake Phase.
 - This must be updated before evaluating Ack, Nak, and Discard Rules in § Section 4.2.3.4.2.1.5 .
- Cleared on entry to IDLE Flit Handshake Phase.
- Usage defined in IMPLICIT_RX_FLIT_SEQ_NUM Rules.

REPLAY_SCHEDULED

Flag to indicate that a Flit has been scheduled to be replayed from the TX Retry Buffer.

- Cleared when in DL_Inactive state.

- Behavior defined in § Section 4.2.3.4.2.1.6 .
- Usage defined in § Section 4.2.3.4.2.1.2 , § Section 4.2.3.4.2.1.6 , and § Section 4.2.3.4.2.1.7 .

REPLAY_SCHEDULED_TYPE

Indicates whether a Standard Replay or a Selective Replay has been scheduled.

- If REPLAY_SCHEDULED is 1b:
 - REPLAY_SCHEDULED_TYPE 0b indicates a Standard Replay.
 - REPLAY_SCHEDULED_TYPE of 0b will be referred to as **STANDARD_REPLAY**.
 - REPLAY_SCHEDULED_TYPE 1b indicates a Selective Replay.
 - REPLAY_SCHEDULED_TYPE of 1b will be referred to as **SELECTIVE_REPLAY**.
- Behavior defined in § Section 4.2.3.4.2.1.6 .
- Usage defined in § Section 4.2.3.4.2.1.6 and § Section 4.2.3.4.2.1.7 .

REPLAY_IN_PROGRESS

Flag to indicate that the Transmitter is sending Flits from the TX Retry Buffer.

- Cleared when in DL_Inactive state.
- Behavior defined in REPLAY_IN_PROGRESS Rules.
- Usage defined in § Section 4.2.3.4.2.1.2 , § Section 4.2.3.4.2.1.6 , and § Section 4.2.3.4.2.1.7 .

TX_REPLAY_FLIT_SEQ_NUM

Stores the 10-bit Flit Sequence Number of the first Flit to be replayed from the TX Retry Buffer.

- Set to 000h in DL_Inactive state.
- Behavior defined in § Section 4.2.3.4.2.1.6 .
- Usage defined in § Section 4.2.3.4.2.1.4 , § Section 4.2.3.4.2.1.6 , and § Section 4.2.3.4.2.1.7 .

FLIT_REPLAY_NUM

3-bit unsigned counter that tracks the number of times that a Replay has been initiated without making forward progress.

- Set to 000b in DL_Inactive state.
- Behavior defined in § Section 4.2.3.4.2.1.4 and § Section 4.2.3.4.2.1.7 .
- Usage defined in § Section 4.2.3.4.2.1.7 .

REPLAY_TIMEOUT_FLIT_COUNT

11-bit unsigned counter that counts the number of Payload Flits and NOP Flits sent since the last Ack of an outstanding Flit.

- Set to 000h in DL_Inactive state.
- This counter saturates at 7FFh and does not roll over to 000h.
- Behavior defined in REPLAY_TIMEOUT_FLIT_COUNT Rules
- Usage defined in § Section 4.2.3.4.2.1.6 .

NAK_SCHEDULED

Flag to indicate that a Nak Flit has been scheduled for transmission.

- Cleared when in DL_Inactive state.
- Behavior defined in § Section 4.2.3.4.2.1.5 .
- Usage defined in § Section 4.2.3.4.2.1.2 , § Section 4.2.3.4.2.1.3 , and § Section 4.2.3.4.2.1.5 .

NAK_SCHEDULED_TYPE

Indicates whether a Standard Nak Flit or a Selective Nak Flit should be sent.

- Set to 0b when in DL_Inactive state.
- If NAK_SCHEDULED is 1b,
 - NAK_SCHEDULED_TYPE 0b indicates a Standard Nak Flit.
 - NAK_SCHEDULED_TYPE of 0b will be referred to as **STANDARD_NAK**.
 - NAK_SCHEDULED_TYPE 1b indicates a Selective Nak Flit.
 - NAK_SCHEDULED_TYPE of 1b will be referred to as **SELECTIVE_NAK**.
- Behavior defined in § Section 4.2.3.4.2.1.5 .
- Usage defined in § Section 4.2.3.4.2.1.2 , § Section 4.2.3.4.2.1.3 , and § Section 4.2.3.4.2.1.5 .

NAK_WITHDRAWAL_ALLOWED

Flag that indicates an invalid Flit was received but should not be Nak'd if the subsequent received Flit has Prior Flit was Payload set to 0b (indicating that the invalid Flit was a NOP Flit).

- Cleared when in DL_Inactive state.
- Behavior and usage defined in § Section 4.2.3.4.2.1.5 .

NAK_IGNORE_FLIT_SEQ_NUM

Stores the 10-bit Flit Sequence Number to be ignored during the Nak Ignore Window.

- Set to 000h when in DL_Inactive state.
- Behavior defined in § Section 4.2.3.4.2.1.4 and § Section 4.2.3.4.2.1.6
- Usage defined in § Section 4.2.3.4.2.1.6 .

NEXT_RX_FLIT_SEQ_NUM_TO_STORE

Stores the 10-bit Flit Sequence Number of the next Flit to be stored in the RX Retry Buffer.

- Cleared when in DL_Inactive state.
- Behavior and usage defined in § Section 4.2.3.4.2.1.5 .

RX_RETRY_BUFFER_OVERFLOW

Flag to indicate that a Flit was unable to be stored in the RX Retry Buffer due to the buffer becoming full before a Selective Replay was received for an outstanding Selective Nak.

- Cleared when in DL_Inactive state.
- Behavior and usage defined in § Section 4.2.3.4.2.1.5 .

RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM

Stores the 10-bit Flit Sequence Number of the last Flit stored in the RX Retry Buffer if the RX Retry Buffer overflows.

- Cleared when in DL_Inactive state.
- Behavior and usage defined in § Section 4.2.3.4.2.1.5 .

MAX_UNACKNOWLEDGED_FLITS

Maximum number of unacknowledged Flits outstanding.

- Set to the lesser of:
 - Number of Flits that can be stored in the TX Retry Buffer.
 - 511 Flits
- Usage defined in § Section 4.2.3.4.2.1.4 , § Section 4.2.3.4.2.1.5 , and § Section 4.2.3.4.2.1.6 .

General Rules**Flit Sequence Number Rules:**

- The valid range of Flit Sequence Numbers for Payload Flits is 1-1023.

- Flit Sequence Number 0 is only used for IDLE Flits.
- NOP Flits do not consume a Flit Sequence Number.
 - A NOP Flit that is also an Explicit Sequence Number Flit sets Flit Sequence Number to NEXT_TX_FLIT_SEQ_NUM - 1.
 - If no Payload Flits have been transmitted, Flit Sequence Number 1023 is used.
- All Flit Sequence Number counters will roll-over from 1023 to 1.
- Whenever text in this section refers to adding to, subtracting from, incrementing, or decrementing a sequence number, it is implied that sequence number rollover rules stated above will be followed.
- Two transmitted or received Flits are considered consecutive, even if they are separated by a SKP OS.
- The Nak Ignore Window should be the lesser of:
 - Measured Ack/Nak Latency of the Link + 1 maximum sized SKP Ordered Set + 2 Flits
 - 300ns
- It is strongly recommended that an Ack or Nak for a received Flit is transmitted within the following times of receiving the Flit on the receiver pins. The following times apply unless the transmitter is sending an Ordered Set. The measurement is from the first bit of the received Flit on the receiver pins to the first bit of the associated Ack Flit or Nak Flit on the transmitter pins. § Section 4.2.3.4.2.1.5 describes when an Ack or Nak should be scheduled.
 - x16: 50ns
 - x8: 52ns
 - x4: 56ns
 - x2: 64ns
 - x1: 80ns

Transmitter Rules

- The Transmitter must store the following information of transmitted Payload Flits in the TX Retry Buffer:
 - TLP Bytes associated with non-NOP TLPs
 - Flit Status
 - Flit Sequence Number

MAX_UNACKNOWLEDGED_FLITS Outstanding:

- If $(\text{NEXT_TX_FLIT_SEQ_NUM} - \text{ACKD_FLIT_SEQ_NUM}) \bmod 1023 > \text{MAX_UNACKNOWLEDGED_FLITS}$:
 - The Transmitter must not accept any new TLPs from the Transaction Layer.
 - The Transmitter must send a NOP Flit if REPLAY_SCHEDULED is 0b and REPLAY_IN_PROGRESS is 0b.

REPLAY_IN_PROGRESS Rules:

- If REPLAY_IN_PROGRESS is 1b:
 - The Transmitter must not accept any new TLPs from the Transaction Layer.
 - REPLAY_IN_PROGRESS is cleared if either of the following conditions are true:
 - REPLAY_SCHEDULED_TYPE is STANDARD_REPLAY and all unacknowledged Flits in the TX Retry Buffer have been transmitted.
 - REPLAY_SCHEDULED_TYPE is SELECTIVE_REPLAY and Flit with Flit Sequence Number equal to TX_REPLAY_FLIT_SEQ_NUM has been transmitted.

CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS Rules

- When an Explicit Sequence Number Flit is transmitted:
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is incremented.
- When a non-Explicit Sequence Number Flit is transmitted:
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is set to 0b.
- Also see Replay Schedule Rule 0.

REPLAY_TIMEOUT_FLIT_COUNT Rules:

- When a Payload Flit or a NOP Flit is transmitted and the TX Retry Buffer is not empty:
 - REPLAY_TIMEOUT_FLIT_COUNT is incremented.
- When an Ack or Nak is received that causes a Flit stored TX Retry Buffer to be purged:
 - REPLAY_TIMEOUT_FLIT_COUNT is set to 0b.
- Also see Replay Schedule Rule 0.

NEXT_TX_FLIT_SEQ_NUM Rules

- After the Transmitter applies the Replay Command to a Payload Flit which is NOT being replayed from the TX Retry Buffer:
 - NEXT_TX_FLIT_SEQ_NUM is incremented.
- NEXT_TX_FLIT_SEQ_NUM does not change when sending any of the following:
 - An IDLE Flit
 - A NOP Flit
 - A Flit being replayed from the TX Retry Buffer

Receiver Rules

- If a Receiver has scheduled a Selective Nak Flit, it must continue to store non-NOP TLP bytes and Flit Sequence Number of subsequent Flits in the RX Retry Buffer.
 - After the Replay for a Selective Nak is received, received Flits must continue to be processed in order of Flit Sequence Number. The management of storage and processing of Flits received after the Selective Replay Flit is received is implementation specific
- See § Section 4.2.3.4.2.1.5 for Ack, Nak, and Discard rules.

IMPLICIT_RX_FLIT_SEQ_NUM Rules

- The value of IMPLICIT_RX_FLIT_SEQ_NUM must be updated before evaluating the rules in § Section 4.2.3.4.2.1.5
- IMPLICIT_RX_FLIT_SEQ_NUM does not change if ANY of the following are true:
 - An IDLE Flit is received.
 - An Explicit Sequence Number Flit is received with Flit Sequence Number 0.
 - Both of the following are true:
 - NON_IDLE_EXPLICIT_SEQ_NUM_FLIT_RCVD is 0b
 - Either of the following are true:
 - An invalid Flit is received.
 - A valid non-Explicit Sequence Number Flit is received.
 - Both of the following are true:
 - A valid NOP Flit is received with a non-explicit Flit Sequence Number.
 - Either of the following are true:

- NAK_WITHDRAWAL_ALLOWED is 0b
- NAK_WITHDRAWAL_ALLOWED is 1b and Prior Flit was Payload is 1b
- All of the following are true:
 - A valid Payload Flit with a non-explicit Flit Sequence Number is received.
 - NAK_WITHDRAWAL_ALLOWED is 1b
 - Prior Flit was Payload is 0b
- IMPLICIT_RX_FLIT_SEQ_NUM is incremented if both of the following are true:
 - NON_IDLE_EXPLICIT_SEQ_NUM_FLIT_RCVD is 1b
 - Any of the following are true:
 - A valid Payload Flit with a non-explicit Flit Sequence Number is received and NAK_WITHDRAWAL_ALLOWED is 0b.
 - A valid Payload Flit with a non-explicit Flit Sequence Number is received with Prior Flit was Payload set to 1b and NAK_WITHDRAWAL_ALLOWED is 1b.
 - A invalid Flit is received.
- IMPLICIT_RX_FLIT_SEQ_NUM is set to N if both of the following are true:
 - A valid non-IDLE Explicit Sequence Number Flit is received with Flit Sequence Number N.
 - $N \neq 0$.
- IMPLICIT_RX_FLIT_SEQ_NUM is decremented if ALL of the following are true:
 - A valid NOP Flit with a non-explicit Flit Sequence Number is received.
 - NAK_WITHDRAWAL_ALLOWED is 1b.
 - Prior Flit was Payload is 0b.

4.2.3.4.2.1.1 IDLE Flit Handshake Phase §

General Rules

- A Port enters this phase when the LTSSM enters Configuration.Idle or Recovery.Idle states.

Transmitter Rules

- The Transmitter must send IDLE Flits as required by the LTSSM rules.
- The Transmitter moves to the Sequence Number Handshake Phase when the LTSSM enters the L0 state.

Receiver Rules

- All received Flits are discarded.
- The Receiver moves to the Sequence Number Handshake Phase when two consecutive valid IDLE Flits have been received.

4.2.3.4.2.1.2 Sequence Number Handshake Phase §

General Rules

- Devices are permitted to perform Data Link Feature Exchange and Flow Control Initialization in this phase if the Data Link Control and Management State Machine is in the DL_Feature or DL_Init states, respectively.
- The Port transitions to the Normal Flit Exchange Phase when both of the following are true:

- The Port has transmitted 3 or more Ack Flits with non-zero Flit Sequence Numbers after having received one or more Explicit Sequence Number Flits with a non-zero Flit Sequence Number.
- The Port has transmitted 9 or more Explicit Sequence Number Flits with a non-zero Flit Sequence Number.
- If the Port is in this phase after sending 512 Flits with 1b/1b encoding or 256 Flits with 8b/10b or 128b/130b encoding, the Port must enter Recovery.

Transmitter Rules

Flit Replay Command Rules

- The Transmitter alternates between sending three consecutive Explicit Sequence Number Flit and one Ack Flit or Nak Flit while in this phase.
 - The following conditions are listed in order of priority.
 - A Transmitter must send an Explicit Sequence Number Flit if the following is true:
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS < 3.
 - A Transmitter must send a Standard Nak Flit if all of the following are true:
 - NAK_SCHEDULED is 1b.
 - NAK_SCHEDULED_TYPE is STANDARD_NAK.
 - The conditions for sending an Explicit Sequence Number Flit were not met.
 - A Transmitter must send a Selective Nak Flit if all of the following are true:
 - NAK_SCHEDULED is 1b.
 - NAK_SCHEDULED_TYPE is SELECTIVE_NAK.
 - The conditions for sending an Explicit Sequence Number Flit were not met.
 - The conditions for sending a Standard Nak Flit were not met.
 - A Transmitter must send an Ack Flit if all of the following are true:
 - The conditions for sending an Explicit Sequence Number Flit were not met.
 - The conditions for sending a Standard Nak Flit were not met.
 - The conditions for sending a Selective Nak Flit were not met.
- The Transmitter may send up to six consecutive Explicit Sequence Number Flits if the CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS counter is reset due to Replay Schedule Rule 0.

Flit Replay Transmit Rules

- The Transmitter must only begin replaying Flits from the TX Retry Buffer when sending an Explicit Sequence Number Flit and CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is 0b.
- If the Transmitter is replaying a Flit from the TX Retry Buffer, it must use the sequence number of the Flit from its TX Retry Buffer when sending an Explicit Sequence Number Flit.
- See § Section 4.2.3.4.2.1.7 for additional replay transmit rules.

Flit Sequence Number Rules

- When transmitting an Ack Flit or Nak Flit with a non-0 Flit Sequence Number:
 - The Flit Sequence Number is set to the value of TX_ACKNAK_FLIT_SEQ_NUM.
- When transmitting an Explicit Sequence Number Flit:
 - A NOP Flit must set Flit Sequence Number to NEXT_TX_FLIT_SEQ_NUM - 1.
 - A replayed Payload Flit must set Flit Sequence Number to the value stored for the Flit in the TX Retry Buffer.

- A non-replayed Payload Flit must set Flit Sequence Number to NEXT_TX_FLIT_SEQ_NUM.

Receiver Rules

- Refer to § Section 4.2.3.4.2.1.4 for Ack and Nak processing rules.
- Refer to § Section 4.2.3.4.2.1.5 for Ack and Nak scheduling rules.
- Refer to § Section 4.2.3.4.2.1.6 for Replay scheduling rules.

4.2.3.4.2.1.3 Normal Flit Exchange Phase §

Transmitter Rules

- While in this Phase, Explicit Sequence Number Flits are only sent according to the Flit Replay Command Rules defined in this section.
- If a Nak Flit is sent in this phase:
 - A minimum of three consecutive Nak Flits must be sent unless any of the following are true:
 - CONSECUTIVE_TX_NAK_FLITS is reset due to Replay Schedule Rule 0.
 - The transmission of Flits is interrupted by an exit from the L0 state.
 - The NAK_SCHEDULED flag is cleared.
- If an Explicit Sequence Number Flit is sent in this phase:
 - Exactly three consecutive Explicit Sequence Number Flits must be sent unless either of the following are true:
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is reset due to Replay Schedule Rule 0.
 - The transmission of Flits is interrupted by an exit from the L0 state.

Flit Replay Command Rules

- The following conditions are listed in order of priority.
- A Transmitter must send an Explicit Sequence Number Flit if all of the following are true:
 - Any of the following are true:
 - REPLAY_SCHEDULED is 1b.
 - REPLAY_IN_PROGRESS is 1b.
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS > 0.
 - All of the following are true⁶⁴:
 - REPLAY_SCHEDULED is 0b.
 - REPLAY_IN_PROGRESS is 0b.
 - NAK_IGNORE_FLIT_SEQ_NUM != 000h
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS < 3.
 - Either of the following are true:
 - CONSECUTIVE_TX_NAK_FLITS equals 0.
 - CONSECUTIVE_TX_NAK_FLITS > 2.
- A Transmitter must send a Standard Nak Flit if all of the following are true:
 - NAK_SCHEDULED is 1b.
 - NAK_SCHEDULED_TYPE is STANDARD_NAK.

64. This covers the case where a Nak is received with Flit Sequence Number = NEXT_TX_FLIT_SEQ_NUM - 1.

- The conditions for sending an Explicit Sequence Number Flit were not met.
- A Transmitter must send a Selective Nak Flit if all of the following are true:
 - NAK_SCHEDULED is 1b.
 - NAK_SCHEDULED_TYPE is SELECTIVE_NAK.
 - The conditions for sending an Explicit Sequence Number Flit were not met.
 - The conditions for sending a Standard Nak Flit were not met.
- A Transmitter must send an Ack Flit if all of the following are true:
 - The conditions for sending an Explicit Sequence Number Flit were not met.
 - The conditions for sending a Standard Nak Flit were not met.
 - The conditions for sending a Selective Nak Flit were not met.
- The Transmitter may send up to six consecutive Explicit Sequence Number Flits if the CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS counter is reset due to Replay Schedule Rule 0.

Flit Replay Transmit Rules

- The Transmitter must only begin replaying Flits from the TX Retry Buffer when sending an Explicit Sequence Number Flit and CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is 0b.
- If the Transmitter is replaying a Flit from the TX Retry Buffer, it must use the sequence number of the Flit from its TX Retry Buffer when sending an Explicit Sequence Number Flit.
- See § Section 4.2.3.4.2.1.7 for additional replay transmit rules.

Flit Sequence Number Rules

- When transmitting an Ack Flit or Nak Flit:
 - The Flit Sequence Number is set to the value of TX_ACKNAK_FLIT_SEQ_NUM.
- When transmitting an Explicit Sequence Number Flit:
 - A NOP Flit must set Flit Sequence Number to NEXT_TX_FLIT_SEQ_NUM - 1.
 - A replayed Payload Flit must set Flit Sequence Number to the value stored for the Flit in the TX Retry Buffer.
 - A non-replayed Payload Flit must set Flit Sequence Number to NEXT_TX_FLIT_SEQ_NUM.

CONSECUTIVE_TX_NAK_FLITS Rules

- When a Nak Flit is transmitted:
 - CONSECUTIVE_TX_NAK_FLITS is incremented.
- When a non-Nak Flit is transmitted:
 - CONSECUTIVE_TX_NAK_FLITS is set to 0b.
- Also see Replay Schedule Rule 0.

Receiver Rules

- Refer to § Section 4.2.3.4.2.1.4 for Ack and Nak processing rules.
- Refer to § Section 4.2.3.4.2.1.5 for Ack and Nak scheduling rules.
- Refer to § Section 4.2.3.4.2.1.6 for Replay scheduling rules.

4.2.3.4.2.1.4 Received Ack and Nak Processing §

- A received Ack or Nak with Flit Sequence Number 0 must be ignored.

- Processing of received Ack or Nak Flits must not interrupt a replay in progress.
- Handling an invalid Flit Sequence Number in a received Ack Flit or Nak Flit:
 - If:
 - A valid Ack Flit or Nak Flit is received with Flit Sequence Number N where one or more of the following are true:
 - $((\text{NEXT_TX_FLIT_SEQ_NUM} - 1) - N) \bmod 1023 > \text{MAX_UNACKNOWLEDGED_FLITS}$
 - $(N - \text{ACKD_FLIT_SEQ_NUM}) \bmod 1023 > \text{MAX_UNACKNOWLEDGED_FLITS}$
 - Then:
 - The received Ack or Nak is ignored.
 - A Data Link Protocol Error is logged in the receiving Port (see § Section 6.2).
- If a Receiver receives a valid Ack Flit or Nak Flit with Flit Sequence Number N, it must:
 - Purge all Flits stored the TX Retry Buffer that are older than and including the Flit with Flit Sequence Number N.
 - If $(N - \text{ACKD_FLIT_SEQ_NUM}) \bmod 1023 > 0$:
 - FLIT_REPLAY_NUM is cleared.
 - ACKD_FLIT_SEQ_NUM is set to N.
 - If the received Flit was an Ack Flit:
 - NAK_IGNORE_FLIT_SEQ_NUM is cleared to 000h.
 - If $(N - \text{TX_REPLAY_FLIT_SEQ_NUM}) \bmod 1023 < \text{MAX_UNACKNOWLEDGED_FLITS}$:
 - Set TX_REPLAY_FLIT_SEQ_NUM to 000h
 - Set REPLAY_SCHEDULED to 0b
 - If the received Flit was a Nak Flit:
 - If $N = \text{NEXT_TX_FLIT_SEQ_NUM} - 1$:
 - NAK_IGNORE_FLIT_SEQ_NUM is set to N.
 - NAK_IGNORE_FLIT_SEQ_NUM is cleared to 000h if all of the following are true:
 - A valid Nak Flit is received with Flit Sequence Number N.
 - $N \neq \text{NAK_IGNORE_FLIT_SEQ_NUM}$
 - $N \neq \text{NEXT_TX_FLIT_SEQ_NUM} - 1$
 - It is recommended that NAK_IGNORE_FLIT_SEQ_NUM is cleared to 000h if all of the following are true:
 - A valid Standard Nak Flit is received with Flit Sequence Number N.
 - $N == \text{NAK_IGNORE_FLIT_SEQ_NUM}$
 - REPLAY_SCHEDULED_TYPE is SELECTIVE_REPLAY
 - $\text{TX_REPLAY_FLIT_SEQ_NUM} == N + 1$
 - Schedule a replay as necessary, following the Flit Replay Scheduling rules in § Section 4.2.3.4.2.1.6 .
 - The value of NAK_IGNORE_FLIT_SEQ_NUM must be updated before evaluating the rules in § Section 4.2.3.4.2.1.6 .

65. Flit Discard 0 is the preferred behavior in this scenario. Nak Schedule 2 is allowed but is less performant.

```

}
}

```

Nak Schedule 0

- The received Flit is discarded.
- NAK_WITHDRAWAL_ALLOWED is set to 1b.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Nak Schedule 1

- The received Flit is discarded.
- NAK_SCHEDULED is set to 1b.
- TX_ACKNAK_FLIT_SEQ_NUM is set to NEXT_EXPECTED_RX_FLIT_SEQ_NUM - 1.
- NAK_SCHEDULED_TYPE is set to STANDARD_NAK.
- NAK_WITHDRAWAL_ALLOWED is cleared.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Nak Schedule 2

- The TLP Bytes of the received Flit are discarded.
- TX_ACKNAK_FLIT_SEQ_NUM is set to NEXT_EXPECTED_RX_FLIT_SEQ_NUM - 1.
- NAK_SCHEDULED is set to 1b.
- NAK_SCHEDULED_TYPE is set to STANDARD_NAK.
- RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM is set to 000h.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Nak Schedule 3

- If NAK_SCHEDULED is 0b
 - NAK_SCHEDULED is set to 1b.
 - NAK_SCHEDULED_TYPE is set to SELECTIVE_NAK
 - TX_ACKNAK_FLIT_SEQ_NUM is set to NEXT_EXPECTED_RX_FLIT_SEQ_NUM - 1.
- Store the Received Flit in the RX Retry Buffer.
- RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM is set to IMPLICIT_RX_FLIT_SEQ_NUM.
- NEXT_RX_FLIT_SEQ_NUM_TO_STORE is incremented.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Nak Schedule 4

- The TLP Bytes of the received Flit that cannot be stored in the RX Retry Buffer are discarded.
- If the Receiver chooses to continue with the Selective Nak:
 - RX_RETRY_BUFFER_OVERFLOW is set to 1b.
 - RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM does not change.
- If the Receiver chooses to change the Selective Nak to a Standard Nak:
 - NAK_SCHEDULED_TYPE is set to STANDARD_NAK.
 - TX_ACKNAK_FLIT_SEQ_NUM is set to NEXT_EXPECTED_RX_FLIT_SEQ_NUM - 1.
 - All Flits stored in the RX Retry Buffer are purged.
 - RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM is set to 000h.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Nak Schedule 5

- NAK_SCHEDULED remains 1b.
- NAK_SCHEDULED_TYPE is set to STANDARD_NAK.
- TX_ACKNAK_FLIT_SEQ_NUM is set to RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM.
- RX_RETRY_BUFFER_OVERFLOW is cleared.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM is set to RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM + 1.
- RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM is set to 000h.

Nak Schedule 6

- The received Flit is discarded.
- NAK_SCHEDULED remains 1b.
- NAK_SCHEDULED_TYPE is set to STANDARD_NAK.
- RX_RETRY_BUFFER_OVERFLOW is cleared.
- TX_ACKNAK_FLIT_SEQ_NUM is set to NEXT_EXPECTED_RX_FLIT_SEQ_NUM - 1.
- All Flits stored in the RX Retry Buffer are purged.
- RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM is set to 000h.

Nak Schedule 7

- A Receiver is permitted to change a scheduled Selective Nak of TX_ACKNAK_FLIT_SEQ_NUM to a Standard Nak of TX_ACKNAK_FLIT_SEQ_NUM for any reason.

Ack Schedule 0

- TX_ACKNAK_FLIT_SEQ_NUM is set to NEXT_EXPECTED_RX_FLIT_SEQ_NUM.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM is incremented.

Ack Schedule 1

- NAK_SCHEDULED is cleared.
- TX_ACKNAK_FLIT_SEQ_NUM is set to IMPLICIT_RX_FLIT_SEQ_NUM.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM is set to IMPLICIT_RX_FLIT_SEQ_NUM + 1.

Ack Schedule 2

- NAK_SCHEDULED is cleared.
- If RX Retry Buffer is empty:
 - TX_ACKNAK_FLIT_SEQ_NUM is set to IMPLICIT_RX_FLIT_SEQ_NUM.
 - NEXT_EXPECTED_RX_FLIT_SEQ_NUM is set to IMPLICIT_RX_FLIT_SEQ_NUM + 1.
- If RX Retry Buffer is NOT empty:
 - TX_ACKNAK_FLIT_SEQ_NUM is set to RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM.
 - NEXT_EXPECTED_RX_FLIT_SEQ_NUM is set to RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM + 1.
- RX_RETRY_BUFFER_LAST_FLIT_SEQ_NUM is set to 000h.

Flit Discard 0

- The TLP Bytes of the received Flit are discarded.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Flit Discard 1

- The received Flit is discarded.
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.

Flit Discard 2

- The received Flit is discarded.
- A Data Link Protocol Error is logged in the receiving Port (see § Section 6.2).
- NEXT_EXPECTED_RX_FLIT_SEQ_NUM does not change.
- NAK_WITHDRAWAL_ALLOWED is cleared.

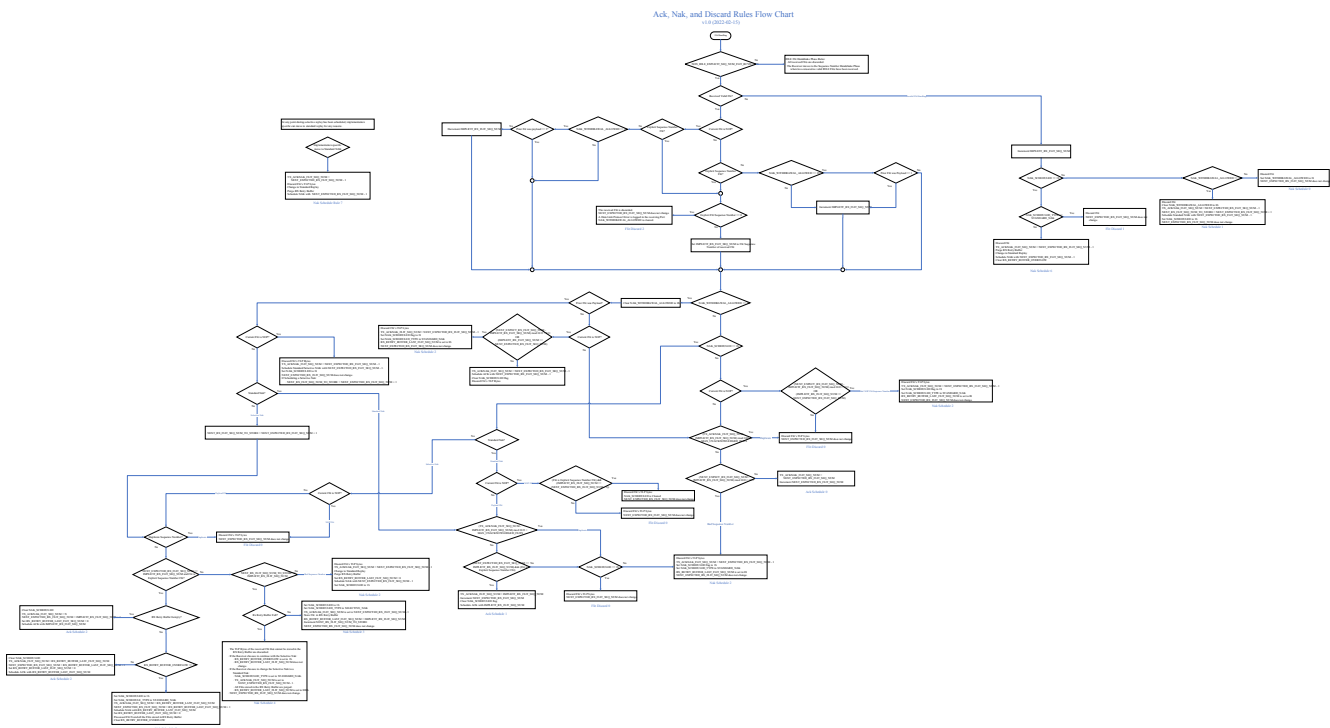

Figure 4-33 Flit Ack, Nak, and Discard Rules Flow Chart (Zoom-In to View) §

4.2.3.4.2.1.6 Flit Replay Scheduling §

Replay Schedule Rule 0

Replay Timeout

- If all of the following are true:
 - REPLAY_TIMEOUT_FLIT_COUNT \geq 1500⁶⁶

- REPLAY_SCHEDULED is 0b.
- REPLAY_IN_PROGRESS is 0b.
- Then:
 - REPLAY_SCHEDULED is set to 1b.
 - REPLAY_SCHEDULED_TYPE is set to STANDARD_REPLAY.
 - TX_REPLAY_FLIT_SEQ_NUM is set to (ACKD_FLIT_SEQ_NUM + 1).
 - CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is set to 0b.⁶⁷
 - CONSECUTIVE_TX_NAK_FLITS is set to 0b.⁶⁸
 - REPLAY_TIMEOUT_FLIT_COUNT is set to 0b.
 - A Replay Timer Timeout error is logged in the Port (see § Section 6.2).

Replay Schedule Rule 1

Received Nak for Payload Flit.

- If all of the following are true:
 - Received a valid Nak Flit with Flit Sequence Number N.
 - A Payload Flit with Flit Sequence Number N + 1 is stored in the TX Retry Buffer.
 - REPLAY_SCHEDULED is 0b.
 - REPLAY_IN_PROGRESS is 0b.
 - Either of the following are true:
 - NAK_IGNORE_FLIT_SEQ_NUM != N.
 - The Nak Ignore Window has not been started or has elapsed.
- Then:
 - REPLAY_SCHEDULED is set to 1b.
 - TX_REPLAY_FLIT_SEQ_NUM is set to N + 1.
 - NAK_IGNORE_FLIT_SEQ_NUM is set to N.
 - If the received Flit is Standard Nak Flit:
 - REPLAY_SCHEDULED_TYPE is set to STANDARD_REPLAY.
 - If the received Flit is a Selective Nak Flit:
 - REPLAY_SCHEDULED_TYPE is set to SELECTIVE_REPLAY.

Replay Schedule Rule 2

Received Standard Nak after Selective Nak for Payload Flit.

- If all of the following are true:
 - Received a valid Standard Nak Flit with Flit Sequence Number N.
 - N+1 equals TX_REPLAY_FLIT_SEQ_NUM.
 - REPLAY_SCHEDULED is 1b.
 - REPLAY_IN_PROGRESS is 0b.
 - REPLAY_SCHEDULED_TYPE is SELECTIVE_REPLAY.
- Then:
 - REPLAY_SCHEDULED is set to 1b.

66. The max Ordered set insertion interval in § Table 4-21 is 748. 1500 is 748*2 rounded up.

67. CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS is cleared to allow the Transmitter to begin replaying Flits right away and avoid overflowing the TX Retry Buffer sending NOP Flits while waiting to send another Explicit Sequence Number Flit to begin the replay.

68. Same reason as clearing CONSECUTIVE_TX_EXPLICIT_SEQ_NUM_FLITS above.

- TX_REPLAY_FLIT_SEQ_NUM does not change.
- REPLAY_SCHEDULED_TYPE is set to STANDARD_REPLAY.

4.2.3.4.2.1.7 Flit Replay Transmit Rules §

Flit Replay Transmit Rule 0

Standard Replay Scenario.

- If all of the following conditions are true:
 - REPLAY_SCHEDULED is 1b.
 - REPLAY_IN_PROGRESS is 0b.
 - REPLAY_SCHEDULED_TYPE is STANDARD_REPLAY.
 - Either of the following are true:
 - The transmitter is in the Sequence Number Handshake Phase.
 - CONSECUTIVE_TX_NAK_FLITS is either 0 or greater than 2.
 - Either of the following are true:
 - Data rate is 64.0 GT/s and FLIT_REPLAY_NUM < 111b.
 - Data rate <= 32.0 GT/s and FLIT_REPLAY_NUM < 110b.
- Then:
 - The Transmitter must replay all unacknowledged Flits from the TX Retry Buffer beginning with the Flit containing Flit Sequence Number TX_REPLAY_FLIT_SEQ_NUM.
 - If the data rate is 64.0 GT/s:
 - FLIT_REPLAY_NUM is incremented by 1.
 - If the data rate <= 32.0 GT/s:
 - FLIT_REPLAY_NUM is incremented by 2^{69} .
 - REPLAY_IN_PROGRESS is set to 1b.
 - REPLAY_SCHEDULED is set to 0b.

Flit Replay Transmit Rule 1

Selective Replay Scenario.

- If all of the following conditions are true:
 - REPLAY_SCHEDULED is 1b.
 - REPLAY_IN_PROGRESS is 0b.
 - REPLAY_SCHEDULED_TYPE is SELECTIVE_REPLAY.
 - Either of the following are true:
 - The transmitter is in the Sequence Number Handshake Phase.
 - CONSECUTIVE_TX_NAK_FLITS is either 0 or greater than 2.
 - Either of the following are true:
 - Data rate is 64.0 GT/s and FLIT_REPLAY_NUM < 111b.
 - Data rate <= 32.0 GT/s and FLIT_REPLAY_NUM < 110b.
- Then:

69. Replays should happen less often at speeds lower than 64.0 GT/s. We increment FLIT_REPLAY_NUM by 2 so that the Replay Rollover will happen after fewer Replays.

- The Transmitter must replay the Flit from the TX Retry Buffer which contains the Flit Sequence Number that matches TX_REPLAY_FLIT_SEQ_NUM.
- If the data rate is 64.0 GT/s:
 - FLIT_REPLAY_NUM is incremented by 1.
- If the data rate \leq 32.0 GT/s:
 - FLIT_REPLAY_NUM is incremented by 2.⁷⁰
- REPLAY_IN_PROGRESS is set to 1b.
- REPLAY_SCHEDULED is set to 0b.

Flit Replay Transmit Rule 2

Replay Rollover Scenario.

- If all of the following conditions are true:
 - REPLAY_SCHEDULED is 1b.
 - REPLAY_IN_PROGRESS is 0b.
 - Either of the following are true:
 - Data rate is 64.0 GT/s and FLIT_REPLAY_NUM equals 111b.
 - Data rate \leq 32.0 GT/s and FLIT_REPLAY_NUM \geq 110b.
- Then:
 - If the data rate is 64.0 GT/s:
 - FLIT_REPLAY_NUM is incremented by 1 (causing a rollover to 000b).
 - If the data rate \leq 32.0 GT/s:
 - FLIT_REPLAY_NUM is incremented by 2 (causing a rollover to 000b or 001b).
 - A REPLAY_NUM Rollover error is logged in the Port (see § Section 6.2).
 - The Port must enter Recovery.

70. Previous versions of this specification had this as increment by 1. This remains permitted, although not optimal, behavior.

IMPLEMENTATION NOTE:

FLIT ACK/NAK/REPLAY EXAMPLE §

Consider two devices A and B connected through a Retimer, as shown in § Figure 4-34.

1. Both Device A and Device B are in the Normal Flit Exchange Phase
2. B receives valid Payload Flits 1 through 10 from A. B sends Acks for those Flits back to A. (Ack Schedule 0)
3. B receives an invalid NOP Flit 10⁷¹ and sets NAK_WITHDRAWAL_ALLOWED to 1b. (Nak Schedule 0)
4. B then receives a valid Flit 11 with Prior Flit was Payload set to 0b, indicating that prior Flit was a NOP Flit. B sends an Ack with Flit Sequence Number 11 to A.
 - NAK_WITHDRAWAL_ALLOWED is cleared and a Nak is never sent for the invalid NOP Flit 10.
5. B then receives an invalid Payload Flit 12 and sends sets NAK_WITHDRAWAL_ALLOWED to 1b. (Nak Schedule 0)
6. B then receives a valid Flit 13 that indicates that Flit 12 was a Payload Flit, and sends a Selective Nak Flit with Flit Sequence Number 11, requesting A to Replay only Flit 12. (Nak Schedule 1)
 - B will then send a minimum of three consecutive Selective Nak Flits with Flit Sequence Number 11.
 - If B was sending Explicit Sequence Number Flits when the Nak of invalid Flit 12 was scheduled, it would have held off sending the Nak Flit until it had finished sending 3 consecutive Explicit Sequence Number Flits (Replay Command Rules in Normal Flit Exchange Phase).
 - The choice of a Selective Nak by B is an optimization in this case. B has enough space in its RX Retry Buffer to store the subsequent Flits.
 - If B were to receive an invalid Flit with a Selective Nak outstanding, it would be required to change the outstanding Selective Nak to a Standard Nak. (Nak Schedule 6)
 - B is also permitted to change the outstanding Selective Nak to a Standard Nak for any implementation specific reason. (Nak Schedule 7)
7. After B sends 3 consecutive Nak Flits with Flit Sequence Number 11, B will continue following the Replay Command Rules in Normal Flit Exchange Phase to determine whether to send Nak Flits or Explicit Sequence Number Flits.
8. In the time it took for A to receive the Selective Nak of Flit 12 and schedule a Replay of Flit 12, valid Payload Flits 13 and 14 and NOP Flit 14 were received by B. B stores Payload Flits 13 and 14 in its RX Retry Buffer. The TLP Bytes of NOP Flit 14 are discarded and the Flit is not stored in the RX Retry Buffer (Flit Discard 0).
9. B then receives replayed Flit 12 from A and processes Flit 12 as well as Payload Flits 13 and 14 that were stored in the B's RX Retry Buffer.
 - Note that Payload Flits 12 and 15 and NOP Flit 15 are all sent with explicit Flit Sequence Numbers in adherence to the Replay Command Rules in Normal Flit Exchange Phase
10. Next, B receives valid Payload Flit 15, and then invalid NOP Flit 15. B sets NAK_WITHDRAWAL_ALLOWED to 1b.
11. B then receives invalid Flit 16, and since there's no way for B to know that the previous invalid Flit was a NOP Flit, the Nak can't be withdrawn and B sends a Standard Nak with Flit Sequence Number 15.
 - Note that B cannot send a Selective Nak since two consecutive invalid Flits were received.

12. B then receives valid Payload Flits 17 and 18, but since B has a Standard Nak outstanding, the TLP Bytes of these Flits are discarded (Flit Discard 0).
13. A then replays all unacknowledged Flits from its TX Retry Buffer (Flits 16, 17, and 18), which B receives as valid Flits and Acks accordingly.

Figure 4-34 Flit Ack/Nak/Replay Example §

71. NOP Flits do not consume a Flit Sequence Number and just use the Flit Sequence Number of the last non-replay Payload Flit sent.

IMPLEMENTATION NOTE:

TRANSMITTER THROTTLING AFTER SELECTIVE REPLAY §

In some situations, it will reduce link latency if the transmitter throttles its Flit transmission rate after sending a Selective Replay Flit.

When the receiver issues a Selective Nak and is waiting for the selective replay, it stores valid Payload Flits in an RX retry buffer and processes these Flits after the selective replay is received. Payload Flits that arrive after the selective replay must also be stored in the RX retry buffer. All Payload Flits are processed in sequence number order.

Without transmitter throttling, this RX retry buffer adds latency to the receive path since all the entries must be consumed in order. Latency can be reduced and this performance impact can be mitigated if the transmitter throttles Flit transmission earlier allowing the RX retry buffer to drain. This early transmitter throttling does not affect overall performance – the TLPs that get delayed at the transmitter would have been delayed at the receiver. Performing early throttling at the transmitter allows the RX retry buffer to drain so that subsequent TLPs have reduced latency.

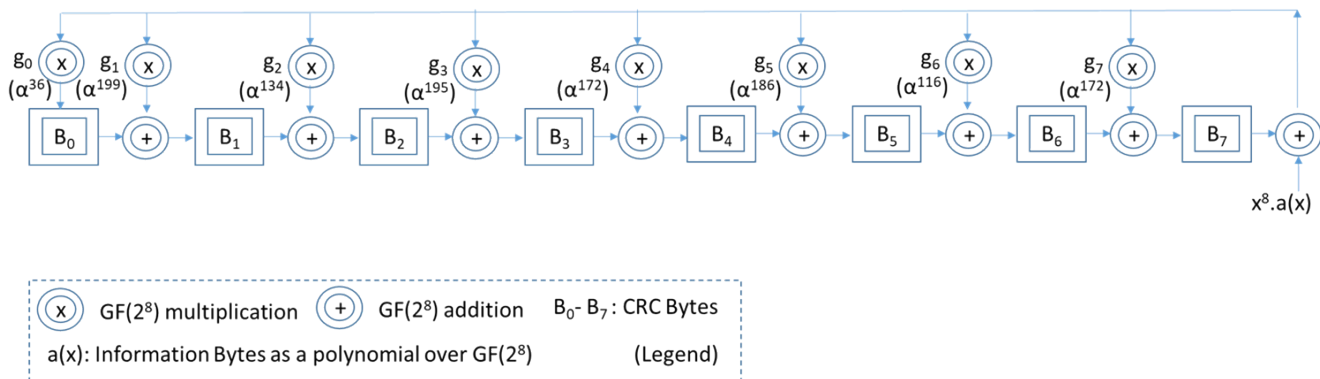

Throttling is only needed when the Link is operating at the drain rate of the receiver. If the Link is operating at a reduced width (e.g., due to L0p), throttling may not be needed as the RX retry buffer drain rate may be faster than the Link rate.

To compute how to throttle, the Transmitter can assume that the initial link width is the drain rate of the receiver. On receiving a selective Nak, the Transmitter can compute the number of Payload Flits in the Receiver's RX retry buffer (or on the way to that buffer) since it knows how many Payload Flits are currently in its TX retry buffer. The transmitter should throttle and/or enforce a certain bandwidth efficiency (i.e., restrict the number of NOP TLPs in a Payload Flit) in each new Payload Flit it transmits from its Transaction Layer to allow the Receiver's RX retry buffer to drain.

For example, suppose a x8 Link receives a selective Nak for Flit number X and the Transmitter has sent 4 Payload Flits after it initially sent Flit number X. In this case, the transmitter should throttle its upper layers to create a 4 Flit "bubble". For a x8 Link, Flits are 16 Symbols and SKP Ordered Sets are 32 Symbols so this "bubble" is either 4 NOP Flits, 2 NOP Flits and 1 SKP Ordered Set, or 2 SKP Ordered Sets. One mechanism to implement the throttling is for the transmitter to enforce <Y% NOP TLPs (e.g., Y = 25) in its Payload Flits until it has sent the "bubble" (if TLPs are constantly being transmitted this could take 2 SKP Ordered Sets).

4.2.3.4.3 CRC Bytes in Flit §

The CRC generator polynomial, defined over GF (2⁸), is $g(x) = (x+\alpha)(x+\alpha^2)\dots(x+\alpha^8)$, where α is the root of the primitive polynomial of degree 8: $x^8+x^5+x^3+x+1$. Thus, $g(x) = x^8 + \alpha^{172}x^7 + \alpha^{116}x^6 + \alpha^{186}x^5 + \alpha^{172}x^4 + \alpha^{195}x^3 + \alpha^{134}x^2 + \alpha^{199}x + \alpha^{36}$. § Figure 4-35 demonstrates how CRC bytes are generated for the Transmit as well as Receive side. On the Receive side the generated CRC bytes are compared against the received CRC bytes (after the FEC decode/ correct) and any mismatch represents an uncorrectable error.

Bytes 0-241 form the input $a(x)$ whereas B_0 - B_7 represent CRC0-crc7

Figure 4-35 CRC generation/ checking in Flit §

The CRC generator using MATLAB code to output the generator matrix, the generator matrix, as well as the RTL code is provided in § Appendix K. . The CRC bytes are generated by 242 Bytes of Data * Gen Matrix. Thus, Data is 1x1936 bits, Gen matrix is 1936x64 bits. Data is arranged from MSB to LSB – [(241,7), (241,6), (241,5), (241,4) (0,7), (0,6),(0,5),(0,4),(0,3),(0,2),(0,1),(0,0)] where (x,y) is yth bit of xth byte. The generator matrix appears in § Appendix K. and must be considered the standard to implement the CRC during encode and decode. Any pipelined implementation must match this mechanism. The code is provided for the Transmit side. It takes 242 Bytes as input and generates the 8B of CRC. On the Receive side, after the ECC decode/ correction, the first 242 Bytes of the Flit will be used to generate the expected 8 Bytes of CRC and each of these 8 Bytes will be compared against the received 8B of CRC. Any mismatch results in the Flit being declared not Valid and a replay requested, if needed, as described earlier.

4.2.3.4.4 ECC Bytes in Flit §

The FEC code is a 3-way interleaved, as described before, where the ECC Symbols are defined over GF(2⁸). Thus, three consecutive Bytes in a wire belong to three different ECC groups, as shown by different colors in § Table 4-10 through § Table 4-14. Thus, any burst of length ≤ 16 in a wire is guaranteed not to impact more than one Symbol in a code word which is capable of correcting single byte errors in an effort to minimize the FEC latency.

A sample RTL code for the FEC is provided in § Appendix J. . The rest of this section describes the construction of the FEC code. The sample RTL in the appendix is the reference should any confusion arise out of the description here. While an implementation may follow a different approach (e.g., pipelining), it must still match the RTL sample results for all permutations of values in the bytes both for the encoder as well as the decoder function.

Let α be the root of a primitive polynomial $x^8+x^4+x^3+x^2+1$ (represented as 0x1D). Hence, $\alpha^8 = \alpha^4 + \alpha^3 + \alpha^2 + 1$ which can also be represented as {0001_1101}. Thus, each 8-bit symbol (over GF(2⁸)) can be expressed as a polynomial as powers of alpha (1 through 254) or as a degree 8 polynomial. We calculate powers of α along with an 8-bit representation as follows: Should be: α^0 (=1): {0000_0001}, α^1 : {0000_0010}, ..., α^7 : {1000_0000}, α^8 : {0001_1101}, ... $\alpha^{255} = 1$. Thus, we get 255 distinct numbers as powers of α (all 0s is not a power of α), as shown in § Figure 4-36. The log function is given in § Figure 4-37 (which is basically the inverse of constructing the power of α from a given 8-bit non-zero Syndrome which will be used for error correction). The H matrix consists of two parts: Horizontal Parity and Check bits, as shown in § Figure 4-38 and § Figure 4-39. The Horizontal Parity is the bit-wise XORs of Symbols (see § Equation 4-1). The Check bits (see § Equation 4-2) is similar to a CRC calculation represented as follows:

$$P = \sum_{i=0}^{83} B_i$$

Equation 4-1 Parity bytes §

$$C = \sum_{i=0}^{83} B_i \times \alpha^{(84-i)}$$

Equation 4-2 Check bytes §

Check Bits

Row Parity [N-3:0]

Powers of alpha for the check bits for Bytes 0 to 84

Figure 4-39 Weight of check bits for different Bytes/bits [§]

The Transmitter has to calculate B_{N-1} (horizontal parity) and B_{N-2} (Check Symbol) during encoding from the remaining (N-2) Bytes, as described above. The same mechanism will be used to compute the corresponding two Syndrome bytes at the Receiver. $N = 86$. However, only one of the three groups has 86B in its code word, whereas the other two have 85 Bytes each to form the 256B Flit. This is resolved by forcing $B_{83} = 0$ for the information part so that two groups that have 85 Bytes each effectively become 86B with 84B as information (the last Byte being 0) and two Bytes of ECC. The mapping of the Flit Byte i to an ECC group and the Byte-offset within the group can be derived as follows:

For $0 \leq i \leq 249$,
 Byte i in Flit is mapped to ECC Group $i \bmod 3$
 with Byte Offset $\text{floor}(i/3)$
 ECC Group 1 Byte Offset 83 is 0
 ECC Group 2 Byte Offset 83 is 0
 For $250 \leq i \leq 255$ (the ECC Bytes),
 Byte i in Flit is mapped to ECC Group $(i-249) \bmod 3$
 with Byte Offset $\text{ceil}(i/3)$

Thus:

- Byte 0 of Flit maps to ECC Group 0, Byte offset 0;
- Byte 1 of Flit maps to ECC Group 1, Byte offset 0;
- Byte 2 of Flit maps to ECC group 2, Byte offset 0;
- Byte 3 of Flit maps to ECC Group 0, Byte offset 1;
- Byte 4 of Flit maps to ECC Group 1, Byte offset 1;
- ...
- Byte 248 maps to ECC group 2, Byte Offset 82;
- Byte 249 maps to ECC group 0, Byte offset 83.
- ECC group 1, Byte offset 83 is 00h.
- ECC group 2, Byte offset 83 is 00h.

The ECC Bytes are then allocated as:

- Bytes 250 and 253 of the Flit maps to ECC Group 1, Byte offsets 84 and 85 respectively;
- Bytes 251 and 254 of the Flit maps to ECC Group 2, Byte offsets 84 and 85 respectively; and
- Bytes 252 and 255 of the Flit maps to ECC Group 0, Bytes offsets 84 and 85 respectively.

The basic idea is that horizontal parity (Synd_Parity) identifies the bits in the Symbol (or Byte) that has flipped and the check bits (Synd_Check) identifies the Symbol number that has the error. Looking at the expanded bit arrangement, one can see that knowing the bit positions one can reverse map the column number. § Figure 4-40 shows the ECC decode function. The Syndrome Parity is the XOR of $B_0..B_{83}$ and B_{85} (Synd_Parity). The Syndrome Check (Synd_Check) is calculated by computing the expected B_{84} from $B_0..B_{83}$ received and XORing with received B_{84} . Once the two Syndrome Symbols (Bytes) are calculated, the following steps are taken:

Synd_Check	Synd_Parity	Description
= 00h	= 00h	No error
= 00h	≠ 00h	Error in B_{85} : Corrected $B_{85} = B_{85} \wedge \text{Synd_Parity}$
≠ 00h	= 00h	Error in B_{84} : Corrected $B_{84} = B_{84} \wedge \text{Synd_Check}$
≠ 00h	≠ 00h	Follow the log table for Synd_Check, Synd_Parity and then follow the modulo subtraction +1 logic to identify the failing column number. It is possible that we point to a non-existing column, in that case it is an uncorrectable error. Once the column number is known, we can correct the Symbol and the corresponding CRC correction (if applicable)

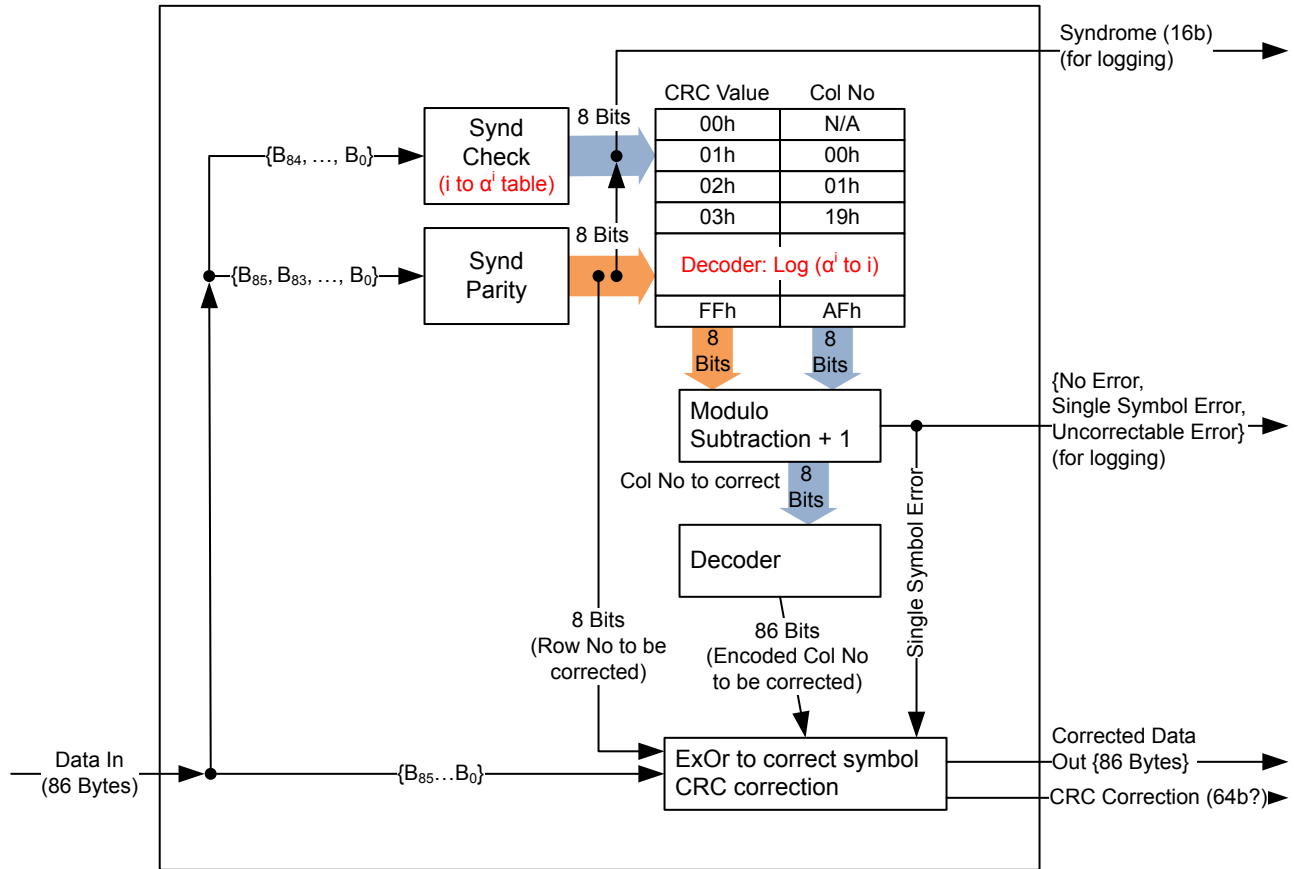

Figure 4-40 ECC Decoder function §

The Receive side check is as follows on the 256B flit (as shown in § Figure 4-41). Each of the three ECC decoders, performs correction and error reporting as needed. In the final stage of CRC check, a decision is made whether the received flit can be accepted or retried.

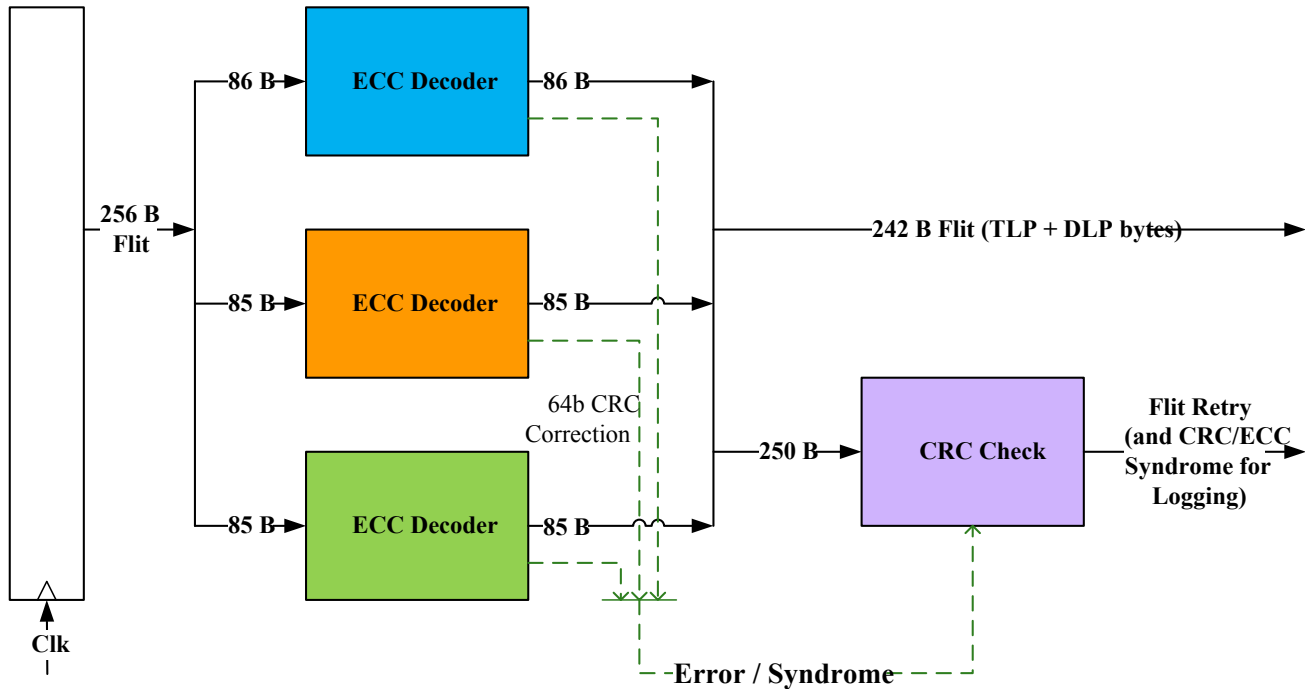

Figure 4-41 3-way ECC decode followed by CRC check of flit on the Receive side §

4.2.3.4.5 Ordered Set insertion in Data Stream in Flit Mode §

For Data Rates of 2.5 GT/s or 5.0 GT/s, the SKP Ordered Set insertion interval does not change (e.g., between 1180 and 1538 Symbols), but occurs at the Flit boundary. The other Ordered Sets that can occur with up-size or down-size with L0p is provided in § Section 4.2.6.7 .

For Data Rates of 8.0 GT/s and above, the following rules apply:

- A Control SKP Ordered Set must immediately follow the SDS Ordered Set sequence marking the start of the Data Stream, irrespective of when the prior Control SKP Ordered Set was transmitted.
- Once the Data Stream has started, an Ordered Set must be transmitted in fixed intervals, as defined § Table 4-21, as follows:
 - If the Data Stream will continue, a SKP Ordered Set must be transmitted on all the active (or to be activated) Lanes.
 - On an up-size with L0p: The Lanes that will be activated to join the active Lanes, an SDS Ordered Set must be transmitted on all the Lanes that will be activated (not in those that are already active) just prior to sending the SKP Ordered Set across all the wider Link, after which Flits will be sent on the wider Link
 - Else If the Link will enter a low-power state, an EIOSQ must be transmitted on all the active Lanes
 - Else (the Link needs to enter Recovery): An EIEOS must be transmitted on all the configured Lanes of the Link
 - If the Link enters Recovery, the appropriate SKP Ordered Set must be transmitted immediately after the first Ordered Set (EIEOS).

Table 4-21 Ordered Set insertion interval once Data Stream starts in terms of number of Flits §

Link Width and Clocking Modes	x16	x8	x4	x2	x1
Common Clock/SRNS Mode with 1b/1b encoding	748	374	187	93	46
Common Clock/SRNS Mode with 128b/130b encoding	374	187	93	46	23
SRIS Mode with 1b/1b encoding	74	37	18	9	4
SRIS Mode with 128b/130b encoding	37	18	9	4	2

IMPLEMENTATION NOTE: CONSECUTIVE SKP ORDERED SETS IN FLIT MODE §

Two consecutive SKP Ordered Sets in a Data Stream in Flit Mode are always equidistant for a given width and clocking mode when either 1b/1b encoding or 128b/130b encoding is used. For example, for a x1 Link in SRIS Mode with 128b/130b encoding, a SKP Ordered Set is always sent after two Flits, which will occupy 32 Data Blocks. However, the same spacing cannot be guaranteed with 8b/10b encoding, as the SKPs are “scheduled” every 1180 to 1583 Symbol times in non-SRIS mode and less than 154 Symbol times in SRIS mode. For example, a x1 Link in SRIS mode with 8b/10b encoding sends an average of 1.66 (=256/154) SKP Ordered Sets after every Flit (256 Symbols): sometimes it sends one SKP Ordered Set after every Flit and other times it sends two back-to-back SKP Ordered Sets.

4.2.4 Link Equalization Procedure for 8.0 GT/s and Higher Data Rates §

The Link equalization procedure enables components to adjust the Transmitter and the Receiver setup of each Lane to improve the signal quality and meet the requirements specified in § Chapter 8. , when operating at 8.0 GT/s and higher data rates. All the Lanes that are associated with the LTSSM (i.e., those Lanes that are currently operational or may be operational in the future due to Link Upconfigure) must participate in the equalization procedure. The procedure must be executed during the first data rate change to any data rate at 8.0 GT/s or above, unless all components in the Link have advertised that no equalization is needed. Components must arrive at the appropriate Transmitter setup for all the operating conditions and data rates that they will encounter in the future when LinkUp=1b. Components must not require that the equalization procedure be repeated at any data rate for reliable operation, although there is provision to repeat the procedure. Components must store the Transmitter setups that were agreed to during the equalization procedures and use them for future operation at 8.0 GT/s and higher data rates. Components are permitted to fine-tune their Receiver setup even after the equalization procedure is complete as long as doing so does not cause the Link to be unreliable (i.e., does not meet the requirements in § Chapter 8.) or go to Recovery.

The Link equalization procedure is not required for any data rates and can be completely bypassed if all components in the Link have advertised that no equalization is needed in its TS1/TS2 Ordered Sets or Modified TS1/TS2 Ordered Sets (see § Table 4-25, § Table 4-26, and § Table 4-27). A component may choose to advertise that it does not need equalization at any rates above 5.0 GT/s if it supports 32.0 GT/s or higher data rates and can either operate reliably with equalization settings stored from a prior equalization procedure or does not need equalization for reliable operation.

The equalization procedure can be initiated either autonomously or by software. It is strongly recommended that components use the autonomous mechanism for all the data rates above 5.0 GT/s that they intend to operate in. However, a component that chooses not to participate in the autonomous mechanism for all the data rates above 5.0 GT/s must have its associated software ensure that the software based mechanism is applied to the data rates above 5.0 GT/s where the autonomous mechanism was not applied, prior to operating at that data rate.

Normally, equalization is performed at a higher data rate only if equalization has successfully completed at all lower data rates above 5.0 GT/s. For example, a Link will complete equalization successfully at 8.0 GT/s, followed by 16.0 GT/s, followed by 32.0 GT/s, followed by 64.0 GT/s. However, an optional mechanism to begin the equalization procedures at the highest NRZ rate supported, 32.0 GT/s, is permitted if all components support data rates of 32.0 GT/s or higher and the mechanism is supported by all components in the Link, as advertised in the TS1/TS2 Ordered sets or Modified TS1/TS2 Ordered Sets. When this optional mechanism is enabled and successfully negotiated between the components, equalization is not performed the 8.0 GT/s and 16.0 GT/s data rates; the equalization procedures are performed at all common data rates above 16.0 GT/s beginning with the 32.0 GT/s data rate. For all the data rates above 5.0 GT/s where equalization is not performed (specifically 8.0 GT/s and 16.0 GT/s), the expectation is that the Link will not operate at those data rates and the components will not advertise those data rates (neither 8.0 GT/s nor 16.0 GT/s) as the highest data rate supported. For example, a Link may train to L0 in 2.5 GT/s, enter Recovery and perform equalization at 32.0 GT/s, and then re-enter Recovery and perform equalization at 64.0 GT/s, skipping equalization at 8.0 GT/s and 16.0 GT/s. In this case, the intended data rates of operation of the Link are 2.5 GT/s, 5.0 GT/s, 32.0 GT/s, or 64.0 GT/s. If any of the equalization procedures attempted at 32.0 GT/s or 64.0 GT/s is unsuccessful even after re-equalization attempts and the Link needs to equalize at lower data rates, the Downstream Port must stop advertising Equalization Bypass to Highest NRZ Rate Support and ensure that the Link returns to operation at 2.5 GT/s or 5.0 GT/s. The required equalization procedures are then performed as they would have been if the optional mechanism to skip over equalization to the highest common data rate(s) was never supported. If the equalization procedure at the highest NRZ rate supported is initially successful but the Link is not able to operate reliably at that data rate, the Downstream Port is permitted to initiate a speed change to any lower data rate followed by an equalization procedure at that rate (when necessary). The requirements of § Table 4-22 must be followed. The Upstream Port must disable Equalization Bypass to Highest NRZ Rate Support as soon as an equalization procedure at the 8.0 GT/s data rate is performed. If the equalization procedure at the lower data rates is driven by software, it must set the Equalization Bypass to Highest NRZ Rate Disable and No Equalization Needed Disable register bits to 1b each; set the target Link speed such that the Link will be operational at 2.5 GT/s or 5.0 GT/s; and then set the target Link speed to equalize at the lower rates starting with 8.0 GT/s onwards. A port must not advertise the Equalization Bypass to Highest NRZ Rate Support if the Equalization Bypass to Highest NRZ Rate Disable bit is Set to 1b.

Another optional mechanism to skip the entire equalization process and go directly to the highest common data rate is permitted if all components support data rates of 32.0 GT/s or higher and the No Equalization Needed mechanism is supported by all components in the Link, as advertised in the TS1/TS2 or Modified TS1/TS2 Ordered sets. This is done if a component is either able to retrieve the equalization and other circuit settings at all the data rates from a prior equalization that will work for the component, or it does not need equalization at all in all data rates above 5.0 GT/s. A component must not advertise this capability if the Equalization Bypass to Highest NRZ Rate Disable bit is Set to 1b. Components supporting 64.0 GT/s or higher data rate are strongly encouraged to support this mode, especially after the equalization has been performed at least once since power was applied. This would be helpful for faster resume times after the devices in the Link go through deep power savings states.

If one direction of the Link is advertising No Equalization Needed and the other side is advertising Equalization Bypass to Highest NRZ Rate Support in the TS1/TS2 Ordered Sets, the Link will operate in the Equalization Bypass to Highest NRZ Rate Support since the No Equalization Needed bit also indicates that the device is capable of bypassing Equalization to the highest data rate. In the Modified TS1/TS2 Ordered Sets, a device that sets No Equalization Needed bit to 1b must also set the Equalization Bypass to Highest NRZ Rate Support to 1b. If one direction of the Link is advertising No Equalization Needed bit and the other side is advertising Equalization Bypass to Highest NRZ Rate Support only in the Modified TS1/TS2 Ordered Sets, the Link will operate in the Equalization Bypass to Highest NRZ Rate Support. Link operation is undefined if a device advertises No Equalization Needed bit as 1b and Equalization Bypass to Highest NRZ Rate Support to 0b in the Modified TS1/TS2 Ordered Sets it transmits. Components are permitted to go straight to 64.0 GT/s from any data rate without having to go through 32.0 GT/s data rate if No Equalization Needed has been negotiated, since no equalization is involved.

The autonomous mechanism is executed if both components advertise that they are capable of at least the 8.0 GT/s data rate (via the TS1 and TS2 Ordered Sets) during the initial Link negotiation (when LinkUp is set to 1b) and the Downstream Port chooses to perform the equalization procedure at the intended data rates of operation above 5.0 GT/s. While not recommended, the Downstream Port may choose to perform the autonomous mechanism only on a subset of

the intended data rates of operation above 5.0 GT/s. In that case, the software based mechanism must be executed in order to perform the equalization procedure for the intended data rates of operation above 5.0 GT/s, not covered by the autonomous mechanism. For example, if both components advertised 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s Data Rates but autonomous equalization was performed for only 8.0 GT/s and 16.0 GT/s Data Rates, then software based mechanism must be adopted for equalization at 32.0 GT/s Data Rate.

In the autonomous mechanism, after entering L0, irrespective of the current Link speed, neither component must transmit any DLLP, except the NOP2 DLLP, if the equalization procedure must be performed and until the equalization procedure completes. The equalization procedure is considered complete once the Transmitter and Receiver setup of each Lane has been adjusted for each common data rate supported above 5.0 GT/s for which the Downstream Port intends to perform equalization using the autonomous mechanism. The Downstream Port is required to initiate the speed change to the data rate where the equalization needs to be performed. During any equalization (autonomous or software initiated or re-equalization), the Downstream Port must not advertise support for any data rate above the data rate for which equalization needs to be performed in Recovery. The following example is provided to illustrate the equalization flow.

Example: Consider a Link where equalization needs to be performed autonomously at 8.0 GT/s, and 16.0 GT/s. The Downstream Port enters Recovery to perform equalization at 8.0 GT/s by not advertising any data rates above 8.0 GT/s. The 8.0 GT/s equalization procedure is deemed to have been successfully executed if the Equalization 8.0 GT/s Phase 3 Successful bit and Equalization 8.0 GT/s Complete bit of the Link Status 2 register are both set to 1b. Immediately following the transition from Recovery to L0, after the initial data rate change to 8.0 GT/s, the Downstream Port is required to transition from L0 to Recovery, advertise 16.0 GT/s data rate support (but not advertise support for 32.0 GT/s, even if it is capable of supporting 32.0 GT/s), change the data rate to 16.0 GT/s and perform the 16.0 GT/s equalization procedure.

If the Downstream Port detects equalization problems or the Upstream Port made an equalization redo request (by setting the Request Equalization bit to 1b) the Downstream Port may redo equalization prior to proceeding to operate at the data rate where the equalization failed or performing equalization at a higher data rate. The number of back-to-back equalization redos at a given data rate is implementation specific but must be finite. If at the conclusion of the initial or subsequent equalization process and the execution of an implementation specific number of equalization redo's, the Link is not able to operate reliably at the data rate where equalization was performed, then it must revert back to a lower data rate of operation.

Components using the autonomous mechanism must not initiate any autonomous Link width downsizing until the equalization procedure completes. An Upstream Port must not transmit any DLLP, except the NOP2 DLLP, until it receives a non-NOP2 DLLP from the Downstream Port. If the Downstream Port performs equalization again, it must not transmit any DLLP, except the NOP2 DLLP, until it completes the equalization procedure. A Downstream Port may perform equalization again based on its own needs or based on the request from the Upstream Port, if it can meet its system requirements. Executing equalization multiple times may interfere with software determination of Link and device status, as described in § Section 6.6.

IMPLEMENTATION NOTE:

DLLP BLOCKING DURING AUTONOMOUS EQUALIZATION §

When using the autonomous mechanism for equalization at 8.0 GT/s or higher data rates, the Downstream Port is required to block the transmission of DLLPs until equalization has completed at all data rates for which the autonomous equalization mechanism will be performed, and the Upstream Port is required to block the transmission of DLLPs until a DLLP is received from the Downstream Port. If both components advertise that they are capable of the 16.0 GT/s (or higher) data rate but the Downstream Port only uses the autonomous mechanism for equalization at 8.0 GT/s, the Downstream Port is only required to block DLLP transmission until 8.0 GT/s equalization has completed. Similarly, if both components advertise that they are capable of the 32.0 GT/s data rate but the Downstream Port only uses the autonomous mechanism for equalization at 16.0 GT/s, the Downstream Port is only required to block DLLP transmission until 16.0 GT/s equalization has completed. If the Downstream Port delays entering Recovery from L0 while DLLP transmission is blocked, either the L0 Inferred Electrical Idle timeout (see § Section 4.2.5.4) or the DLLP timeout (see § Section 2.6.1.2) may expire in the Upstream or Downstream Ports. If either of these two timeouts occurs, it will result in the initiation of an entry to Recovery to perform Link retraining. Neither of these two timeouts is a reportable error condition, and the resulting Link retraining has no impact on proper Link operation.

The DLLP limitations described in this implementation note do not apply to NOP2 DLLPs. When operating in Flit Mode, since entry to Recovery must happen on an Ordered Set boundary, Flit transmission may occur prior to the completion of equalization at all data rates for which the autonomous equalization mechanism will be performed. These Flits will be transmitting NOP2 DLLPs. The receipt of NOP2 DLLPs cannot be used by the Upstream Port to unblock the transmission of non-NOP2 DLLPs.

When using the software based mechanism, software must guarantee that there will be no side-effects for transactions in flight (e.g., no timeout), if any, due to the Link undergoing the equalization procedure. Software can write 1b to the Perform Equalization bit in the Link Control 3 Register, followed by a write to the Target Link Speed field in the Link Control 2 register to enable the Link to run at 8.0 GT/s or higher, followed by a write of 1b to the Retrain Link bit in the Link Control register of the Downstream Port to perform equalization. Software must not enable the Link to run at a data rate above 8.0 GT/s during a software initiated equalization procedure if the equalization procedure at all the lower data rates starting with 8.0 GT/s have not been successfully executed and the Link is not capable of bypassing equalization to higher data rate(s) (i.e., either Equalization Bypass to Highest NRZ Rate Supported is 0b or Equalization Bypass to Highest NRZ Rate Disable is 1b). The equalization procedure is deemed successful as follows for the following data rates:

- 8.0 GT/s: Equalization 8.0 GT/s Phase 3 Successful bit and Equalization 8.0 GT/s Complete bit of the Link Status 2 register are both set to 1b
- 16.0 GT/s: Equalization 16.0 GT/s Phase 3 Successful bit and Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register are both set to 1b
- 32.0 GT/s: Equalization 32.0 GT/s Phase 3 Successful bit and Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Link Status Register are both set to 1b
- 64.0 GT/s: Equalization 64.0 GT/s Phase 3 Successful bit and Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Link Status Register are both set to 1b

Software may set the Hardware Autonomous Width Disable bit of the Link Control register in both components, or use some other mechanism to ensure that the Link is in its full functional width prior to setting the Perform Equalization bit in the Downstream Port. The component that had initiated the autonomous width downsizing is responsible to upconfigure the Link to go to its full functional width by initiating the transition to Recovery and Configuration within 1 ms of the Hardware Autonomous Width Disable bit being set to 1b. If an Upstream Port does not advertise the 8.0 GT/s data rate, the 16.0 GT/s data rate, the 32.0 GT/s, or the 64.0 GT/s data rate initially and did not participate in the autonomous

equalization mechanism for the non-advertised rates, its associated software must ensure there will be no side-effects for transactions in flight, if any, during equalization, before it instructs the Upstream Port to go to Recovery and advertise the previously non-advertised data rates and initiate a speed change. The Downstream Port subsequently initiates the equalization procedure during the initial speed change to the data rate advertised by the Upstream Port when it transitions to Recovery.

Upstream Ports are required to check for equalization setting problems in the Recovery.RcvrLock state (see § Section 4.2.7.4.1). However, both Downstream and Upstream Ports are permitted to use implementation specific methods to detect equalization problems at any time. A Port that detects a problem with its equalization settings is required to undertake the following actions, for each the following data rates:

- 8.0 GT/s: Link Equalization Request 8.0 GT/s bit in the Link Status 2 Register is set to 1b.
- 16.0 GT/s: Link Equalization Request 16.0 GT/s bit in the 16.0 GT/s Status Register is set to 1b.
- 32.0 GT/s: Link Equalization Request 32.0 GT/s bit in the 32.0 GT/s Status Register is set to 1b.
- 64.0 GT/s: Link Equalization Request 64.0 GT/s bit in the 64.0 GT/s Status Register is set to 1b.

In addition to setting the appropriate Link Equalization Request bit to 1b, an Upstream Port must initiate a transition to Recovery (if necessary) and request equalization at the appropriate data rate in the Recovery.RcvrCfg state by setting the Request Equalization bit of its transmitted TS2 Ordered Sets to 1b and the Equalization Request Data Rate bits to the data rate of the detected problem. If it requests equalization, it must request equalization for each detected problem only once. When requesting equalization, the Upstream Port is also permitted, but not required, to set the Quiesce Guarantee bit to 1b to inform the Downstream Port that an equalization process initiated within 1 ms will not cause any side-effects to its operation.

When a Downstream Port receives an equalization request from an Upstream Port (when it is in the Recovery.RcvrCfg state and receives 8 consecutive TS2 Ordered Sets with the Request Equalization bit set to 1b), it must either initiate an equalization process at the requested data rate (as defined by the received Equalization Request Data Rate bits) within 1 ms of completing the next Recovery to L0 transition, or it must set the appropriate Link Equalization Request 8.0 GT/s in its Link Status 2 register, Link Equalization Request 16.0 GT/s bit in its 16.0 GT/s Status Register, Link Equalization Request 32.0 GT/s bit in its 32.0 GT/s Status Register, or Link Equalization Request 64.0 GT/s bit in its 64.0 GT/s Status Register. It should initiate an equalization process only if it can guarantee that executing the equalization process will not cause any side-effects to either its operation or the Upstream Port's operation. The Downstream Port is permitted, but not required, to use the received Quiesce Guarantee bit to determine the Upstream Port's ability to execute an equalization process without side-effects.

If a Downstream Port wants to initiate an equalization process and can guarantee that it will not cause side-effects to its own operation but is unable to directly determine whether the equalization process will cause side-effects to the Upstream Port's operation, then it is permitted to request that the Upstream Port initiate an equalization request. The Downstream Port does so by transitioning to Recovery and in the Recovery.RcvrCfg state setting the Request Equalization bit of its transmitted TS2 Ordered Sets to 1b, the Equalization Request Data Rate bits to the desired data rate, and the Quiesce Guarantee bit to 1b. When an Upstream Port receives such an equalization request from a Downstream Port (when it is in the Recovery.RcvrCfg state and receives 8 consecutive TS2 Ordered Sets with the Request Equalization and Quiesce Guarantee bits set to 1b), it is permitted, but not required, to quiesce its operation and prepare to execute an equalization process at the data rate requested by the Downstream Port, and then request equalization at that same data rate (using the method described previously for reporting equalization setting problems) and with the Quiesce Guarantee bit set to 1b. There is no time limit on how long the Upstream Port can take to respond, but it should attempt to do so as quickly as possible. If a Downstream Port makes a request and receives such a response from the Upstream Port, then it must either initiate an equalization process at the agreed-upon data rate within 1 ms of completing the next Recovery to L0 transition if it can still guarantee that executing the equalization process will not cause any side-effects to its operation, or it must set the appropriate Link Equalization Request 8.0 GT/s bit in its Link Status 2 register, Link Equalization Request 16.0 GT/s bit in its 16.0 GT/s Status Register, Link Equalization Request 32.0 GT/s bit in its 32.0 GT/s Status Register, or Link Equalization Request 64.0 GT/s bit in its 64.0 GT/s Status Register.

IMPLEMENTATION NOTE: USING QUIESCE GUARANTEE MECHANISM §

Side-effects due to executing equalization after the Data Link Layer is in DL_Active can occur at the Port, Device, or system level. For example, the time required to execute the equalization process could cause a Completion Timeout error to occur - possibly in a different system component. The Quiesce Guarantee information allows Ports to decide whether to execute a requested equalization or not.

A component may operate at a lower data rate after reporting its equalization problems, either by timing out through Recovery.Speed or by initiating a data rate change to a lower data rate. Any data rate change required to perform the equalization procedure is exempt from the 200 ms requirement in § Section 6.11 . § Table 4-22 describes the mechanism for performing redo Equalization. Sometimes it may be necessary to perform a speed change to an intermediate data rate to redo equalization. For example, if the Downstream Port wants to redo equalization at 16.0 GT/s, bypass equalization is not supported, and the current data rate is either 2.5 GT/s or 5.0 GT/s, the Downstream Port must first initiate a speed change to 8.0 GT/s (the 8.0 GT/s equalization procedure will not be executed unless necessary) from which it will launch the redo equalization for 16.0 GT/s. The equalization procedure can be performed at most once in each trip through the Recovery state.

Table 4-22 Equalization Requirements Under Different Conditions §

<p>From 2.5 GT/s or 5.0 GT/s to 8.0 GT/s Equalization</p>	<p>The mechanisms described here are identical for all flavors of equalization: initial or redo equalization; autonomous or software initiated.</p> <p>The Downstream Port communicates the Transmitter preset values and the Receiver preset hints, if applicable, for each Lane to the Upstream Port using 8b/10b encoding. These values are communicated using the <u>EQ TS2 Ordered Sets</u> (defined in § Section 4.2.5.1) in <u>Recovery.RcvrCfg</u>, when a data rate change to the higher data rate has been negotiated, prior to transitioning to the higher data rate to perform equalization. The preset values sent in the <u>EQ TS2 Ordered Sets</u> are derived as follows:</p> <ul style="list-style-type: none"> For equalization at 8.0 GT/s: <u>Upstream Port 8.0 GT/s Transmitter Preset</u> and <u>Upstream Port 8.0 GT/s Receiver Preset Hint</u> fields of each <u>Lane Equalization Control Register Entry</u>. <p>After the data rate change to the higher data rate where equalization needs to be performed, the Upstream Port transmits <u>TS1 Ordered Sets</u> with the preset values it received. The preset values must be within the operable range defined in § Section 8.3.3.3 if reduced swing will be used by the Transmitter.</p> <p>After the data rate change to the higher data rate where equalization needs to be performed, the Downstream Port transmits <u>TS1 Ordered Sets</u> with the preset values as follows with the assumption that the preset values must be within the operable range defined in § Section 8.3.3.3 if reduced swing will be used by the Transmitter:</p> <ul style="list-style-type: none"> For equalization at 8.0 GT/s: <u>Downstream Port 8.0 GT/s Transmitter Preset</u> and optionally <u>Downstream Port 8.0 GT/s Receiver Preset Hint</u> fields of each <u>Lane Equalization Control Register Entry</u>. <p>To perform redo equalization, the Downstream Port must request speed change through <u>EQ TS1 Ordered Sets</u> in <u>Recovery.RcvrLock</u> at 2.5 GT/s or 5.0 GT/s to inform the Upstream Port that it intends to redo equalization at the higher data rate. An Upstream Port should advertise the higher data rate in <u>Recovery</u> if it receives <u>EQ TS1 Ordered Sets</u> with speed change bit set to 1b and if it intends to operate at the higher data rate in the future.</p>
<p>From 8.0 GT/s to 16.0 GT/s Equalization, from 16.0 GT/s to</p>	<p>The mechanisms described here are identical for all flavors of equalization: initial or redo equalization; autonomous or software initiated.</p> <p>When negotiating to the higher data rate, the Downstream Port communicates the Transmitter preset values for each Lane to the Upstream Port using 128b/130b encoding. These values are communicated using <u>128b/130b EQ TS2 Ordered Sets</u> (defined in § Section 4.2.5.1) in <u>Recovery.RcvrCfg</u>, when a data rate change to the higher</p>

<p>32.0 GT/s Equalization, OR from 32.0 GT/s to 64.0 GT/s Equalization</p>	<p>data rate has been negotiated, prior to transitioning to the higher data rate. The preset values sent in the <u>128b/130b EQ TS2 Ordered Sets</u> are derived as follows:</p> <ul style="list-style-type: none"> • For equalization at 16.0 GT/s: <u>Upstream Port 16.0 GT/s Transmitter Preset field of the 16.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. • For equalization at 32.0 GT/s: <u>Upstream Port 32.0 GT/s Transmitter Preset field of the 32.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. • For equalization at 64.0 GT/s: <u>Upstream Port 64.0 GT/s Transmitter Preset field of the 64.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. <p>Optionally, the Upstream Port communicates initial Transmitter preset settings to the Downstream Port using the <u>128b/130b EQ TS2 Ordered Sets</u> sent in <u>Recovery.RcvrCfg</u>, when a data rate change to the higher data rate has been negotiated, prior to transitioning to the higher data rate at which equalization needs to be performed. These preset values are determined by implementation specific means. After the data rate change to the higher data rate, the Upstream Port transmits <u>TS1 Ordered Sets</u> with the preset values it received. If the Downstream Port did not receive preset values in <u>Recovery.RcvrCfg</u>, after the data rate change to the higher data rate, it transmits <u>TS1 Ordered Sets</u> with the presets as follows:</p> <ul style="list-style-type: none"> • For equalization at 16.0 GT/s: <u>Downstream Port 16.0 GT/s Transmitter Preset field of the 16.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. • For equalization at 32.0 GT/s: <u>Downstream Port 32.0 GT/s Transmitter Preset field of the 32.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. • For equalization at 64.0 GT/s: <u>Downstream Port 64.0 GT/s Transmitter Preset field of the 64.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. <p>The preset values must be within the operable range defined in <u>§ Section 8.3.3.3</u> if reduced swing will be used by the Transmitter.</p> <p>To perform redo equalization, the Downstream Port must request speed change through <u>TS1 Ordered Sets</u> in <u>Recovery.RcvrLock</u> with the <u>Equalization Redo bit</u> set to 1b to inform the Upstream Port that it intends to redo equalization. An Upstream Port should advertise the higher data rate in <u>Recovery</u> if it receives <u>TS1 Ordered Sets</u> with speed change bit set to 1b, <u>Equalization Redo bit</u> set to 1b and it intends to operate at the higher data rate in the future.</p>
<p>From 2.5 GT/s or 5.0 GT/s to 32.0 GT/s Equalization</p>	<p>Equalization to 32.0 GT/s from 2.5 GT/s or 5.0 GT/s is possible only if the Link is capable of bypassing equalization to higher data rate(s) (i.e., <u>Equalization Bypass to Highest NRZ Rate Supported in 32.0 GT/s Capabilities register</u> is 1b and <u>Equalization Bypass to Highest NRZ Rate Disable in the 32.0 GT/s Control Register</u> is 0b).</p> <p>The mechanisms described here are identical for all flavors of equalization: initial or redo equalization; autonomous or software initiated.</p> <p>The Downstream Port communicates the Transmitter preset values and the Receiver preset hints, if applicable, for each Lane to the Upstream Port using 8b/10b encoding. These values are communicated using the <u>EQ TS2 Ordered Sets</u> (defined in <u>§ Section 4.2.5.1</u>) in <u>Recovery.RcvrCfg</u>, when a data rate change to the higher data rate has been negotiated, prior to transitioning to the higher data rate to perform equalization. The preset values sent in the <u>EQ TS2 Ordered Sets</u> are derived as follows:</p> <ul style="list-style-type: none"> • For equalization at 32.0 GT/s: <u>Upstream Port 32.0 GT/s Transmitter Preset field of the 32.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane. The <u>Receiver Preset Hint field</u> must be set to 000b. <p>After the data rate change to the higher data rate where equalization needs to be performed, the Upstream Port transmits <u>TS1 Ordered Sets</u> with the preset values it received. The preset values must be within the operable range defined in <u>§ Section 8.3.3.3</u> if reduced swing will be used by the Transmitter.</p>

	<p>After the data rate change to the higher data rate where equalization needs to be performed, the Downstream Port transmits <u>TS1 Ordered Sets</u> with the preset values as follows with the assumption that the preset values must be within the operable range defined in § <u>Section 8.3.3.3</u> if reduced swing will be used by the Transmitter:</p> <ul style="list-style-type: none"> • If eight consecutive <u>EQ TS2 Ordered Sets</u> were received with supported Transmitter Preset values in the most recent transition through <u>Recovery.RcvrCfg</u>, the Transmitter Preset value from those <u>EQ TS2 Ordered Sets</u> must be used. • Otherwise: Downstream Port 32.0 GT/s Transmitter Preset field of the <u>32.0 GT/s Lane Equalization Control Register Entry</u> corresponding to the Lane must be used. <p>To perform redo equalization, the Downstream Port must request speed change through <u>EQ TS1 Ordered Sets</u> in <u>Recovery.RcvrLock</u> at 2.5 GT/s or 5.0 GT/s to inform the Upstream Port that it intends to redo equalization at the higher data rate. An Upstream Port should advertise the higher data rate in <u>Recovery</u> if it receives <u>EQ TS1 Ordered Sets</u> with speed change bit set to 1b and if it intends to operate at the higher data rate in the future.</p>
From 2.5 GT/s or 5.0 GT/s to 64.0 GT/s Equalization	Equalization to 64.0 GT/s from 2.5 GT/s or 5.0 GT/s is not supported. All equalization procedures at the 64.0 GT/s data rate, including re-equalization, must be initiated from the 32.0 GT/s data rate only.
Equalization at a data rate from a data rate equal to the target equalization data rate	<p>This is only possible with a redo equalization. The combinations covered here are: 8.0 GT/s equalization from 8.0 GT/s data rate, 16.0 GT/s equalization from 16.0 GT/s data rate, and 32.0 GT/s equalization from 32.0 GT/s data rate.</p> <p>In this case, the initial preset used during equalization is equal to the initial preset used during the last time the equalization was performed at the data rate where equalization is being performed.</p> <p>64.0 GT/s equalization from 64.0 GT/s is not supported.</p>

The equalization procedure consists of up to four Phases, as described below. When operating at 8.0 GT/s or higher data rates, the Phase information is transmitted using the Equalization Control (EC) field in the TS0 or TS1 Ordered Sets.

Phase 0

This phase is executed while negotiating (and prior to) to the data rate where equalization would be performed. The preset to be used for equalization is determined as described in § Table 4-22.

Phase 1

Both components make the Link operational enough at the current data rate to be able to exchange TS1 Ordered Sets to complete the remaining phases for the fine-tuning of their Transmitter/Receiver pairs. For the Data Rates of 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s, TS1 Ordered Sets are exchanged in this Phase. For the Data Rate of 64.0 GT/s, TS0 Ordered Sets are exchanged in this Phase and each Pseudo-Port or Port must be able to exchange the TS0 Ordered Sets for Phase 1 and Phase 2 in the Upstream Direction (from the Upstream Port to Downstream Port) reliably when it exits this Phase. It is expected that the Link will operate at a BER of less than 10^{-4} before the component is ready to move on to the next Phase. Each Transmitter uses the preset values as described in § Table 4-22.

The Downstream Port initiates Phase 1 by transmitting TS1 Ordered Sets for Data Rates of 8.0 GT/s, 16.0 GT/s and 32.0 GT/s and TS0 Ordered Sets for the Data Rate of 64.0 GT/s with EC=01b (indicating Phase 1). The Upstream Port, after adjusting its Receiver, if necessary, to ensure that it can progress with the equalization process, receives these TS0 or TS1 Ordered Sets and transitions to Phase 1 (where it transmits TS1 Ordered Sets with EC=01b if the Data Rate is 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s or TS0 Ordered Sets with EC=01b if the Data Rate is 64.0 GT/s). The Downstream Port ensures that it can reliably receive the bit stream from the Upstream Port to continue through the rest of the Phases when it receives TS0 or TS1 Ordered Sets from the Upstream Port with EC=01b before it moves on to Phase 2.

Phase 2

In this Phase the Upstream Port adjusts the Transmitter setting of the Downstream Port along with its own Receiver setting, independently, on each Lane, to ensure it receives the bit stream compliant with the requirements in § Chapter 8. (e.g., each operational Downstream Lane has a BER less than 10^{-12} for a Data Rate of 32.0 GT/s or lower or 10^{-6} for the Data Rate of 64.0 GT/s). If the Data Rate is 8.0 GT/s, 16.0 GT/s or 32.0 GT/s, both the Downstream Port and the Upstream Port transmit TS1 Ordered Sets. If the Data Rate is 64.0 GT/s, the Downstream Port transmits TS0 Ordered Sets until it receives TS0 Ordered Sets and then it transmits TS1 Ordered Sets whereas the Upstream Port transmits TS0 Ordered Sets. The Downstream Port initiates the move to Phase 2 by transmitting TS0/TS1 Ordered Sets with EC=10b to the Upstream Port. The Downstream Port advertises the Transmitter coefficients and the preset it is using per the rules below in Phase 1 for preset only and in Phase 2 for preset and coefficients. The Upstream Port receives these Ordered Sets and may request different coefficient or preset settings and continue to evaluate each setting until it arrives at the best setting for operating the Downstream Lanes. After the Upstream Port has completed this Phase, it moves the Link to Phase 3 by transmitting TS1 Ordered Sets for a Data Rate of 32.0 GT/s or lower and TS0 Ordered Sets for a Data Rate of 64.0 GT/s with EC=11b to the Downstream Port.

Phase 3

In this Phase the Downstream Port adjusts the Transmitter setting of the Upstream Port along with its own Receiver setting, independently, on each Lane, using a handshake and evaluation process similar to Phase 2 with the exception that EC=11b. The Downstream Port signals the end of Phase 3 (and the equalization procedure) by transmitting TS1 Ordered Sets with EC=00b.

The algorithm used by a component to adjust the transmitter of its Link partner and the evaluation of that Transmitter set-up with its Receiver set-up is implementation specific. A component may request changes to any number of Lanes and can request different settings for each Lane. Each requested setting can be a preset or a set of coefficients that meets the requirements defined in § Section 4.2.4.1. Each component is responsible for ensuring that at the end of the fine-tuning (Phase 2 for Upstream Ports and Phase 3 for Downstream Ports), its Link partner has the Transmitter setting in each Lane that will cause the Link to meet the requirements in § Chapter 8.

A Link partner receiving the request to adjust its Transmitter must evaluate the request and act on it. If a valid preset value is requested and the Transmitter is operating in full swing mode, it must be reflected in the Transmitter set-up and subsequently in the preset and coefficient fields of the TS1 Ordered Set that the Link partner transmits. If a preset value is requested, the Transmitter is operating in reduced swing mode, and the requested preset is supported as defined in § Section 8.3.3.3 it must be reflected in the Transmitter set-up and subsequently in the preset and coefficient fields of the TS1 Ordered Set that the Link partner transmits. Transmitters operating in reduced swing mode are permitted to reject preset requests that are not supported as defined in § Section 8.3.3.3. A request for adjusting the coefficients may be accepted or rejected. If the set of coefficients requested for a Lane is accepted, it must be reflected in the Transmitter set-up and subsequently in the transmitted TS1 Ordered Sets. If the set of coefficients requested for a Lane is rejected, the Transmitter set-up is not changed, but the transmitted TS1 Ordered Sets must reflect the requested coefficients along with the Reject Coefficient Values bit set to 1b. In either case of responding to a coefficient request, the preset field of the transmitted TS1 Ordered Sets is not changed from the last preset value that was transmitted. A request for adjusting the coefficients may be rejected by the Link partner only if the set of coefficients requested is not compliant with the rules defined in § Section 4.2.4.1.

When performing equalization of a crosslink, the component that played the role of the Downstream Port during the earlier crosslink initialization at the lower data rate also assumes the responsibility of the Downstream Port for equalization.

If a Lane receives a Transmitter Preset value (from a TS0, TS1 or TS2 sequence) with a Reserved or unsupported value in Polling.Compliance, Loopback, or Phase 0 or Phase 1 of Recovery.Equalization, then the Lane is permitted to use any supported Transmitter preset setting in an implementation specific manner. The Reserved or unsupported Transmitter preset value is transmitted in any subsequent compliance patterns or Ordered Sets, and not the implementation specific Transmitter preset value chosen by the Lane. For example, if a Lane of an Upstream Port receives a Transmitter preset value 1111b (Reserved) with the EQ TS2 Ordered Sets it receives in Recovery.RcvrCfg, it is permitted to use any supported Transmitter preset value for its transmitter setting after changing the data rate to 8.0 GT/s, but it must

transmit 1111b as its Transmitter preset value in the TS1 Ordered Sets it transmits in Phase 0 and Phase 1 of Recovery.Equalization.

In the Loopback state, the Loopback Lead is responsible for communicating the Transmitter and Receiver settings it wants the Follower to use through the EQ TS1 Ordered Sets it transmits in the 2.5 GT/s or 5.0 GT/s data rate, and the preset or coefficient settings it wants the device under test to operate under in the TS1 Ordered Sets it transmits in the 8.0 GT/s or higher data rate. Similarly, if the Polling.Compliance state for 8.0 GT/s or higher Data Rates is entered through TS1 Ordered Sets, the entity that is performing the test is required to send the appropriate settings in EQ TS1 Ordered Sets and presets for the device under test to operate with, according to the mechanism defined in § Section 4.2.7.2.

IMPLEMENTATION NOTE: EQUALIZATION EXAMPLE §

Some examples are presented in this note to help explain Link equalization. This is not a complete listing of all allowable equalization scenarios.

The following diagram is an example illustrating how two devices may complete the equalization procedure. If the maximum common data rate supported by both Ports is 8.0 GT/s, the equalization procedure is complete at the conclusion of the 8.0 GT/s equalization procedure. If the maximum common data rate supported by both Ports is 16.0 GT/s, the 8.0 GT/s equalization procedure is followed by the 16.0 GT/s equalization procedure. If either the 8.0 GT/s or 16.0 GT/s equalization procedure is repeated and is performed while the Link is in 8.0 GT/s data rate (for the 8.0 GT/s equalization) or in 16.0 GT/s (for the 16.0 GT/s equalization), Phase 0 may be skipped since there is no need for the Link to go back to 2.5 GT/s or 5.0 GT/s (for the 8.0 GT/s equalization) or 8.0 GT/s (for the 16.0 GT/s equalization) to resend the same EQ TS2 Ordered Sets to convey the presets. A Downstream Port may choose to skip Phase 2 and Phase 3 if it determines that fine-tuning of the Transmitter is not needed based on the channel and components in the platform.

§ Figure 4-44 shows an example flow for 64.0 GT/s after the Link completes the 32.0 GT/s equalization with the use of TS0 and TS1 Ordered Sets.

Note that some transitions may not be covered; such as the transition from receiving TS0 to receiving TS1 in a given sub-state.

Figure 4-42 8.0 GT/s Equalization Flow §

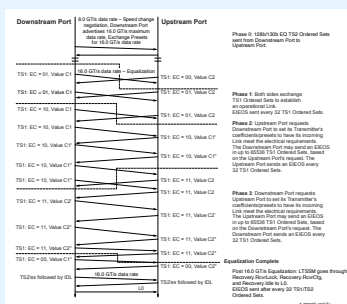

Figure 4-43 16.0 GT/s Equalization Flow §

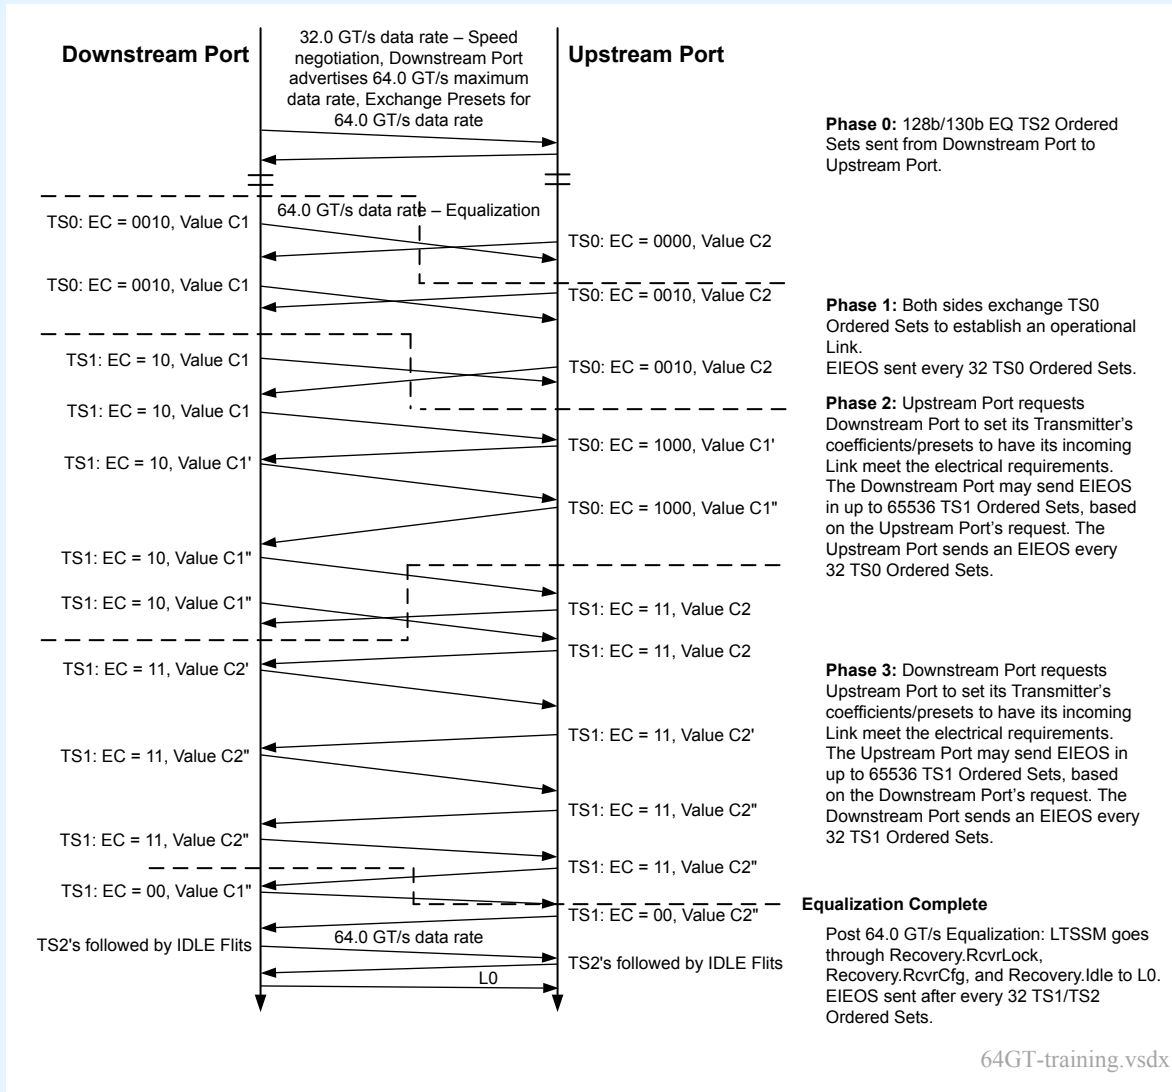

Figure 4-44 64.0 GT/s Equalization Flow §

IMPLEMENTATION NOTE: EQUALIZATION BYPASS EXAMPLE §

The following flow-chart provides an example flow where a Link may bypass equalization at lower Data Rates and go to the highest supported NRZ rate for equalization. For example, when $n=5$, the Link can train to L0 in Gen 1 data rate, establish that all components (including Retimers, if any) can bypass equalization to Gen 5, change the data rate to Gen 5 and just perform equalization at Gen 5.

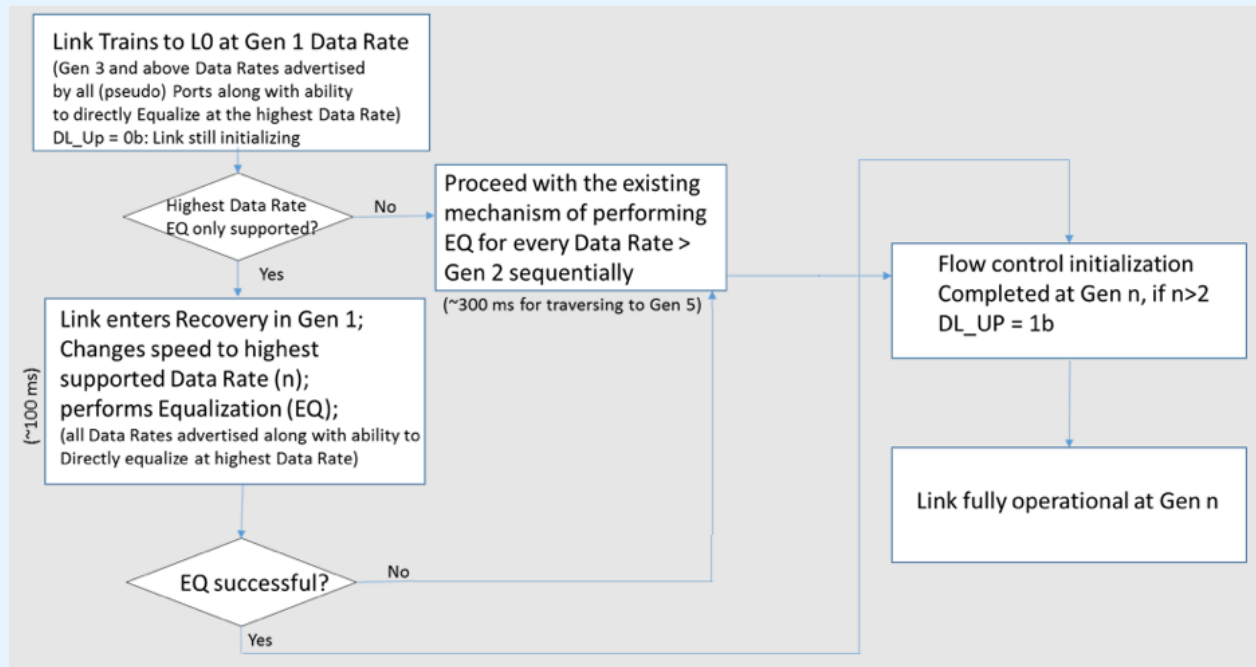

Figure 4-45 Equalization Bypass Example §

4.2.4.1 Rules for Transmitter Coefficients §

The explanation of the coefficients and the FIR filter it represents are provided in § Section 8.3.3.1. The following rules apply to both the advertised as well as requested coefficient settings.

1. C_{-2} , C_{-1} , and C_{+1} are the coefficients used in the FIR equation and represent the 2nd pre-cursor, pre-cursor and post-cursor, respectively. The pre-cursors and post-cursor values communicated in the TS1 Ordered Sets represent their absolute values. C_0 represents the cursor coefficient setting and is a positive entity. The coefficient C_{-2} is used only for 64.0 GT/s and higher Data Rates.
2. The sum of the absolute values of the coefficients defines the FS (Full Swing; $FS = |C_{-2}| + |C_{-1}| + C_0 + |C_{+1}|$). FS is advertised to the Link partner in Phase 1. The Transmitter FS range is defined below:
 - $FS \in \{24, \dots, 63\}$ (i.e., FS must have a value from 24 through 63) for full swing mode.
 - $FS \in \{12, \dots, 63\}$ for reduced swing mode.
 - C_{-2} is set to 0 for Data Rates lower than 64.0 GT/s.

3. A Transmitter advertises its LF (Low Frequency) value during Phase 1.
 - This corresponds to the minimum differential voltage that can be generated by the Transmitter which is LF/FS times the Transmitters maximum differential voltage. The Transmitter must ensure that LF meets the electrical requirements defined in § Section 8.3.3.9 for $V_{TX-EIEOS-FS}$ and $V_{TX-EIEOS-RS}$.
4. The following rules must be satisfied before a set of coefficients can be requested of the Link partner's Transmitter. Upon reception of an update request for TX coefficient settings, a Port must verify that the new request meets the following conditions and reject the request if any of following conditions are violated:
 - a. $|C_{-1}| \leq \text{Floor}(FS/4)$
 - b. $|C_{-1}| + |C_{-2}| + C_0 + |C_{+1}| = FS$
(Do not allow peak power to change with adaptation)
 - c. $C_0 - |C_{-1}| + |C_{-2}| - |C_{+1}| \geq LF$
 - d. $|C_{-2}| \leq \text{Floor}(FS/8)$

4.2.4.2 Encoding of Presets §

Definition of the Transmitter and Receiver Preset Hints appears in § Chapter 8. . The encoding for the Transmitter Preset and Receiver Preset Hint are provided in § Table 4-23 and § Table 4-24. There are two classes of presets: P0 through P10 are defined for data rates of 8.0 GT/s, 16.0 GT/s, and 32.0 GT/s whereas Q0 through Q10 are defined for the data rate of 64.0 GT/s. Even though 8 of the 11 presets across these two sets overlap, it is possible that the same preset values may get different encodings between the two classes. Receiver Preset Hints are optional and only defined for the 8.0 GT/s data rate.

Table 4-23 Transmitter Preset Encoding §

Encoding	Preset Number in § Table 8-1	Preset Number in § Table 8-2
0000b	P0	Q0
0001b	P1	Q1
0010b	P2	Q2
0011b	P3	Q3
0100b	P4	Q4
0101b	P5	Q5
0110b	P6	Q6
0111b	P7	Q7
1000b	P8	Q8
1001b	P9	Q9
1010b	P10	Q10
1011b through 1111b	Reserved	Reserved

*Table 4-24 Receiver Preset Hint
Encoding for 8.0 GT/s §*

Encoding	Receiver Preset Value
000b	-6 dB
001b	-7 dB
010b	-8 dB
011b	-9 dB
100b	-10 dB
101b	-11 dB
110b	-12 dB
111b	Reserved

IMPLEMENTATION NOTE: QUANTIZATION ERRORS AT 64.0 GT/S §

Due to the tighter preset tolerance at 64.0 GT/s some FS values will result in a quantization error larger than is allowed for the specified tolerance of the presets in § Table 8-2 of § Section 8.3.3.3 . The implementation must compensate for any quantization error from its selection of FS to meet the specified preset accuracy.

4.2.5 Link Initialization and Training §

This section defines the Physical Layer control process that configures and initializes each Link for normal operation. This section covers the following features:

- configuring and initializing the Link
- supporting normal packet transfers
- supported state transitions when recovering from Link errors
- restarting a Port from low power states.

The following are discovered and determined during the training process:

- Link width
- Link data rate
- Lane reversal
- Lane polarity

Training does:

- Link data rate negotiation
- Bit lock per Lane

- Lane polarity
- Symbol lock or Block alignment per Lane
- Lane ordering within a Link
- Link width negotiation
- Lane-to-Lane de-skew within a multi-Lane Link.

4.2.5.1 Training Sequences §

Training sequences are composed of Ordered Sets used for initializing bit alignment, Symbol alignment and to exchange Physical Layer parameters.

1. When the data rate is 2.5 GT/s or 5.0 GT/s, Ordered Sets are never scrambled but are always 8b/10b encoded.
2. When the data rate is between 8.0 GT/s and 32.0 GT/s, the 128b/130b encoding is used and Symbols may or may not be scrambled, according to the rules in § Section 4.2.2.4 .
3. When the data rate is 64.0 GT/s the 1b/1b encoding is used and Symbols may or may not be scrambled, according to the rules in § Section 4.2.3.1.2 .

Training sequences (TS0, TS1, TS2, Modified TS1, or Modified TS2) are transmitted consecutively and can only be interrupted by SKP Ordered Sets (see § Section 4.2.8) or, for data rates other than 2.5 GT/s, EIEOS (see § Section 4.2.5.3).

When 8.0 GT/s or higher data rates are supported, a TS1 (or TS2) Ordered Set using 8b/10b encoding (i.e., 2.5 or 5.0 GT/s data rate) can be either a standard TS1 (or TS2) Ordered Set (i.e., Symbol 6 is D10.2 for a TS1 Ordered Set or D5.2 for a TS2 Ordered Set) or an **EQ TS1 Ordered Set** (or **EQ TS2 Ordered Set**) (i.e., Symbol 6 bit 7 is 1b). The ability to transmit EQ TS1 Ordered Sets is implementation specific. Ports supporting 8.0 GT/s or higher data rates must accept either TS1 (or TS2) type in the LTSSM states unless explicitly required to look for a specific type. Ports that do not support the 8.0 GT/s data rate are permitted, but not required, to accept EQ TS1 (or TS2) Ordered Sets.

When the 16.0 GT/s and higher data rate is supported, a TS2 using 128b/130b encoding (i.e., 8.0 or higher data rate) can be either a standard TS2 Ordered Set (i.e., Symbol 7 is 45h) or an **128b/130b EQ TS2** (i.e., Symbol 7 bit 7 is 1b). Ports supporting the 16.0 GT/s or higher data rate must accept either TS2 type in the LTSSM states unless explicitly required to look for a specific type. Ports that do not support the 16.0 GT/s data rate are permitted, but not required, to accept 128b/130b EQ TS2 Ordered Sets.

When using 8b/10b encoding, TS1 or TS2 Ordered Sets are considered consecutive only if Symbol 6 matches Symbol 6 of the previous TS1 or TS2 Ordered Set.

Components that intend to either negotiate alternate protocols or pass a Training Set Message must use Modified TS1/TS2 Ordered Sets instead of standard TS1/TS2 Ordered Sets in Configuration.Lanenum.Wait, Configuration.Lanenum.Accept, and Configuration.Complete substates. In order to be eligible to send the Modified TS1/TS2 Ordered Sets, components must set the Enhanced Link behavior Control bits (bit 7:6 of Symbol 5) in TS1 and TS2 Ordered Sets to 11b in Polling.Active, Polling.Configuration, Configuration.Linkwidth.Start, and Configuration.Linkwidth.Accept substates and follow through the steps outlined on transition to Configuration.Lanenum.Wait substate when LinkUp=0b. If the Link partner does not support Modified TS1/TS2 Ordered Sets, then starting with Configuration.Lanenum.Wait, the standard TSs should stop sending 11b in the Enhanced Link Behavior Control field and switch to the appropriate encodings.

When using 8b/10b encoding, modified TS1 or modified TS2 Ordered Sets are considered consecutive only if all Symbols matches the corresponding Symbols of the previous modified TS1 or modified TS2 Ordered Sets and the parity in Symbol 15 matches with the expected value. Symbols 8-14 must be identical in each Modified TS1/TS2 Ordered Sets across all Lanes of a Link.

When using 128b/130b encoding, TS1 or TS2 Ordered Sets are considered consecutive only if Symbols 6-9 match Symbols 6-9 of the previous TS1 or TS2 Ordered Set, with Reserved bits treated as described below.

With 1b/1b encoding, TS0, TS1 and TS2 Ordered Sets consist of the first 8 symbols of the Ordered Set being replicated in the second 8 symbols of the Ordered Set, as shown in § Table 4-28 and § Table 4-29. The TS0 Ordered Set is used with 1b/1b encoding during the Recovery.Equalization, as described in the LTSSM section. Each UI in the TS0 Ordered Set is either voltage level 0 or 3 with PAM-4 signaling, as shown in § Figure 4-24. Hence, the scrambled symbols in TS0 Ordered Sets are **Half scrambled**; the odd bit positions are scrambled whereas even bit position j is identical to the odd bit position $j+1$. Precoding is bypassed in both the Transmitter and Receiver.

In 1b/1b encoding, a received TS0, TS1, or TS2 Ordered Set is considered valid when either half is valid:

- The first half is valid if Symbol 0 is a valid TS0/TS1/TS2 encoding, Symbols 0 to 7 passes its parity check after decoding Gray code and descrambling, and Symbol 7 is not equal to a DC balance pattern prior to performing gray code and descrambling.
- The second half is valid if Symbol 8 is a valid TS0/TS1/TS2 encoding, Symbols 8 to 15 passes its parity check after decoding Gray code and descrambling, and symbol 15 is not equal to a DC balance pattern prior to performing gray code and descrambling.
- Both halves are valid if Symbols 0 to 6 are identical to Symbols 8 to 14 after decoding Gray code and descrambling, and Symbols 7 and 15 are DC balance symbols prior to decoding Gray code and descrambling.
- The type of the Ordered Set (TS0, TS1, or TS2) is determined by the first symbol of the valid half.
- The even bits in the half-scrambled Symbols must be ignored after descrambling in the Receiver. (Note: because the gray code was done by forcing the even bit to be identical to the odd bit in the Transmitter, the even bit position may not be identical to the odd bit position on the Receiver after descrambling.)

IMPLEMENTATION NOTE: HALF SCRAMBLING EXAMPLE §

Since the half-scrambled symbols are not fully gray-coded on the transmitter, rather the even bit is made identical to odd bit to have that UI be either a voltage level 0 or voltage level 3, it is possible that an even bit position in the half-scrambled symbol in the Receiver after gray-coding and descrambling may not match what was transmitted. For example, the Transmitter intends to send 80h prior to scrambling. After scrambling, the symbol becomes 57h and the gray-coded value by forcing the even bit to be identical to the odd bit becomes 03h. On the receiver side, 03h after gray coding remains at 03h and after descrambling becomes 94h. Here bit 0 is different between the transmitted side 80h vs. the receive side 94h. However, all the odd bit positions that carry meaningful information are identical. By AND'ing 94h with AAh, we get 80h which was sent.

With 1b/1b encoding, two TS0, TS1 or TS2 Ordered Sets are considered consecutive if all of the following conditions apply to both the Ordered Sets:

- both Ordered Sets are of the same type
- they arrived one after the other, even though they may be separated by one or more SKP Ordered Set(s)
- each ordered set has a valid half and the first 7 symbols of the valid halves of each of the Ordered Set are identical, with Reserved bits treated as described below.

An invalid Ordered Set is a Training Set that does not pass the checks in § Section 4.2.5.1 .

Reserved bits in TS0, TS1, TS2, Modified TS1 or Modified TS2 Ordered Sets must be handled as follows:

- The Transmitter must transmit 0s for Reserved bits.
- The Receiver:
 - must not determine that a TS0, TS1, TS2, Modified TS1 or Modified TS2 Ordered Set is invalid based on the received value of Reserved bits
 - must use the received value of Reserved bits for the purpose of a parity computation if the Reserved bits are included in a parity calculation
 - may optionally compare the received value of Reserved bits within Symbols that are explicitly called out as being required to be identical in TS0, TS1, TS2, Modified TS1, or Modified TS2 Ordered Sets to determine if they are consecutive
 - must not otherwise take any functional action based on the value of any received Reserved bits

When using 128b/130b or 1b/1b encoding, Transmitters are required to track the running DC Balance of the bits transmitted on the wire (after Gray code in 1b/1b, scrambling, and if turned on: precoding) that constitute the TS0, TS1, and TS2 Ordered Sets only. The running DC Balance is the difference between the number of 1s transmitted and the number of 0s transmitted in 8.0 GT/s, 16.0 GT/s or 32.0 GT/s Data Rates. The running DC Balance is the running sum of the DC balance values assigned to each voltage level in each UI, as shown in § Figure 4-24, for 64.0 GT/s Data Rate. Each Lane must track its running DC Balance independently and be capable of tracking a difference of at least +/-511 bits. Any counters used must saturate at their limit (not roll-over) and continue to track reductions after their limit is reached. For example, a counter that can track a difference of 511 will saturate at 511 if a difference of 513 is detected, and then change to 509 if the difference is reduced by 2 in the future.

The running DC Balance is set to 0 by two events:

1. The Transmitter exiting Electrical Idle;
2. Transmission of an EIEOS following a Data Block.

For every TS1 or TS2 Ordered Set transmitted with 128b/130b encoding, Transmitters must evaluate the running DC Balance and transmit one of the DC Balance Symbols defined for Symbols 14 and 15 as defined by the algorithm below. If the number of 1s needs to be reduced, the DC Balance Symbols 20h (for Symbol 14) and 08h (for Symbol 15) are transmitted. If the number of 0s needs to be reduced, the DC Balance Symbols DFh (for Symbol 14) and F7h (for Symbol 15) are transmitted. If no change is required, the appropriate TS1 or TS2 Identifier Symbol is transmitted. Any DC Balance Symbols transmitted for Symbols 14 or 15 bypass scrambling, while TS1 and TS2 Identifier Symbols follow the standard scrambling rules. The following algorithm must be used to control the DC Balance with 128b/130b encoding:

- If the running DC Balance is >31 at the end of Symbol 11 of the TS Ordered Set, transmit DFh for Symbol 14 and F7h for Symbol 15 to reduce the number of 0s, or 20h for Symbol 14 and 08h for Symbol 15 to reduce the number of 1s.
- Else, if the running DC Balance is >15 at the end of Symbol 11 of the TS Ordered Set, transmit F7h for Symbol 15 to reduce the number of 0s, or 08h for Symbol 15 to reduce the number of 1s. Transmit the normal TS Identifier Symbol (scrambled) for Symbol 14.
- Else, transmit the normal TS Identifier Symbol (scrambled) for Symbols 14 and 15.

Receivers are permitted, but not required, to check Symbols 14 and 15 for the following values when determining whether a TS1 or TS2 Ordered Set is valid with 128b/130b encoding:

- The appropriate TS Identifier Symbol after de-scrambling, or
- a valid DC Balance Symbol of DFh or 20h before de-scrambling for Symbol 14, or
- a valid DC Balance Symbol of F7h or 08h before de-scrambling for Symbol 15.

If a Receiver receives a DC balance pattern in Symbol 14 in 128b/130b encoding, it is possible that the pattern is scrambled (and precoded). Thus, if the Receiver is performing this optional check, it must keep descrambler and receive precoding running for checking Symbol 15, which can be either scrambled (and precoded) or the DC balance pattern.

IMPLEMENTATION NOTE: SYNC HEADER AND DC BALANCE §

Block Sync Header bits and the first Symbol of TS1 and TS2 Ordered Sets do not affect the running DC Balance, because they have equal an number of 1s and 0s.

For every TS0, TS1 or TS2 Ordered Set transmitted with 1b/1b encoding, Transmitters must evaluate the running DC Balance and transmit one of the DC Balance Symbols defined for Symbols 7 and 15 as defined by the algorithm below. Any DC Balance Symbols transmitted in Symbols 7 and 15 bypass scrambling, while the byte-wise parity, if sent in Symbols 7 and 15, follows the standard scrambling rules.

- If the running DC Balance was $>+47$ at the start of the TS Ordered Set, transmit 00h in Symbols 7 and 15 without scrambling.
- If the running DC Balance was <-47 at the start of the TS Ordered Set, transmit FFh in Symbols 7 and 15 without scrambling.
- Else, transmit the even byte parity of Symbols 0-6 (pre-scrambling) in Symbols 7 and 15 with scrambling.

While using TS0 Ordered Sets, the coefficients are not the full 6-bit value but adjusted to the appropriate number of bits that the corresponding coefficients, based on the constraints. For example, 3 bits are enough for the 2nd pre-cursor since it cannot be higher than 7.

The Training Control bits Hot Reset bit, Disable Link bit, and Loopback bit are mutually exclusive, only one of these bits is permitted to be set at a time as well as transmitted on all Lanes in a configured (all Lanes that were in L0) or possible (all Lanes in Configuration) Link. If more than one of Hot Reset bit, Disable Link bit, or Loopback bit are Set at the same time, the Link behavior is undefined.

The TS1 Ordered Set's Retimer Equalization Extend bit is always set to 0b when transmitted by an Upstream Port or Downstream Port. Retimers set the bit to 1b as described in § Section 4.3.7.2 .

Table 4-25 TS1 Ordered Set in 8b/10b and 128b/130b Encoding §

TS1 Ordered Set in 8b/10b and 128b/130b Encoding	
Symbol Number	Description
0	<p>TS1 Identifier</p> <ul style="list-style-type: none"> • When operating at 2.5 or 5.0 GT/s: COM (K28.5) for Symbol alignment. • When operating at 8.0 GT/s or above: Encoded as 1Eh (TS1 Ordered Set).
1	<p>Link Number</p> <ul style="list-style-type: none"> • Ports that do not support 8.0 GT/s or above: 0-255, PAD. • Downstream Ports that support 8.0 GT/s or above: 0-31, PAD. • Upstream Ports that support 8.0 GT/s or above: 0-255, PAD.

TS1 Ordered Set in 8b/10b and 128b/130b Encoding	
Symbol Number	Description
	<ul style="list-style-type: none"> When operating at 2.5 or 5.0 GT/s: PAD is encoded as <u>K23.7</u>. When operating at 8.0 GT/s or above: PAD is encoded as <u>F7h</u>.

This bit can only be set to 1b in specific Phases of the <u>Recovery.Equalization LTSSM State</u>. See § Section 4.2.7.4.2. In all other LTSSM states, it must be set to 0b. Bit 7 Parity (P). This bit is the even parity computed over all bits of Symbols 6, 7, and 8 and bits 6:0 of Symbol 9 (i.e., XOR of all covered bits). Receivers must calculate the parity of the received bits and compare it to the received Parity bit. Received <u>TS1 Ordered Sets</u> are valid only if the calculated and received Parity match.
10 - 13	<ul style="list-style-type: none"> When operating at 2.5 or 5.0 GT/s: <u>TS1 Identifier</u>. Encoded as D10.2 (4Ah). When operating at 8.0 GT/s or above: <u>TS1 Identifier</u>. Encoded as 4Ah.
14 - 15	<ul style="list-style-type: none"> When operating at 2.5 or 5.0 GT/s: <u>TS1 Identifier</u>. Encoded as D10.2 (4Ah). When operating at 8.0 GT/s or above: <u>TS1 Identifier</u> (encoded as 4Ah) or a DC Balance Symbol.

IMPLEMENTATION NOTE: EXPECTED USAGE OF THE 64.0 GT/S SUPPORTED LINK SPEEDS ENCODING §

The TS1 and TS2 Ordered Sets for 8b/10b and 128b/130b encoding are permitted to have the Supported Link Speeds field encoded as 1 0111b (indicating 2.5 GT/s to 64.0 GT/s support, inclusive) in the following scenarios:

1. Initial Link Training to L0 (Configuration.Complete and beyond)

The Link is training to L0 and Flit Mode has been negotiated during the training procedure (i.e., when LinkUp=0b). In this scenario the 1 0111b encoding is permitted to be used once the Link enters Configuration.Complete.

2. Configuration.Linkwidth.Start (as a Receiver only)

When the Link transitions from Configuration.Linkwidth.Start to Loopback when LinkUp=0b, the Loopback Lead is permitted to transmit TS1 Ordered Sets with the Supported Link Speeds advertising 1 0111b if it has prior knowledge that the Loopback Follower (i.e., the Receiver, which is still in Configuration.Linkwidth.Start) supports 64.0 GT/s. How the Loopback Lead obtains the prior knowledge of 64.0 GT/s support is outside the scope of the specification.

3. Recovery.Equalization when LinkUp=0b

Advertising the 1 0111b encoding in Phase 1 of Recovery.Equalization when “Equalization for Loopback” is being performed. More specifically, this is the test scenario where Recovery.Equalization is entered from Loopback, the Link is equalized at the current data rate and then the Link returns to Loopback. In the case where the data rate is less than required (i.e., Link is equalized for 32.0 GT/s but 64.0 GT/s is needed), the 1 0111b setting will be used to indicate to the Link partner the ability to transition to 64.0 GT/s upon re-entry to Loopback (after which an equalization procedure at 64.0 GT/s will be performed followed by a return to Loopback).

4. Loopback

When Loopback is entered through Configuration.Linkwidth.Start and LinkUp=0b, the Loopback Lead is permitted to use the 1 0111b encoding in the TS1 Ordered sets that it transmits upon entry to Loopback.Entry (prior to the EIOSQ that proceeds Electrical Idle and the speed change).

5. Polling.Active (as a Receiver only)

Test apparatus that understands the capabilities of the Port (i.e., that the Port being exercised is capable of 64.0 GT/s operation) may transmit TS1 Ordered Sets with the Supported Link Speeds field set to the 64.0 GT/s supported encoding (1 0111b), and the Flit Mode Supported bit set (1b) in Polling.Active when the TS1 Ordered Sets also have the Compliance Receive bit asserted and the Loopback bit de-asserted. A Port that transitions to Polling.Compliance from Polling.Active because it received the appropriate TS1 Ordered Sets in Polling.Active will accept 1 0111b as a valid Supported Link Speeds encoding (and consider it in its determination of the highest common data rate) if it supports the 64.0 GT/s data rate.

These are bits[2:0] of Symbol 8.</p> <p>Bits 15:3 Modified TS Information 1</p> <p>If <u>Modified TS Usage</u> = 001b or 010b; else Reserved.</p>
10-11	<p>Training Set Message Vendor ID if <u>Modified TS Usage</u> = 001b.</p> <p>Alternate Protocol Vendor ID if <u>Modified TS Usage</u> = 010b.</p> <p>Reserved for other cases.</p>
12-14	<p>If <u>Modified TS Usage</u> = 001b or 010b, Modified TS Information 2</p> <p>Else, Reserved</p>
15	<p>Bit-wise even parity of Symbols 4 through 14.</p> <p>Symbol 15 = Symbol 4 ^ Symbol 5 ^ ... Symbol 14</p>

Fields in the Modified TS1/TS2 Ordered Sets that extend over multiple Symbols use the little endian format using all the bits over those multiple Symbols. For example, Symbols 8 and 9 of the Modified TS1/TS2 comprise 16 bits. The Modified TS Usage field goes in bits [2:0] of Symbol 8 with the bit 0 of Modified TS Usage field placed in bit 0 of Symbol 8, bit 1 of Modified TS Usage field placed in bit 1 of Symbol 8, and bit 2 of Modified TS Usage field placed in bit 2 of Symbol 8. Similarly, bit 12 of the 13 bits of Modified TS Information 1 field is placed in bit 7 of Symbol 9 whereas bit 0 of Modified TS Information 1 is placed in bit 3 of Symbol 8.

4.2.5.2 Alternate Protocol Negotiation §

In addition to the decision to skip equalization, alternate protocols can also be negotiated during the Configuration.Lanenum.Wait, Configuration.Lanenum.Accept, and Configuration.Complete substates, while LinkUp=0b, through the exchange of Modified TS1/TS2 Ordered sets in the 8b/10b encoding. It is strongly recommended that a data rate of 32.0 GT/s or higher is advertised in all three substates throughout the entire alternate protocol negotiation procedure.

Alternate protocol(s) are permitted to be supported with PCIe PHY in 128b/130b or 1b/1b encodings. An alternate protocol is defined to be a non-PCIe protocol using the PCIe PHY layer. One may choose to run PCIe protocol in addition to one or multiple alternate protocols in the alternate protocol mode. The Ordered Set blocks are used as-is, along with the rules governing SKP Ordered Set insertion and the transition between Ordered Set and Data Blocks. The contents of the Data Blocks, however, may be modified according to the rules of the alternate protocol.

IMPLEMENTATION NOTE: ALTERNATE PROTOCOLS SHOULD HAVE AN EDS TOKEN EQUIVALENT §

The EDS Token is used in PCI Express to indicate a switch from Data Blocks to Ordered Set blocks. This additional "redundant" information ensures that a random bit error in the 2 bit block header isn't incorrectly interpreted as the end of a data stream. This is one mechanism used by PCI Express to accomplish an undetected data error Hamming Distance of 4.

Alternate protocols should have an equivalent mechanism.

The following diagram represents the states where alternate protocol and equalization bypass negotiation occurs:

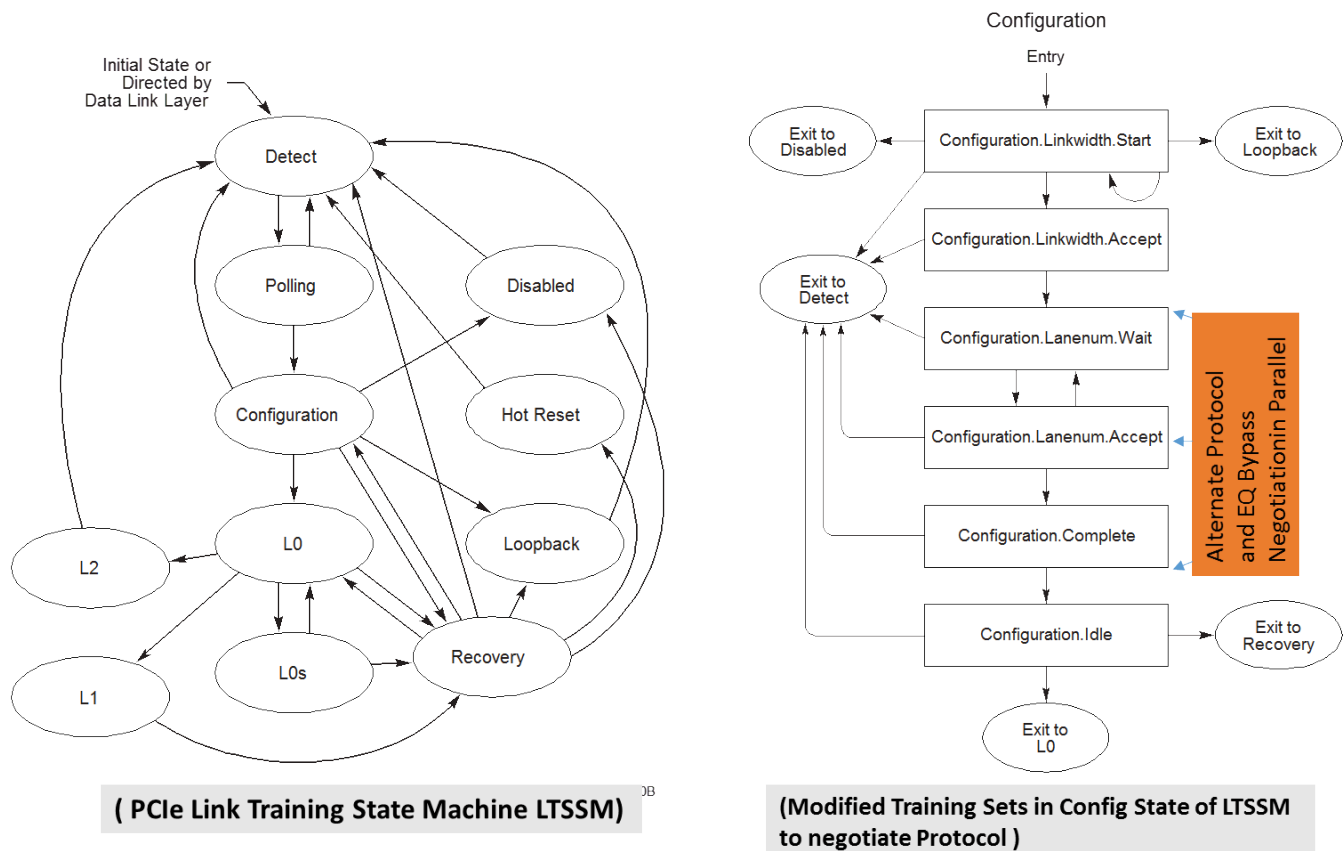

Figure 4-46 Alternate Protocol Negotiation and Equalization Bypass LTSSM States §

Downstream Ports manage Alternate Protocol Negotiation and Training Set Messages based on the value of the Modified TS Usage Mode Selected field when the Port is in Configuration.Lanenum.Wait, Configuration.Lanenum.Accept, and Configuration.Complete substates with LinkUp = 0.

Upstream Ports must respond to unsupported Modified TS Usage values by transmitting Modified TS Usage 000b.

If Modified TS Usage Mode Selected is:

000b

No Alternate Protocol Negotiation or Training Set Message occurs. The link will operate as a PCI Express Link.

001b

Training Set Messages are enabled. Modified TS Information 1 and Modified TS Information 2 fields carry the vendor specific messages defined by the Training Set Message Vendor ID field.

010b

Alternate Protocol Negotiation is enabled. Modified TS Information 1 and Modified TS Information 2 fields carry the alternate protocol details defined by the Alternate Protocol Vendor ID field. A protocol request or response is associated with the protocol defined by the Alternate Protocol Vendor ID field.

The Alternate Protocol Negotiation Status field indicates the progress of the negotiation protocol.

others

Reserved

A Downstream Port that supports Alternate Protocol Negotiation will start the negotiation process when it first enters Configuration.Lanenum.Wait, LinkUp = 0, and Modified TS Usage Mode Selected field is 010b. Starting negotiation consists of sending Modified TS1/TS2 Ordered Sets with Modified TS Usage = 010b.

Table 4-30 Modified TS Information 1 field in Modified TS1/TS2 Ordered Sets if Modified TS Usage = 010b (Alternate Protocol) §

Bits	Field	Description
4:3	Alternate Protocol Negotiation Status	<p>For Modified TS1 Ordered Sets:</p> <p>00b DP Indicates a protocol request from the Downstream Port asking whether the Upstream Port supports a particular alternate protocol.</p> <p>UP Indicates that the Upstream Port does not have an answer for a protocol request yet. This occurs either when it is evaluating the protocol request or it has not received two consecutive Modified TS1s to perform the evaluation. In the former case, Alternate Protocol Vendor ID and Alternate Protocol Details reflect what it received, while Modified TS Information 2 is protocol specific. In the latter case, all 3 fields must be 0.</p> <p>01b DP Reserved</p> <p>UP Indicates that the Upstream Port does not support the requested protocol. Alternate Protocol Vendor ID and Alternate Protocol Details reflect what it received. Modified TS Information 2 must be all 0s.</p> <p>10b DP Reserved</p> <p>UP Indicates that the Upstream Port supports the requested protocol. Alternate Protocol Vendor ID and Alternate Protocol Details reflect what it received, while Modified TS Information 2 field is protocol specific.</p> <p>11b Reserved</p> <p>For Modified TS2 Ordered Sets:</p> <p>00b Indicates a protocol confirmation from the Downstream Port as well as the Upstream Port. Behavior is undefined if the Downstream Port had not earlier received status 10b for this protocol in this instance of protocol negotiation during the Modified TS1 Ordered Sets. Similarly, behavior is undefined if the Upstream Port had not earlier transmitted status 10b for this protocol in this instance of protocol negotiation during the Modified TS1 Ordered Sets.</p> <p>No protocol is selected unless the Downstream Port sends and receives a protocol confirmation in the Modified TS2 Ordered Sets. If the Downstream Port decides not to use any Alternate Protocol, it must indicate this by transmitting Modified TS2 Ordered Set with Modified TS Usage of 000b or 001b.</p> <p>01b, 10b, 11b Reserved</p>
15:5	Alternate Protocol Details	Alternate Protocol Details is Modified TS Usage = 010b.

If Modified TS Usage = 001b, then Modified TS Information 1 and Modified TS Information 2 contain details of the training set messages.

Alternate Protocol Negotiation must be concurrent with the Lane number negotiation. The Downstream Port is responsible for ensuring that they arrive at a consensus on the Alternate Protocol Negotiation prior to transitioning to Configuration.Complete substate. It is permitted to fall back to PCIe protocol if the Alternate Protocol Negotiation does not arrive at a consensus. On a successful negotiation to alternate protocol, the Link moves to L0 at 2.5 GT/s, changes the data rate to the higher data rates, performing equalization, if needed and enters L0 at the highest data rate desired. After

transmitting the SDS Ordered Set in the highest data rate after equalization has been performed, the Data Blocks will carry the alternate protocol and the Link will be under the control of the alternate protocol.

4.2.5.3 Electrical Idle Sequences (EIOS and EIOSQ) §

Before a Transmitter enters Electrical Idle, it must always send an Electrical Idle Ordered Set Sequence (EIOSQ), unless otherwise specified. An **Electrical Idle Ordered Set Sequence (EIOSQ)** is defined as one EIOS if the current Data Rate is 2.5 GT/s, 8.0 GT/s, 16.0 GT/s, 32.0 GT/s, or 64.0 GT/s Data Rate, or two consecutive EIOSs if the current Data Rate is 5.0 GT/s.

When using 8b/10b encoding, an EIOS is a K28.5 (COM) followed by three K28.3 (IDL) Symbols. Transmitters must transmit all Symbols of an EIOS. An EIOS is received when the COM and two of the three IDL Symbols are received. When using 128b/130b encoding, an EIOS is an Ordered Set block, as defined in § Table 4-32. When using 1b/1b encoding, an EIOS is an Ordered Set block, as defined in § Table 4-33. Transmitters must transmit all Symbols of an EIOS if additional EIOSs are to be transmitted following it. Transmitters must transmit Symbols 0-13 of an EIOS, but are permitted to terminate the EIOS anywhere in Symbols 14 or 15, when transitioning to Electrical Idle after it. An EIOS is considered received when Symbols 0-3 of an Ordered Set Block match the definition of an EIOS if the data rate is less than 64.0 GT/s. At 64.0 GT/s, the rules governing receipt of an EIOS appears in § Section 4.2.3.1.5.

IMPLEMENTATION NOTE: TRUNCATION OF EIOS ORDERED SET §

Truncation in the last EIOS is allowed to help implementations where a transmitter may terminate on an internal clock boundary that may not align on a Symbol boundary due to 128b/130b encoding. Truncation is okay since Receivers will just look at the first four Symbols to conclude it is an EIOS.

After transmitting the last Symbol of the last Electrical Idle Ordered Set, the Transmitter must be in a valid Electrical Idle state as specified by $T_{TX-IDLE-SET-TO-IDLE}$ (see § Table 8-7).

Table 4-31 Electrical Idle Ordered Set (EIOS) for 2.5 GT/s and 5.0 GT/s Data Rates §

Symbol Number	Encoded Values	Description
0	K28.5	COM for Symbol alignment
1	K28.3	IDL
2	K28.3	IDL
3	K28.3	IDL

Table 4-32 Electrical Idle Ordered Set (EIOS) for 128b/130b Encoding §

Symbol Numbers	Value	Description
0-15	66h	EIOS Identifier and Payload

Table 4-33 Electrical Idle Ordered Set (EIOS) for 1b/1b Encoding §

Symbol Numbers	Value	Description
0, 2, 4, 6, 8, 10, 12, 14	0Fh	EIOS Identifier and Payload
1, 3, 5, 7, 9, 11, 13, 15	F0h	EIOS Identifier and Payload

Table 4-34 Electrical Idle Exit Ordered Set (EIEOS) for 5.0 GT/s Data Rate §

Symbol Number	Encoded Values	Description
0	K28.5	COM for Symbol alignment
1-14	K28.7	EIE - K Symbol with low frequency components for helping achieve exit from Electrical Idle
15	D10.2	TS1 Identifier (See Note 1)

Notes:

1. This symbol is not scrambled. Previous versions of this specification were less clear and some implementations may have incorrectly scrambled this symbol. It is recommended that devices be tolerant of receiving EIEOS in which this symbol is scrambled.

Table 4-35 Electrical Idle Exit Ordered Set (EIEOS) for 8.0 GT/s Data Rate §

Symbol Numbers	Value	Description
0, 2, 4, 6, 8, 10, 12, 14	00h	Symbol 0: EIEOS Identifier A low frequency pattern that alternates between eight 0s and eight 1s.
1, 3, 5, 7, 9, 11, 13, 15	FFh	A low frequency pattern that alternates between eight 0s and eight 1s.

Table 4-36 Electrical Idle Exit Ordered Set (EIEOS) for 16.0 GT/s Data Rate §

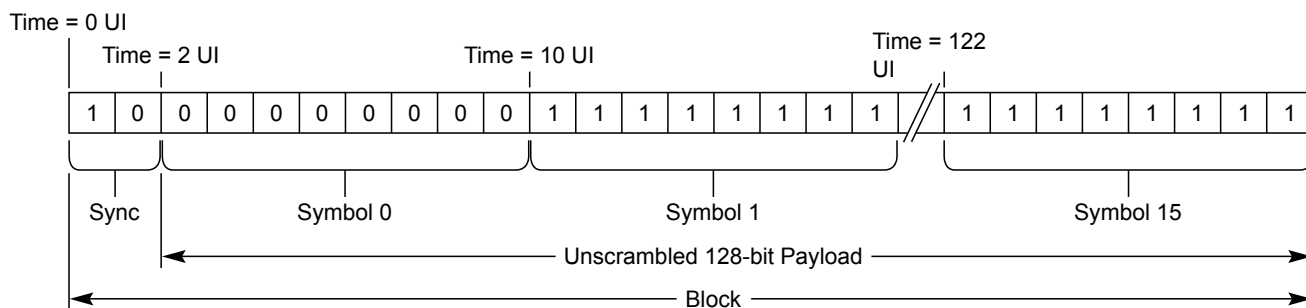

Symbol Numbers	Value	Description
0, 1, 4, 5, 8, 9, 12, 13	00h	Symbol 0: EIEOS Identifier A low frequency pattern that alternates between sixteen 0s and sixteen 1s.
2, 3, 6, 7, 10, 11, 14, 15	FFh	A low frequency pattern that alternates between sixteen 0s and sixteen 1s.

Table 4-37 Electrical Idle Exit Ordered Set (EIEOS) for 32.0 GT/s Data Rate §

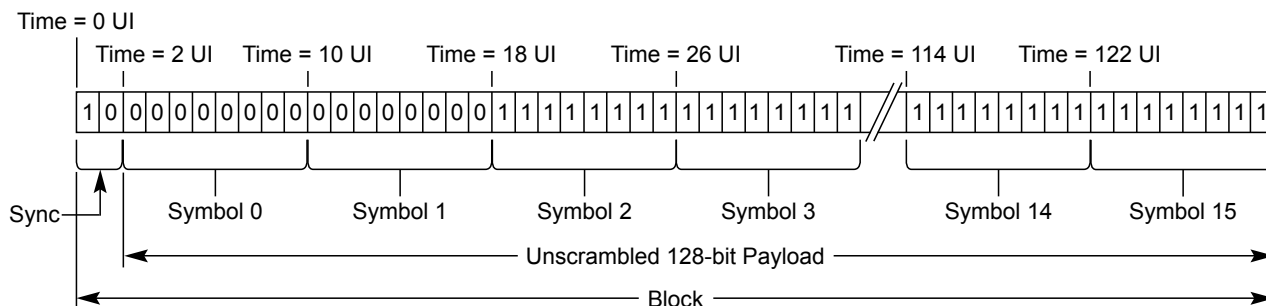

Symbol Numbers	Value	Description
0, 1, 2, 3, 8, 9, 10, 11	00h	Symbol 0: EIEOS Identifier A low frequency pattern that alternates between thirty-two 0s and thirty-two 1s.
4, 5, 6, 7, 12, 13, 14, 15	FFh	A low frequency pattern that alternates between thirty-two 0s and thirty-two 1s.

Table 4-38 Electrical Idle Exit Ordered Set (EIEOS)

Figure 4-47 Electrical Idle Exit Ordered Set for 8.0 GT/s to 32.0 GT/s Data Rates (EIEOS) §

The Electrical Idle Exit Ordered Set (EIEOS) is transmitted only when operating at speeds other than 2.5 GT/s. It is a low frequency pattern transmitted periodically to help ensure that receiver Electrical Idle exit detection circuitry can detect an exit from Electrical Idle. When using 128b/130b encoding, it is also used for Block Alignment as described in § Section 4.2.2.2.1 .

An **Electrical Idle Exit Ordered Set Sequence (EIEOSQ)** comprises of two consecutive EIEOS for the Data Rate of 32.0 GT/s and one EIEOS for 5.0 GT/s, 8.0 GT/s, and 16.0 GT/s. The two EIEOS at 32.0 GT/s must be back to back and uninterrupted in order to be considered consecutive and form an EIEOSQ. Irrespective of the length of the EIEOSQ, block alignment still occurs on an EIEOS.

At the Data Rate of 64.0 GT/s, an EIEOSQ is defined as follows:

- On entry to Recovery.RcvrLock either from Recovery.Speed or from L1, until either the Receiver detects exit Electrical Idle on all Lanes or it receives two consecutive valid TS1 Ordered Sets on any Lane:
 - Four consecutive EIEOS, uninterrupted by any other Ordered Set including the Control SKP Ordered Set
- While increasing Link Width with L0p till the Receiver detects exit Electrical Idle on all Lanes that need to be activated or receives two consecutive valid TS1 Ordered Sets on any Lane that needs to be activated:
 - Four consecutive EIEOS, uninterrupted by any other Ordered Set including the Control SKP Ordered Set
- On entry to the Loopback state from electrical idle till the Receiver detects exit Electrical Idle on all Lanes that need to be activated or receives two consecutive valid TS1 Ordered Sets on any Lane:
 - Four consecutive EIEOS, uninterrupted by any other Ordered Set including the Control SKP Ordered Set
- While transmitting Compliance Patterns or Modified Compliance Patterns:
 - One EIEOS
- Else one EIEOS

When using 8b/10b encoding and operating at 5.0 GT/s, an EIEOSQ, as defined in § Table 4-34, is transmitted in the following situations:

- Before the first TS1 Ordered Set after entering the LTSSM Configuration.Linkwidth.Start state.
- Before the first TS1 Ordered Set after entering the LTSSM Recovery.RcvrLock state.
- After every 32 TS1 or TS2 Ordered Sets are transmitted in the LTSSM Configuration.Linkwidth.Start, Recovery.RcvrLock, and Recovery.RcvrCfg states. The TS1/TS2 count is set to 0 when:
 - An EIEOS is transmitted.
 - The first TS2 Ordered Set is received while in the LTSSM Recovery.RcvrCfg state.

When using 128b/130b encoding, an EIEOSQ, as defined in § Table 4-35 through § Table 4-37 and § Figure 4-47, is transmitted in the following situations:

- Before the first TS1 Ordered Set after entering the LTSSM Configuration.Linkwidth.Start substate.
- Before the first TS1 Ordered Set after entering the LTSSM Recovery.RcvrLock substate.
- Immediately following an EDS Framing Token in Non-Flit Mode when ending a Data Stream and not transmitting an EIOS and not entering the LTSSM Recovery.RcvrLock substate.
- At the scheduled Ordered Set interval to end a Data Stream in Flit Mode.
- After every 32 TS1 or TS2 Ordered Sets are transmitted in all LTSSM states which require transmission of TS1 or TS2 Ordered Sets. The TS1/TS2 count is set to 0 when:
 - An EIEOS is transmitted.
 - The first TS2 Ordered Set is received while in the LTSSM Recovery.RcvrCfg state.
 - The first TS2 Ordered Set is received while in the LTSSM Configuration.Complete state.

- A Downstream Port is in Phase 2 of the LTSSM Recovery.Equalization state and two consecutive TS1 Ordered Sets are received on any Lane with the Reset EIEOS Interval Count bit set.
- An Upstream Port is in Phase 3 of the LTSSM Recovery.Equalization state and two consecutive TS1 Ordered Sets are received on any Lane with the Reset EIEOS Interval Count bit set.
- After every 65,536 TS1 Ordered Sets are transmitted in the LTSSM Recovery.Equalization state if the Reset EIEOS Interval Count bit has prevented it from being transmitted for that interval. Implementations are permitted to satisfy this requirement by transmitting an EIEOSQ within two TS1 Ordered Sets of whenever the current scrambling LFSR matches its seed value.
- As part of an FTS Ordered Set, Compliance Pattern, or Modified Compliance Pattern as described in the relevant sections.

When using 1b/1b encoding, an EIEOSQ, as defined in § Table 4-38 is transmitted in the following situations:

- Before the first TS1 Ordered Set after entering the LTSSM Configuration.Linkwidth.Start substate.
- Before the first TS1 Ordered Set after entering the LTSSM Recovery.RcvrLock substate.
- Before the first TS0 Ordered Set after entering Recovery.Equalization substate.
- At the scheduled Ordered Set interval to indicate the end of the Data Stream.
- After every 32 TS1, TS2, or TS0 Ordered Sets are transmitted in all LTSSM states which require transmission of TS1, TS2, or TS0 Ordered Sets. The TS1/TS2/TS0 count is set to 0 when:
 - An EIEOS is transmitted.
 - The first TS2 Ordered Set is received while in the LTSSM Recovery.RcvrCfg state.
 - The first TS2 Ordered Set is received while in the LTSSM Configuration.Complete state.
 - The first TS1 Ordered Set is received while in the LTSSM Recovery.Equalization state if the TS1 Ordered Set is received after TS0 Ordered Sets.
 - A Downstream Port is in Phase 2 of the LTSSM Recovery.Equalization state and two consecutive TS0 Ordered Sets are received on any Lane with the Reset EIEOS Interval Count bit set.
 - An Upstream Port is in Phase 3 of the LTSSM Recovery.Equalization state and two consecutive TS1 Ordered Sets are received on any Lane with the Reset EIEOS Interval Count bit set.
- After every 65,536 TS1 Ordered Sets are transmitted in the LTSSM Recovery.Equalization state if the Reset EIEOS Interval Count bit has prevented it from being transmitted for that interval. Implementations are permitted to satisfy this requirement by transmitting an EIEOSQ within two TS1 Ordered Sets of whenever the current scrambling LFSR matches its seed value.
- As part of a Compliance Pattern, or Modified Compliance Pattern as described in the relevant sections.

Example: An LTSSM enters Recovery.RcvrLock from L0 in 5.0 GT/s data rate. It transmits an EIEOS followed by TS1 Ordered Sets. It transmits 32 TS1 Ordered Sets following which it transmits the second EIEOS. Subsequently it sends two more TS1 Ordered Sets and enters Recovery.RcvrCfg where it transmits the third EIEOS after transmitting 30 TS2 Ordered Sets. It transmits 31 more TS2 Ordered Sets (after the first 30 TS2 Ordered Sets) in Recovery.RcvrCfg when it receives a TS2 Ordered Set. Since it receives its first TS2 Ordered Set, it will reset its EIEOS interval count to 0 and keep transmitting another 16 TS2 Ordered Sets before transitioning to Recovery.Idle. Thus, it did not send an EIEOS in the midst of the last 47 TS2 Ordered Sets since the EIEOS interval count got reset to 0. From Recovery.Idle, the LTSSM transitions to Configuration.Linkwidth.Start and transmits an EIEOS after which it starts transmitting the TS1 Ordered Sets.

While operating in speeds other than 2.5 GT/s, an implementation is permitted to not rely on the output of the Electrical Idle detection circuitry except when receiving the EIEOS during certain LTSSM states or during the receipt of the FTS prepended by the four consecutive EIE Symbols (see § Section 4.2.5.6) at the Receiver during Rx L0s or the Modified Compliance Pattern in Polling.Compliance when the circuitry is required to signal an exit from Electrical Idle.

4.2.5.4 Inferring Electrical Idle §

A device is permitted in all speeds of operation to infer Electrical Idle instead of detecting Electrical Idle using analog circuitry. § Table 4-39 summarizes the conditions to infer Electrical Idle in the various substates.

Table 4-39 Electrical Idle Inference Conditions §

State	2.5 GT/s	5.0 GT/s	8.0 GT/s and higher data rates
L0	Absence of at least one of: <ul style="list-style-type: none"> an UpdateFC DLLP, an <u>Optimized_Update_FC</u> (in Flit Mode), or a SKP Ordered Set in a 128 μ s window		
<u>Recovery.RcvrCfg</u>	Absence of a <u>TS1</u> or <u>TS2</u> Ordered Set in a 1280 UI interval	Absence of a <u>TS1</u> or <u>TS2</u> Ordered Set in a 4 ms window	
<u>Recovery.Speed</u> when <u>successful_speed_negotiation</u> = 1b	Absence of a <u>TS1</u> or <u>TS2</u> Ordered Set in a 1280 UI interval	Absence of a <u>TS1</u> or <u>TS2</u> Ordered Set in a 4680 UI interval	
<u>Recovery.Speed</u> when <u>successful_speed_negotiation</u> = 0b	Absence of an exit from Electrical Idle in a 2000 UI interval	Absence of an exit from Electrical Idle in a 16000 UI interval	
<u>Loopback.Active</u> (as Follower)	Absence of an exit from Electrical Idle in a 128 μ s window	N/A	N/A

The Electrical Idle exit condition must not be determined based on inference of Electrical Idle condition. For area efficiency, an implementation is permitted to choose to implement a common timeout counter per LTSSM and look for the Electrical Idle inference condition within the common timeout window determined by the common counter for each of the Lanes the LTSSM controls instead of having a timeout counter per Lane.

IMPLEMENTATION NOTE: INFERENCE OF ELECTRICAL IDLE §

In the L0 state, one or more Flow Control Update DLLPs are expected to be received in a 128 μ s window. Also in L0, one or more SKP Ordered Sets are expected to be received in a 128 μ s window. As a simplification, it is permitted to use either one (or both) of these indicators to infer Electrical Idle. Hence, the absence of a Flow Control Update DLLP and/or a SKP Ordered Set in any 128 μ s window can be inferred as Electrical Idle. In Recovery.RcvrCfg as well as Recovery.Speed with successful speed negotiation, the Receiver should receive TS1 or TS2 Ordered Sets continuously with the exception of the EIEOS and the SKP Ordered Set. Hence, the absence of a TS1 or TS2 Ordered Set in the interval specified above must be treated as Electrical Idle for components that implement the inference mechanism. In the event that the device enters Recovery.Speed with successful_speed_negotiation = 0b, there is a possibility that the device had failed to receive Symbols. Hence, the Electrical Idle inference is done as an absence of exit from Electrical Idle. In data rates other than 2.5 GT/s, Electrical Idle exit is guaranteed only on receipt of an EIEOS. Hence, the window is set to 16000 UI for detecting an exit from Electrical Idle in 5.0 GT/s and above data rates. In 2.5 GT/s data rate, Electrical Idle exit must be detected with every Symbol received. Hence, absence of Electrical Idle exit in a 2000 UI window constitutes an Electrical Idle condition.

4.2.5.5 Lane Polarity Inversion §

During the training sequence in Polling, the Receiver looks at Symbols 6-15 of the TS1 and TS2 Ordered Sets as the indicator of Lane polarity inversion (D+ and D- are swapped). If Lane polarity inversion occurs, the TS1 Symbols 6-15 received will be D21.5 as opposed to the expected D10.2. Similarly, if Lane polarity inversion occurs, Symbols 6-15 of the TS2 Ordered Set will be D26.5 as opposed to the expected D5.2. This provides the clear indication of Lane polarity inversion.

If polarity inversion is detected the Receiver must invert the received data. The Transmitter must never invert the transmitted data. Support for Lane Polarity Inversion is required on all PCI Express Receivers across all Lanes independently.

4.2.5.6 Fast Training Sequence (FTS) §

Fast Training Sequence (FTS) is the mechanism that is used for bit and Symbol lock when transitioning from L0s to L0. The FTS is used by the Receiver to detect the exit from Electrical Idle and align the Receiver's bit and Symbol receive circuitry to the incoming data. Refer to § Section 4.2.6 for a description of L0 and L0s.

- **At 2.5 GT/s and 5.0 GT/s data rates:**

A single FTS is comprised of one K28.5 (COM) Symbol followed by three K28.1 Symbols. The maximum number of FTSs (N_FTS) that a component can request is 255, providing a bit time lock of $4 * 255 * 10 * UI$. If the data rate is 5.0 GT/s, four consecutive EIE Symbols are transmitted at valid signal levels prior to transmitting the first FTS. These Symbols will help the Receiver detect exit from Electrical Idle. An implementation that does not guarantee proper signaling levels for up to the allowable time on the Transmitter pins (see § Section 4.2.5.6) since exiting Electrical Idle condition is required to prepend its first FTS by extra EIE Symbols so that the Receiver can receive at least four EIE Symbols at valid signal levels. Implementations must not transmit more than eight EIE Symbols prior to transmitting the first FTS. A component is permitted to advertise different N_FTS rates at different speeds. At 5.0 GT/s, a component may choose to advertise an appropriate N_FTS number considering that it will receive the four EIE Symbols. 4096 FTSs must be sent when the Extended Synch bit is Set in order to provide external Link monitoring tools with enough time to achieve bit and framing synchronization. SKP Ordered Sets must be scheduled and transmitted between FTSs as necessary to meet the definitions in § Section 4.2.8 with the exception that no SKP Ordered Sets can be transmitted during the first N_FTS FTSs. A single SKP Ordered Set is always sent after the last FTS is transmitted. It is permitted for this SKP Ordered Set to affect or not affect the scheduling of subsequent SKP Ordered Sets for Clock Tolerance Compensation by the Transmitter as described in § Section 4.2.8. Note that it is possible that two SKP Ordered Sets can be transmitted back to back (one SKP Ordered Set to signify the completion of the 4096 FTSs and one scheduled and transmitted to meet the definitions described in § Section 4.2.8).

- **At 8.0 GT/s, 16.0 GT/s, or 32.0 GT/s data rates:**

A single FTS is a 130-bit unscrambled Ordered Set Block, as shown in § Table 4-40. The maximum number of FTSs (N_FTS) that a component can request is 255, providing a bit time lock of $130 * 255 UI$ ($130 * 263$ or $273 UI$ if including the periodic EIEOS). A component is permitted to advertise different N_FTS values at different speeds. On exit from L0s, the transmitter first transmits an EIEOSQ which will help the receiver detect exit from Electrical Idle due to its low frequency content. After that first EIEOSQ, the transmitter must send the required number of FTS (4096 when the Extended Synch bit is Set; otherwise N_FTS), with an EIEOSQ transmitted after every 32 FTS. The FTS sequence will enable the receiver obtain bit lock (and optionally to do Block alignment). When the Extended Synch bit is Set, SKP Ordered Sets must be scheduled and transmitted between FTSs and EIEOSQ as necessary to meet the definitions in § Section 4.2.8. The last FTS Ordered Set of the FTS sequence, if any (no FTS Ordered Sets are sent if N_FTS is equal to zero), is followed by a final EIEOSQ that will help the receiver acquire Block alignment. Implementations are permitted to send two EIEOS back to back even at a data rate below 32.0 GT/s following the last FTS Ordered Set if the N_FTS is a multiple of 32. The EIEOS resets

the scrambler in both the Transmitter as well as the Receiver. Following the final EIEOSQ, an SDS Ordered Set is transmitted to help the receiver perform de-skew and to indicate the transition from Ordered Sets to Data Stream. After the SDS Ordered Set is transmitted, a Data Block must be transmitted.

IMPLEMENTATION NOTE: SCRAMBLING LFSR DURING FTS TRANSMISSION IN 128B/ 130B ENCODING §

Since the scrambler is reset on the last EIEOS, and none of the Ordered Set in the FTS sequence is scrambled, it does not matter whether implementations choose to advance the scrambler or not during the time FTS is received.

*Table 4-40 FTS for
8.0 GT/s and Above Data
Rates §*

Symbol Number	Value
0	55h
1	47h
2	4Eh
3	C7h
4	CCh
5	C6h
6	C9h
7	25h
8	6Eh
9	ECh
10	88h
11	7Fh
12	80h
13	8Dh
14	8Bh
15	8Eh

N_FTS defines the number of FTSs that must be transmitted when transitioning from L0s to L0. At the 2.5 GT/s data rate, the value that can be requested by a component corresponds to a Symbol lock time of 16 ns (N_FTS set to 0b and one SKP Ordered Set) to ~4 µs (N_FTS set to 255), except when the Extended Synch bit is Set, which requires the transmission of 4096 FTSs resulting in a bit lock time of 64 µs. For 8.0 GT/s and above data rates, when the Extended Synch bit is Set, the transmitter is required to send 4096 FTS Ordered Set Blocks. Note that the N_FTS value reported by a component

may change; for example, due to software modifying the value in the Common Clock Configuration bit (see § Section 7.5.3.7).

If the N_FTS period of time expires before the Receiver obtains bit lock, Symbol lock or Block alignment, and Lane-to-Lane de-skew on all Lanes of the configured Link, the Receiver must transition to the Recovery state. This sequence is detailed in the LTSSM in § Section 4.2.6.

4.2.5.7 Start of Data Stream Ordered Set (SDS Ordered Set) §

The Start of Data Stream (SDS) Ordered Set, described in § Table 4-41, § Table 4-42, and § Table 4-43 is defined only for 128b/130b encoding and 1b/1b encoding. It is transmitted in the Configuration.Idle, Recovery.Idle, and Tx_L0s.FTS LTSSM states to define the transition from Ordered Set Blocks to a Data Stream, and Loopback Leads are permitted to transmit it as described in § Section 4.2.2.6. It must not be transmitted at any other time. While not in the Loopback state, the Block following an SDS Ordered Set must be a Data Block in Non-Flit Mode, and the first Symbol of that Data Block is the first Symbol of the Data Stream. In 1b/1b encoding, the Transmitter must send two back to back SDS when the conditions to send an SDS are met. The SDS Ordered Set in 1b/1b encoding must be on an aligned 128b (16B) boundary. An SDS Ordered Set sequence refers to either the single SDS Ordered set with 128b/130b encoding or the two back to back SDS Ordered Sets with 1b/1b encoding. In Flit Mode, with 128b/130b encoding and 1b/1b encoding, a Control SKP Ordered Set must be sent after the SDS Ordered Set. The first Symbol of the Data Stream starts immediately after the Control SKP Ordered Set. With 1b/1b encoding, a Receiver considers an SDS sequence valid if four good B1_C6_C6_C6 (4B) sets are received, at least two of which are in an even 4 byte aligned position (i.e., bytes 0-3, 8-11).

Table 4-41 SDS Ordered Set (for 8.0 GT/s and 16.0 GT/s Data Rate) §

4.2.5.8 Link Error Recovery §

- Link Errors, when operating with 8b/10b encoding are:
 - 8b/10b decode errors, Non-Flit Mode framing related errors defined in § Section 4.2.1.2.1, loss of Symbol lock, Elasticity Buffer Overflow/Underflow, or loss of Lane-to-Lane de-skew.
 - 8b/10b decode errors must be checked and must trigger a Receiver Error in specified LTSSM states (see § Table 4-48), which is a reported error associated with the Port (see § Section 6.2). Triggering a

Receiver Error on any or all of Non-Flit Mode framing related errors defined in § Section 4.2.1.2.1 , loss of Symbol Lock, Lane De-skew Error, and Elasticity Buffer Overflow/Underflow is optional.

- Link Errors, when operating with 128b/130b encoding, are:
 - Framing Errors, loss of Block Alignment, Elasticity Buffer Overflow/Underflow, or loss of Lane-to-Lane de-skew.
 - Framing errors must be checked and trigger a Receiver Error in the LTSSM states specified in § Table 4-48. The Receiver Error is a reported error associated with the Port (see § Section 6.2). Triggering a Receiver Error on any of all of loss of Block Alignment, Elasticity Buffer Overflow/Underflow, and loss of Lane-to-Lane de-skew is optional.
- Link Errors, when operating with 1b/1b encoding, are:
 - Framing Errors, Elasticity Buffer Overflow/Underflow, or loss of Lane-to-Lane de-skew.
 - Framing errors must be checked and trigger a Receiver Error in the LTSSM states specified in § Table 4-48. The Receiver Error is a reported error associated with the Port (see § Section 6.2). Triggering a Receiver Error on any of all of Elasticity Buffer Overflow/Underflow, and loss of Lane-to-Lane de-skew is optional.
- On a configured Link, which is in L0, error recovery will at a minimum be managed in a Layer above the Physical Layer (as described in § Section 3.6) by directing the Link to transition to Recovery.
 - Note: Link Errors may also result in the Physical Layer initiating an LTSSM state transition from L0 to Recovery.
- All LTSSM states other than L0 make progress⁷² when Link Errors occur.
 - When operating with 8b/10b encoding, Link Errors that occur in LTSSM states other than L0 must not result in the Physical Layer initiating an LTSSM state transition.
 - When operating with 128b/130b encoding and not processing a Data Stream, Link Errors that occur in LTSSM states other than L0 must not result in the Physical Layer initiating an LTSSM state transition.
- When operating with 8b/10b encoding, if a Lane detects an implementation specific number of 8b/10b errors, Symbol lock must be verified or re-established as soon as possible.⁷³

4.2.5.9 Reset §

Reset is described from a system point of view in § Section 6.6 .

4.2.5.9.1 Fundamental Reset §

When Fundamental Reset is asserted:

- The Receiver terminations are required to meet $Z_{RX-HIGH-IMP-DC-POS}$ and $Z_{RX-HIGH-IMP-DC-NEG}$ (see § Table 8-12).
- The Transmitter is required only to meet $I_{TX-SHORT}$ (see § Table 8-7).
- The Transmitter holds a constant DC common mode voltage.⁷⁴

When Fundamental Reset is deasserted:

72. In this context, progress is defined as the LTSSM not remaining indefinitely in one state with the possible exception of Detect, or Disabled.

73. The method to verify and re-establish Symbol lock is implementation specific.

74. The common mode being driven is not required to meet the Absolute Delta Between DC Common Mode during L0 and Electrical Idle ($V_{TX-CM-DC-ACTIVE-IDLE-DELTA}$) specification (see § Table 8-7).

- The Port LTSSM (see § Section 4.2.6) is initialized (see § Section 6.6.1 for additional requirements).

4.2.5.9.2 Hot Reset §

Hot Reset is a protocol reset defined in § Section 4.2.6.12.

4.2.5.10 Link Data Rate Negotiation §

All devices are required to start Link initialization using a 2.5 GT/s data rate on each Lane. A field in the training sequence Ordered Set (see § Section 4.2.5.1) is used to advertise all supported data rates. The Link trains to L0 initially in 2.5 GT/s data rate after which a data rate change occurs by going through the Recovery state.

4.2.5.11 Link Width and Lane Sequence Negotiation §

PCI Express Links must consist of 1, 2, 4, 8, or 16 Lanes in parallel, referred to as x1, x2, x4, x8, and x16 Links, respectively. All Lanes within a Link must simultaneously transmit data based on the same frequency with a skew between Lanes not to exceed $L_{TX-SKEW}$ (§ Table 8-6). The negotiation process is described as a sequence of steps.

The negotiation establishes values for Link number and Lane number for each Lane that is part of a valid Link; each Lane that is not part of a valid Link exits the negotiation to become a separate Link or remains in Electrical Idle.

During Link width and Lane number negotiation, the two communicating Ports must accommodate the maximum allowed Lane-to-Lane skew as specified by $L_{RX-SKEW}$ in § Table 8-12.

Optional Link negotiation behaviors include Lane reversal, variable width Links, splitting of Ports into multiple Links and the configuration of a crosslink.

Other specifications may impose other rules and restrictions that must be comprehended by components compliant to those other specifications; it is the intent of this specification to comprehend interoperability for a broad range of component capabilities.

4.2.5.11.1 Required and Optional Port Behavior §

- The ability for a xN Port to form a xN Link as well as a x1 Link (where N can be 16, 8, 4, 2, and 1) is required.
 - Designers must connect Ports between two different components in a way that allows those components to meet the above requirement. If the Ports between components are connected in ways that are not consistent with intended usage as defined by the component's Port descriptions/data sheets, behavior is undefined.
- The ability for a xN Port to form any Link width between N and 1 is optional.
 - An example of this behavior includes a x16 Port which can only configure into only one Link, but the width of the Link can be configured to be x8, x4, x2 as well as the required widths of x16 and x1.
- The ability to split a Port into two or more Links is optional.
 - An example of this behavior would be a x16 Port that may be able to configure two x8 Links, four x4 Links, or 16 x1 Links.
- Support for Lane reversal is optional.
 - If implemented, Lane reversal must be done for both the Transmitter and Receiver of a given Port for a multi-Lane Link.

- An example of Lane reversal consists of Lane 0 of an Upstream Port attached to Lane N-1 of a Downstream Port where either the Downstream or Upstream device may reverse the Lane order to configure a xN Link.

Support for formation of a crosslink is optional. In this context, a Downstream Port connected to a Downstream Port or an Upstream Port connected to an Upstream Port is a crosslink.

Current and future electromechanical and/or form factor specifications may require the implementation of some optional features listed above. Component designers must read the specifications for the systems that the component(s) they are designing will be used in to ensure compliance to those specifications.

4.2.5.12 Lane-to-Lane De-skew §

The Receiver must compensate for the allowable skew between all Lanes within a multi-Lane Link (see § Table 8-7 and § Table 8-12) before delivering the data and control to the Data Link Layer.

When using 8b/10b encoding, an unambiguous Lane-to-Lane de-skew mechanism may use one or more of the following:

- The COM Symbol of a received TS1 or TS2 Ordered Set
- The COM Symbol of a received Electrical Idle Exit Ordered Set
- The COM Symbol of the first received SKP Ordered Set after an FTS sequence
- The COM Symbol of a received SKP Ordered Set during a training sequence when not using SRIS.

When using 128b/130b encoding, an unambiguous Lane-to-Lane de-skew mechanism may use one or more of the following:

- A received SDS Ordered Set
- A received Electrical Idle Exit Ordered Set except when exiting L0s
- The first received Electrical Idle Exit Ordered Set after an FTS Ordered Set when exiting L0s
- When operating at 8.0 GT/s, a received SKP Ordered Set
- When operating at a data rate of 16.0 GT/s or higher, the first received SKP Ordered Set after an FTS sequence
- When operating at a data rate of 16.0 GT/s or higher, a received SKP Ordered Set except when:
 - exiting a training sequence or
 - two SKP Ordered Sets are separated by an EDS

When using 1b/1b encoding, an unambiguous Lane-to-Lane de-skew mechanism may use one or more of the following:

- A received SDS Ordered Set
- A received Electrical Idle Exit Ordered Set
- A received Control SKP Ordered Set

Other de-skew mechanisms may also be employed, provided they are unambiguous. Lane-to-Lane de-skew must be performed during Configuration, Recovery, and L0s in the LTSSM.

IMPLEMENTATION NOTE:

UNAMBIGUOUS LANE-TO-LANE DE-SKEW: §

The max skew at 2.5 GT/s that a receiver must be able to de-skew is 20 ns. A nominal SKP Ordered Set (i.e., one that does not have SKP Symbols added or removed by a Retimer) is 4 Symbols long, or 16 ns, at 2.5 GT/s. Generally SKP Ordered Sets are transmitted such that they are well spaced out, and no particular care is needed to use them for de-skew (i.e., they provide an unambiguous mechanism). If back-to-back SKP Ordered Sets are transmitted, an implementation that simply looks for the COM of the SKP Ordered Set to occur on each Lane at the same point in time may fail. When exiting L0s a transmitter may send back-to-back SKP Ordered Sets after the last FTS Ordered Set of the Fast Training Sequence. De-skew must be obtained in L0s, therefore the implementation must comprehend back-to-back SKP Ordered Sets when performing de-skew in this case.

Exceptions to the unambiguous mechanism in § Section 4.2.5.12 occur because back-to-back Ordered Sets might be sent (i.e., EIEOS might be sent back-to-back when exiting L0s when using 128b/130b encoding.) EIEOS can still be used for de-skew in this case, however the implementation must comprehend back-to-back EIEOS when performing de-skew.

When operating at a data rate of 16.0 GT/s or higher, a transmitter may send back-to-back SKP Ordered Sets at the end of a Training Sequence (e.g., TS2 Ordered Set, SKP Ordered Set, SKP Ordered Set, SDS Ordered Set). Implementations that choose to use SKP Ordered Sets for de-skew in this case are recommended to recognize that the back-to-back SKP Ordered Sets are different (i.e., Standard SKP Ordered Set followed by Control SKP Ordered Set).

4.2.5.13 Lane vs. Link Training §

The Link initialization process builds unassociated Lanes of a Port into associated Lanes that form a Link. For Lanes to configure properly into a desired Link, the TS1 and TS2 Ordered Sets must have the appropriate fields (Symbol 3, 4, and 5) set to the same values on all Lanes.

Links are formed at the conclusion of Configuration.

- If the optional behavior of a Port being able to configure multiple Links is employed, the following observations can be made:
 - A separate LTSSM is needed for each separate Link that is desired to be configured by any given Port.
 - The LTSSM Rules are written for configuring one Link. The decision to configure Links in a serial fashion or parallel is implementation specific.

4.2.6 Link Training and Status State Machine (LTSSM) Descriptions §

The LTSSM states are illustrated in § Figure 4-49. These states are described in following sections.

All timeout values specified for the Link Training and Status state machine (LTSSM) are minus 0 seconds and plus 50% unless explicitly stated otherwise. All timeout values must be set to the specified values after Fundamental Reset. All counter values must be set to the specified values after Fundamental Reset.

4.2.6.1 Detect Overview §

The purpose of this state is to detect when a far end termination is present.

4.2.6.2 Polling Overview §

The Port transmits training Ordered Sets and responds to the received training Ordered Sets. In this state, bit lock and Symbol lock are established and Lane polarity is configured.

The Polling state includes Polling.Compliance (see § Section 4.2.7.2.2). This state is intended for use with test equipment used to assess if the Transmitter and the interconnect present in the device under test setup is compliant with the voltage and timing specifications in § Table 8-6, § Table 8-7, and § Table 8-12.

The Polling.Compliance state also includes a simplified inter-operability testing scheme that is intended to be performed using a wide array of test and measurement equipment (i.e., pattern generator, oscilloscope, BERT, etc.). This portion of the Polling.Compliance state is logically entered by at least one component asserting the Compliance Receive bit (bit 4 in Symbol 5 of TS1) while not asserting the Loopback bit (bit 2 in Symbol 5 of TS1) upon entering Polling.Active. The ability to set the Compliance Receive bit is implementation specific. A provision for changing data rates to that indicated by the highest common transmitted and received Data Rate Identifiers (Symbol 4 of TS1) is also included to make this behavior scalable to various data rates.

IMPLEMENTATION NOTE: USE OF POLLING.COMPLIANCE §

Polling.Compliance is intended for a compliance test environment and not entered during normal operation and cannot be disabled for any reason. Polling.Compliance is entered based on the physical system environment or configuration register access mechanism as described in § Section 4.2.7.2.1. Any other mechanism that causes a Transmitter to output the compliance pattern is implementation specific and is beyond the scope of this specification.

4.2.6.3 Configuration Overview §

In Configuration, both the Transmitter and Receiver are sending and receiving data at the negotiated data rate. The Lanes of a Port configure into a Link through a width and Lane negotiation sequence. Also, Lane-to-Lane de-skew must occur, scrambling can be disabled if permitted, the N_FTS is set, and the Disabled or Loopback states can be entered.

4.2.6.4 Recovery Overview §

In Recovery, both the Transmitter and Receiver are sending and receiving data using the configured Link and Lane number as well as the previously supported data rate(s). Recovery allows a configured Link to change the data rate of operation if desired, re-establish bit lock, Symbol lock or Block alignment, and Lane-to-Lane de-skew. Recovery is also used to set a new N_FTS value and enter the Loopback, Disabled, Hot Reset, and Configuration states.

4.2.6.5 L0 Overview §

L0 is the normal operational state where data and control packets can be transmitted and received. All power management states are entered from this state.

4.2.6.6 L0s Overview §

L0s is intended as a power savings state.

- L0s is not supported in Flit Mode and hardware must ignore the value of the L0s Enable bit for a Link operating in FM,
- L0s is not supported on a Link that contains Retimers, or
- L0s is not supported when operating with separate reference clocks with independent Spread Spectrum Clocking (SSC) (see § Section 4.2.8 and § Section 4.3.9).

L0s allows a Link to quickly enter and recover from a power conservation state without going through Recovery.

The entry to L0s occurs after receiving an EIOS.

The exit from L0s to L0 must re-establish bit lock, Symbol lock or Block alignment, and Lane-to-Lane de-skew.

A Transmitter and Receiver Lane pair on a Port are not required to both be in L0s simultaneously.

4.2.6.7 L0p Overview §

L0p is a part of the L0 state and intended as a power savings state. L0p is supported only in Flit Mode, for all data rates. L0p support is optional but strongly recommended for Ports. L0p support is mandatory for Pseudo-Ports (Retimers) that support Flit Mode. L0p enables a Link to have some Lanes active while the remaining Lanes will be in electrical idle state. With Flit Mode, Link Upconfigure, which performs dynamic link width adjustment through the state transition L0 → Recovery → Configuration → L0, is not supported.

L0p is symmetric in width. All legal widths (x1, x2, x4, x8, x16) up to the configured Link width must be supported by Ports that support L0p. When the Link is in L0p, at least one Lane in each direction must be active. L0p support is negotiated only during Configuration. Complete state when LinkUp=0b, as described in § Section 4.2.7.

Device Port Functions indicate support for L0p by Setting L0p Supported and by supplying a Port L0p Exit Latency value.

A Port Function for which L0p Enable is set to 1b, Hardware Autonomous Width Disable is set to 0b, and Target Link Width is set to 111b, is permitted to initiate L0p requests with no architected software intervention by sending Link Management DLLPs (see § Section 4.2.6.7.1) to its Link Partner. System software can direct a Port Function to initiate an L0p Link Width change by sending to that Function a CfgWr TLP to set L0p Enable to 1b and Target Link Width to a value from 000b through 100b. It is strongly recommended that system software leave Target Link Width unchanged (i.e., 111b) other than for usage cases such as test or debug.

If the link is L0p capable and the Link width has been changed by entering the Configuration state, the following rules apply:

1. On entry to Recovery the Link will revert to its configured Link width on the last entry to L0
2. L0p cannot be used to turn on Lanes that were turned off in Configuration state.

IMPLEMENTATION NOTE:

The Lanes that are turned off during Configuration state may be due to issues such as reliability and are no longer associated with the LTSSM while LinkUp=1b (see § Section 4.2.7.3).

With L0p, any Lane that goes to electrical idle must be in electrical idle for a minimum time of $T_{TX-IDLE-MIN}$. The DC common mode voltage in TX during electrical idle must be within specification. The Receiver needs to wait a minimum of $T_{TX-IDLE-MIN}$ to start looking for Electrical Idle Exit.

Once L0p is enabled, any Port can request a Link width change by sending up to three identical Link Management DLLPs within five consecutive Flits. Two Flits are considered consecutive even if they are separated by an Ordered Set. This can be either up-size to increase the number of active Lanes or down-size to reduce the number of active Lanes. The Link partner must either Ack or Nak each L0p request on a valid Flit, unless it is required to ignore the request. A Port must respond to an L0p request within the following time interval of receiving a valid Flit with the request: 4 μ s if 8b/10b encoding is used, 1 μ s otherwise. Time is measured from the last bit of the Flit with the request on the ingress package pin to the first bit of the Flit with the response on the egress package pin. A Port that has requested a Link width change but has not received a response within the following time interval of issuing the request must either re-request the identical Link width change or abandon the request: 8 μ s if 8b/10b encoding is used, 4 μ s otherwise. If identical L0p requests are received within five consecutive Flits, the same response must be sent. After responding to a request, the Link partner must consider the request to be abandoned if one of the following conditions are true:

- On an up-size request:
 - the requester did not initiate the Link width upsize within 16 μ s after the Flit with the Ack was transmitted AND
 - the requester did not re-send the up-size request within 8 μ s after the Flit with the Ack was transmitted
- On a down-size request with an Ack response:
 - the requester did not resend the Link width downsize request within 4 μ s after the Flit with the Ack was transmitted, AND
 - the requester did not initiate the Link width downsize within 16 μ s after the Flit with the Ack was transmitted and the Link Partner did not down-size the Link by sending an EIOSQ
- On a down-size request with a Nak response:
 - the requester did not resend the Link width down-size request within 4 μ s after the Flit with the Nak was transmitted

The following rules must be followed for L0p:

- If the Hardware Autonomous Width Disable bit in the Link Control register is set to 1b or if the L0p Enable bit is set to 0b, a Port:
 - Must not request any down-size.
 - Must initiate an up-size request to fully configured Link width if the Link is not at the fully configured width.
- L0p Ack and Nak Rules:
 - A Port is permitted to Nak an L0p Request for a lower width than the current width if L0p.Priority is not set.
 - If a Port is requesting link width down-size due to thermal throttling or reliability reasons, then it should set L0p.Priority in the L0p Request. The Link partner must Ack priority L0p Requests if it is not requesting an L0p width change and it is not going to request an L0p width change in the next Flit. If

the Link partner is going to request an L0p width change in the next Flit, it must show up on the Transmitter pins in 100 ns with L0p.Priority set in the L0p Request. The requirements for setting L0p.Priority are implementation specific and behavior is undefined if L0p.Priority bit is set on an upsize.

- Any Port requesting a link width down-size that receives an Ack from its Link partner is responsible for initiating the up-size request eventually when the underlying conditions no longer prohibit the link from operating at full width.
- If both Ports are simultaneously requesting link width change the following rules apply to determine which request wins. A Port is permitted to consider a pending request for L0p as simultaneous as long as it has the L0p request scheduled to appear in its Transmitter pins within 100 ns. The Port that does not win must Ack the request to the winning Port through the proper L0p response.
 - If both requests have L0p.Priority set:
 - if both sides are requesting the same width, the Downstream Port wins
 - else, the request with the lower width wins
 - If one request has L0p.Priority set, it wins
 - If neither side has L0p.Priority set:
 - if both sides are requesting the same width, the Downstream Port wins
 - else, the request with the higher width wins
- A Port is permitted to Nak a request for a lower width than the current L0p width if L0p.Priority is not set.
- A Port must ignore another L0p Request with the same width if it has already Ack'ed an L0p request and its Transmitter Lanes are already at or in the process of transitioning to the same width.
- An entry to Recovery results in the Link going to its configured Link width on the most recent transition from Configuration to L0 and all the associated L0p transition states (such as width change request/ response and all the tracking information such as time since Ack/ Nak) are reset as if no width change request was made.

Once an L0p request to change link width has been initiated, it must be completed or abandoned.

A Port must not initiate a request for a new Link width unless the following conditions are met:

1. No link width resizing has been in progress in the last 1 μ s if 1b/1b or 128b/130b encoding is used or 4 μ s if 8b/10b encoding is used.
2. At least 16 μ s, has elapsed since the Port abandoned its last L0p Request, if any
3. The last L0p request from the remote Port, if any, was abandoned after being Ack'ed by the Port

On a Link width down-size, the following steps must be taken by each Port independently after the Link width down-configure request has been 'Ack'ed:

- On the next scheduled SKP Ordered Set interval, the Lanes that are being turned off will send an EIOSQ instead of a SKP Ordered Set.
- The Lanes that sent an EIOSQ go to Electrical Idle after the EIOSQ is sent. The Lanes that sent a SKP Ordered Set resume transmitting Flits with a SKP Ordered Set insertion interval that corresponds to the new Link width (see § Section 4.2.3.4.5).
- If the requesting Port did not receive an Ack for the L0p request, but sees the Link Partner sending the EIOSQ Ordered Set, it must treat that as an 'Ack'. (An example scenario where this may happen is if the Flit containing the Ack DLLP was corrupted.)

- During the down-size negotiation, an EIOS must be received on all lanes to be deactivated at the same time after adjusting for lane to lane skew; else the LTSSM must enter Recovery.
 - A Port is permitted to enter Recovery after 24 msec of sending the EIOSQ on a downsize if the Link did not achieve the desired Link width in both directions

On a Link width up-size the following steps must be taken:

- The up-sizing action must be initiated by the requesting port. The non-requesting Port waits for detection of Electrical Idle exit on the lanes to be activated before starting the up-sizing actions.
- Data Stream continues on the active Lanes
- For the Lanes to be activated the following sequence must be followed:⁷⁵
 - SKP Ordered Sets must be scheduled at the same time as Lane 0 and the same number of SKPs must be added or deleted as Lane 0 by the Receiver in the (Pseudo-)Port. A Port is permitted to truncate a TS1/TS2 Ordered Set in 8b/10b encoding to transmit the SKP Ordered Set at the same time as Lane 0.
 - Transmit TS1 Ordered Sets meeting the requirements for TS1 Ordered Sets in § Section 4.2.7.4.1 and § Section 4.2.5.3 . The Transmitter must ensure it follows the EIEOSQ rule of not being broken up by a SKP Ordered Set even though it has to send SKP Ordered Set at the same time as the active Lanes. This can be done by scheduling the start of EIEOSQ appropriately. However, a Transmitter is permitted to restart the EIEOSQ sequence after the SKP Ordered Set if the SKP Ordered Set interrupted an EIEOSQ in progress. If an EIEOSQ is scheduled to precede a subsequent scheduled SDS Ordered Set within 256 UI, the transmitter is permitted to not send that EIEOSQ or to delay the SDS until the next SKP interval.
 - If eight consecutive TS1 or TS2 Ordered sets are received on all Lanes that are to be activated, the transmitter must transition to sending TS2 Ordered Sets meeting the requirements for TS2 Ordered Sets in § Section 4.2.7.4.4 and § Section 4.2.5.3 .
 - After receiving eight consecutive TS2 Ordered Sets and sending at least 16 TS2 Ordered sets after the receipt of one TS2 Ordered Set on all the Lanes to be activated, the Port sends an SDS Ordered Set sequence if the data rate is 8.0 GT/s or higher just prior to sending the next scheduled SKP Ordered Set that will be sent (on the active as well as to be activated Lanes).
 - Lane to Lane de-skew must be completed by the Receiver using the SKP Ordered Set across all the currently active as well as the Lanes being activated that have received eight consecutive TS2 Ordered Set and the SDS Ordered Set, if the data rate is 8.0 GT/s or higher. Starting with the SKP Ordered Set that follows the SDS Ordered Set, the SKP Ordered Set insertion interval that corresponds to the new Link width takes effect (see § Section 4.2.3.4.5).
 - If 24 ms has elapsed since the start of activation and the Lanes are not part of the active Lanes, the LTSSM must be directed to enter Recovery.

The DLLP encoding for the various L0p commands and responses is shown in § Figure 3-15. The definition of the various fields in the DLLP are shown in § Table 4-44.

75. This is similar but not identical to Recovery.

IMPLEMENTATION NOTE: ORTHOGONALITY OF L0P AND L1/L2 §

L0p is a reduced power sub-state of L0. It is orthogonal to L1 and L2. For a Port that is in the process of initiating or accepting an L1 or L2 request, it is recommended to not initiate, renew, or respond to an L0p request. Nevertheless, negotiations of L0p and L1 or L0p and L2 are permitted to occur concurrently and will ultimately resolve in one of the power states being negotiated, depending on the sequence of the negotiations and the desired intention of each Port. Refer to § Section 5.3.2 for rules that govern Link power management.

4.2.6.7.1 Link Management DLLP §

Table 4-44 Link Management DLLP §

Field	Description								
Byte 0	Link Management DLLP - must be 0010 1000b

		0100b x4
		1000b x8
		0000b x16
		Others Reserved
Others		Reserved
Reserved if <u>Link Mgmt Type</u> is other than 00h.		

Receivers must silently ignore Link Management DLLPs if:

- The Link is operating in Non-Flit Mode.
- The Link Mgmt Type field contains a Reserved value.
- The Link Mgmt Type field is 00h and the L0p.Cmd field contains a reserved value.
- The Link Mgmt Type field is 00h, the L0p.Cmd field contains L0p Request and the L0p Link Width field contains a reserved value.
- The Link Mgmt Type field is 00h, the L0p.Cmd field contains L0p Request Ack or L0p Request Nak and Response Payload contains a reserved value.

IMPLEMENTATION NOTE:

L0p ENTRY / EXIT TIMES §

The Lanes that are electrically idle, are expected to have power savings and entry/ exit times similar to L1. The deeper the power savings, the higher the exit latency to bring those idle Lanes back to active state. For example, a PLL associated exclusively with the set of Lanes that are idle can be turned off. This will result in better power savings but the exit time to activate the Lanes will be higher.

Receiver hardware should use the L0p Exit Latency values from the Data Link Feature DLLP to help determine when to request L0p. These values are visible to software in the Local L0p Exit Latency and Remote L0p Exit Latency fields.

System software should ensure that the exit latency of all Retimers are included some Retimer L0p Exit Latency field (either Upstream or Downstream Port). In general, Retimers located on an add-in card should be included in the add-in card's Upstream Port's Retimer L0p Exit Latency and Retimers located in the system chassis should be included in the Downstream Port's Retimer L0p Exit Latency.

Example of L0p Flows: § Figure 4-48 demonstrates L0p flows in a x16 Link.

1. L0p is enabled on the Link during the Configuration.Complete state.
2. The USP requests the Link to downsize to x8 which is Ack'ed by the DSP.
3. On the next SKP Ordered Set the L0p indication is provided by the Port on a per-Lane basis. Lanes 0-7 continue with the traffic whereas Lanes 8-15 send an EIOSQ and go to electrical Idle. Thus, the Link now has 8 active Lanes and 8 Lanes in idle state.
4. At a later point, the DSP requests upsizing the Link to x16 while the USP has made a request to further downsize to x4. The x4 request gets NAK'ed, the x16 gets Ack'ed. Then link training proceeds in Lanes 8-15, initiated by the DSP with the exchange of TS1/TS2 Ordered Sets with EIEOS inserted at appropriate intervals. When Lanes 8-15 are ready, an SDS is sent immediately preceding the next scheduled SKP Ordered Set in the Lanes.
5. The Link operates as a x16 Link after sending the SKP Ordered Set across all 16 Lanes. Even though L0p is symmetric during the transitions, the two sides may be operating at different widths for a while. This is similar to the situation during entry to L1 or L0.

Note that if the data rates is 2.5 GT/s, the EIEOS and SDS will not be present. If the data rate is 5.0 GT/s, EIEOS will be present but not SDS.

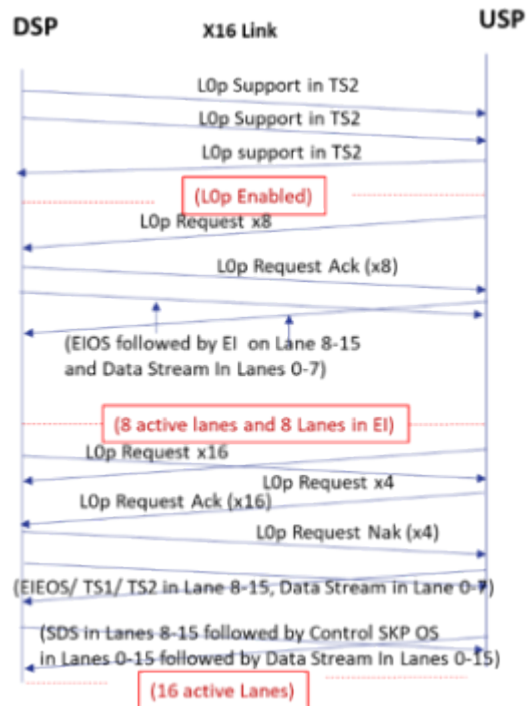

Figure 4-48 Example of L0p flow in a x16 Link §

4.2.6.8 L1 Overview §

L1 is intended as a power savings state.

The L1 state allows an additional power savings over L0s at the cost of additional resume latency.

The entry to L1 occurs after being directed by the Data Link Layer and receiving an EIOS.

4.2.6.9 L2 Overview §

Power can be aggressively conserved in L2. Most of the Transmitter and Receiver may be shut off.⁷⁶ Main power and clocks are not guaranteed, but Aux⁷⁷ power is available.

When Beacon support is required by the associated system or form factor specification, an Upstream Port that supports the wakeup capability must be able to send; and a Downstream Port must be able to receive; a wakeup signal referred to as a Beacon.

The entry to L2 occurs after being directed by the Data Link Layer and receiving an EIOS.

4.2.6.10 Disabled Overview §

The intent of the Disabled state is to allow a configured Link to be disabled as long as directed or until Electrical Idle is exited (i.e., due to a hot removal and insertion) after entering Disabled.

76. The exception is the Receiver termination, which must remain in a low impedance state.

77. In this context, Aux power means a power source which can be used to drive the Beacon circuitry.

4.2.6.11 Loopback Overview §

Loopback is intended for test and fault isolation use. Only the entry and exit behavior is specified, all other details are implementation specific. Loopback can operate on either a per-Lane or configured Link basis.

A **Loopback Lead** is the component requesting Loopback.

A **Loopback Follower** is the component looping back the data.

In 8b/10b and 128b/130b encoding, Loopback uses bit 2 (Loopback) in the Training Control Field of TS1 and TS2 Ordered Sets (see § Table 4-25 and § Table 4-26). In 1b/1b encoding, Loopback uses an encoding of bits 3:0 in the Training Control field of TS1 and TS2 Ordered Sets (see § Table 4-28).

The entry mechanism for a Loopback Lead is device specific.

The Loopback Follower device enters Loopback whenever two consecutive TS1 Ordered Sets are received with the Loopback bit set.

IMPLEMENTATION NOTE: USE OF LOOPBACK §

Once in the Loopback state, the Lead can send any pattern of Symbols as long as the encoding rules are followed. Once in Loopback, the concept of data scrambling is no longer relevant; what is sent out is looped back. The mechanism(s) and/or interface(s) utilized by the Data Link Layer to notify the Physical Layer to enter the Loopback state is implementation specific and beyond the scope of this specification.

IMPLEMENTATION NOTE: LOOPBACK LEAD AND LOOPBACK FOLLOWER REPLACING OLDER TERMS §

The terms Loopback Lead and Loopback Follower are newer terms while preserving the identical Loopback functionality as in [PCIe-5.0]. These terms appropriately represent the functionality performed by the component. Any Port or a test equipment can be a Loopback Lead if it has that optional capability. Every Port is required to be a Loopback Follower. The test set up needs to comprehend that in such a way that it designates one Port to be the Loopback Lead and its Link Partner to be the Loopback Follower.

4.2.6.12 Hot Reset Overview §

The intent of the Hot Reset state is to allow a configured Link and associated downstream device to be reset using in-band signaling.

4.2.7 Link Training and Status State Rules §

Various Link status bits are monitored through software with the exception of **LinkUp** which is monitored by the Data Link Layer. § Table 4-48 describes how the Link status bits must be handled throughout the LTSSM (for more information, see § Section 3.2 for LinkUp; § Section 7.5.3.8 for Link Speed, Link Width, and Link Training; § Section 6.2 for Receiver

Error; and § Section 6.7 for In-Band Presence). A Receiver may also optionally report an 8b/10b Error in the Lane Error Status Register when operating in 8b/10b encoding, when allowed to report the error as a Receiver Error in § Table 4-48.

IMPLEMENTATION NOTE: RECEIVER ERRORS DURING CONFIGURATION AND RECOVERY STATES §

Allowing Receiver Errors to be set while in Configuration or Recovery is intended to allow implementations to report Link Errors that occur while processing packets in those states. For example, if the LTSSM transitions from L0 to Recovery while a TLP is being received, a Link Error that occurs after the LTSSM transition can be reported.

Table 4-48 Link Status Mapped to the LTSSM §

LTSSM State	Link Width	Link Speed	LinkUp	Link Training	Receiver Error	In-Band Presence ⁷⁸
<u>Detect</u>	Undefined	Undefined	0b	0b	No action	0b
<u>Polling</u>	Undefined	Set to 2.5 GT/s on entry from Detect. Link speed may change on entry to <u>Polling.Compliance</u> .	0b	0b	No action	1b
<u>Configuration</u>	Set	No action	0b/1b ⁷⁹	1b	Set on 8b/10b Error. Optional: Set on Link Error when using 128b/130b encoding.	1b
<u>Recovery</u>	No action	Set to new speed when speed changes	1b	1b	Optionally set on Link Error.	1b
<u>L0</u>	No action	No action	1b	0b	Set on Link Error.	1b
<u>L0s</u>	No action	No action	1b	0b	No action	1b
<u>L1</u>	No action	No action	1b	0b	No action	1b
<u>L2</u>	No action	No action	1b	0b	No action	1b
<u>Disabled</u>	Undefined	Undefined	0b	0b	Optional: Set on 8b/10b Error	1b
<u>Loopback</u>	No action	Link speed may change on entry to <u>Loopback</u> from <u>Configuration</u> .	0b	0b	No action	1b
<u>Hot Reset</u>	No action	No action	0b	0b	Optional: Set on 8b/10b Error	1b

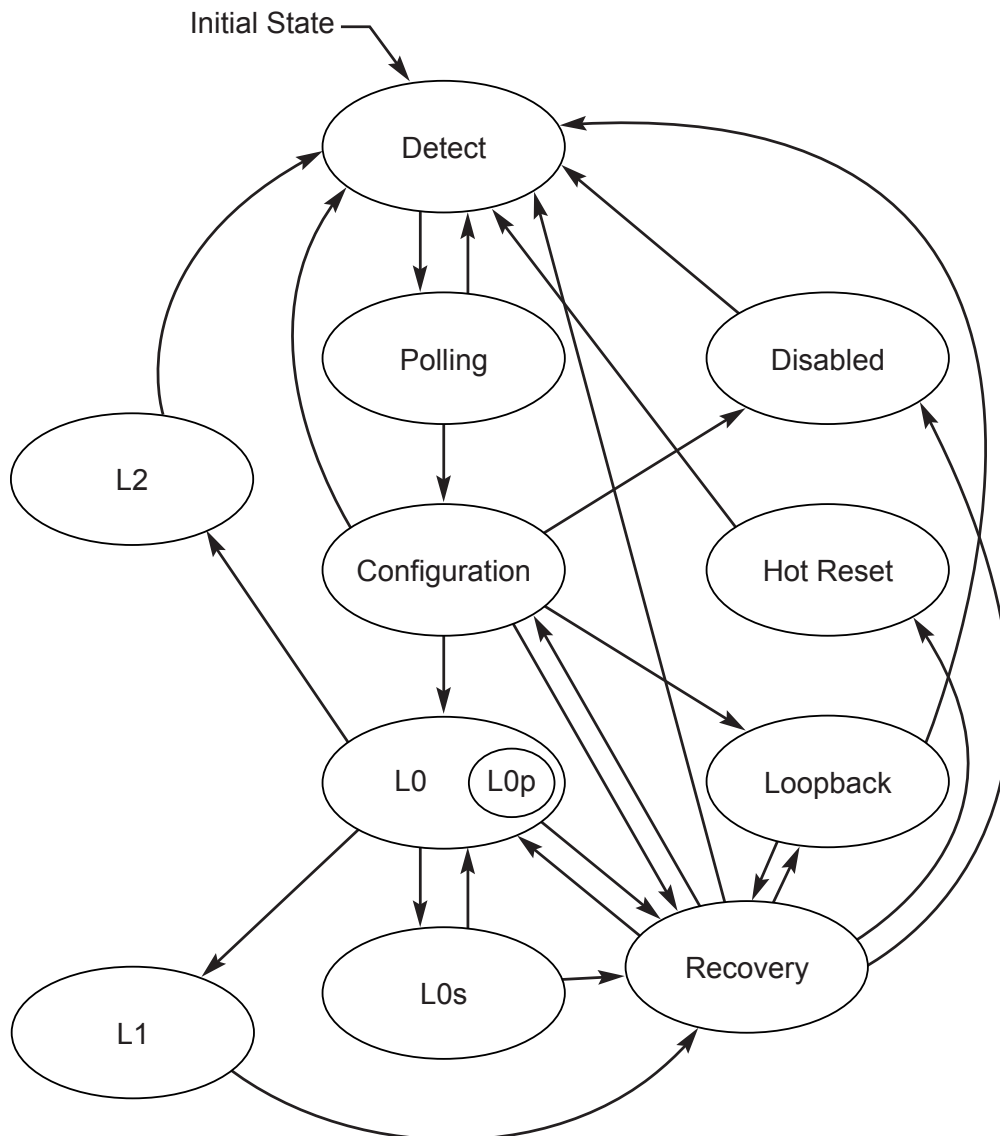

The state machine rules for configuring and operating a PCI Express Link are defined in the following sections.

78. In-band refers to the fact that no sideband signals are used to calculate the presence of a powered up device on the other end of a Link.

79. LinkUp will always be 0 if coming into Configuration via Detect → Polling → Configuration and LinkUp will always be 1 if coming into Configuration from any other state.

Matching Link and Lane Numbers for 1b/1b Encoding

With 1b/1b encoding, the Link and Lane numbers are not sent explicitly in the TS1/TS2 Ordered Sets in any States other than those listed in § Table 4-28. Thus, when using 1b/1b encoding in any LTSSM state other than where Link and Lane numbers are transmitted, any references to an exact match in the Link and/or Lane numbers between the transmitted and received TS0/TS1/TS2 Ordered Sets must be assumed to be true as long as the Ordered Set is a valid one. Similarly, when using 1b/1b encoding in any LTSSM state other than Configuration, any references to transmitting a TS0/TS1/TS2 Ordered Set using the Link number and/or Lane number negotiated during the Configuration LTSSM state must be interpreted as using the Lane number for the purposes of scrambling in the TS0/TS1/TS2 Ordered Set.

OM13800F

Figure 4-49 Main State Diagram for Link Training and Status State Machine §

4.2.7.1 Detect §

The Detect substate machine is shown in § Figure 4-50.

4.2.7.1.1 Detect.Quiet §

- Transmitter is in an Electrical Idle state.
 - The DC common mode voltage is not required to be within specification.
- 2.5 GT/s data rate is selected as the frequency of operation. If the frequency of operation was not 2.5 GT/s data rate on entry to this substate, the LTSSM must stay in this substate for at least 1 ms, during which the frequency of operation must be changed to the 2.5 GT/s data rate.
 - Note: This does not affect the advertised data rate in the TS1 and TS2 Ordered Sets.
- All Receivers must meet the Z_{RX-DC} specification for 2.5 GT/s within 1 ms (see § Table 8-12) of entering this substate. The LTSSM must stay in this substate until the Z_{RX-DC} specification for 2.5 GT/s is met.
- LinkUp = 0b (status is cleared).

- The Equalization 8.0 GT/s Phase 1 Successful, Equalization 8.0 GT/s Phase 2 Successful, Equalization 8.0 GT/s Phase 3 Successful, and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register are all set to 0b.

The Equalization 16.0 GT/s Phase 1 Successful, Equalization 16.0 GT/s Phase 2 Successful, Equalization 16.0 GT/s Phase 3 Successful and Equalization 16.0 GT/s Complete bits of the 16.0 GT/s Status Register are all set to 0b.

The Equalization 32.0 GT/s Phase 1 Successful, Equalization 32.0 GT/s Phase 2 Successful, Equalization 32.0 GT/s Phase 3 Successful and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register are all set to 0b.

The Equalization 64.0 GT/s Phase 1 Successful, Equalization 64.0 GT/s Phase 2 Successful, Equalization 64.0 GT/s Phase 3 Successful, and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register are all set to 0b.

- The use_modified_TS1_TS2_Ordered_Set variable is reset to 0b.
- The Remote L0p Supported bit in the Device Status 3 Register is reset to 0b.
- The Flit_Mode_Enabled variable is reset to 0b. (When Flit_Mode_Enabled is set to 0b, the link will not operate in Flit Mode.)
- The L0p_capable variable is reset to 0b.
- The SRIS_Mode_Enabled variable is reset to 0b. When the SRIS_Mode_Enabled variable is set to 1b in Flit Mode, the SKP Ordered Set transmission frequency must follow the SRIS mode frequency for the data rate of operation. Otherwise, the SKP Ordered Set transmission frequency for the SRNS / Common Clock must be followed.
- The directed_speed_change variable is reset to 0b. The upconfigure_capable variable is reset to 0b. The idle_to_rlock_transitioned variable is reset to 00h. The select_deemphasis variable must be set to either 0b or 1b based on platform specific needs for an Upstream Port and identical to the Selectable Preset/De-emphasis bit in the Link Control 2 Register for a Downstream Port. The equalization_done_8GT_data_rate, equalization_done_16GT_data_rate, equalization_done_32GT_data_rate, and equalization_done_64GT_data_rate variables are reset to 0b. The perform_equalization_for_loopback and perform_equalization_for_loopback_64GT variables are reset to 0b.
 - Note that since these variables are defined with [PCIe-2.0], earlier devices would not implement these variables and will always take the path as if the directed_speed_change and upconfigure_capable variables are constantly reset to 0b and the idle_to_rlock_transitioned variable is constantly set to FFh.

- The next state is Detect.Active after a 12 ms timeout or if Electrical Idle Exit is detected on any Lane. If the transition to this state is from Hot Reset, it is strongly recommended that the Downstream Port wait for 2 ms before enabling Electrical Idle Exit detection.

4.2.7.1.2 Detect.Active §

- The Transmitter performs a Receiver Detection sequence on all un-configured Lanes that can form one or more Links (see § Section 8.4.5.7 for more information).
- Next state is Polling if a Receiver is detected on all unconfigured Lanes.
- Next state is Detect.Quiet if a Receiver is not detected on any Lane.
- If at least one but not all un-configured Lanes detect a Receiver, then:
 1. Wait for 12 ms.
 2. The Transmitter performs a Receiver Detection sequence on all un-configured Lanes that can form one or more Links (see § Section 8.4.5.7 for more information).
 - The next state is Polling if exactly the same Lanes detect a Receiver as the first Receiver Detection sequence.
 - Lanes that did not detect a Receiver must:
 - i. Be associated with a new LTSSM if this optional feature is supported.
 - or
 - ii. All Lanes that cannot be associated with an optional new LTSSM must transition to Electrical Idle.⁸⁰
 - These Lanes must be re-associated with the LTSSM immediately after the LTSSM in progress transitions back to Detect.
 - An EIOS does not need to be sent before transitioning to Electrical Idle.
 - Otherwise, the next state is Detect.Quiet.

OM14313A

Figure 4-50 Detect Substate Machine §

4.2.7.2 Polling §

The Polling substate machine is shown in § Figure 4-51.

80. The common mode being driven is not required to meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle (V_{TX-CM-DC-ACTIVE-IDLE-DELTA}) specification (see § Table 8-7).

4.2.7.2.1 *Polling.Active* §

- Transmitter sends TS1 Ordered Sets with Lane and Link numbers set to PAD on all Lanes that detected a Receiver during Detect.
 - The Data Rate Identifier Symbol of the TS1 Ordered Sets must advertise all data rates between 2.5 GT/s and 32.0 GT/s that the Port supports, including those that it does not intend to use.

Note: Ports are not permitted to advertise higher than 32.0 GT/s data rates in this state.

 - The Transmitter must wait for its TX common mode to settle before exiting from Electrical Idle and transmitting the TS1 Ordered Sets.
 - The Transmitter must drive patterns in the default voltage level of the Transmit Margin field within 192 ns from entry to this state. This transmit voltage level will remain in effect until Polling.Compliance or Recovery.RcvrLock is entered.
- Next state is Polling.Compliance if the Enter Compliance bit (bit 4) in the Link Control 2 Register is 1b. If the Enter Compliance bit was set prior to entry to Polling.Active, the transition to Polling.Compliance must be immediate without sending any TS1 Ordered Sets.
- Next state is Polling.Configuration after at least 1024 TS1 Ordered Sets were transmitted, and all Lanes that detected a Receiver during Detect receive eight consecutive training sequences (or their complement) satisfying any of the following conditions:
 - TS1 with Lane and Link numbers set to PAD and the Compliance Receive bit (bit 4 of Symbol 5) is 0b.
 - TS1 with Lane and Link numbers set to PAD and the Loopback bit (bit 2 of Symbol 5) is 1b.
 - TS2 with Lane and Link numbers set to PAD.
- Otherwise, after a 24 ms timeout the next state is:
 - Polling.Configuration if,
 - i. Any Lane, which detected a Receiver during Detect, received eight consecutive training sequences (or their complement) satisfying any of the following conditions:
 1. TS1 with Lane and Link numbers set to PAD and the Compliance Receive bit (bit 4 of Symbol 5) is 0b.
 2. TS1 with Lane and Link numbers set to PAD and the Loopback bit (bit 2 of Symbol 5) is 1b.
 3. TS2 with Lane and Link numbers set to PAD.

and a minimum of 1024 TS1 Ordered Sets are transmitted after receiving one TS1 or TS2 Ordered Set⁸¹.

And

- ii. At least a predetermined set of Lanes that detected a Receiver during Detect have detected an exit from Electrical Idle at least once since entering Polling.Active.
 - Note: This may prevent one or more bad Receivers or Transmitters from holding up a valid Link from being configured, and allow for additional training in Polling.Configuration. The exact set of predetermined Lanes is implementation specific. Note that up to [PCIe-1.1] this predetermined set was equal to the total set of Lanes that detected a Receiver.

81. Earlier versions of this specification required transmission of 1024 TS1 Ordered Sets after receiving one TS1 Ordered Set. This behavior is still permitted but the implementation will be more robust if it follows the behavior of transmitting 1024 TS1 Ordered Sets after receiving one TS1 or TS2 Ordered Set.

- Note: Any Lane that receives eight consecutive TS1 or TS2 Ordered Sets should have detected an exit from Electrical Idle at least once since entering Polling.Active.
- Else Polling.Compliance if either (a) or (b) is true:
 - a. not all Lanes from the predetermined set of Lanes from (ii) above have detected an exit from Electrical Idle since entering Polling.Active.
 - b. any Lane that detected a Receiver during Detect received eight consecutive TS1 Ordered Sets (or their complement) with the Lane and Link numbers set to PAD, the Compliance Receive bit (bit 4 of Symbol 5) is 1b, and the Loopback bit (bit 2 of Symbol 5) is 0b.
 - A port that is capable of transmitting at the 64.0 GT/s data rate may receive TS1 Ordered Sets with the Flit Mode Supported bit set to 1b and the Supported Link Speeds field set to 1 0111b.
 - Note: If a passive test load is applied on all Lanes then the device will go to Polling.Compliance.
- Else Detect if the conditions to transition to Polling.Configuration or Polling.Compliance are not met

4.2.7.2.2 Polling.Compliance §

- The Transmit Margin field of the Link Control 2 Register is sampled on entry to this substate and becomes effective on the transmit package pins within 192 ns of entry to this substate and remains effective through the time the LTSSM is in this substate.
- The data rate and de-emphasis level for transmitting the compliance pattern are determined on the transition from Polling.Active to Polling.Compliance using the following algorithm.
 - If the Port is capable of transmitting at the 2.5 GT/s data rate only, the data rate for transmitting the compliance pattern is 2.5 GT/s and the de-emphasis level is -3.5 dB.
 - Else if the Port entered Polling.Compliance due to detecting eight consecutive TS1 Ordered Sets in Polling.Active with the Compliance Receive bit (bit 4 of Symbol 5) asserted and the Loopback bit (bit 2 of Symbol 5) deasserted then the data rate for transmission is determined as follows:
 - If the port is capable of transmitting at the 64.0 GT/s data rate and the eight consecutive TS1 Ordered Sets received in Polling.Active that directed the port to this state had the Flit Mode Supported bit set to 1b and the Supported Link Speeds field set to 1 0111b, the data rate for transmitting the compliance pattern must be 64.0 GT/s.
 - Else, the data rate for transmission is determined by the highest common transmitted and received Data Rate Identifiers (Symbols 4 of the TS1 sequence) advertised in the eight consecutive TS1 Ordered Sets received on any Lane that detected a Receiver during Detect.

The select_deemphasis variable must be set equal to the Selectable De-emphasis bit (Symbol 4 bit 6) in the eight consecutive TS1 Ordered Sets it received in Polling.Active substate. If the common data rate is 8.0 GT/s or higher, the select_preset variable on each Lane is set to the Transmitter preset value advertised in the Transmitter Preset bits of the eight consecutive EQ TS1 Ordered Sets on the corresponding Lane, provided the value is not a Reserved encoding, and this value must be used by the transmitter (for 8.0 GT/s Data Rate, use of the Receiver preset hint value advertised in those eight consecutive EQ TS1 Ordered Sets is optional). If the common Data Rate is 8.0 GT/s or higher, any Lanes that did not receive eight consecutive EQ TS1 Ordered Sets with Transmitter preset information, or that received a value for a Reserved encoding, can use any supported Transmitter preset in an implementation specific manner.

- Else if the Enter Compliance bit in the Link Control 2 Register is 1b, the data rate for transmitting the compliance pattern is defined by the Target Link Speed field in the Link Control 2 Register. The

select_deemphasis variable is Set when the Compliance Preset/De-emphasis field in the Link Control 2 Register equals 0001b if the data rate will be 5.0 GT/s. If the data rate will be 8.0 GT/s or higher, the **select_preset** variable on each Lane is set to, and the transmitter must operate with, the preset value provided in the Compliance Preset/De-emphasis Value (bits 15:12) in the Link Control 2 Register provided the value is not a Reserved encoding.

- Else the data rate, preset, and de-emphasis level settings are defined as follows based on the component's maximum supported data rate and the number of times Polling.Compliance has been entered with this entry criteria, in the same sequence of setting numbers as described in § Table 4-49:

Table 4-49 Compliance Pattern Settings §

Setting Nos	Data Rate	Transmitter De-emphasis or preset sequence
#1	2.5 GT/s	-3.5 dB
#2, #3	5.0 GT/s	-3.5 dB followed by -6 dB
#4 through #14	8.0 GT/s	Transmitter Preset Encoding 0000b through 1010b, as defined in § Section 4.2.4.2, in increasing order
#15 through #25	16.0 GT/s	Transmitter Preset Encoding 0000b through 1010b, as defined in § Section 4.2.4.2, in increasing order
#26 through #34	16.0 GT/s	Transmitter Preset Encoding 0100b as defined in § Section 4.2.4.2
#35 through #45	32.0 GT/s	Transmitter Preset Encoding 0000b through 1010b, as defined in § Section 4.2.4.2, in increasing order
#46 through #54	32.0 GT/s	Transmitter Preset Encoding 0100b as defined in § Section 4.2.4.2
#55 through #65	64.0 GT/s	Transmitter Preset Encoding 0000b through 1010b, as defined in § Section 4.2.4.2, in increasing order
#66 through #84	64.0 GT/s	Transmitter Preset Encoding 0000b as defined in § Section 4.2.4.2

Subsequent entries to Polling.Compliance repeat the above sequence. For example, the state sequence which causes a Port to transmit the Compliance Pattern at a data rate of 5.0 GT/s and a de-emphasis level of -6 dB is: Polling.Active, Polling.Compliance (2.5 GT/s and -3.5 dB), Polling.Active, Polling.Compliance (5.0 GT/s and -3.5 dB), Polling.Active, Polling.Compliance (5.0 GT/s and -6 dB).

The sequence must be set to Setting #1 in the Polling.Configuration state if the Port supports 16.0 GT/s or higher Data Rates, or the Port's Receivers do not meet the Z_{RX-DC} specification for 2.5 GT/s when they are operating at 8.0 GT/s or higher data rates (see § Table 8-12). All Ports are permitted to set the sequence to Setting #1 in the Polling.Configuration state.

IMPLEMENTATION NOTE: COMPLIANCE LOAD BOARD USAGE TO GENERATE COMPLIANCE PATTERNS §

It is envisioned that the compliance load (base) board may send a 100 MHz signal for about 1 ms on one leg of a differential pair at 350 mV peak-to-peak on any Lane to cycle the device to the desired speed and de-emphasis level. The device under test is required, based on its maximum supported data rate, to cycle through the following settings in order, for each entry to `Polling.Compliance` from `Polling.Active`, starting with the first setting on the first entry to `Polling.Compliance` after the Fundamental Reset as defined in § Table 4-49.

- If the compliance pattern data rate is not 2.5 GT/s and any `TS1 Ordered Sets` were transmitted in `Polling.Active` prior to entering `Polling.Compliance`:
 - The Transmitter sends two `Compliance TS1 Ordered Sets` if all of the following conditions are true:
 - The current data rate is 2.5 GT/s.
 - Flit Mode is supported.
 - The Transmitter is sequencing through one of the settings defined in § Table 4-49.
 - Transmitter sends either one `EIOS` or two consecutive `EIOSs` prior to entering Electrical Idle.
- If the compliance pattern data rate is not 2.5 GT/s and `TS1 Ordered Sets` were not transmitted in `Polling.Active` prior to entering `Polling.Compliance`, the Transmitter must enter Electrical Idle without transmitting any `EIOSs`. During the period of Electrical Idle, the data rate is changed to the new speed and stabilized. If the frequency of operation will be 5.0 GT/s, the de-emphasis/preset level must be set to -3.5 dB if the `select_deemphasis` variable is 1b else it must be set to -6 dB. If the frequency of operation will be 8.0 GT/s or higher, the Transmitter preset value must be set to the value in the `select_preset` variable. The period of Electrical Idle is greater than 1 ms but it is not to exceed 2 ms.
- Behavior during `Polling.Compliance` after the data rate and de-emphasis/preset level are determined must follow the following rules:
 - If the Port entered `Polling.Compliance` due to detecting eight consecutive `TS1 Ordered Sets` in `Polling.Active` with the `Compliance Receive bit` (bit 4 of Symbol 5) asserted and the `Loopback bit` (bit 2 of Symbol 5) deasserted or both the `Enter Compliance bit` and the `Enter Modified Compliance bit` in the Link Control 2 Register are set to 1b then the Transmitter sends out the Modified Compliance Pattern at the above determined data rate with the error status Symbol set to all 0's on all Lanes that detected a Receiver during Detect.
 - If the data rate is 2.5 GT/s or 5.0 GT/s, a particular Lane's Receiver independently signifies a successful lock to the incoming Modified Compliance Pattern by looking for any one occurrence of the Modified Compliance Pattern and then setting the Pattern Lock bit (bit 7 of the error status Symbol) in the same Lane of its own transmitted Modified Compliance Pattern.
 - The error status Symbols are not to be used for the lock process since they are undefined at any given moment.
 - An occurrence is defined above as the following sequence of 8b/10b Symbols; `K28.5`, `D21.5`, `K28.5`, and `D10.2` or the complement of each of the individual Symbols.
 - The device under test must set the Pattern Lock bit of the Modified Compliance Pattern it transmits at the Transmitter package pin(s) after successfully locking to

the incoming Modified Compliance Pattern within 1 ms of receiving the Modified Compliance Pattern at its Receiver package pin(s).

- If the data rate is 8.0 GT/s or higher: The Error_Status field is set to 00h on entry to this substate. Each Lane sets the Pattern Lock bit independently when it achieves Block Alignment as described in § Section 4.2.2.2.1 . After Pattern Lock is achieved, Symbols received in Data Blocks are compared to the Idle data Symbol (00h) and each mismatched Symbol causes the Receiver Error Count field to be incremented by 1. The Receiver Error Count saturates at 127 (further mismatched Symbols do not change the Receiver Error Count). The Pattern Lock and Receiver Error Count information for each Lane is transmitted as part of the SKP Ordered Sets transmitted in that Lane's Modified Compliance Pattern. See § Section 4.2.8 for more information. The device under test must set the Pattern Lock bit in the SKP Ordered Set it transmits within 4 ms of receiving the Modified Compliance Pattern at its Receiver package pin(s).
- The scrambling requirements defined in § Section 4.2.2.4 are applied to the received Modified Compliance Pattern. For example, the scrambling LFSR seed is set per Lane, an EIEOS initializes the LFSR and SKP Ordered Sets do not advance the LFSR.

IMPLEMENTATION NOTE: HANDLING BIT SLIP AND BLOCK ALIGNMENT §

Devices should ensure that their Receivers have stabilized before attempting to obtain Block alignment and signaling Pattern Lock. For example, if an implementation expects to see bit slips in the initial few bits, it should wait for that time to be over before settling on a Block Alignment. Devices may also want to revalidate their Block alignment prior to setting the Pattern Lock bit.

- If the data rate is 2.5 GT/s or 5.0 GT/s, once a particular Lane indicates it has locked to the incoming Modified Compliance Pattern the Receiver Error Count for that particular Lane is incremented every time a Receiver Error occurs.
 - The error status Symbol uses the lower 7 bits as the Receiver Error Count field and this field will remain stuck at all 1's if the count reaches 127.
 - The Receiver must not make any assumption about the 10-bit patterns it will receive when in this substate if 8b/10b encoding is used.
- If the Enter Compliance bit in the Link Control 2 Register is 0b, the next state is Detect if directed
- Else if the Enter Compliance bit was set to 1b on entry to Polling.Compliance, next state is Polling.Active if any of the following conditions apply:
 - The Enter Compliance bit in the Link Control 2 Register has changed to 0b
 - The Port is an Upstream Port and an EIOS is received on any Lane. The Enter Compliance bit is reset to 0b when this condition is true.

If the Transmitter was transmitting at a data rate other than 2.5 GT/s, or the Enter Compliance bit in the Link Control 2 Register was set to 1b during entry to Polling.Compliance, the Transmitter sends eight consecutive EIOS and enters Electrical Idle prior to transitioning to Polling.Active. During the period of Electrical Idle, the data rate is changed to 2.5 GT/s and stabilized and the de-emphasis level is set to -3.5 dB. The period of Electrical Idle is greater than 1 ms but must not exceed 2 ms.

Note: Sending multiple EIOS provides enough robustness such that the other Port detects at least one EIOS and exits Polling.Compliance substate when the configuration register mechanism was used for entry.

- Else if the Port entered Polling.Compliance due to the Enter Compliance bit of the Link Control 2 Register being set to 1b and the Enter Modified Compliance bit of the Link Control 2 Register being set to 0b:
 - a. Transmitter sends out the compliance pattern on all Lanes that detected a Receiver during Detect at the data rate and de-emphasis/preset level determined above.
 - b. Next state is Polling.Active if any of the following two conditions are true:
 1. The Enter Compliance bit in the Link Control 2 Register has changed to 0b (from 1b) since entering Polling.Compliance.
 2. The Port is an Upstream Port, the Enter Compliance bit in the Link Control 2 Register is set to 1b and an EIOS has been detected on any Lane. The Enter Compliance bit is reset to 0b when this condition is true.

The Transmitter sends eight consecutive EIOSs and enters Electrical Idle prior to transitioning to Polling.Active. During the period of Electrical Idle, the data rate is changed to 2.5 GT/s and stabilized. The period of Electrical Idle is greater than 1 ms but must not exceed 2 ms.

Note: Sending multiple EIOSs provides enough robustness such that the other Port detects at least one EIOS and exits Polling.

- Else:
 - a. Transmitter sends out the following patterns on Lanes that detected a Receiver during Detect at the data rate and de-emphasis/preset level determined above:
 - For Settings #1 to #25, #35 to #45, and #55 to #65: Compliance Pattern on all Lanes.
 - For Setting #26, #46, #66: Jitter Measurement Pattern on all Lanes.
 - For Setting #27, #47, #67: Jitter Measurement Pattern on Lanes 0/8 and Compliance Pattern on all other Lanes.
 - For Setting #28, #48, #68: Jitter Measurement Pattern on Lanes 1/9 and Compliance Pattern on all other Lanes.
 - For Setting #29, #49, #69: Jitter Measurement Pattern on Lanes 2/10 and Compliance Pattern on all other Lanes.
 - For Setting #30, #50, #70: Jitter Measurement Pattern on Lanes 3/11 and Compliance Pattern on all other Lanes.
 - For Setting #31, #51, #71: Jitter Measurement Pattern on Lanes 4/12 and Compliance Pattern on all other Lanes.
 - For Setting #32, #52, #72: Jitter Measurement Pattern on Lanes 5/13 and Compliance Pattern on all other Lanes.
 - For Setting #33, #53, #73: Jitter Measurement Pattern on Lanes 6/14 and Compliance Pattern on all other Lanes.
 - For Setting #34, #54, #74: Jitter Measurement Pattern on Lanes 7/15 and Compliance Pattern on all other Lanes.
 - For Setting #75: High Swing Toggle Pattern on all Lanes
 - For Setting #76: High Swing Toggle Pattern on Lanes 0/8 and Compliance Pattern on all other Lanes.
 - For Setting #77: High Swing Toggle Pattern on Lanes 1/9 and Compliance Pattern on all other Lanes.
 - For Setting #78: High Swing Toggle Pattern on Lanes 2/10 and Compliance Pattern on all other Lanes.

- For Setting #79: High Swing Toggle Pattern on Lanes 3/11 and Compliance patter on all other Lanes.
 - For Setting #80: High Swing Toggle Pattern on Lanes 4/12 and Compliance Pattern on all other Lanes.
 - For Setting #81: High Swing Toggle Pattern on Lanes 5/13 and Compliance Pattern on all other Lanes.
 - For Setting #82: High Swing Toggle Pattern on Lanes 6/14 and Compliance Pattern on all other Lanes.
 - For Setting #83: High Swing Toggle Pattern on Lanes 7/15 and Compliance Pattern on all other Lanes.
 - For Setting #84: Low Swing Toggle Pattern on all Lanes
- b. Next state is Polling.Active if an exit of Electrical Idle is detected at the Receiver of any Lane that detected a Receiver during Detect. If the Transmitter is transmitting at a data rate other than 2.5 GT/s, the Transmitter sends eight consecutive EIOs and enters Electrical Idle prior to transitioning to Polling.Active. During the period of Electrical Idle, the data rate is changed to 2.5 GT/s and stabilized. The period of Electrical Idle is greater than 1 ms but must not exceed 2 ms.

4.2.7.2.3 Polling.Configuration §

- Receiver must invert polarity if necessary (see § Section 4.2.5.5).
- The Transmit Margin field of the Link Control 2 Register must be reset to 000b on entry to this substate.
- The Transmitter's Polling.Compliance sequence setting is updated, if required, as described in § Section 4.2.7.2.2 .
- Transmitter sends TS2 Ordered Sets with Link and Lane numbers set to PAD on all Lanes that detected a Receiver during Detect.
 - The Data Rate Identifier Symbol of the TS2 Ordered Sets must advertise all data rates between 2.5 GT/s and 32.0 GT/s that the Port supports, including those that it does not intend to use.

Note: Ports are not permitted to advertise higher than 32.0 GT/s data rates in this state.

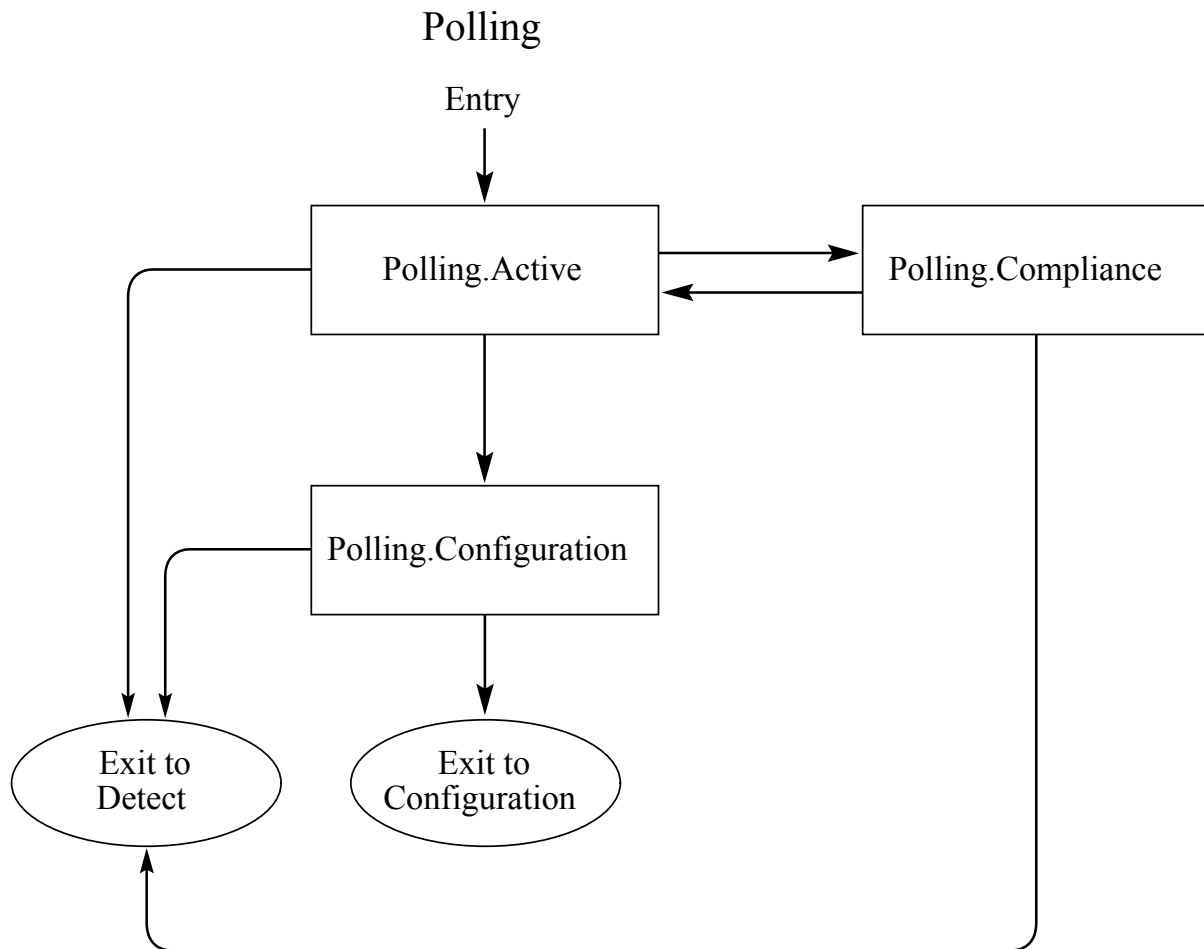

- The next state is Configuration after eight consecutive TS2 Ordered Sets, with Link and Lane numbers set to PAD, are received on any Lanes that detected a Receiver during Detect, and 16 TS2 Ordered Sets are transmitted after receiving one TS2 Ordered Set.
- Otherwise, next state is Detect after a 48 ms timeout.

4.2.7.2.4 Polling.Speed §

This state is unreachable given that the Link comes up to L0 in 2.5 GT/s data rate only and changes speed by entering Recovery.

IMPLEMENTATION NOTE: SUPPORT FOR HIGHER DATA RATES THAN 2.5 GT/S §

A Link will initially train to the L0 state at the 2.5 GT/s data rate even if both sides are capable of operating at a data rate greater than 2.5 GT/s. Supported higher data rates are advertised in the TS Ordered Sets. The other side's speed capability is registered during the Configuration.Complete substate. Based on the highest supported common data rate, either side can initiate a change in speed from the L0 state by transitioning to Recovery.

OM13801B

Figure 4-51 Polling Substate Machine §

4.2.7.3 Configuration §

The Configuration substate machine is shown in § Figure 4-52.

4.2.7.3.1 Configuration.Linkwidth.Start §

4.2.7.3.1.1 Downstream Lanes §

- Next state is Disabled if directed.
 - Note: “if directed” applies to a Downstream Port that is instructed by a higher Layer to assert the Disable Link bit (TS1 and TS2) on all Lanes that detected a Receiver during Detect.
- Next state is Loopback if directed by an implementation specific method and the Transmitter is capable of being a Loopback Lead.
 - Note: “if directed” applies to a Port that is instructed by a higher Layer to assert the Loopback bit (TS1 and TS2) on all Lanes that detected a Receiver during Detect.
- In the optional case where a crosslink is supported, the next state is Disabled after all Lanes that are transmitting TS1 Ordered Sets receive two consecutive TS1 Ordered Sets with the Disable Link bit asserted.
- Next state is Loopback if one of the following two conditions are satisfied:
 - All Lanes that are transmitting TS1 Ordered Sets, that are also receiving TS1 Ordered Sets, receive the Loopback bit asserted in two consecutive TS1 Ordered Sets.
 - Any Lane that is transmitting TS1 Ordered Sets receives two consecutive TS1 Ordered Sets with the Loopback bit asserted and with the Enhanced Link Behavior Control bits set to 01b.

A Port that is capable of transmitting at the 64.0 GT/s data rate may receive TS1 Ordered Sets with the Flit Mode Supported bit set to 1b and the Supported Link Speeds field set to 1 0111b.

The device receiving the Ordered Set with the Loopback bit set becomes the Loopback Follower. If the Loopback Follower supports 1b/1b encoding, it must take into account whether SRIS clocking is enabled (Symbol 4, Bit 7) for identifying SKP OS boundary during Loopback.

- The Transmitter sends TS1 Ordered Sets with selected Link numbers and sets Lane numbers to PAD on all the active Downstream Lanes if LinkUp is 0b or if the LTSSM is not initiating upconfiguration of the Link width. In addition, if upconfigure_capable is set to 1b, and the LTSSM is not initiating upconfiguration of the Link width, the LTSSM sends TS1 Ordered Sets with the selected Link number and sets the Lane number to PAD on each inactive Lane after it detected an exit from Electrical Idle since entering Recovery and has subsequently received two consecutive TS1 Ordered Sets with the Link and Lane numbers each set to PAD while in this substate.
 - On transition to this substate from Polling, any Lane that detected a Receiver during Detect is considered an active Lane.
 - On transition to this substate from Recovery, any Lane that is part of the configured Link the previous time through Configuration.Complete is considered an active Lane.
 - The Data Rate Identifier Symbol of the TS1 Ordered Sets must advertise all data rates that the Port supports, including those that it does not intend to use.
- If LinkUp is 1b and the LTSSM is initiating upconfiguration of the Link width, initially it transmits TS1 Ordered Sets with both the Link and Lane numbers set to PAD on the current set of active Lanes; the inactive Lanes it intends to activate; and those Lanes where it detected an exit from Electrical Idle since entering Recovery and has received two consecutive TS1 Ordered Sets with the Link and Lane numbers each set to PAD. The LTSSM transmits TS1 Ordered Sets with the selected Link number and the Lane number set to PAD when each of the Lanes transmitting TS1 Ordered Sets receives two consecutive TS1 Ordered Sets with the Link and Lane numbers each set to PAD or 1 ms has expired since entering this substate.
 - After activating any inactive Lane, the Transmitter must wait for its TX common mode to settle before exiting from Electrical Idle and transmitting the TS1 Ordered Sets.

- Link numbers are only permitted to be different for groups of Lanes capable of being a unique Link.
- Note: An example of Link number assignments is a set of eight Downstream Lanes capable of negotiating to become one x8 Port when connected to one component or two x4 Ports when connected to two different components. The Downstream Lanes send out TS1 Ordered Sets with the Link number set to N on four Lanes and Link number set to N+1 on the other four Lanes. The Lane numbers are all set to PAD.
- If any Lanes first received at least one or more TS1 Ordered Sets with a Link and Lane number set to PAD, the next state is Configuration.Linkwidth.Accept immediately after any of those same Downstream Lanes receive two consecutive TS1 Ordered Sets with a non-PAD Link number that matches any of the transmitted Link numbers, and with a Lane number set to PAD.
 - If the crosslink configuration is not supported, the condition of first receiving a Link and Lane number set to PAD is always true.
- Else: Optionally, if LinkUp is 0b and if crosslinks are supported, then all Downstream Lanes that detected a Receiver during Detect must first transmit 16 to 32 TS1 Ordered Sets with a non-PAD Link number and PAD Lane number and after this occurs if any Downstream Lanes receive two consecutive TS1 Ordered Sets with a Link number different than PAD and a Lane Number set to PAD, the Downstream Lanes are now designated as Upstream Lanes and a new random crosslink timeout is chosen (see T_{crosslink} in § Table 8-7). The next state is Configuration.Linkwidth.Start as Upstream Lanes.
 - Note: This supports the optional crosslink where both sides may try to act as a Downstream Port. This is resolved by making both Ports become Upstream and assigning a random timeout until one side of the Link becomes a Downstream Port and the other side remains an Upstream Port. This timeout must be random even when hooking up two of the same devices so as to eventually break any possible deadlock.
 - If crosslinks are supported, receiving a sequence of TS1 Ordered Sets with a Link number of PAD followed by a Link number of non-PAD that matches the transmitted Link number is only valid when not interrupted by the reception of a TS2 Ordered Set.

IMPLEMENTATION NOTE: CROSSLINK INITIALIZATION §

In the case where the Downstream Lanes are connected to both Downstream Lanes (crosslink) and Upstream Lanes, the Port with the Downstream Lanes may continue with a single LTSSM as described in this section or optionally, split into multiple LTSSMs.

- The next state is Detect after a 24 ms timeout.

4.2.7.3.1.2 Upstream Lanes §

- In the optional case where crosslinks are supported the next state is Disabled if directed.
 - Note: “if directed” only applies to an optional crosslink Port that is instructed by a higher Layer to assert the Disable Link bit (TS1 and TS2) on all Lanes that detected a Receiver during Detect.
- Next state is Loopback if directed to this state by an implementation specific method.
 - Note: “if directed” applies to a Port that is instructed by a higher Layer to assert the Loopback bit (TS1 and TS2) on all Lanes that detected a Receiver during Detect.

- Next state is Disabled after any Lanes that are transmitting TS1 Ordered Sets receive two consecutive TS1 Ordered Sets with the Disable Link bit asserted.
 - In the optional case where a crosslink is supported, the next state is Disabled only after all Lanes that are transmitting TS1 Ordered Sets, that are also receiving TS1 Ordered Sets, receive the Disable Link bit asserted in two consecutive TS1 Ordered Sets.
- Next state is Loopback if one of the following two conditions are satisfied:
 - All Lanes that are transmitting TS1 Ordered Sets, that are also receiving TS1 Ordered Sets, receive the Loopback bit asserted in two consecutive TS1 Ordered Sets.
 - Any Lane that is transmitting TS1 Ordered Sets receives two consecutive TS1 Ordered Sets with the Loopback bit asserted and with the Enhanced Link Behavior Control bits set to 01b.

A Port that is capable of transmitting at the 64.0 GT/s data rate may receive TS1 Ordered Sets with the Flit Mode Supported bit set to 1b and the Supported Link Speeds field set to 1 0111b.

The device receiving the Ordered Set with the Loopback bit set becomes the Loopback Follower. If the Loopback Follower supports 1b/1b encoding, it must take into account whether SRIS Clocking is enabled (Symbol 4, Bit 7 = 1b) for identifying SKP OS boundaries during Loopback.

- The Transmitter sends out TS1 Ordered Sets with Link numbers and Lane numbers set to PAD on all the active Upstream Lanes; the inactive Lanes it is initiating to upconfigure the Link width; and if upconfigure_capable is set to 1b, on each of the inactive Lanes where it detected an exit from Electrical Idle since entering Recovery and has subsequently received two consecutive TS1 Ordered Sets with Link and Lane numbers, each set to PAD, in this substate.
 - On transition to this substate from Polling, any Lane that detected a Receiver during Detect is considered an active Lane.
 - On transition to this substate from Recovery, any Lane that is part of the configured Link the previous time through Configuration.Complete is considered an active Lane.
 - On transition to this substate from Recovery, if the transition is not caused by LTSSM timeout, the Transmitter must set the Autonomous Change bit (Symbol 4 bit 6) to 1b in the TS1 Ordered Sets that it sends while in the Configuration state if the Transmitter intends to change the Link width for autonomous reasons.
 - The Data Rate Identifier Symbol of the TS1 Ordered Sets must advertise all data rates that the Port supports, including those that it does not intend to use.
- If any Lane receives two consecutive TS1 Ordered Sets with Link numbers that are different than PAD and Lane number set to PAD, a single Link number is selected and Lane number set to PAD are transmitted on all Lanes that both detected a Receiver and also received two consecutive TS1 Ordered Sets with Link numbers that are different than PAD and Lane number set to PAD. Any left over Lanes that detected a Receiver during Detect must transmit TS1 Ordered Sets with the Link and Lane number set to PAD. The next state is Configuration.Linkwidth.Accept:
 - If the LTSSM is initiating upconfiguration of the Link width, it waits until it receives two consecutive TS1 Ordered Sets with a non-PAD Link Number and a PAD Lane number on all the inactive Lanes it wants to activate, or, 1 ms after entry to this substate, it receives two consecutive TS1 Ordered Sets on any Lane with a non-PAD Link number and PAD Lane number, whichever occurs earlier, before transmitting TS1 Ordered Sets with selected Link number and Lane number set to PAD.
 - It is recommended that any possible multi-Lane Link that received an error in a TS1 Ordered Set or lost 128b/130b Block Alignment or Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes; delay the evaluation listed above by an additional two, or more, TS1 Ordered Sets when using 8b/10b encoding, or by an additional 34, or more, TS1 Ordered Sets when using 128b/130b or 1b/1b encoding, but must not exceed 1 ms, so as not to prematurely configure a smaller Link than possible.

- After activating any inactive Lane, the Transmitter must wait for its TX common mode to settle before exiting Electrical Idle and transmitting the TS1 Ordered Sets.
- Optionally, if LinkUp is 0b and if crosslinks are supported, then all Upstream Lanes that detected a Receiver during Detect must first transmit 16-32 TS1 Ordered Sets with a PAD Link number and PAD Lane number and after this occurs and if any Upstream Lanes first receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD, then:
 - The Transmitter continues to send out TS1 Ordered Sets with Link numbers and Lane numbers set to PAD.
 - If any Lanes receive two consecutive TS1 Ordered Sets with Link numbers that are different than PAD and Lane number set to PAD, a single Link number is selected and Lane number set to PAD are transmitted on all Lanes that both detected a Receiver and also received two consecutive TS1 Ordered Sets with Link numbers that are different than PAD and Lane number set to PAD. Any left over Lanes that detected a Receiver during Detect must transmit TS1 Ordered Sets with the Link and Lane number set to PAD. The next state is Configuration.Linkwidth.Accept.
 - It is recommended that any possible multi-Lane Link that received an error in a TS1 Ordered Set or lost 128b/130b Block Alignment or Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes; delay the evaluation listed above by an additional two, or more, TS1 Ordered Sets when using 8b/10b encoding, or by an additional 34, or more, TS1 Ordered Sets when using 128b/130b or 1b/1b encoding, but must not exceed 1 ms, so as not to prematurely configure a smaller Link than possible.
 - Otherwise, after a T_{crosslink} timeout, 16 to 32 TS2 Ordered Sets with PAD Link numbers and PAD Lane numbers are sent. The Upstream Lanes become Downstream Lanes and the next state is Configuration.Linkwidth.Start as Downstream Lanes.
 - Note: This optional behavior is required for crosslink behavior where two Ports may start off with Upstream Ports, and one will eventually take the lead as a Downstream Port.
- The next state is Detect after a 24 ms timeout.

4.2.7.3.2 Configuration.Linkwidth.Accept §

4.2.7.3.2.1 Downstream Lanes §

- If a configured Link can be formed with at least one group of Lanes that received two consecutive TS1 Ordered Sets with the same received Link number (non-PAD and matching one that was transmitted by the Downstream Lanes), TS1 Ordered Sets are transmitted with the same Link number and unique non-PAD Lane numbers are assigned to all these same Lanes. The next state is Configuration.Lanenum.Wait.
 - The assigned non-PAD Lane numbers must range from 0 to n-1, be assigned sequentially to the same grouping of Lanes that are receiving the same Link number, and Downstream Lanes which are not receiving TS1 Ordered Sets must not disrupt the initial sequential numbering of the widest possible Link. Any left over Lanes must transmit TS1 Ordered Sets with the Link and Lane number set to PAD.
 - It is recommended that any possible multi-Lane Link that received an error in a TS1 Ordered Set or lost 128b/130b Block Alignment or Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes delay the evaluation listed above by an additional two, or more, TS1 Ordered Sets when using 8b/10b encoding, or by an additional 34, or more, TS1 Ordered Sets when using 128b/130b or 1b/1b encoding, but must not exceed 1 ms, so as not to prematurely configure a smaller Link than possible.
 - The use_modified_TS1_TS2_Ordered_Set variable must be set to 1b if all of the following conditions are true:

- LinkUp = 0b
- The component had transmitted Modified TS1/TS2 Ordered Sets supported value (11b) in the Enhanced Link Behavior Control field in Symbol 5 of TS1 and TS2 Ordered Sets in Polling and Configuration states since entering the Polling State
- The received eight consecutive TS2 Ordered Sets on all Lanes of the configured Link that could be formed (see 1st bullet of § Section 4.2.7.3.2.1) that were part of the group that caused the transition from Polling.Configuration to Configuration state had the Modified TS1/TS2 Ordered Sets supported value (11b) in the Enhanced Link Behavior Control field in Symbol 5 and 32.0 GT/s data rate is supported bit is Set to 1b in the received eight consecutive TS2 Ordered Sets
- The Flit_Mode_Enabled variable must be set to 1b if all of the following conditions are true:
 - LinkUp = 0b
 - The component had transmitted Flit Mode Supported bit in the ‘Data Rate Identifier’ field (Symbol 4, Bit 0) in the TS1 and TS2 Ordered Sets in Polling and Configuration states since entering the Polling State
 - The received eight consecutive TS2 Ordered Sets on all Lanes of the currently configured Link that caused the transition from Polling.Configuration to Configuration state had the Flit Mode Supported bit in the Data Rate Identifier field (Symbol 4, Bit 0) set to 1b in the received eight consecutive TS2 Ordered Sets
- The next state is Detect after a 2 ms timeout or if no Link can be configured or if all Lanes receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD.

4.2.7.3.2.2 Upstream Lanes §

- If a configured Link can be formed using Lanes that transmitted a non-PAD Link number which are receiving two consecutive TS1 Ordered Sets with the same non-PAD Link number and any non-PAD Lane number, TS1 Ordered Sets are transmitted with the same non-PAD Link number and Lane numbers that, if possible, match the received Lane numbers or are different, if necessary (i.e., Lane reversed). The next state is Configuration.Lanenum.Wait.
 - The received consecutive TS1 Ordered Sets may be either standard TS1 Ordered Sets or Modified TS1 Ordered Sets. Modified TS1 Ordered Sets will only be received if the conditions to Set the use_modified_TS1_TS2_Ordered_Set variable (as described below) are met.
 - The newly assigned Lane numbers must range from 0 to m-1, be assigned sequentially only to some continuous grouping of Lanes that are receiving non-PAD Lane numbers (i.e., Lanes which are not receiving any TS1 Ordered Sets always disrupt a continuous grouping and must not be included in this grouping), must include either Lane 0 or Lane n-1 (largest received Lane number), and m-1 must be equal to or smaller than the largest received Lane number (n-1). Remaining Lanes must transmit TS1 Ordered Sets with Link and Lane numbers set to PAD.
 - If any possible multi-Lane Link received an error in a TS1 Ordered Set, lost 128b/130b Block Alignment, or lost Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes, it is recommended to do the following to avoid configuring a smaller Link than is possible:
 - When using 8b/10b encoding, delay the evaluation listed above by an additional two or more TS1 Ordered Sets, but must not delay by more than 1 ms.
 - When using 128b/130b or 1b/1b encoding, delay the evaluation listed above by an additional 34 or more TS1 Ordered Sets, but must not delay by more than 1 ms.
 - The use_modified_TS1_TS2_Ordered_Set variable must be set to 1b if all of the following conditions are true:

- LinkUp = 0b
- The component has transmitted Modified TS1/TS2 Ordered Sets supported value (11b) in the Enhanced Link Behavior Control field in Symbol 5 of all TS1 and TS2 Ordered Sets in Polling and Configuration states since entering the Polling State
- The received eight consecutive TS2 Ordered Sets on all Lanes of the configured Link that could be formed (see 1st bullet of § Section 4.2.7.3.2.2) that were part of the group that caused the transition from Polling.Configuration to Configuration state had the Modified TS1/TS2 Ordered Sets supported value (11b) in the Enhanced Link Behavior Control field in Symbol 5 and 32.0 GT/s data rate is supported bit is Set to 1b in the received eight consecutive TS2 Ordered Sets
- The Flit_Mode_Enabled variable must be set to 1b if all of the following conditions are true:
 - LinkUp = 0b
 - The component had transmitted Flit Mode Supported bit in the ‘Data Rate Identifier’ field (Symbol 4, Bit 0) in the TS1 and TS2 Ordered Sets in Polling and Configuration states since entering the Polling State
 - The received eight consecutive TS2 Ordered Sets on all Lanes of the currently configured Link that caused the transition from Polling.Configuration to Configuration state had the Flit Mode Supported bit in the Data Rate Identifier field (Symbol 4, Bit 0) set to 1b in the received eight consecutive TS2 Ordered Sets

IMPLEMENTATION NOTE: NEGOTIATING FLIT MODE AND THE MODIFIED TS1/TS2 USAGE §

Negotiating Flit Mode and the Modified TS1/TS2 usage is orthogonal (i.e., a device can advertise and negotiate support for neither, either, or both). This note applies to the Downstream and Upstream Ports.

- The next state is Detect after a 2 ms timeout or if no Link can be configured or if all Lanes receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD.

IMPLEMENTATION NOTE:

EXAMPLE CASES §

Notable examples related to the configuration of Downstream Lanes:

1. A x8 Downstream Port, which can be divided into two x4 Links, sends two different Link numbers on to two x4 Upstream Ports. The Upstream Ports respond simultaneously by picking the two Link numbers. The Downstream Port will have to choose one of these sets of Link numbers to configure as a Link, and leave the other for a secondary LTSSM to configure (which will ultimately happen in Configuration.Complete).
2. A x8 Downstream Port where only seven Lanes are receiving TS1 Ordered Sets with the same received Link number (non-PAD and matching one that was transmitted by the Downstream Lanes) and an eighth Lane, which is in the middle or adjacent to those same Lanes, is not receiving a TS1 Ordered Set. In this case, the eighth Lane is treated the same as the other seven Lanes and Lane numbering for a x8 Lane should occur as described above.

Notable examples related to the configuration of Upstream Lanes:

1. A x8 Upstream Port is presented with Lane numbers that are backward from the preferred numbering. If the optional behavior of Lane reversal is supported by the Upstream Port, the Upstream Port transmits the same Lane numbers back to the Downstream Port. Otherwise, the opposite Lane numbers are transmitted back to the Downstream Port, and it will be up to the Downstream Port to optionally fix the Lane ordering or exit Configuration.

Optional Lane reversal behavior is required to configure a Link where the Lane numbers are reversed and the Downstream Port does not support Lane reversal. Specifically, the Upstream Port Lane reversal will accommodate the scenario where the default Upstream sequential Lane numbering (0 to n-1) is receiving a reversed Downstream sequential Lane number (n-1 to 0).

2. A x8 Upstream Port is not receiving TS1 Ordered Sets on the Upstream Port Lane 0:
 - a. In the case where the Upstream Port can only support a x8 or x1 Link and the Upstream Port can support Lane reversal. The Upstream Port will assign a Lane 0 to only the received Lane 7 (received Lane number n-1) and the remaining seven Lanes must transmit TS1 Ordered Sets with Link and Lane numbers set to PAD.
 - b. In the case where the Upstream Port can only support a x8 or x1 Link and the Upstream Port cannot support Lane reversal. No Link can be formed and the Upstream Port will eventually timeout after 2 ms and exit to Detect.
3. An optional x8 Upstream crosslink Port, which can be divided into two x4 Links, is attached to two x4 Downstream Ports that present the same Link number, and each x4 Downstream Port presents Lane numbers simultaneously that were each numbered 0 to 3. The Upstream Port will have to choose one of these sets of Lane numbers to configure as a Link, and leave the other for a second pass through Configuration.

4.2.7.3.3 Configuration.Lanenum.Accept §

In this sub-state, if use_modified_TS1_TS2_Ordered_Set variable is set to 1b:

- Transmitter must send Modified TS1 Ordered sets instead of TS1 Ordered Sets

- Receiver must check for receipt of Modified TS1 Ordered Sets instead of TS1 Ordered Sets [Note: See § Section 4.2.5.1 for the definition of identical consecutive modified TS1 Ordered Sets.]

4.2.7.3.3.1 Downstream Lanes §

- If two consecutive TS1 Ordered Sets are received with non-PAD Link and non-PAD Lane numbers that match all the non-PAD Link and non-PAD Lane numbers (or reversed Lane numbers if Lane reversal is optionally supported) that are being transmitted in Downstream Lane TS1 Ordered Sets, the next state is Configuration.Complete. If the use_modified_TS1_TS2_Ordered_Set variable is Set and an Alternate Protocol Negotiation is being performed, the transition to Configuration.Complete must be delayed for 10 μ s or until the Downstream Port receives the Upstream Port's response to that protocol request (whichever happens first). See § Section 4.2.5.2 for Alternate Protocol Negotiation details. Note that Retimers are permitted to delay the transition to Configuration.Complete, as described in § Section 4.3.9 .
 - The SRIS_Mode_Enabled variable is Set to 1b if all of the following conditions are true:
 - LinkUp = 0b
 - The Port has been transmitting SRIS Clocking (Symbol 4, bit 7 = 1b) in the transmitted TS1 Ordered Sets since it entered Configuration state.
 - The Link Bandwidth Management Status and Link Autonomous Bandwidth Status bits of the Link Status Register must be updated as follows on a Link bandwidth change if the current transition to Configuration state was from the Recovery state:
 - If the bandwidth change was initiated by the Downstream Port due to reliability issues, the Link Bandwidth Management Status bit is Set.
 - Else if the bandwidth change was not initiated by the Downstream Port and the Autonomous Change bit (Symbol 4 bit 6) in two consecutive received TS1 Ordered Sets is 0b, the Link Bandwidth Management Status bit is Set.
 - Else the Link Autonomous Bandwidth Status bit is Set.
 - The condition of Reversed Lane numbers is defined strictly as the Downstream Lane 0 receiving a TS1 Ordered Set with a Lane number equal to n-1 and the Downstream Lane n-1 receiving a TS1 Ordered Set with a Lane number equal to 0.
 - If any possible multi-Lane Link received an error in a TS1 Ordered Set, lost 128b/130b Block Alignment, or lost Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes, it is recommended to do the following to avoid configuring a smaller Link than is possible:
 - When using 8b/10b encoding, delay the evaluation listed above by an additional two or more TS1 Ordered Sets, but must not delay by more than 1 ms.
 - When using 128b/130b or 1b/1b encoding, delay the evaluation listed above by an additional 34 or more TS1 Ordered Sets, but must not delay by more than 1 ms.
- If a configured Link can be formed with any subset of the Lanes that receive two consecutive TS1 Ordered Sets with the same transmitted non-PAD Link numbers and any non-PAD Lane numbers, TS1 Ordered Sets are transmitted with the same non-PAD Link numbers and new Lane numbers assigned and the next state is Configuration.Lanenum.Wait.
 - The newly assigned transmitted Lane numbers must range from 0 to m-1, be assigned sequentially only to some continuous grouping of the Lanes that are receiving non-PAD Lane numbers (i.e., Lanes which are not receiving any TS1 Ordered Sets always disrupt a continuous grouping and must not be included in this grouping), must include either Lane 0 or Lane n-1 (largest received Lane number), and m-1 must be equal to or smaller than the largest received Lane number (n-1). Any left over Lanes must transmit TS1 Ordered Sets with the Link and Lane number set to PAD.

- If any possible multi-Lane Link received an error in a TS1 Ordered Set, lost 128b/130b Block Alignment, or lost Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes, it is recommended to do the following to avoid configuring a smaller Link than is possible:
 - When using 8b/10b encoding, delay the evaluation listed above by an additional two or more TS1 Ordered Sets, but must not delay by more than 1 ms.
 - When using 128b/130b or 1b/1b encoding, delay the evaluation listed above by an additional 34 or more TS1 Ordered Sets, but must not delay by more than 1 ms.
- The next state is Detect if no Link can be configured or if all Lanes receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD.

4.2.7.3.3.2 Upstream Lanes §

- If two consecutive TS2 Ordered Sets are received with non-PAD Link and non-PAD Lane numbers that match all non-PAD Link and non-PAD Lane numbers that are being transmitted in Upstream Lane TS1 Ordered Sets, the next state is Configuration.Complete. If the use_modified_TS1_TS2_Ordered_Set variable is Set, an Alternate Protocol Negotiation was performed, and the Downstream Port decided not to use any Alternate Protocol, the received TS2 Ordered Sets will have Modified TS Usage set to a value as defined in § Table 4-30. See § Section 4.2.5.2 for Alternate Protocol Negotiation details.

The SRIS_Mode_Enabled variable is set to 1b if all of the following conditions are true:

- LinkUp = 0b
- Any configured Lane in the Port has the SRIS Clocking bit set (Symbol 4, bit 7 = 1b) in the two consecutive TS2 Ordered Sets

Note that Retimers are permitted to delay the transition to Configuration.Complete, as described in § Section 4.3.9.

IMPLEMENTATION NOTE:

CLOCKING WITH SRIS MODE VS. NON-SRIS MODE §

Clocking with SRIS mode vs. non-SRIS mode advertisement was added for Flit Mode support since there is no sync hdr in the 1b/1b encoding. It is advertised by the Downstream Port. However, it is defined as orthogonal to Flit Mode support. This note applies to the Downstream and Upstream Ports.

- If a configured Link can be formed with any subset of the Lanes that receive two consecutive TS1 Ordered Sets with the same transmitted non-PAD Link numbers and any non-PAD Lane numbers, TS1 Ordered Sets are transmitted with the same non-PAD Link numbers and new Lane numbers assigned and the next state is Configuration.Lanenum.Wait.
 - The newly assigned transmitted Lane numbers must range from 0 to m-1, be assigned sequentially only to some continuous grouping of Lanes that are receiving non-PAD Lane numbers (i.e., Lanes which are not receiving any TS1 Ordered Sets always disrupt a continuous grouping and must not be included in this grouping), must include either Lane 0 or Lane n-1 (largest received Lane number), and m-1 must be equal to or smaller than the largest received Lane number (n-1). Any left over Lanes must transmit TS1 Ordered Sets with the Link and Lane number set to PAD.
 - If any possible multi-Lane Link received an error in a TS1 Ordered Set, lost 128b/130b Block Alignment, or lost Block/Flit alignment with 1b/1b encoding on a subset of the received Lanes, it is recommended to do the following to avoid configuring a smaller Link than is possible:

- When using 8b/10b encoding, delay the evaluation listed above by an additional two or more TS1 Ordered Sets, but must not delay by more than 1 ms.
- When using 128b/130b or 1b/1b encoding, delay the evaluation listed above by an additional 34 or more TS1 Ordered Sets, but must not delay by more than 1 ms.
- The next state is Detect if no Link can be configured or if all Lanes receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD.

4.2.7.3.4 Configuration.Lanenum.Wait §

In this sub-state, if use_modified_TS1_TS2_Ordered_Set variable is set to 1b:

- Transmitter must send Modified TS1 Ordered Sets instead of TS1 Ordered Sets
- Receiver must check for receipt of Modified TS1 Ordered Sets instead of TS1 Ordered Sets though it may receive TS1 Ordered Sets initially while the Link partner is transitioning to this sub-state [Note: These must be identical consecutive Modified TS1 Ordered Sets with valid parity in the last Symbol]

4.2.7.3.4.1 Downstream Lanes §

- The next state is Configuration.Lanenum.Accept if any of the Lanes that detected a Receiver during Detect receive two consecutive TS1 Ordered Sets which have a Lane number different from when the Lane first entered Configuration.Lanenum.Wait, and not all the Lanes' Link numbers are set to PAD or two consecutive TS1 Ordered Sets have been received on all Lanes, with Link and Lane numbers that match what is being transmitted on all Lanes.

The Upstream Lanes are permitted to delay up to 1 ms before transitioning to Configuration.Lanenum.Accept.

The reason for delaying up to 1 ms before transitioning is to prevent received errors or skew between Lanes affecting the final configured Link width.

The condition of requiring reception of any Lane number different from when the Lane(s) first entered Configuration.Lanenum.Wait is necessary in order to allow the two Ports to settle on an agreed upon Link width. The exact meaning of the statement “any of the Lanes receive two consecutive TS1 Ordered Sets, which have a Lane number different from when the Lane first entered Configuration.Lanenum.Wait” requires that a Lane number must have changed from when the Lanes most recently entered Configuration.Lanenum.Wait before a transition to Configuration.Lanenum.Accept can occur.

- The next state is Detect after a 2 ms timeout or if all Lanes receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD.

4.2.7.3.4.2 Upstream Lanes §

- The next state is Configuration.Lanenum.Accept
 - a. If any of the Lanes receive two consecutive TS1 Ordered Sets that have a Lane number different from when the Lane first entered Configuration.Lanenum.Wait, and not all the Lanes' Link numbers are set to PAD
 - or
 - b. If any Lane receives two consecutive TS2 Ordered Sets

- The next state is Detect after a 2 ms timeout or if all Lanes receive two consecutive TS1 Ordered Sets with Link and Lane numbers set to PAD.

4.2.7.3.5 Configuration.Complete §

A Port is allowed to change the supported data rates that it advertises when it enters this substate, but it must not change those values while in this substate.

If Flit_Mode_Enabled is 0b and LinkUp=1b, a Port is permitted to change the Upconfigure that it advertises when it enters this substate, but it must not change the value while in this substate.

If Flit_Mode_Enabled is 1b and LinkUp=0b, a Port is permitted to change the L0p Capability that it advertises when it enters this substate, but it must not change the value while in this substate.

In this sub-state, if use_modified_TS1_TS2_Ordered_Set variable is set to 1b:

- Transmitter must send Modified TS2 Ordered sets instead of TS2 Ordered Sets
- Receiver must check for receipt of Modified TS2 Ordered Sets, instead of TS2 Ordered Sets [Note: See § Section 4.2.5.1 for the definition of identical consecutive Modified TS1 Ordered Sets.]

4.2.7.3.5.1 Downstream Lanes §

- TS2 Ordered Sets are transmitted using Link and Lane numbers that match the received TS1 Ordered Set Link and Lane numbers.
 - The Link Upconfigure / L0p Capability bit of the TS2 Ordered Sets is permitted to be set to 1b to indicate that the Port is capable of supporting down to a x1 Link on the currently assigned Lane 0 and up-configuring the Link while LinkUp = 1b. Advertising this capability is optional.
- N_FTS must be noted for use in L0s when leaving this state.
- When using 8b/10b encoding, Lane-to-Lane de-skew must be completed when leaving this state.
- Scrambling is disabled if all configured Lanes have the Disable Scrambling bit asserted in two consecutively received TS2 Ordered Sets.
 - The Port that is sending the Disable Scrambling bit on all of the configured Lanes must also disable scrambling. Scrambling can only be disabled when using 8b/10b encoding.
- The next state is Configuration.Idle immediately after all Lanes that are transmitting TS2 Ordered Sets receive eight consecutive TS2 Ordered Sets with matching Lane and Link numbers (non-PAD) and identical data rate identifiers (including identical Link Upconfigure / L0p Capability bit(Symbol 4 bit 6)), and 16 TS2 Ordered Sets are sent after receiving one TS2 Ordered Set. Implementations with the Retimer Presence Detect Supported bit of the Link Capabilities 2 Register set to 1b must also receive the eight consecutive TS2 Ordered Sets with identical Retimer Present (Symbol 5 bit 4) when the data rate is 2.5 GT/s. Implementations with Two Retimers Presence Detect Supported bit of the Link Capabilities 2 Register set to 1b must also receive the eight consecutive TS2 Ordered Sets with identical Retimer Present (Symbol 5 bits 5:4) when the data rate is 2.5 GT/s.
 - If the data rate of operation is 2.5 GT/s:
 - If the Retimer Presence Detect Supported bit of the Link Capabilities 2 Register is set to 1b and any configured Lane received the Retimer Present bit set to 1b in the eight consecutively received TS2 Ordered Sets, then the Retimer Presence Detected bit must be set to 1b in the Link Status 2 Register otherwise the Retimer Presence Detected bit must be set to 0b.
 - If the Two Retimers Presence Detect Supported bit of the Link Capabilities 2 Register is set to 1b and any configured Lane received the Two Retimers Present bit set to 1b in the eight

consecutively received TS2 Ordered Sets then the Two Retimers Presence Detected bit must be set to 1b in the Link Status 2 Register, otherwise the Two Retimers Presence Detected bit must be set to 0b.

- If the device supports greater than 2.5 GT/s data rate, it must record the data rate identifier received on any configured Lane of the Link. This will override any previously recorded value. A variable to track speed change in recovery state, ***changed_speed_recovery***, is reset to 0b.

- If Flit_Mode_Enabled is 0b:

If the device sends TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit (Symbol 4 bit 6) set to 1b, and receives eight consecutive TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit set to 1b, the variable upconfigure_capable is set to 1b, else it is reset to 0b.

- If Flit_Mode_Enabled is 1b and LinkUp=0b:

If the device sends TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit (Symbol 4 bit 6) set to 1b, and receives eight consecutive TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit set to 1b:

- The variable L0p_capable is set to 1b.
- The Remote L0p Supported bit in the Device Status 3 Register is set to 1b.

- All remaining Lanes that are not part of the configured Link are no longer associated with the LTSSM in progress and must:

- i. Be associated with a new LTSSM if this optional feature is supported.
or

- ii. All Lanes that cannot be associated with an optional new LTSSM must transition to Electrical Idle.⁸² Those Lanes that formed a Link up to the L0 state, and LinkUp has been 1b since then, but are not a part of the currently configured Link, must be associated with the same LTSSM if the LTSSM advertises Link width upconfigure capability. It is recommended that the Receiver terminations of these Lanes be left on. If they are not left on, they must be turned on when the LTSSM enters the Recovery.RcvrCfg substate until it reaches the Configuration.Complete substate if upconfigure_capable is set to 1b to allow for potential Link width upconfiguration. Any Lane that was not part of the LTSSM during the initial Link training through L0 cannot become a part of the LTSSM as part of the Link width upconfiguration process.

- In the case of an optional crosslink, the Receiver terminations are required to meet Z_{RX-HIGH-IMP-DC-POS} and Z_{RX-HIGH-IMP-DC-NEG} (see § Table 8-12).
- These Lanes must be re-associated with the LTSSM immediately after the LTSSM in progress transitions back to Detect.
- An EIOS does not need to be sent before transitioning to Electrical Idle, and the transition to Electrical Idle does not need to occur on a Symbol or Ordered Set boundary.

- After a 2 ms timeout:

- The next state is Detect if the current data rate is 2.5 GT/s or 5.0 GT/s.
- The next state is Configuration.Idle if the idle_to_rlock_transitioned variable is less than FFh and the current data rate is 8.0 GT/s or higher.
 - i. The changed_speed_recovery variable is reset to 0b.

82. The common mode being driven does not need to meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle (V_{TX-CM-DC-ACTIVE-IDLE-DELTA}) specification (see § Table 8-7).

- ii. Lanes that are not part of the configured Link are no longer associated with the LTSSM in progress and must meet requirement (i) or (ii) specified above for the non-timeout transition to Configuration.Idle.
- iii. The upconfigure_capable variable is permitted, but not required, to be updated if at least one Lane received eight consecutive TS2 Ordered Sets with matching Lane and Link numbers (non-PAD). If updated, the upconfigure_capable variable is set to 1b when the transmitted and received Link Upconfigure bits are 1b, else it is reset to 0b.
- Else the next state is Detect.

4.2.7.3.5.2 Upstream Lanes §

- TS2 Ordered Sets are transmitted using Link and Lane numbers that match the received TS2 Link and Lane numbers.
 - The Link Upconfigure / L0p Capability bit of the TS2 Ordered Sets is permitted to be set to 1b to indicate that the Port is capable of supporting a x1 Link on the currently assigned Lane 0 and up-configuring the Link while LinkUp = 1b. Advertising this capability is optional.
- N_FTS must be noted for use in L0s when leaving this state.
- When using 8b/10b encoding, Lane-to-Lane de-skew must be completed when leaving this state.
- Scrambling is disabled if all configured Lanes have the Disable Scrambling bit asserted in two consecutively received TS2 Ordered Sets.
 - The Port that is sending the Disable Scrambling bit on all of the configured Lanes must also disable scrambling. Scrambling can only be disabled when using 8b/10b encoding.
- The next state is Configuration.Idle immediately after all Lanes that are transmitting TS2 Ordered Sets receive eight consecutive TS2 Ordered Sets with matching Lane and Link numbers (non-PAD) and identical data rate identifiers (including identical Link Upconfigure / L0p Capability bit (Symbol 4 bit 6)), and 16 consecutive TS2 Ordered Sets are sent after receiving one TS2 Ordered Set. Implementations with the Retimer Presence Detect Supported bit of the Link Capabilities 2 Register set to 1b must also receive the eight consecutive TS2 Ordered Sets with identical Retimer Present (Symbol 5 bit 4) when the data rate is 2.5 GT/s. Implementations with Two Retimers Presence Detect Supported bit of the Link Capabilities 2 Register set to 1b must also receive the eight consecutive TS2 Ordered Sets with identical Retimer Present (Symbol 5 bits 5:4) when the data rate is 2.5 GT/s.
 - If the data rate of operation is 2.5 GT/s:
 - If the Retimer Presence Detect Supported bit of the Link Capabilities 2 Register is set to 1b and any configured Lane received the Retimer Present bit set to 1b in the eight consecutively received TS2 Ordered Sets, then the Retimer Presence Detected bit must be set to 1b in the Link Status 2 Register otherwise the Retimer Presence Detected bit must be set to 0b.
 - If the Two Retimers Presence Detect Supported bit of the Link Capabilities 2 Register is set to 1b and any configured Lane received the Two Retimers Present bit set to 1b in the eight consecutively received TS2 Ordered Sets then the Two Retimers Presence Detected bit must be set to 1b in the Link Status 2 Register, otherwise the Two Retimers Presence Detected bit must be set to 0b.
 - If the device supports greater than 2.5 GT/s data rate, it must record the data rate identifier received on any configured Lane of the Link. This will override any previously recorded value. A variable to track speed change in recovery state, changed_speed_recovery, is reset to 0b.
 - If Flit_Mode_Enabled is 0b:

If the device sends TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit (Symbol 4 bit 6) set to 1b, as well as receives eight consecutive TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit set to 1b, the variable upconfigure_capable is set to 1b, else it is reset to 0b.

- If Flit_Mode_Enabled is 1b and LinkUp=0b:

If the device sends TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit (Symbol 4 bit 6) set to 1b, and receives eight consecutive TS2 Ordered Sets with the Link Upconfigure / L0p Capability bit set to 1b:

- The variable L0p_capable is set to 1b.
- The Remote L0p Supported bit in the Device Status 3 Register is set to 1b.

- All remaining Lanes that are not part of the configured Link are no longer associated with the LTSSM in progress and must:

- i. Optionally be associated with a new crosslink LTSSM if this feature is supported.
or

- ii. All remaining Lanes that are not associated with a new crosslink LTSSM must transition to Electrical Idle,⁸³ and Receiver terminations are required to meet Z_{RX-HIGH-IMP-DC-POS} and Z_{RX-HIGH-IMP-DC-NEG} (see § Table 8-12). Those Lanes that formed a Link up to the L0 state, and LinkUp has been 1b since then, but are not a part of the currently configured Link, must be associated with the same LTSSM if the LTSSM advertises Link width upconfigure capability. It is recommended that the Receiver terminations of these Lanes be left on. If they are not left on, they must be turned on when the LTSSM enters the Recovery.RcvrCfg substate until it reaches the Configuration.Complete substate if upconfigure_capable is set to 1b to allow for potential Link width upconfiguration. Any Lane that was not part of the LTSSM during the initial Link training through L0 cannot become a part of the LTSSM as part of the Link width upconfiguration process.

- These Lanes must be re-associated with the LTSSM immediately after the LTSSM in progress transitions back to Detect.
- EIOS does not need to be sent before transitioning to Electrical Idle, and the transition to Electrical Idle does not need to occur on a Symbol or Ordered Set boundary.

- After a 2 ms timeout:

- The next state is Detect if the current data rate is 2.5 GT/s or 5.0 GT/s.
- The next state is Configuration.Idle if the idle_to_rlock_transitioned variable is less than FFh and the current data rate is 8.0 GT/s or higher.
 - i. The changed_speed_recovery variable is reset to 0b.
 - ii. Lanes that are not part of the configured Link are no longer associated with the LTSSM in progress and must meet requirement (i) or (ii) specified above for the non-timeout transition to Configuration.Idle.
 - iii. The upconfigure_capable variable is permitted, but not required, to be updated if at least one Lane received eight consecutive TS2 Ordered Sets with matching Lane and Link numbers (non-PAD). If updated, the upconfigure_capable variable is set to 1b when the transmitted and received Link Upconfigure bits are 1b, else it is reset to 0b.

- Else the next state is Detect.

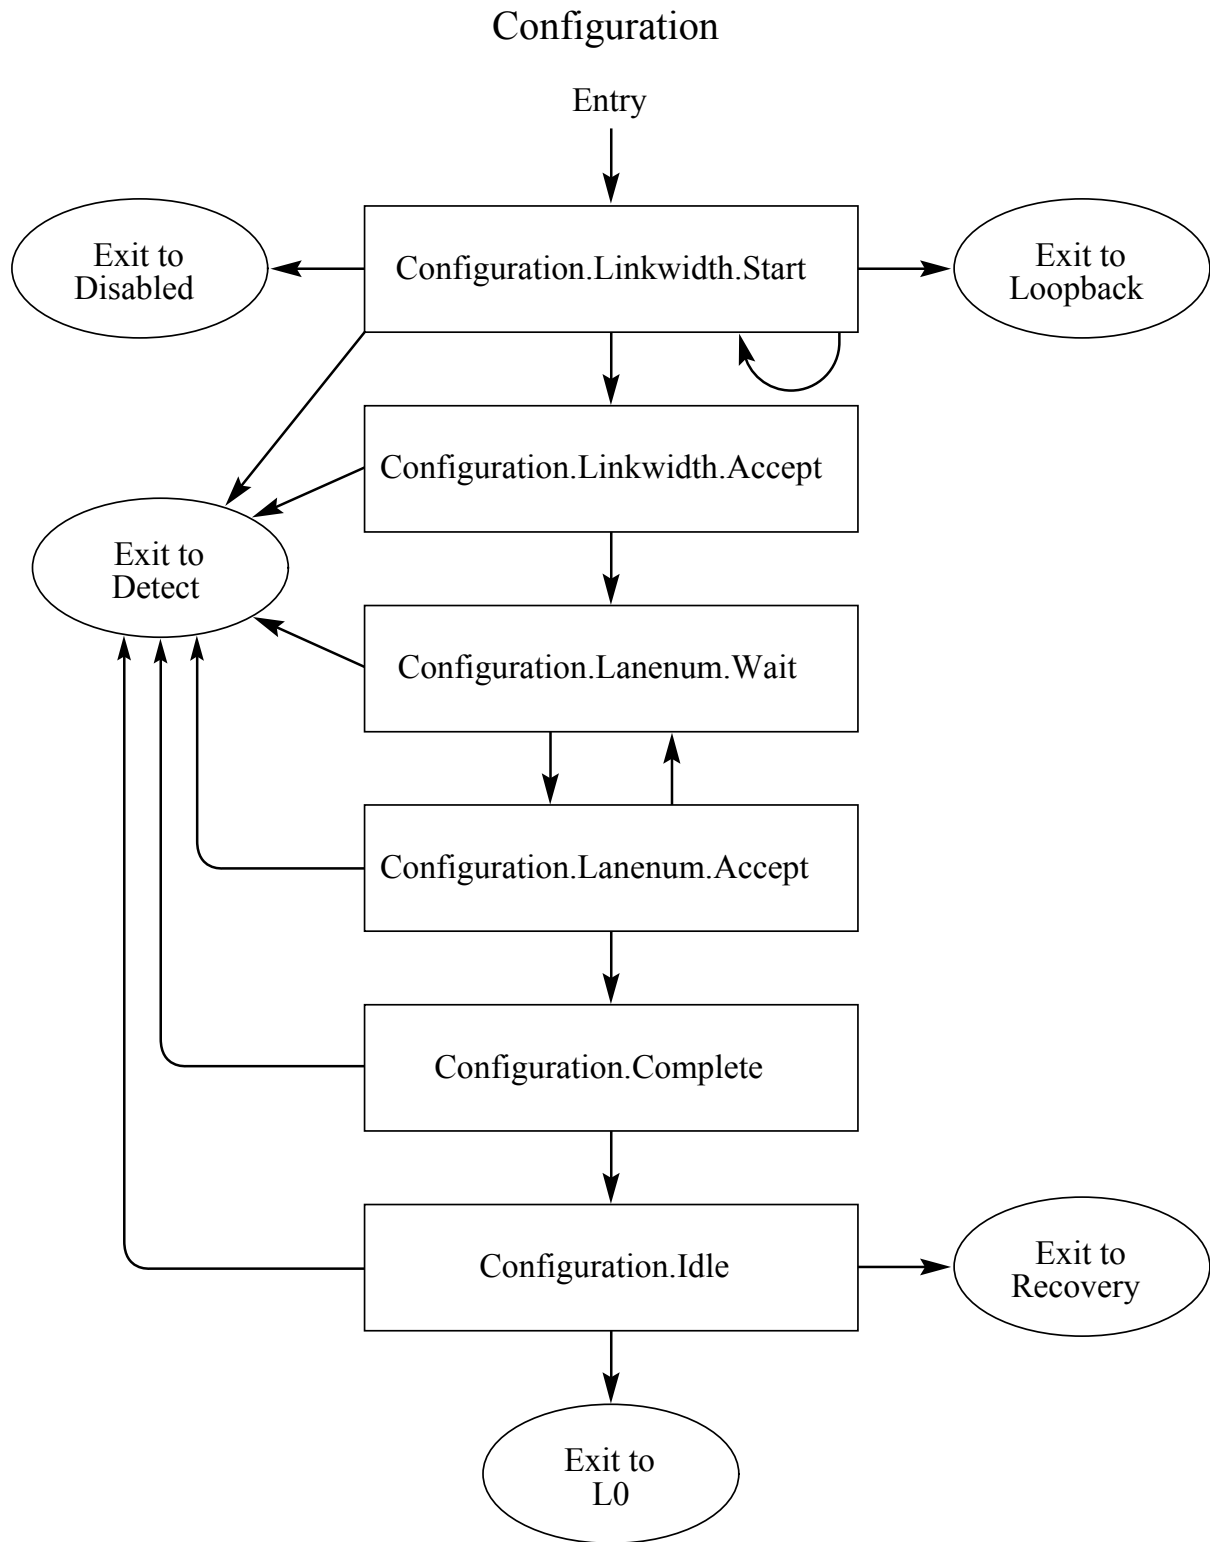

83. The common mode being driven does not need to meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle (V_{TX-CM-DC-ACTIVE-IDLE-DELTA}) specification (see § Table 8-7).

4.2.7.3.6 Configuration.Idle §

- When using 8b/10b encoding, the Transmitter sends Idle data Symbols on all configured Lanes in Non-Flit Mode and IDLE Flits across all configured Lanes in Flit Mode.
- If LinkUp = 0b and 64.0 GT/s data rate is supported by all components in the Link, as advertised in the eight consecutive TS2 or eight consecutive and identical Modified TS2 Ordered Sets received prior to entering Configuration.Idle:
 - If the No Equalization Needed bit (bit 1 of Symbol 5) was set to 1b in the received eight consecutive and identical Modified TS2 Ordered Sets and in the transmitted Modified TS2 Ordered Sets in all the configured Lanes of the Link or if No Equalization Needed value (10b) was received in the Enhanced Link Behavior Control field (bits 7:6 of Symbol 5) in the eight consecutive TS2 Ordered Sets and was also set in the Enhanced Link Behavior Control field of the transmitted TS2 Ordered Sets:
 - The equalization_done_8GT_data_rate, equalization_done_16GT_data_rate, equalization_done_32GT_data_rate, and equalization_done_64GT_data_rate variables are each set to 1b.
 - The No Equalization Needed Received bit in the 64.0 GT/s Status Register is set to 1b.
 - Else If the Equalization Bypass to Highest NRZ Rate bit (bit 0 of Symbol 5) was set to 1b in the received eight consecutive and identical Modified TS2 Ordered Sets as well as in the transmitted Modified TS2 Ordered Sets in all the configured Lanes of the Link or if either No Equalization Needed or Equalization Bypass to Highest NRZ Rate value (01b or 10b) was received in the Enhanced Link Behavior Control field (bits 7:6 of Symbol 5) in the eight consecutive TS2 Ordered Sets and either No Equalization Needed or Equalization Bypass to Highest NRZ Rate value (01b or 10b) was also set in the Enhanced Link Behavior Control field of the transmitted TS2 Ordered Sets:
 - The equalization_done_8GT_data_rate and equalization_done_16GT_data_rate variables are each set to 1b.
 - If entry to this sub-state was caused by receipt of eight consecutive and identical Modified TS2 Ordered Sets and LinkUp = 0b
 - If the Modified TS Usage field in the received eight consecutive Modified TS2 Ordered Sets was set to 010b (Alternate Protocols) and the same value was set in the Modified TS Usage field of the transmitted Modified TS2 Ordered Sets and the Modified TS Information 1 and Alternate Protocol Vendor ID fields are identical between the transmitted and received Modified TS2 Ordered Sets in all the configured Lanes of the Link:
 - The Modified TS Received bit in the 32.0 GT/s Status Register is set to 1b. The details of the negotiation will be reflected in the Received Modified TS Data 1 Register and Received Modified TS Data 2 Register based on the eight consecutive Modified TS2 Ordered Sets received.
- If LinkUp = 0b and 32.0 GT/s data rate is supported by all components in the Link, as advertised in the eight consecutive TS2 or eight consecutive and identical Modified TS2 Ordered Sets received prior to entering Configuration.Idle:
 - If the No Equalization Needed bit (bit 1 of Symbol 5) was set to 1b in the received eight consecutive and identical Modified TS2 Ordered Sets and was also set in the transmitted Modified TS2 Ordered Sets in all the configured Lanes of the Link or if No Equalization Needed value (10b) was received in the Enhanced Link Behavior Control field (bits 7:6 of Symbol 5) in the eight consecutive TS2 Ordered Sets and was also set in the Enhanced Link Behavior Control field of the transmitted TS2 Ordered Sets:
 - The equalization_done_8GT_data_rate, equalization_done_16GT_data_rate, and equalization_done_32GT_data_rate variables are each set to 1b.

- The No Equalization Needed Received bit in the 32.0 GT/s Status Register is set to 1b.
- Else If the Equalization Bypass to Highest NRZ Rate bit (bit 0 of Symbol 5) was set to 1b in the received eight consecutive and identical Modified TS2 Ordered Sets and was also set in the transmitted Modified TS2 Ordered Sets in all the configured Lanes of the Link or if either No Equalization Needed or Equalization Bypass to Highest NRZ Rate value (01b or 10b) was received in the Enhanced Link Behavior Control field (bits 7:6 of Symbol 5) in the eight consecutive TS2 Ordered Sets and either No Equalization Needed or Equalization Bypass to Highest NRZ Rate value (01b or 10b) was also set in the Enhanced Link Behavior Control field of the transmitted TS2 Ordered Sets:
 - The equalization_done_8GT_data_rate and equalization_done_16GT_data_rate variables are each set to 1b.
- If entry to this sub-state was caused by receipt of eight consecutive and identical Modified TS2 Ordered Sets and LinkUp = 0b
 - If the Modified TS Usage field in the received eight consecutive Modified TS2 Ordered Sets was set to 010b (Alternate Protocols) and the same value was set in the Modified TS Usage field of the transmitted Modified TS2 Ordered Sets and the Modified TS Information 1 and Alternate Protocol Vendor ID fields are identical between the transmitted and received Modified TS2 Ordered Sets in all the configured Lanes of the Link:
 - The Modified TS Received bit in the 32.0 GT/s Status Register is set to 1b. The details of the negotiation will be reflected in the Received Modified TS Data 1 Register and Received Modified TS Data 2 Register based on the eight consecutive modified TS2 Ordered Sets received.
- When using 128b/130b encoding in Non-Flit Mode:
 - If the data rate is 8.0 GT/s, the Transmitter sends one SDS Ordered Set on all configured Lanes to start a Data Stream and then sends Idle data Symbols on all configured Lanes. The first Idle data Symbol transmitted on Lane 0 is the first Symbol of the Data Stream.
 - If the data rate is 16.0 GT/s or higher, the Transmitter sends one Control SKP Ordered Set followed immediately by one SDS Ordered Set on all configured Lanes to start a Data Stream and then sends Idle data Symbols on all configured Lanes. The first Idle data Symbol transmitted on Lane 0 is the first Symbol of the Data Stream.
- When using 1b/1b encoding or 128b/130b encoding in Flit Mode:
 - Transmitter sends an SDS Ordered Set sequence followed by one Control SKP Ordered Set on all configured Lanes to start a Data Stream with IDLE Flits.
- Receiver waits for Idle data in Non-Flit Mode and for IDLE Flits in Flit Mode.
- LinkUp = 1b
- When using 8b/10b encoding in Non-Flit Mode, the next state is L0 if eight consecutive Symbol Times of Idle data are received on all configured Lanes and 16 Idle data Symbols are sent after receiving one Idle data Symbol.
 - If software has written a 1b to the Retrain Link bit in the Link Control Register since the last transition to L0 from Recovery or Configuration, the Downstream Port must set the Link Bandwidth Management Status bit of the Link Status Register to 1b.
 - The use_modified_TS1_TS2_Ordered_Set variable is reset to 0b on transition to L0.
- When using 128b/130b encoding in Non-Flit Mode, next state is L0 if eight consecutive Symbol Times of Idle data are received on all configured Lanes, 16 Idle data Symbols are sent after receiving one Idle data Symbol, and this state was not entered by a timeout from Configuration.Complete.
 - The Idle data Symbols must be received in Data Blocks.
 - Lane-to-Lane de-skew must be completed before Data Stream processing starts.

- If software has written a 1b to the Retrain Link bit in the Link Control Register since the last transition to L0 from Recovery or Configuration, the Downstream Port must set the Link Bandwidth Management Status bit of the Link Status Register to 1b.
- The idle_to_rlock_transitioned variable is reset to 00h on transition to L0.
- In Flit Mode, the next state is L0 if two consecutive IDLE Flits are received and the minimum number of IDLE Flits are sent after receiving one IDLE Flit and this state was not entered by a timeout from Configuration.Complete. The minimum number of IDLE Flits to send is 4 with 8b/10b or 128b/130b encoding and 8 with 1b/1b encoding.
 - Lane-to-Lane de-skew must be completed before Data Stream processing starts.
 - If software has written a 1b to the Retrain Link bit in the Link Control Register since the last transition to L0 from Recovery or Configuration, the Downstream Port must set the Link Bandwidth Management Status bit of the Link Status Register to 1b.
 - The idle_to_rlock_transitioned variable is reset to 00h and the use_modified_TS1_TS2_Ordered_Set variable is reset to 0b on transition to L0.
- Otherwise, after a minimum 2 ms timeout:
 - If the idle_to_rlock_transitioned variable is less than FFh, the next state is Recovery.RcvrLock.
 - On transition to Recovery.RcvrLock:
 - If the data rate is 8.0 GT/s or higher, the idle_to_rlock_transitioned variable is incremented by 1.
 - If the data rate is 2.5 GT/s or 5.0 GT/s, the idle_to_rlock_transitioned variable is set to FFh and the use_modified_TS1_TS2_Ordered_Set variable is reset to 0b.
 - Else the next state is Detect.

OM13802C

Figure 4-52 Configuration Substate Machine §

4.2.7.4 Recovery §

The Recovery substate machine is shown in § Figure 4-53. For the data rate of 64.0 GT/s, any reference to Pre-cursor implies the two pre-cursors used.

4.2.7.4.1 Recovery.RcvrLock §

If the Link is operating at a data rate of 8.0 GT/s or higher, a Receiver must consider any TS0, TS1, or TS2 Ordered Set to be received only after it obtains Block Alignment in that Lane. If entry to this substate is from L1 or Recovery.Speed or L0s, the Block Alignment must be obtained after exiting Electrical Idle condition. If entry to this substate is from L0, the Block Alignment must be obtained after the end of the last Data Stream.

- If the data rate of operation is 8.0 GT/s or higher:
 - If the start_equalization_w_preset variable is set to 1b:
 - An Upstream Port must use the Transmitter preset values it registered from the received appropriate eight consecutive TS2 Ordered Sets (EQ TS2 if 8.0 GT/s, EQ TS2 if 32.0 GT/s and Equalization Bypass to Highest NRZ Rate was negotiated, and 128b/130b EQ TS2 if 16.0 GT/s, 32.0 GT/s, or 64.0 GT/s) in Recovery.RcvrCfg in its Transmitter setting as soon as it starts transmitting in the data rate at which equalization will be performed and ensure that it meets the preset definition in § Chapter 8. . Lanes that received a Reserved or unsupported Transmitter preset value must use an implementation specific method to choose a supported Transmitter preset setting for use as soon as it starts transmitting at the data rate where equalization needs to be performed.
 - A Downstream Port must use the Transmitter preset settings according to the rules below as soon as it starts transmitting at the data rate where equalization must be performed:
 1. If the data rate of equalization is 16.0 GT/s or 32.0 GT/s or 64.0 GT/s and eight consecutive EQ TS2 Ordered Sets (for the case where equalization bypass to 32.0 GT/s is to be performed) or 128b/130b EQ TS2 Ordered Sets were received with supported Transmitter Preset values in the most recent transition through Recovery.RcvrCfg, the Transmitter Preset value from those EQ TS2 or 128b/130b EQ TS2 Ordered Sets must be used.
 2. Else, if the Transmitter Preset value defined in the Downstream Port Transmitter Preset field of the appropriate Lane Equalization Control Register Entry, as defined below is supported, then it must be used:

Data Rate of Equalization	Transmitter Preset value to be used as soon as the Link transitions to the data rate of equalization
8.0 GT/s	Transmitter Preset field defined in the Lane Equalization Control Register Entry for each Lane. The Downstream Port may optionally use the Downstream Port 8.0 GT/s Receiver Preset Hint field defined in the Lane Equalization Control Register Entry for each of its Receivers corresponding to the Lane, if they are not Reserved values.
16.0 GT/s	Downstream Port 16.0 GT/s Transmitter Preset field of the <u>16.0 GT/s Lane Equalization Control Register Entry</u>
32.0 GT/s	Downstream Port 32.0 GT/s Transmitter Preset field of the <u>32.0 GT/s Lane Equalization Control Register Entry</u>

Data Rate of Equalization	Transmitter Preset value to be used as soon as the Link transitions to the data rate of equalization
64.0 GT/s	Downstream Port 64.0 GT/s Transmitter Preset field of the 64.0 GT/s Lane Equalization Control Register Entry

3. Else, use an implementation specific method to choose a supported Transmitter preset setting.

The Downstream Port must ensure that it meets the preset definition in § Chapter 8. .

- Next state is Recovery.Equalization.
- Else:
 - The Transmitter must use the coefficient settings agreed upon at the conclusion of the last equalization procedure.
 - If this substate was entered from Recovery.Equalization, in the transmitted TS1 Ordered Sets, a Downstream Port must set the Pre-cursor, Cursor, and Post-cursor Coefficient fields to the current Transmitter settings, and if the last accepted request in Phase 2 of Recovery.Equalization was a preset request, it must set the Transmitter Preset bits to the accepted preset of that request.
 - It is recommended that in this substate, in the transmitted TS1 Ordered Sets, all Ports set the Pre-cursor, Cursor, and Post-cursor Coefficient fields to the current Transmitter settings, and set the Transmitter Preset bits to the most recent preset that the Transmitter settings were set to.
 - An Upstream Port that receives eight consecutive TS0 or eight consecutive TS1 Ordered Sets on all configured Lanes with the following characteristics must transition to Recovery.Equalization
 - If eight consecutive TS1 Ordered Sets were received, Link and Lane numbers in the received TS1 Ordered Sets match with the Link and Lane numbers in the transmitted TS1 Ordered Sets on each Lane. See § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding.
 - If eight consecutive TS1 Ordered Sets were received, speed_change bit is equal to 0b
 - If eight consecutive TS0 Ordered Sets were received, and the latest transition to Recovery.RcvrLock was from Recovery.Speed substate
 - If eight consecutive TS1 Ordered Sets were received, with the EC bits not equal to 00b

IMPLEMENTATION NOTE: REDOING EQUALIZATION §

A Downstream Port may use this provision to redo some parts of the Transmitter Equalization process using software help or some other implementation specific means while ensuring no transactions are in flight on the Link to avoid any timeouts.

- Next state for a Downstream Port is Recovery.Equalization if Recovery.RcvrLock was not entered from Configuration.Idle or Recovery.Idle and the Perform Equalization bit in the Link

Control 3 Register is set or an implementation specific mechanism determined equalization needs to be performed, following procedures described in § Section 4.2.4 .

The Downstream Port must ensure that no more than 2 TS1 Ordered Sets with EC=00b are transmitted due to being in Recovery.RcvrLock before transitioning to Recovery.Equalization and starting to transmit the TS0/TS1 Ordered Sets.

- Transmitter sends TS1 Ordered Sets on all configured Lanes using the same Link and Lane numbers that were set after leaving Configuration. The speed_change bit (bit 7 of the Data Rate Identifier Symbol in TS1 Ordered Set) must be set to 1b if the directed_speed_change variable is set to 1b. The directed_speed_change variable is set to 1b if any configured Lane receives eight consecutive TS1 Ordered Sets with the speed_change bit set to 1b. Only those data rates greater than 2.5 GT/s should be advertised that can be supported reliably. In Non-Flit Mode of operation, the N_FTS value in the TS1 Ordered Set transmitted reflects the number at the current speed of operation. A device is allowed to change the supported data rates that it advertises when it enters this substate.

A Downstream Port that intends to redo equalization with a data rate change from 2.5 GT/s or 5.0 GT/s to 8.0 GT/s or 32.0 GT/s when Equalization Bypass to Highest NRZ Rate is supported must:

- Send EQ TS1 Ordered Sets with the speed_change bit set to 1b and advertising the following data rates:
 - 8.0 GT/s Data Rate Identifier if redo equalization is for 8.0 GT/s Data Rate
 - 32.0 GT/s Data Rate Identifier if redo equalization is for 32.0 GT/s Data Rate
- If the equalization redo attempt is initiated by the hardware as described in § Section 4.2.4 , then hardware must ensure that the Data Rate is 2.5 GT/s or 5.0 GT/s before initiating the attempt.
- If the equalization redo attempt is initiated by the software mechanism as described in § Section 4.2.4 , then software must ensure that the Data Rate is 2.5 GT/s or 5.0 GT/s before initiating the attempt.

A Downstream Port that intends to redo equalization with a data rate change from 8.0 GT/s to 16.0 GT/s, 16.0 GT/s to 32.0 GT/s, or 32.0 GT/s to 64.0 GT/s must:

- Send TS1 Ordered Sets with the Equalization Redo bit set to 1b, the speed_change bit set to 1b, and advertising the Data Rate Identifier at which equalization redo will be performed (16.0 GT/s, 32.0 GT/s, or 64.0 GT/s).
- If the equalization redo attempt is initiated by the hardware as described in § Section 4.2.4 , then hardware must ensure that the Data Rate is the following before initiating the attempt to redo equalization:
 - 8.0 GT/s if the equalization redo is for 16.0 GT/s Data Rate
 - 16.0 GT/s if the equalization redo is for 32.0 GT/s Data Rate
 - 32.0 GT/s if the equalization redo is for 64.0 GT/s Data Rate
- If the equalization redo attempt is initiated by the software mechanism as described in § Section 4.2.4 , then software must ensure that the Data Rate is the following before initiating the attempt to redo equalization:
 - 8.0 GT/s if the equalization redo is for 16.0 GT/s Data Rate
 - 16.0 GT/s if the equalization redo is for 32.0 GT/s Data Rate
 - 32.0 GT/s if the equalization redo is for 64.0 GT/s Data Rate

An Upstream Port must advertise the highest data rate support in the TS2 Ordered Sets it transmits in Recovery.RcvrCfg, and optionally in the TS1 Ordered Sets it transmits in this substate, unless the Upstream Port has determined that a problem unrelated to the highest data rate equalization prevents it from operating

reliably at the highest data rate at which equalization is being requested to be performed, if the eight consecutive Ordered Sets it receives are one of the following:

- EQ TS1 or EQ TS2 Ordered Sets with the speed_change bit set to 1b
- TS1 Ordered Sets with the Equalization Redo bit set to 1b or 128b/130b EQ TS2 Ordered Sets with the speed_change bit set to 1b.

Under other conditions, a device must not change the supported data rate values either in this substate or while in the Recovery.RcvrCfg or Recovery.Equalization substates. The **successful_speed_negotiation** variable is reset to 0b upon entry to this substate.

IMPLEMENTATION NOTE: HANDLING A REQUEST TO ADVERTISE 8.0 GT/S DATA RATE IDENTIFIER §

If an Upstream Port that is not advertising 8.0 GT/s Data Rate Identifiers receives EQ TSs with 8.0 GT/s Data Rate Identifiers and with the speed_change bit set in Recovery.RcvrLock, that indicates that the Downstream Port is attempting to switch the Link speed to 8.0 GT/s in order to perform the 8.0 GT/s Link Equalization Procedure. If for some reason the Upstream Port is unable or unwilling to switch to advertising 8.0 GT/s Data Rate Identifiers in the TS2 Ordered Sets it transmits once it transitions to Recovery.RcvrCfg, the 8.0 GT/s Link Equalization Procedure will not be performed in the current tenure in Recovery. This may cause the Downstream Port to permanently abandon its attempt to change the Link speed to 8.0 GT/s and perform the 8.0 GT/s Link Equalization Procedure, resulting in an operational link speed of less than 8.0 GT/s until after the link transitions through Detect and is re-trained. It is recommended that if an Upstream Port is for some temporary reason unable or unwilling to switch to advertising 8.0 GT/s Data Rate Identifiers in the condition described above, and does not intend to prohibit the Link from operating at 8.0 GT/s, that it perform one of the following two actions below as soon as is reasonable for it to do so:

- If the Upstream Port supports the Quiesce Guarantee mechanism for performing the Link Equalization Procedure, enter Recovery and advertise 8.0 GT/s Data Rate Identifiers with the speed_change bit set to 1b in the TSs that it sends. If Recovery.Equalization is not entered after changing speed to 8.0 GT/s and before entering Recovery.RcvrCfg at 8.0 GT/s (the Downstream Port did not direct an entry to Recovery.Equalization), it should set the Request Equalization and Quiesce Guarantee bits to 1b in the TS2 Ordered Sets sent at 8.0 GT/s in Recovery.RcvrCfg in order to request the Downstream Port to initiate the Link Equalization Procedure.
- Enter Recovery and advertise 8.0 GT/s Data Rate Identifiers with the speed_change bit cleared to 0b. The Downstream Port may then later initiate a speed change to 8.0 GT/s and perform the Link Equalization Procedure, though there is no guarantee that it will do so.

The process for handling a request to advertise 16.0 GT/s, 32.0 GT/s, or 64.0 GT/s Data Rate Identifier is similar to 8.0 GT/s Data Rate Identifier with 16.0 GT/s, 32.0 GT/s, or 64.0 GT/s Data Rate Identifier substituting 8.0 GT/s Data Rate Identifier and 128b/130b EQ TS2s substituting EQ TSs.

An Upstream Port must set the Selectable De-emphasis bit (bit 6 of Symbol 4) of the TS1 Ordered Sets it transmits to match the desired de-emphasis level at 5.0 GT/s. The mechanism an Upstream Port may adopt to request a de-emphasis level if it chooses to do so is implementation specific. It must also be noted that since the Upstream Port's request may not reach the Downstream Port due to bit errors in the TS1 Ordered Sets, the Upstream Port may attempt to re-request the desired de-emphasis level in subsequent entries to Recovery state when speed change is requested. If the

Downstream Port intends to use the Upstream Port's de-emphasis information in Recovery.RcvrCfg, then it must record the value of the Selectable De-emphasis bit received in this state.

The Transmit Margin field of the Link Control 2 Register is sampled on entry to this substate and becomes effective on the transmit package pins within 192 ns of entry to this substate and remains effective until a new value is sampled on a subsequent entry to this substate from L0, L0s, or L1.

- After activating any inactive Lane, the Transmitter must wait for its TX common mode to settle before exiting Electrical Idle and transmitting the TS1 Ordered Sets with the following exceptions.
- When exiting from the L1.2 L1 PM Substate, common mode is permitted to be established passively during L1.0, and actively during Recovery. In order to ensure common mode has been established in Recovery.RcvrLock, the Downstream Port must maintain a timer, and the Downstream Port must not send TS2 Ordered Sets until a minimum of $T_{COMMONMODE}$ has elapsed since the Downstream Port has started transmitting TS1 Ordered Sets and has detected electrical idle exit on any Lane of the configured Link. See § Section 5.5.3.3.
- Implementations must note that the voltage levels may change after an early bit lock and Symbol or Block alignment since the new Transmit Margin field becomes effective within 192 ns after the other side enter Recovery.RcvrLock. The Receiver needs to reacquire bit lock and Symbol or Block alignment under those conditions.
 - a. Note: The directed_speed_change variable is set to 1b in L0 or L1 state for the side that is initiating a speed change. For the side that is not initiating a speed change, this bit is Set in this substate if the received TS Ordered Sets have the speed change bit Set. This bit is reset to 0b in the Recovery.Speed substate.
 - b. A device must accept all good TLPs and DLLPs it receives after entering this substate from L0 prior to receiving the first TS Ordered Set. If operating with 128b/130b encoding, any received TLPs and DLLPs are subject to the framing rules for 128b/130b encoding in § Section 4.2.2.3.
- Next state is Recovery.RcvrCfg if eight consecutive TS1 or TS2 Ordered Sets are received on all configured Lanes with the same Link and Lane numbers that match what is being transmitted on those same Lanes and the speed_change bit is equal to the directed_speed_change variable and the EC field is 00b in all the consecutive TS1 Ordered Sets if the current data rate is 8.0 GT/s or higher. See § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding.
 - If the Extended Synch bit is Set, the Transmitter must send a minimum of 1024 consecutive TS1 Ordered Sets before transitioning to Recovery.RcvrCfg.
 - If this substate was entered from Recovery.Equalization, the Upstream Port must evaluate the equalization coefficients or preset received by all Lanes that receive eight TS1 Ordered Sets and note whether they are different from the final set of coefficients or preset that was accepted in Phase 2 of the equalization process. Note: Mismatches are reported in Recovery.RcvrCfg by setting the Request Equalization bit of TS2 Ordered Sets.
- Otherwise, after a 24 ms timeout:
 - Next state is Recovery.RcvrCfg if the following two conditions are true:
 - Either of the following conditions are true:
 - Eight consecutive TS1 or TS2 Ordered Sets are received on any configured Lane with the same Link and Lane numbers that match what is being transmitted on the same Lane and the speed_change bit equal to 1b. See § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding.
 - The Link is operating in Flit Mode and eight consecutive TS2s are received on any configured Lane with the Link number set to PAD and the Lane number

matches what is being transmitted on the same Lane. See § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding.

- Either of the following conditions are true:
 - The current data rate of operation is greater than 2.5 GT/s.
 - The highest data rate advertised in the Data Rate Identifier symbol of both the transmitted TS1 Ordered Sets and the (eight consecutive) received TS1 or TS2 Ordered Sets is 5.0 GT/s or greater.

IMPLEMENTATION NOTE: RECOMMENDED MECHANISM FOR LINK WIDTH REDUCTION IN FLIT MODE §

It is envisioned that when the Link Width is reduced in Flit Mode, both Ports will transition to Configuration from Recovery.RcvrCfg. If a Port proactively reduces the Link Width, it is recommended that that Port either: (1) Waits until it receives a TS2 Ordered Set on one of its Lanes or (2) Waits an additional 1 msec after the conditions are met for the Recovery.RcvrLock to Recovery.RcvrCfg transition. This decreases the likelihood that the initiator's Link Partner will take the timeout arc to Recovery.RcvrCfg since the initiator will continue to send TS1s with a valid Link and Lane number while in Recovery.RcvrLock.

- Else the next state is Recovery.Speed if the speed of operation has not changed to a mutually negotiated data rate since entering Recovery from L0 or L1 (i.e., changed_speed_recovery = 0b) and the current speed of operation is greater than 2.5 GT/s.
 - The new data rate to operate after leaving Recovery.Speed will be at 2.5 GT/s if 8b/10b or 128b/130b encoding is used. The new data rate of operation after leaving Recovery.Speed will be 32.0 GT/s if 1b/1b encoding is used. Note: This indicates that the Link was unable to operate at the current data rate and the Link will operate at the lower data rate of either 2.5 GT/s data rate or 32.0 GT/s.
- Else the next state is Recovery.Speed if the operating speed has been changed to a mutually negotiated data rate since entering Recovery from L0 or L1 (changed_speed_recovery = 1b; i.e., the arc to this substate has been taken from Recovery.Speed). The new data rate to operate after leaving Recovery.Speed is reverted back to the speed it was when Recovery was entered from L0 or L1.

Note: This indicates that the Link was unable to operate at the new negotiated data rate and will revert back to the old data rate with which it entered Recovery from L0 or L1.

- Else the next state is Configuration and the directed_speed_change variable is reset to 0b if the following conditions are true:
 - If any of the configured Lanes that are receiving a TS1 or TS2 Ordered Set have received at least one TS1 or TS2 Ordered Set with Link and Lane numbers that match what is being transmitted on those same Lanes. See § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding.
 - The operating speed has not changed to a mutually negotiated data rate (i.e., changed_speed_recovery = 0b) since entering Recovery.

and at least one of the following conditions is true:

- The directed_speed_change variable is equal to 0b and the speed_change bit on the received TS1 or TS2 Ordered Set is equal to 0b.

- The current data rate of operation is 2.5 GT/s and 2.5 GT/s data rate is the highest commonly advertised data rate among the transmitted TS1 Ordered Sets and the received TS1 or TS2 Ordered Set(s).
- Otherwise, the next state is Detect.

IMPLEMENTATION NOTE: EXAMPLE SHOWING SPEED CHANGE ALGORITHM BETWEEN 2.5 GT/S AND 5.0 GT/S §

Suppose a Link connects two greater than 5.0 GT/s capable components, A and B. The Link comes up to the L0 state in 2.5 GT/s data rate. Component A decides to change the speed to greater than 5.0 GT/s, sets the directed_speed_change variable to 1b and enters Recovery.RcvrLock from L0. Component A sends TS1 Ordered Sets with the speed_change bit set to 1b and advertises the 2.5 GT/s, 5.0 GT/s, and 8.0 GT/s data rates. Component B sees the first TS1 in L0 state and enters Recovery.RcvrLock state. Initially, component B sends TS1s with the speed_change set to 0b. Component B will start sending the speed_change indication in its TS1 after it receives eight consecutive TS1 Ordered Sets from component A and advertises all of the data rates it can support. Component B will enter Recovery.RcvrCfg from where it will enter Recovery.Speed. Component A will wait for eight consecutive TS1/TS2 with speed_change bit set from component B before moving to Recovery.RcvrCfg and on to Recovery.Speed. Both component A and component B enter Recovery.Speed and record 8.0 GT/s as the maximum speed they can operate with. The directed_speed_change variable will be reset to 0b when in Recovery.Speed. When they enter Recovery.RcvrLock from Recovery.Speed, they will operate at 8.0 GT/s and send TS1s with speed_change set to 0b. If both sides work well at 8.0 GT/s, they will continue on to Recovery.RcvrCfg and enter L0 through Recovery.Idle at 8.0 GT/s. However, if component B fails to achieve Symbol lock, it will timeout in Recovery.RcvrLock and enters Recovery.Speed. Component A would have moved on to Recovery.RcvrCfg but would see the Electrical Idle after receiving TS1s at 8.0 GT/s after component B enters Recovery.Speed. This will cause component A to move to Recovery.Speed. After entering Recovery.Speed for the second time, both sides will revert back to the speed they operated with prior to entering the Recovery state (2.5 GT/s). Both sides will enter L0 from Recovery in 2.5 GT/s. Component A may initiate the directed_speed_change variable for a second time, requesting 8.0 GT/s data rate in its Data Rate Identifier, go through the same steps, fail to establish the 8.0 GT/s data rate and go back to L0 in 2.5 GT/s data rate. On the third attempt, however, component A may decide to only advertise 2.5 GT/s and 5.0 GT/s data rates and successfully establish the Link at 5.0 GT/s data rate and enter L0 at that speed. However, if either side entered Detect, that side should advertise all of the data rates it can support, since there may have been a hot plug event.

4.2.7.4.2 Recovery.Equalization §

If this state was entered from Recovery.RcvrLock, Transmitter sends either TS0 or TS1 Ordered Sets on all configured Lanes, as described in § Table 4-51, using the same Link and Lane numbers that were set after leaving Configuration. A Receiver must consider any TS1 or TS0 Ordered Set to be received only after it obtains Block Alignment in that Lane.

If this state was entered from Loopback.Entry:

- Transmitter sends either TS0 or TS1 Ordered Sets, as described in § Table 4-51, on all Lanes that detected a Receiver during Detect using the Link and Lane numbers defined in Loopback.Entry.
- The Lane under test is the only Lane that participates in the equalization procedure.
- The Lanes that are not under test must not be included in the equalization procedure and anything received by them is permitted to be ignored. The Lanes that are not under test must have their Transmitter preset values

set to P4 / Q0. The sole purpose of the lanes that are not under test is to create the noise that is needed in Loopback.Active.

The Lanes must transmit the proper type of Ordered Set (TS0 vs TS1) and check for the receipt of the proper Ordered Set (TS0 vs TS1), according to § Table 4-51, in Recovery.Equalization anywhere TS0/TS1 is mentioned.

Table 4-51 Use of TS0 or TS1 Ordered Sets in different phases §

Current Data Rate / Port	Phase 0 / Phase 1	Phase 2	Phase 3
8.0 GT/s, 16.0 GT/s, or 32.0 GT/s; Upstream/Downstream Lanes	<u>TS1</u>	<u>TS1</u>	<u>TS1</u>
64.0 GT/s Downstream Lanes	<u>TS0</u>	<u>TS0</u> followed by <u>TS1</u>	<u>TS1</u>
64.0 GT/s Upstream Lanes	<u>TS0</u>	<u>TS0</u>	<u>TS0</u> followed by <u>TS1</u>

IMPLEMENTATION NOTE: TS0 TO TS1 TRANSITIONS §

All the TS0 to TS1 transitions are expected and initiated by a Port so that its receiver is prepared for the NRZ to PAM4 transition.

The first transition occurs for the Downstream Lanes when entering Phase 2. The Downstream Lanes send TS0 with EC = 00b till they get their receiver to a 1E-4 BER and then they send EC = 01b. Then they just wait for the EC = 01b from the Upstream Port to make the transition. When the Upstream Port sends EC = 01b, it is guaranteed of the transition within a fixed time since the Downstream Port has already acquired its target BER of 1E-4.

The other transition happens during Phase 3 for the Upstream Lanes, when the Upstream Port receives EC=11b. Since the Downstream Port sends EC=11b, it is expecting the NRZ to PAM4 transition.

We have also made a provision for the Retimer to request extended EQ during Phase 0 & 1 for 64.0 GT/s equalization.

4.2.7.4.2.1 Downstream Lanes §

Upon entry to this substate:

- Current phase is Phase 1
 - If the data rate of operation is 8.0 GT/s:
 - The Equalization 8.0 GT/s Phase 1 Successful, Equalization 8.0 GT/s Phase 2 Successful, Equalization 8.0 GT/s Phase 3 Successful, Link Equalization Request 8.0 GT/s, and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register and the Perform Equalization bit of the Link Control 3 Register are all set to 0b.
 - The equalization_done_8GT_data_rate variable is set to 1b.
 - If the data rate of operation is 16.0 GT/s:
 - The Equalization 16.0 GT/s Phase 1 Successful, Equalization 16.0 GT/s Phase 2 Successful, Equalization 16.0 GT/s Phase 3 Successful, Link Equalization Request 16.0 GT/s, and Equalization

16.0 GT/s Complete bits of the 16.0 GT/s Status Register and the Perform Equalization bit of the Link Control 3 Register are all set to 0b.

- The equalization_done_16GT_data_rate variable is set to 1b.
- If the data rate of operation is 32.0 GT/s:
 - The Equalization 32.0 GT/s Phase 1 Successful, Equalization 32.0 GT/s Phase 2 Successful, Equalization 32.0 GT/s Phase 3 Successful, Link Equalization Request 32.0 GT/s, and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register and the Perform Equalization bit of the Link Control 3 Register are all set to 0b.
 - The equalization_done_32GT_data_rate variable is set to 1b.
- If the data rate of operation is 64.0 GT/s:
 - The Equalization 64.0 GT/s Phase 1 Successful, Equalization 64.0 GT/s Phase 2 Successful, Equalization 64.0 GT/s Phase 3 Successful, Link Equalization Request 64.0 GT/s, and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register and the Perform Equalization bit of the Link Control 3 Register are all set to 0b.
 - The equalization_done_64GT_data_rate variable is set to 1b.
- The start_equalization_w_preset variable is set to 0b.

4.2.7.4.2.1.1 Phase 1 of Transmitter Equalization §

- Transmitter sends TS0/TS1 Ordered Sets using the Transmitter preset settings for the current data rate of operation. In the TS0/TS1 Ordered Sets, the EC field is set to 01b. For TS0 ordered sets, the EC field is initially set to 00b. After two consecutive TS0 ordered sets are received with Retimer Equalization Extend bit set to 0b, the EC field is set to 01b. The TS0/TS1 Transmitter Preset bits of each Lane are set to the value of its corresponding Transmitter preset setting for the current data rate. The FS and LF fields are set to the appropriate values. The Post-cursor Coefficient field is set to the value corresponding to the Lane's Transmitter Preset bits if TS1 Ordered Sets are transmitted. The Transmitter preset settings, for each configured Lane, must be chosen as follows:
 1. If Recovery.Equalization was entered from Loopback.Entry:
 - If EQ TS1 Ordered Sets directed the device from Configuration.Linkwidth.Start to Loopback.Entry, the Transmitter preset value specified in the Preset field of the EQ TS1 Ordered Sets must be used by the Lane under test.
 - If standard TS1 Ordered Sets directed the device from Configuration.Linkwidth.Start to Loopback.Entry, an implementation specific method must be used to choose a supported Transmitter Preset value for use.
 - If perform_equalization_for_loopback_64GT is 1b, Loopback Follower must advertise 64.0 GT/s support in the transmitted TS0/TS1 Ordered Sets (i.e, Data Rate Identifier must use the Flit Mode Encoding).
 2. Else, if eight consecutive 128b/130b EQ TS2 Ordered Sets were received with supported Transmitter preset values in the most recent transition through Recovery.RcvrCfg and the current data rate of operation is 16.0 GT/s or higher, the Transmitter preset value requested in the 128b/130b EQ TS2 Ordered Sets must be used.
 3. Else, if eight consecutive EQ TS2 Ordered Sets were received with supported Transmitter preset values in the most recent transition through Recovery.RcvrCfg, the current data rate of operation is 32.0 GT/s, and equalization bypass to 32.0 GT/s is being performed, the Transmitter preset value requested in the EQ TS2 Ordered Sets must be used.

4. Else, if the Transmitter preset setting specified by the Downstream Port 8.0 GT/s Transmitter Preset field of the Lane Equalization Control Register Entry (for operation at the 8.0 GT/s data rate) or the Downstream Port 16.0 GT/s Transmitter Preset field of the 16.0 GT/s Lane Equalization Control Register Entry (for operation at the 16.0 GT/s data rate) or the Downstream Port 32.0 GT/s Transmitter Preset field of the 32.0 GT/s Lane Equalization Control Register Entry (for operation at the 32.0 GT/s data rate) or the Downstream Port 64.0 GT/s Transmitter Preset field of the 64.0 GT/s Lane Equalization Control Register Entry (for operation at the 64.0 GT/s data rate) is a supported value and is not a Reserved value, it must be used.
 5. Else, use an implementation specific method to choose a supported Transmitter preset setting for use.
- The Downstream Port is permitted to wait for up to 500 ns after entering Phase 1 before evaluating received information for TS0/TS1 Ordered Sets if it needs the time to stabilize its Receiver logic.
 - Next phase is Phase 2 if all configured Lanes receive two consecutive TS0/TS1 Ordered Sets with EC=01b and the Downstream Port wants to execute Phase 2 and Phase 3. When the perform_equalization_for_loopback variable is 1b and the Downstream Port's Flit Mode Supported field of its PCI Express Capabilities Register is set to 1b, Phase 2 and Phase 3 must be executed.
 - The Receiver must complete its bit lock process and then recognize Ordered Sets within 2 ms after receiving the first bit of the first valid Ordered Set on its Receiver pin.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Phase 1 Successful bit of the Link Status 2 Register is set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Phase 1 Successful bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate is 32.0 GT/s and perform_equalization_for_loopback is 0b, the Equalization 32.0 GT/s Phase 1 Successful bit of the 32.0 GT/s Status Register is set to 1b.
 - If the data rate is 64.0 GT/s and perform_equalization_for_loopback is 0b, the Equalization 64.0 GT/s Phase 1 Successful bit of the 64.0 GT/s Status Register is set to 1b.
 - The LF and FS values received in the two consecutive TS0/TS1 Ordered Sets must be stored for use during Phase 3, if the Downstream Port wants to adjust the Upstream Port's Transmitter coefficients.
 - Next state is Recovery.RcvrLock if all configured Lanes receive two consecutive TS0/TS1 Ordered Sets with EC=01b, perform_equalization_for_loopback is 0b and the Downstream Port does not want to execute Phase 2 and Phase 3.
 - If the data rate is 8.0 GT/s, The Equalization 8.0 GT/s Phase 1 Successful, Equalization 8.0 GT/s Phase 2 Successful, Equalization 8.0 GT/s Phase 3 Successful, and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register are set to 1b.
 - If the data rate is 16.0 GT/s, The Equalization 16.0 GT/s Phase 1 Successful, Equalization 16.0 GT/s Phase 2 Successful, Equalization 16.0 GT/s Phase 3 Successful, and Equalization 16.0 GT/s Complete bits of the 16.0 GT/s Status Register are set to 1b.
 - If the data rate is 32.0 GT/s, The Equalization 32.0 GT/s Phase 1 Successful, Equalization 32.0 GT/s Phase 2 Successful, Equalization 32.0 GT/s Phase 3 Successful, and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register are set to 1b.
 - If the data rate is 64.0 GT/s, The Equalization 64.0 GT/s Phase 1 Successful, Equalization 64.0 GT/s Phase 2 Successful, Equalization 64.0 GT/s Phase 3 Successful, and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register are set to 1b.
 - If the data rate is 64.0 GT/s, the Transmitter must send 24 TS0 Ordered Sets with EC=00b prior to transitioning to Recovery.RcvrLock

- Note: A transition to Recovery.RcvrLock might be used in the case where the Downstream Port determines that Phase 2 and Phase 3 are not needed based on the platform and channel characteristics.
- Next state is Loopback.Entry after a 24 ms timeout if perform_equalization_for_loopback is 1b.
- Else, next state is Recovery.Speed after a 24 ms timeout if perform_equalization_for_loopback is 0b.
 - successful_speed_negotiation is set to 0b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Complete bit of the Link Status 2 Register is set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate is 32.0 GT/s, the Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.
 - If the data rate is 64.0 GT/s, the Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.2.1.2 Phase 2 of Transmitter Equalization §

- The Transmitter sends TS0 Ordered Sets with EC=10b if the data rate is 64.0 GT/s and all Lanes have not received two consecutive TS0 Ordered Sets with EC=10b since entering this Phase; else it sends TS1 Ordered Sets.
- Transmitter sends TS1 Ordered Sets with EC = 10b and the coefficient settings, set on each Lane independently, as follows:
 - If two consecutive TS0/TS1 Ordered Sets with EC=10b have been received since entering Phase 2, or two consecutive TS0/TS1 Ordered Sets with EC=10b and a preset or set of coefficients (as specified by the Use Preset bit) different than the last two consecutive TS0/TS1 Ordered Sets with EC=10b:
 - If the preset or coefficients requested in the most recent two consecutive TS0/TS1 Ordered Sets are legal and supported (see § Section 4.2.4):
 - Change the transmitter settings to the requested preset or coefficients such that the new settings are effective at the Transmitter pins within 500 ns of when the end of the second TS0/TS1 Ordered Set requesting the new setting was received at the Receiver pin. The change of Transmitter settings must not cause any illegal voltage level or parameter at the Transmitter pin for more than 1 ns.
 - In the transmitted TS1 Ordered Sets, the Transmitter Preset bits are set to the requested preset (for a preset request), the Pre-cursor, Cursor, and Post-cursor Coefficient fields are set to the Transmitter settings (for a preset or a coefficients request), and the Reject Coefficient Values bit is Clear.
 - Else (the requested preset or coefficients are illegal or unsupported): Do not change the Transmitter settings used, but reflect the requested preset or coefficient values in the transmitted TS1 Ordered Sets and set the Reject Coefficient Values bit to 1b.
 - Else: the preset and coefficients currently being used by the Transmitter.
- Next phase is Phase 3 if all configured Lanes receive two consecutive TS0/TS1 Ordered Sets with EC=11b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Phase 2 Successful bit of the Link Status 2 Register is set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Phase 2 Successful bit of the 16.0 GT/s Status Register is set to 1b.

- If the data rate is 32.0 GT/s and perform_equalization_for_loopback is 0b, the Equalization 32.0 GT/s Phase 2 Successful bit of the 32.0 GT/s Status Register is set to 1b.
- If the data rate is 64.0 GT/s and perform_equalization_for_loopback is 0b, the Equalization 64.0 GT/s Phase 2 Successful bit of the 64.0 GT/s Status Register is set to 1b.
- For data rates less than 64.0 GT/s, next state is Loopback.Entry after a 32 ms timeout with a tolerance of -0 ms and +4 ms if perform_equalization_for_loopback is 1b.
- For the data rate of 64.0 GT/s, Next state is Loopback.Entry after a 64 ms timeout with a tolerance of -0 ms and +4 ms if perform_equalization_for_loopback is 1b.
- Else, if the data rate is less than 64.0 GT/s: next state is Recovery.Speed after a 32 ms timeout with a tolerance of -0 ms and +4 ms
 - successful_speed_negotiation is set to 0b.
 - If the data rate is 8.0 GT/s, The Equalization 8.0 GT/s Complete bit of the Link Status 2 Register is set to 1b.
 - If the data rate is 16.0 GT/s, The Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate is 32.0 GT/s, The Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.
- Else, if the data rate is 64.0 GT/s: next state is Recovery.Speed after a 64 ms timeout with a tolerance of -0 ms and +4 ms
 - successful_speed_negotiation is set to 0b.
 - The Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.2.1.3 Phase 3 of Transmitter Equalization §

- Transmitter sends TS1 Ordered Sets with EC = 11b
- The Port must evaluate and arrive at the optimal settings independently on each Lane. When perform_equalization_for_loopback is 1b, the equalization procedure is only performed on the Lane under test. To evaluate a new preset or coefficient setting that is legal, as per the rules in § Section 4.2.4 and § Chapter 8 :
 - Request a new preset by setting the Transmitter Preset bits to the desired value and set the Use Preset bit to 1b. Alternatively, request a new set of coefficients by setting the Pre-cursor, Cursor, and Post-Cursor Coefficient fields to the desired values and set the Use Preset bit to 0b. Once a request is made, it must be continuously requested for at least 1 μ s or until the evaluation of the request is completed, whichever is later.
 - Wait for the required time (500 ns plus the roundtrip delay including the logic delays through the Downstream Port) to ensure that, if accepted, the Upstream Port is transmitting using the requested settings. Obtain Block Alignment and then evaluate the incoming Ordered Sets. Note: The Downstream Port may simply ignore anything it receives during this waiting period as the incoming bit stream may be illegal during the transition to the requested settings. Hence the requirement to validate Block Alignment after this waiting period. If Block Alignment cannot be obtained after an implementation specific amount of time (in addition to the required waiting period specified above) it is recommended to proceed to perform receiver evaluation on the incoming bit stream regardless.
 - If two consecutive TS1 Ordered Sets are received with the Transmitter Preset bits (for a preset request) or the Pre-cursor, Cursor, and Post-Cursor Coefficient fields (for a coefficients request) identical to what was requested and the Reject Coefficient Values bit is Clear, then the requested

setting was accepted and, depending on the results of receiver evaluation, can be considered as a candidate final setting.

- If two consecutive TS1 Ordered Sets are received with the Transmitter Preset bits (for a preset request) or the Pre-cursor, Cursor, and Post-Cursor Coefficient fields (for a coefficients request) identical to what was requested and the Reject Coefficient Values bit is Set, then the requested setting was rejected and must not be considered as a candidate final setting.
- If, after an implementation specific amount of time following the start of receiver evaluation, no consecutive TS1s with the Transmitter Preset bits (for a preset request) or the Pre-Cursor, Cursor, and Post-Cursor Coefficient fields (for a coefficients request) identical to what was requested are received, then the requested setting must not be considered as a candidate final setting.
- The Downstream Port is responsible for setting the Reset EIEOS Interval Count bit in the TS1 Ordered Sets it transmits according to its evaluation criteria and requirements. The Use Preset bit of the received TS1 Ordered Sets must not be used to determine whether a request is accepted or rejected.

IMPLEMENTATION NOTE: RESET EIEOS AND COEFFICIENT/PRESET REQUESTS §

A Port may set Reset EIEOS Interval Count to 1b when it wants a longer PRBS pattern and subsequently clear it when it needs to obtain Block Alignment.

All TS1 Ordered Sets transmitted in this phase are requests. The first request maybe a new preset or a new coefficient request or a request to maintain the current link partner transmitter settings by reflecting the settings received in the two consecutive TS1 Ordered Sets with EC=11b that cause the transition to Phase 3.

- At 32.0 GT/s and below data rates, the total amount of time spent per preset or coefficients request from transmission of the request to the completion of the evaluation must be less than 2 ms. Implementations that need a longer evaluation time at the final stage of optimization may continue requesting the same preset or coefficient setting beyond the 2 ms limit but must adhere to the timeout (24 ms for 8.0, 16.0, and 32.0 GT/s and 48 ms for 64.0 GT/s) in this phase and must not take this exception more than two times. If the requester is unable to receive Ordered Sets within the timeout period, it may assume that the requested setting does not work in that Lane.
- At 64.0 GT/s and higher data rates, a device is permitted to evaluate each preset or coefficients request for an arbitrary amount of time. Evaluation must be carefully managed such that the search for an acceptable preset or coefficients can be successful. The total time spent in this Phase must still adhere to the timeout.
- All new preset or coefficient settings must be presented on all configured Lanes simultaneously. Any given Lane is permitted to continue to transmit the current preset or coefficients as its new value if it does not want to change the setting at that time.
- Next state is Loopback.Entry if the data rate of operation is 32.0 GT/s, perform_equalization_for_loopback is 1b and one of the following conditions is satisfied:
 - a. The Lane under test is operating at its optimal setting and it received two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b.
 - b. A 24 ms timeout with a tolerance of -0 ms and +2 ms.

- Next state is Loopback.Entry if the data rate of operation is 64.0 GT/s, perform_equalization_for_loopback is 1b and one of the following conditions is satisfied:
 - a. The Lane under test is operating at its optimal setting and all Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b are received.
 - b. A 48 ms timeout with a tolerance of -0 ms and +2 ms.
- Next state is Recovery.RcvrLock if perform_equalization_for_loopback is 0b, all configured Lanes are operating at their optimal setting and either the data rate of operation is 8.0 GT/s or all Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b.
 - If the data rate of operation is 8.0 GT/s: The Equalization 8.0 GT/s Phase 3 Successful and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register are set to 1b.
 - If the data rate of operation is 16.0 GT/s: The Equalization 16.0 GT/s Phase 3 Successful and Equalization 16.0 GT/s Complete bits of the 16.0 GT/s Status Register are set to 1b.
 - If the data rate of operation is 32.0 GT/s: The Equalization 32.0 GT/s Phase 3 Successful and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register are set to 1b.
 - If the data rate of operation is 64.0 GT/s: The Equalization 64.0 GT/s Phase 3 Successful and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register are set to 1b.
- Else, if the data rate is less than 64.0 GT/s: next state is Recovery.Speed after a timeout of 24 ms with a tolerance of -0 ms and +2 ms
 - successful_speed_negotiation is set to 0b.
 - If the data rate of operation is 8.0 GT/s: The Equalization 8.0 GT/s Complete bit of the Link Status 2 Register is set to 1b.
 - If the data rate of operation is 16.0 GT/s: The Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate of operation is 32.0 GT/s: The Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.
- Else, if the data rate is 64.0 GT/s: next state is Recovery.Speed after a timeout of 48 ms with a tolerance of -0 ms and +2 ms
 - successful_speed_negotiation is set to 0b.
 - The Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.2.2 Upstream Lanes §

Upon entry to this substate:

- Current phase is Phase 0
 - If the data rate of operation is 8.0 GT/s:
 - The Equalization 8.0 GT/s Phase 1 Successful, Equalization 8.0 GT/s Phase 2 Successful, Equalization 8.0 GT/s Phase 3 Successful, Link Equalization Request 8.0 GT/s, and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register are all set to 0b
 - The equalization_done_8GT_data_rate variable is set to 1b.
 - If the data rate of operation is 16.0 GT/s:
 - The Equalization 16.0 GT/s Phase 1 Successful, Equalization 16.0 GT/s Phase 2 Successful, Equalization 16.0 GT/s Phase 3 Successful, Link Equalization Request 16.0 GT/s, and Equalization 16.0 GT/s Complete bits of the 16.0 GT/s Status Register are all set to 0b.

- The equalization_done_16GT_data_rate variable is set to 1b.
- If the data rate of operation is 32.0 GT/s:
 - The Equalization 32.0 GT/s Phase 1 Successful, Equalization 32.0 GT/s Phase 2 Successful, Equalization 32.0 GT/s Phase 3 Successful, Link Equalization Request 32.0 GT/s, and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register are all set to 0b.
 - The equalization_done_32GT_data_rate variable is set to 1b.
- If the data rate of operation is 64.0 GT/s:
 - The Equalization 64.0 GT/s Phase 1 Successful, Equalization 64.0 GT/s Phase 2 Successful, Equalization 64.0 GT/s Phase 3 Successful, Link Equalization Request 64.0 GT/s, and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register are all set to 0b.
 - The equalization_done_64GT_data_rate variable is set to 1b.
- The start_equalization_w_preset variable is set to 0b.

4.2.7.4.2.2.1 Phase 0 of Transmitter Equalization §

- If Recovery.Equalization was entered from Loopback.Entry, transmitter sends TS0/TS1 Ordered Sets with the EC field set to 00b, the Transmitter Preset bits of the Lane is set to the value being used. The Pre-cursor Coefficient, Cursor Coefficient, and Post-cursor Coefficient fields are set to values corresponding to the Lane's Transmitter Preset bits if TS1 ordered Sets are transmitted. The Transmitter preset settings for the Lane under test must be chosen as follows:
 - If TS1 Ordered Sets are transmitted:
 - If EQ TS1 Ordered Sets directed the device from Configuration.Linkwidth.Start to Loopback.Entry, the Transmitter preset value specified in the Preset field of the EQ TS1 Ordered Sets must be used.
 - If standard TS1 Ordered Sets directed the device from Configuration.Linkwidth.Start to Loopback.Entry, an implementation specific method must be used to choose a supported Transmitter preset value for use.
- If the current data rate of operation is 8.0 GT/s, transmitter sends TS1 Ordered Sets using the Transmitter settings specified by the Transmitter Preset bits received in the EQ TS2 Ordered Sets during the most recent transition to 8.0 GT/s data rate from 2.5 GT/s or 5.0 GT/s data rate.

If the current data rate of operation is 16.0 GT/s, transmitter sends TS1 Ordered Sets using the 16.0 GT/s Transmitter settings specified by the Transmitter Preset bits received in the 128b/130b EQ TS2 Ordered Sets during the most recent transition to 16.0 GT/s data rate from 8.0 GT/s data rate.

If the current data rate of operation is 32.0 GT/s and perform_equalization_for_loopback is 0b, transmitter sends TS1 Ordered Sets using the 32.0 GT/s Transmitter settings specified by the Transmitter Preset bits received in the appropriate TS2 Ordered Sets during the most recent transition to the 32.0 GT/s data rate (EQ TS2 if equalization bypass was negotiated, 128b/130b EQ TS2 Ordered Sets if the most recent transition to the 32.0 GT/s data rate was from the 16.0 GT/s data rate).

If the current data rate of operation is 64.0 GT/s and perform_equalization_for_loopback is 0b, transmitter sends TS0 Ordered Sets using the 64.0 GT/s Transmitter settings specified by the Transmitter Preset bits received in the 128b/130b EQ TS2 Ordered Sets at 32.0 GT/s during the most recent transition to the 64.0 GT/s data rate.

Lanes that received a Reserved or unsupported Transmitter preset value must use an implementation specific method to choose a supported Transmitter preset setting for use. Any reference to Transmitter Preset bits received in EQ TS2 Ordered Sets or 16.0 GT/s or higher data rate Transmitter Preset bits in 128b/130b EQ TS2

Ordered Sets (depending on the Data Rate) for the remainder of the Recovery.Equalization state is in reference to the presets determined above. In the TS1 Ordered Sets, the EC field is set to 00b, the Transmitter Preset bits of each Lane is set to the value it received in the Transmitter Preset bits of EQ TS2 Ordered Sets or 16.0 GT/s or higher data rate Transmitter Preset bits of 128b/130b EQ TS2 Ordered Sets, and the Pre-cursor Coefficient, Cursor Coefficient, and Post-cursor Coefficient fields are set to values corresponding to the Transmitter Preset bits.

- For Lanes that received a Reserved or unsupported Transmitter preset value in the EQ TS2 Ordered Sets or 128b/130b EQ TS2 Ordered Sets (depending on the Data Rate): in the TS1 Ordered Sets, the Transmitter Preset field is set to the received Transmitter preset value, the Reject Coefficient Values bit is Set and the Coefficient fields are set to values corresponding to the implementation specific Transmitter preset setting chosen by the Lane.⁸⁴
- For Lanes that did not receive EQ TS2 Ordered Sets or 128b/130b EQ TS2 Ordered Sets (depending on the Data Rate): in the TS1 Ordered Sets, the Transmitter Preset field is set to the implementation specific Transmitter preset value chosen by the Lane, the Reject Coefficient Values bit is Clear, and the Coefficient fields are set to values corresponding to the same implementation specific Transmitter preset value chosen by the Lane and advertised in the Transmitter Preset bits.⁸⁵

IMPLEMENTATION NOTE: REJECT COEFFICIENT VALUES WITH TS0 ORDERED SETS §

The Reject Coefficient Values bit is intentionally omitted from the TS0 Ordered Set definition. As a result, Upstream Lanes are not able to explicitly indicate that a Reserved or unsupported Transmitter preset value was received in the 128b/130b EQ TS2 Ordered Sets at 32.0 GT/s during the most recent transition to the 64.0 GT/s data rate. In order to determine whether an Upstream Lane is using said Transmitter Preset, the Downstream Lane is permitted to observe the Transmitter Preset setting in the TS0 Ordered Sets received in Recovery.Equalization Phase 1 with the EC field set to 00b or 01b.

- The Upstream Port is permitted to wait for up to 500 ns after entering Phase 0 before evaluating receiver information for TS0/TS1 Ordered Sets if it needs the time to stabilize its Receiver logic.
- Next phase is Phase 1 if all the configured Lanes receive two consecutive TS1 Ordered Sets with EC = 01b or if all the configured Lanes receive two consecutive TS0 Ordered Sets with EC = 01b and Retimer Equalization Extend bit set to 0b
 - The Receiver must complete its bit lock process and then recognize Ordered Sets within 2 ms after receiving the first bit of the first valid Ordered Set on its Receiver pin.
 - The LF and FS values received in the two consecutive TS0/TS1 Ordered Sets must be stored for use during Phase 2 if the Upstream Port wants to adjust the Downstream Port's Transmitter coefficients.
- Next state is Loopback.Entry after a 12 ms timeout if perform_equalization_for_loopback is 1b.
- Else, next state is Recovery.Speed after a 12 ms timeout.
 - successful_speed_negotiation is set to 0b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Complete bit of the Link Status 2 Register is set to 1b.

84. An earlier version of this specification permitted the Reject Coefficient Values bit to be clear for this case. This is not recommended, but is permitted.

85. An earlier version of this specification permitted the Transmitter Preset bits to be undefined and the Reject Coefficient Values bit to be clear for this case. This is not recommended, but is permitted.

- If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
- If the data rate is 32.0 GT/s, the Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.
- If the data rate is 64.0 GT/s, the Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.2.2.2 Phase 1 of Transmitter Equalization §

- Transmitter sends TS0/TS1 Ordered Sets using the Transmitter settings determined in Phase 0. In the TS0/TS1 Ordered Sets, the EC field is set to 01b, and the FS, LF, and (in TS1 Ordered Sets only) Post-cursor Coefficient fields of each Lane are set to values corresponding to the Lane's current Transmitter settings.
- If Recovery.Equalization was entered from Loopback.Entry and perform_equalization_for_loopback_64GT is 1b, Loopback Follower must advertise 64.0 GT/s support in the transmitted TS0/TS1 Ordered Sets (i.e, Data Rate Identifier must use the Flit Mode Encoding).
- Next phase is Phase 2 if all configured Lanes receive two consecutive TS0/TS1 Ordered Sets with EC=10b
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Phase 1 Successful bit of the Link Status 2 Register are set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Phase 1 Successful bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate is 32.0 GT/s and perform_equalization_for_loopback is 0b, the Equalization 32.0 GT/s Phase 1 Successful bit of the 32.0 GT/s Status Register is set to 1b.
 - If the data rate is 64.0 GT/s and perform_equalization_for_loopback is 0b, the Equalization 64.0 GT/s Phase 1 Successful bit of the 64.0 GT/s Status Register is set to 1b.
- Next state is Loopback.Entry after a 12 ms timeout if perform_equalization_for_loopback is 1b.
- Next state is Recovery.RcvrLock if all configured Lanes receive eight consecutive TS0/TS1 Ordered Sets with EC=00b and perform_equalization_for_loopback is 0b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Phase 1 Successful and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register are set to 1b
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Phase 1 Successful and Equalization 16.0 GT/s Complete bits of the 16.0 GT/s Status Register are set to 1b.
 - If the data rate is 32.0 GT/s, the Equalization 32.0 GT/s Phase 1 Successful and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register are set to 1b.
 - If the data rate is 64.0 GT/s, the Equalization 64.0 GT/s Phase 1 Successful and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register are set to 1b.
- Else, next state is Recovery.Speed after a 12 ms timeout if perform_equalization_for_loopback is 0b
 - successful_speed_negotiation is set to 0b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Complete bit of the Link Status 2 Register for the current data rate of operation is set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate is 32.0 GT/s, the Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.

- If the data rate is 64.0 GT/s, the Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.2.2.3 Phase 2 of Transmitter Equalization §

- Transmitter sends TS0/TS1 Ordered Sets with EC = 10b
- The Port must evaluate and arrive at the optimal settings independently on each Lane. When perform_equalization_for_loopback is 1b, the equalization procedure is only performed on the Lane under test. To evaluate a new preset or coefficient setting that is legal, as per the rules in § Section 4.2.4 and § Chapter 8. :
 - Request a new preset by setting the Transmitter Preset bits to the desired value and set the Use Preset bit to 1b. Alternatively, request a new set of coefficients by setting the Pre-cursor, Cursor, and Post-cursor Coefficient fields to the desired values and set the Use Preset bit to 0b. Once a request is made, it must be continuously requested for at least 1 μ s or until the evaluation of the request is completed, whichever is later.
 - Wait for the required time (500 ns plus the roundtrip delay including the logic delays through the Upstream Port) to ensure that, if accepted, the Downstream Port is transmitting using the requested settings. Obtain Block Alignment and then evaluate the incoming Ordered Sets. Note: The Upstream Port may simply ignore anything it receives during this waiting period as the incoming bit stream may be illegal during the transition to the requested settings. Hence the requirement to validate Block Alignment after this waiting period. If Block Alignment cannot be obtained after an implementation specific amount of time (in addition to the required waiting period specified above) it is recommended to proceed to perform receiver evaluation on the incoming bit stream regardless.
 - If two consecutive TS1 Ordered Sets are received with the Transmitter Preset bits (for a preset request) or the Pre-cursor, Cursor, and Post-Cursor Coefficient fields (for a coefficients request) identical to what was requested and the Reject Coefficient Values bit is Clear, then the requested setting was accepted and, depending on the results of receiver evaluation, can be considered as a candidate final setting.
 - If two consecutive TS1 Ordered Sets are received with the Transmitter Preset bits (for a preset request) or the Pre-Cursor, Cursor, and Post-Cursor Coefficient fields (for a coefficients request) identical to what was requested and the Reject Coefficient Values bit is Set, then the requested setting was rejected and must not be considered as a candidate final setting.
 - If, after an implementation specific amount of time following the start of receiver evaluation, no consecutive TS1s with the Transmitter Preset bits (for a preset request) or the Pre-Cursor, Cursor, and Post-Cursor Coefficient fields (for a coefficients request) identical to what was requested are received, then the requested setting must not be considered as a candidate final setting.
 - The Upstream Port is responsible for setting the Reset EIEOS Interval Count bit in the TS0/TS1 Ordered Sets it transmits according to its evaluation criteria and requirements. The Use Preset bit of the received TS1 Ordered Sets must not be used to determine whether a request is accepted or rejected.

IMPLEMENTATION NOTE: RESET EIEOS AND COEFFICIENT/PRESET REQUESTS §

A Port may set Reset EIEOS Interval Count to 1b when it wants a longer PRBS pattern and subsequently clear it when it needs to obtain Block Alignment.

All TS0/TS1 Ordered Sets transmitted in this phase are requests. The first request maybe a new preset or a new coefficient request or a request to maintain the current link partner transmitter settings by reflecting the settings received in the two consecutive TS1 Ordered Sets with EC=10b that cause the transition to Phase 2.

- At 32.0 GT/s and below data rates, the total amount of time spent per preset or coefficients request from transmission of the request to the completion of the evaluation must be less than 2 ms. Implementations that need a longer evaluation time at the final stage of optimization may continue requesting the same setting beyond the 2 ms limit but must adhere to the timeout in this phase (24 ms for 8.0, 16.0, and 32.0 GT/s and 48 ms for 64.0 GT/s) and must not take this exception more than two times. If the requester is unable to receive Ordered Sets within the timeout period, it may assume that the requested setting does not work in that Lane.
- At 64.0 GT/s and higher data rates, a device is permitted to evaluate each preset or coefficients request for an arbitrary amount of time. Evaluation must be carefully managed such that the search for an acceptable preset or coefficients can be successful. The total time spent in this Phase must still adhere to the timeout.
- All new preset or coefficient settings must be presented on all configured Lanes simultaneously. Any given Lane is permitted to continue to transmit the current preset or coefficients as its new value if it does not want to change the setting at that time.
- If perform_equalization_for_loopback is 1b and the Lane under test is operating at its optimal setting and two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b are received, next phase is Phase 3.
- If perform_equalization_for_loopback is 0b and all configured Lanes are operating at their optimal settings and either the data rate of operation is 8.0 GT/s or all Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b, next phase is Phase 3.
 - If the data rate of operation is 8.0 GT/s: The Equalization 8.0 GT/s Phase 2 Successful bit of the Link Status 2 Register are set to 1b.
 - If the data rate of operation is 16.0 GT/s: The Equalization 16.0 GT/s Phase 2 Successful bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate of operation is 32.0 GT/s: The Equalization 32.0 GT/s Phase 2 Successful bit of the 32.0 GT/s Status Register is set to 1b.
 - If the data rate of operation is 64.0 GT/s: The Equalization 64.0 GT/s Phase 2 Successful bit of the 64.0 GT/s Status Register is set to 1b.
- Next state is Loopback.Entry after a timeout of 24 ms with a tolerance of -0 ms and +2 ms if perform_equalization_for_loopback is 1b and current data rate is less than 64.0 GT/s.
- Next state is Loopback.Entry after a timeout of 48 ms with a tolerance of -0 ms and +2 ms if perform_equalization_for_loopback is 1b and current data rate is 64.0 GT/s.

- Else, if the current data rate is less than 64.0 GT/s: next state is Recovery.Speed after a timeout of 24 ms with a tolerance of -0 ms and +2 ms
 - successful_speed_negotiation is set to 0b.
 - If the data rate of operation is 8.0 GT/s: The Equalization 8.0 GT/s Complete bit of the Link Status 2 Register is set to 1b.
 - If the data rate of operation is 16.0 GT/s: The Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate of operation is 32.0 GT/s: The Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.
- Else, if the current data rate is 64.0 GT/s: next state is Recovery.Speed after a timeout of 48 ms with a tolerance of -0 ms and +2 ms
 - successful_speed_negotiation is set to 0b.
 - The Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.2.2.4 Phase 3 of Transmitter Equalization §

- The Transmitter sends TS0 Ordered Sets with EC=11b if the data rate is 64.0 GT/s and all Lanes have not received two consecutive TS1 Ordered Sets with EC=11b since entering this Phase; else it sends TS1 Ordered Sets.
- Transmitter sends TS0/TS1 Ordered Sets with EC = 11b and the coefficient settings, set on each configured Lane independently, as follows:
 - If two consecutive TS1 Ordered Sets with EC=11b have been received since entering Phase 3, or two consecutive TS1 Ordered Sets with EC=11b and a preset or set of coefficients (as specified by the Use Preset bit) different than the last two consecutive TS1 Ordered Sets with EC=11b:
 - If the preset or coefficients requested in the most recent two consecutive TS Ordered Sets are legal and supported (see § Section 4.2.4 and § Chapter 8.):
 - Change the transmitter settings to the requested preset or coefficients such that the new settings are effective at the Transmitter pins within 500 ns of when the end of the second TS1 Ordered Set requesting the new setting was received at the Receiver pin. The change of Transmitter settings must not cause any illegal voltage level or parameter at the Transmitter pin for more than 1 ns.
 - In the transmitted TS1 Ordered Sets, the Transmitter Preset bits are set to the requested preset (for a preset request), the Pre-cursor, Cursor, and Post-cursor Coefficient fields are set to the Transmitter settings (for a preset or a coefficients request), and the Reject Coefficient Values bit is Clear.
 - Else (the requested preset or coefficients are illegal or unsupported): Do not change the Transmitter settings used, but reflect the requested preset or coefficient values in the transmitted TS1 Ordered Sets and set the Reject Coefficient Values bit to 1b.
 - Else: the preset and coefficients currently being used by the Transmitter.
 - The Transmitter preset value initially transmitted on entry to Phase 3 can be the Transmitter preset value transmitted in Phase 0 for the same Data Rate or the Transmitter preset setting currently being used by the Transmitter.
- Next state is Loopback.Entry if perform_equalization_for_loopback is 1b, the current data rate is less than 64.0 GT/s, and one of the following conditions is satisfied:
 - a. The Lane under test receives two consecutive TS1 Ordered Sets with EC=00b.

- b. A timeout of 32 ms with a tolerance of -0 ms and +4 ms.
- Next state is Loopback.Entry if perform_equalization_for_loopback is 1b, the current data rate is equal to 64.0 GT/s, and one of the following conditions is satisfied:
 - a. The Lane under test receives two consecutive TS1 Ordered Sets with EC=00b.
 - b. A timeout of 64 ms with a tolerance of -0 ms and +4 ms.
- Next state is Recovery.RcvrLock if all configured Lanes receive two consecutive TS1 Ordered Sets with EC=00b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Phase 3 Successful and Equalization 8.0 GT/s Complete bits of the Link Status 2 Register are set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Phase 3 Successful and Equalization 16.0 GT/s Complete bits of the 16.0 GT/s Status Register are set to 1b.
 - If the data rate is 32.0 GT/s, the Equalization 32.0 GT/s Phase 3 Successful and Equalization 32.0 GT/s Complete bits of the 32.0 GT/s Status Register are set to 1b.
 - If the data rate is 64.0 GT/s, the Equalization 64.0 GT/s Phase 3 Successful and Equalization 64.0 GT/s Complete bits of the 64.0 GT/s Status Register are set to 1b.
- Else, if the current data rate is less than 64.0 GT/s: next state is Recovery.Speed after a timeout of 32 ms with a tolerance of -0 ms and +4 ms
 - successful_speed_negotiation is set to 0b.
 - If the data rate is 8.0 GT/s, the Equalization 8.0 GT/s Complete bit of the Link Status 2 Register is set to 1b.
 - If the data rate is 16.0 GT/s, the Equalization 16.0 GT/s Complete bit of the 16.0 GT/s Status Register is set to 1b.
 - If the data rate is 32.0 GT/s, the Equalization 32.0 GT/s Complete bit of the 32.0 GT/s Status Register is set to 1b.
- Else, if current data rate is 64.0 GT/s: next state is Recovery.Speed after a timeout of 64 ms with a tolerance of -0 ms and +4 ms
 - successful_speed_negotiation is set to 0b.
 - The Equalization 64.0 GT/s Complete bit of the 64.0 GT/s Status Register is set to 1b.

4.2.7.4.3 Recovery.Speed §

- The Transmitter enters Electrical Idle and stays there until the Receiver Lanes have entered Electrical Idle, and then additionally remains there for at least 800 ns on a successful speed negotiation (i.e., successful_speed_negotiation = 1b) or at least 6 μ s on an unsuccessful speed negotiation (i.e., successful_speed_negotiation = 0b), but stays there no longer than an additional 1 ms. The frequency of operation is permitted to be changed to the new data rate only after the Receiver Lanes have entered Electrical Idle. If the negotiated data rate is 5.0 GT/s, and if operating in full swing mode, -6 dB de-emphasis level must be selected for operation if the select_deemphasis variable is 0b and -3.5 dB de-emphasis level must be selected for operation if the select_deemphasis variable is 1b. Note that if the link is already operating at the highest data rate supported by both Ports, Recovery.Speed is executed but the data rate is not changed.

An EIOSQ must be sent prior to entering Electrical Idle.

The DC common mode voltage is not required to be within specification.

An Electrical Idle condition exists on the Lanes if an EIOS is received on any of the configured Lanes or Electrical Idle is detected/inferred as described in § Section 4.2.5.4.

- On entry to this substate following a successful speed negotiation (i.e., `successful_speed_negotiation = 1b`), an Electrical Idle condition may be inferred on the Receiver Lanes if a `TS1` or `TS2` Ordered Set has not been received in any configured Lane in a time interval specified in § Table 4-39. (This covers the case where the Link is operational and both sides have successfully received `TS` Ordered Sets. Hence, a lack of a `TS1` or `TS2` Ordered Set in the specified interval can be interpreted as entry to Electrical Idle.)
- Else on entry to this substate following an unsuccessful speed negotiation (i.e., `successful_speed_negotiation = 0b`) if an exit from Electrical Idle has not been detected at least once in any configured Lane in a time interval specified in § Table 4-39. (This covers the case where at least one side is having trouble receiving `TS` Ordered Sets that was transmitted by the other agent, and hence a lack of exit from Electrical Idle in a longer interval can be treated as equivalent to entry to Electrical Idle.)
- Next state is `Recovery.RcvrLock` after the Transmitter Lanes are no longer required to be in Electrical Idle as described in the condition above.
 - If this substate has been entered from `Recovery.RcvrCfg` following a successful speed change negotiation (i.e., `successful_speed_negotiation = 1b`), the new data rate is changed on all the configured Lanes to the highest common data rate advertised by both sides of the Link. The `changed_speed_recovery` variable is set to `1b`.
 - Else if this substate is being entered for a second time since entering `Recovery` from `L0` or `L1` (i.e., `changed_speed_recovery = 1b`), the new data rate will be the data rate at which the LTSSM entered `Recovery` from `L0` or `L1`. The `changed_speed_recovery` variable will be reset to `0b`.
 - Else if the latest encoding used before entering `Recovery.Speed` was `1b/1b`, the new data rate will be `32.0 GT/s`. The `changed_speed_recovery` variable remains reset at `0b`.
 - Else the new data rate will be `2.5 GT/s`. The `changed_speed_recovery` variable remains reset at `0b`.

Note: This represents the case where the frequency of operation in `L0` was greater than `2.5 GT/s` and one side could not operate at that frequency and timed out in `Recovery.RcvrLock` the first time it entered that substate from `L0` or `L1`.
- Next state is `Detect` after a `48 ms` timeout if the Link Speed at which `Recovery.Speed` was entered was < 64.0 `GT/s`.
 - Note: This transition is not possible under normal conditions.
- Next state is `Detect` after a `96 ms` timeout or `48 ms` timeout if the Link Speed at which `Recovery.Speed` was entered was ≥ 64.0 `GT/s`.
 - Note: The `96 ms` timeout is strongly recommended because the `48 ms` timeout could cause an unintended timeout to `Detect` at `64.0 GT/s`. This timeout to `Detect` can occur due to the `64.0 GT/s Recovery.Equalization Phase 2` timeout (`64 ms`) being larger than the `Phase 1` timeout (`12 ms`) + `Recovery.Speed` timeout (`48 ms`).
- The `directed_speed_change` variable will be reset to `0b`. The new data rate must be reflected in the Current Link Speed field of the `Link Status Register`.
 - On a Link bandwidth change, if `successful_speed_negotiation` is set to `1b` and the `Autonomous Change` bit (bit 6 of Symbol 4) in the eight consecutive `TS2` Ordered Sets received while in `Recovery.RcvrCfg` is set to `1b` or the speed change was initiated by the Downstream Port for autonomous reasons (non-reliability and not due to the setting of the Link Retrain bit), the `Link Autonomous Bandwidth Status` bit of the `Link Status Register` is set to `1b`.
 - Else: on a Link bandwidth change, the `Link Bandwidth Management Status` bit of the `Link Status Register` is set to `1b`.

4.2.7.4.4 Recovery.RcvrCfg §

In Non-Flit Mode, Transmitter sends TS2 Ordered Sets on all configured Lanes using the same Link and Lane numbers that were set after leaving Configuration. In Flit Mode, Transmitter sends TS2 Ordered Sets on all configured Lanes with the Link number field sets as follows: if the LTSSM is initiating a Link width change by transitioning to Configuration from this State and the Lane will be removed from the Link, then the Link number field is set to PAD; otherwise it is set as the Link number. In 1b/1b TS2 Ordered Sets, if an equalization request is being communicated, Symbols 1,9 represent Equalization Byte 0 (instead of Link Number), the Request Equalization bit is set to 1b and the other fields are set as described in § Section 4.2.4 and § Table 4-28. The LTSSM must not initiate a width change if speed_change is set to 1b or the LTSSM went through Recovery.Equalization followed by Recovery.RcvrLock prior to entering this substate. The speed_change bit (bit 7 of data rate identifier Symbol in TS2 Ordered Set) must be set to 1b if the directed_speed_change variable is already set to 1b. The N_FTS value in the transmitted TS2 Ordered Sets should reflect the number at the current data rate for Non-Flit Mode of operation. In Flit Mode, the appropriate Training Control bit of the TS2 Ordered set must be set, if the Port intends to drive the Link to Hot Reset, Disabled, or Loopback state immediately after exiting this sub-state.

The Downstream Port must transmit EQ TS2 Ordered Sets (TS2 Ordered Sets with Symbol 6 bit 7 set to 1b) on each configured Lane with the Transmitter Preset and Receiver Preset Hint fields set to the values specified by the Upstream 8.0 GT/s Port Transmitter Preset and the Upstream 8.0 GT/s Port Receiver Preset Hint fields from the corresponding Lane Equalization Control Register Entry if all of the following conditions are satisfied:

- a. The Downstream Port advertised 8.0 GT/s data rate support in Recovery.RcvrLock, and 8.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates by the Upstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_8GT_data_rate variable is 0b or if the Perform Equalization bit in the Link Control 3 Register is Set or if an implementation specific mechanism determined equalization needs to be performed, following procedures described in § Section 4.2.4
- c. The current data rate of operation is 2.5 GT/s or 5.0 GT/s

The Downstream Port must transmit EQ TS2 Ordered Sets (TS2 Ordered Sets with Symbol 6 bit 7 set to 1b) on each configured Lane with the Transmitter Preset bits set to the values specified by the 32.0 GT/s Upstream Port Transmitter Preset bits from the corresponding 32.0 GT/s Lane Equalization Control Register Entry and Receiver Preset Hint field set to 000b if all of the following conditions are satisfied:

- a. The Downstream Port advertised 32.0 GT/s data rate support in Recovery.RcvrLock, and 32.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates by the Upstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_32GT_data_rate variable is 0b or if the Perform Equalization bit in the Link Control 3 Register is Set or if an implementation specific mechanism determined equalization needs to be performed, following procedures described in § Section 4.2.4
- c. The equalization_done_8GT_data_rate and equalization_done_16GT_data_rate variables are 1b each
- d. Equalization Bypass to Highest NRZ Rate was negotiated between the components during Configuration state
- e. The current data rate of operation is 2.5 GT/s or 5.0 GT/s

The Downstream Port must transmit 128b/130b EQ TS2 Ordered Sets (TS2 Ordered Sets with Symbol 7 bit 7 set to 1b) on each configured Lane with the Transmitter Preset bits set to the values specified by the 16.0 GT/s Upstream Port Transmitter Preset bits from the corresponding 16.0 GT/s Lane Equalization Control Register Entry if all of the following conditions are satisfied:

- a. The Downstream Port advertised 16.0 GT/s data rate support in Recovery.RcvrLock, and 16.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates by the Upstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_16GT_data_rate variable is 0b or if the Perform Equalization bit in the Link Control 3 Register is set or an implementation specific mechanism determined equalization needs to be performed, following procedures described in § Section 4.2.4
- c. The current data rate of operation is 8.0 GT/s

The Downstream Port must transmit 128b/130b EQ TS2 Ordered Sets (TS2 Ordered Sets with Symbol 7 bit 7 set to 1b) on each configured Lane with the Transmitter Preset bits set to the values specified by the 32.0 GT/s Upstream Port Transmitter Preset bits from the corresponding 32.0 GT/s Lane Equalization Control Register Entry if all of the following conditions are satisfied:

- a. The Downstream Port advertised 32.0 GT/s data rate support in Recovery.RcvrLock, and 32.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates by the Upstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_32GT_data_rate variable is 0b or the Perform Equalization bit in the Link Control 3 Register is set or an implementation specific mechanism determined equalization needs to be performed, following procedures described in § Section 4.2.4
- c. The current data rate of operation is 16.0 GT/s

The Downstream Port must transmit 128b/130b EQ TS2 Ordered Sets (TS2 Ordered Sets with Symbol 7 bit 7 set to 1b) on each configured Lane with the Transmitter Preset bits set to the values specified by the 64.0 GT/s Upstream Port Transmitter Preset bits from the corresponding 64.0 GT/s Lane Equalization Control Register Entry if all of the following conditions are satisfied:

- a. The Downstream Port advertised 64.0 GT/s data rate support in Recovery.RcvrLock, and 64.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates by the Upstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_64GT_data_rate variable is 0b or the Perform Equalization bit in the Link Control 3 Register is set or an implementation specific mechanism determined equalization needs to be performed, following procedures described in § Section 4.2.4
- c. The current data rate of operation is 32.0 GT/s

The Upstream Port is permitted to transmit 128b/130b EQ TS2 Ordered Sets with the 16.0 GT/s Transmitter Preset bits set to implementation specific values if all of the following conditions are satisfied:

- a. The Upstream Port advertised 16.0 GT/s data rate support in Recovery.RcvrLock, and 16.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates, or optionally, but strongly recommended, in the Recovery.RcvrLock substate by the Downstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_16GT_data_rate variable is 0b or if directed by an implementation specific mechanism, following procedures described in § Section 4.2.4
- c. The current data rate of operation is 8.0 GT/s

The Upstream Port that intends to bypass equalization to the highest data rate of 32.0 GT/s or higher must transmit 8b/10b EQ TS2 Ordered Sets with the 32.0 GT/s Transmitter Preset bits set to implementation specific values if all of the following conditions are satisfied:

- a. The equalization bypass to the highest NRZ rate was negotiated during the Configuration state
- b. Either the Upstream Port requires precoding, or the Upstream Port intends to provide the Downstream Port's starting 32.0 GT/s Transmitter Preset for equalization
- c. The Upstream Port advertised 32.0 GT/s data rate support in Recovery.RcvrLock, and 32.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates by the Downstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- d. The equalization_done_32GT_data_rate variable is 0b or if directed by an implementation specific mechanism, following procedures described in § Section 4.2.4
- e. The current data rate of operation is 2.5 GT/s or 5.0 GT/s

The Upstream Port is permitted to transmit 128b/130b EQ TS2 Ordered Sets with the 32.0 GT/s Transmitter Preset bits set to implementation specific values if all of the following conditions are satisfied:

- a. The Upstream Port advertised 32.0 GT/s data rate support in Recovery.RcvrLock, and 32.0 GT/s data rate support has been advertised in the Configuration.Complete or Recovery.RcvrCfg substates, or optionally, but strongly recommended, in the Recovery.RcvrLock substate by the Downstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_32GT_data_rate variable is 0b or if directed
- c. The current data rate of operation is 16.0 GT/s

The Upstream Port is permitted to transmit 128b/130b EQ TS2 Ordered Sets with the 64.0 GT/s Transmitter Preset bits set to implementation specific values if all of the following conditions are satisfied:

- a. The Upstream Port advertised 64.0 GT/s data rate support in Recovery.RcvrLock, and 64.0 GT/s data rate support has been advertised in the Configuration.Complete, Recovery.RcvrLock or Recovery.RcvrCfg substates by the Downstream Port since exiting the Detect state, and eight consecutive TS1 or TS2 Ordered Sets were received on any configured Lane prior to entry to this substate with speed_change bit set to 1b
- b. The equalization_done_64GT_data_rate variable is 0b or if directed
- c. The current data rate of operation is 32.0 GT/s

IMPLEMENTATION NOTE:

ISSUES WITH SOFTWARE INITIATED SPEED CHANGE §

In prior versions of the specification, the EQ TS2 Ordered Sets from the Upstream Port may not be registered by the Downstream Port in the case where hardware autonomous equalization was not adopted. The Downstream Port enters Recovery and advertises a higher data rate (16.0 GT/s and above) for the first time with the software initiated speed change; the Upstream Port did not observe the new speed in Configuration.Complete. So if it was acting on the new speed based on observation in Recovery.RcvrCfg (as was required in prior versions of this specification), it may decide to switch from TS2 to EQ TS2 Ordered Sets while in Recovery.RcvrCfg. The Downstream Port may have satisfied its requirements with 8 consecutive TS2 Ordered Sets and missed the Preset request (for 16.0 GT/s or higher data rate) or Precoding request (for 32.0 GT/s or higher data rate) in the subsequent EQ TS2 Ordered Sets.

The situation described above can be avoided if the Upstream Port decides to send EQ TS2 Ordered Sets based on the higher speed being advertised by the Downstream Port while it is in Recovery.RcvrLock or if software requests re-equalization at the same data rate through the configuration register in the Downstream Port.

When using 128b/130b or 1b/1b encoding, Upstream and Downstream Ports use the Request Equalization, Equalization Request Data Rate, and Quiesce Guarantee bits of their transmitted TS2 Ordered Sets to communicate equalization requests as described in § Section 4.2.4 . When not requesting equalization, the Request Equalization, Equalization Request Data Rate, and Quiesce Guarantee bits must be set to 0b.

The **start_equalization_w_preset** variable is reset to 0b upon entry to this substate.

- On entry to this substate, a Downstream Port must set the select_deemphasis variable equal to the Selectable De-emphasis field in the Link Control 2 Register or adopt some implementation specific mechanism to set the select_deemphasis variable, including using the value requested by the Upstream Port in the eight consecutive TS1 Ordered Sets it received. A Downstream Port advertising 5.0 GT/s data rate support must set the Selectable De-emphasis bit (Symbol 4 bit 6) of the TS2 Ordered Sets it transmits identical to the select_deemphasis variable. An Upstream Port must set its Autonomous Change bit (Symbol 4 bit 6) to 1b in the TS2 Ordered Set if it intends to change the Link bandwidth for autonomous reasons.
 - For devices that support Link width upconfigure, it is recommended that the Electrical Idle detection circuitry be activated in the set of currently inactive Lanes in this substate, the Recovery.Idle substate, and Configuration.Linkwidth.Start substates, if the directed_speed_change variable is reset to 0b. This is done so that during a Link upconfigure, the side that does not initiate the upconfiguration does not miss the first EIEOSQ sent by the initiator during the Configuration.Linkwidth.Start substate.
- Next state is Recovery.Speed if all of the following conditions are true:
 - One of the following conditions is satisfied:
 - i. Eight consecutive TS2 Ordered Sets are received on any configured Lane with identical data rate identifiers, identical values in Symbol 6, and the speed_change bit set to 1b and eight consecutive TS2 Ordered Sets are standard TS2 Ordered Sets if either 8b/10b or 128b/130b encoding is used
 - ii. Eight consecutive EQ TS2 or 128b/130b EQ TS2 Ordered Sets are received on all configured Lanes with identical data rate identifiers, identical value in Symbol 6, and the speed_change bit set to 1b
 - iii. Eight consecutive EQ TS2 or 128b/130b EQ TS2 Ordered Sets are received on any configured Lane with identical data rate identifiers, identical value in Symbol 6, and the speed_change

bit set to 1b and 1 ms has expired since the receipt of the eight consecutive EQ Ordered Sets on any configured Lane

- iv. Eight consecutive and identical TS2 Ordered Sets are received on any configured Lane with the speed_change bit set to 1b when 1b/1b encoding is used
- Either the current data rate is greater than 2.5 GT/s or greater than 2.5 GT/s data rate identifiers are set both in the transmitted and the (eight consecutive) received TS2 Ordered Sets
- For 8b/10b encoding, at least 32 TS2 Ordered Sets, without being interrupted by any intervening EIEOS, are transmitted with the speed_change bit set to 1b after receiving one TS2 Ordered Set with the speed_change bit set to 1b in the same configured Lane. For 128b/130b and 1b/1b encoding, at least 128 TS2 Ordered Sets are transmitted with the speed_change bit set to 1b after receiving one TS2 Ordered Set with the speed_change bit set to 1b in the same configured Lane.

The data rate(s) advertised on the received eight consecutive TS2 Ordered Sets with the speed_change bit set is noted as the data rate(s) that can be supported by the other Port. The Autonomous Change bit (Symbol 4 bit 6) in these received eight consecutive TS2 Ordered Sets is noted by the Downstream Port for possible logging in the Link Status Register in Recovery.Speed substate. Upstream Ports must register the Selectable De-emphasis bit (bit 6 of Symbol 4) advertised in these eight consecutive TS2 Ordered Sets in the select_deemphasis variable. The new speed to change to in Recovery.Speed is the highest data rate that can be supported by both Ports on the Link.

For an Upstream Port, if the current data rate of operation is 2.5 GT/s or 5.0 GT/s and these eight consecutive TS2 Ordered Sets are EQ TS2 Ordered Sets advertising 8.0 GT/s as the highest data rate supported, it must set the start_equalization_w_preset variable to 1b and update the Upstream Port 8.0 GT/s Transmitter Preset and Upstream Port 8.0 GT/s Receiver Preset Hint fields of the Lane Equalization Control Register Entry with the values received in the eight consecutive EQ TS2 Ordered Sets for the corresponding Lane.

For an Upstream Port, if the current data rate of operation is 2.5 GT/s or 5.0 GT/s and these eight consecutive TS2 Ordered Sets are EQ TS2 Ordered Sets advertising 32.0 GT/s as the highest data rate supported and equalization bypass to the highest NRZ rate was negotiated between the components during the Configuration state, it must set the start_equalization_w_preset variable to 1b and update the Upstream Port 32.0 GT/s Transmitter Preset field of the 32.0 GT/s Lane Equalization Control Register Entry with the values received in the eight consecutive EQ TS2 Ordered Sets for the corresponding Lane.

For an Upstream Port, if the current data rate of operation is 8.0 GT/s, 16.0 GT/s support is advertised by both ends, and these eight consecutive TS2 Ordered Sets are 128b/130b EQ TS2 Ordered Sets, it must set the start_equalization_w_preset variable to 1b and update the Upstream Port 16.0 GT/s Transmitter Preset field of the 16.0 GT/s Lane Equalization Control Register Entry with the values received in the eight consecutive 128b/130b EQ TS2 Ordered Sets for the corresponding Lane.

For an Upstream Port, if the current data rate of operation is 16.0 GT/s, 32.0 GT/s support is advertised by both ends, and these eight consecutive TS2 Ordered Sets are 128b/130b EQ TS2 Ordered Sets, it must set the start_equalization_w_preset variable to 1b and update the Upstream Port 32.0 GT/s Transmitter Preset field of the 32.0 GT/s Lane Equalization Control Register Entry with the values received in the eight consecutive 128b/130b EQ TS2 Ordered Sets for the corresponding Lane.

For an Upstream Port, if the current data rate of operation is 32.0 GT/s, 64.0 GT/s support is advertised by both ends, and these eight consecutive TS2 Ordered Sets are 128b/130b EQ TS2 Ordered Sets, it must set the start_equalization_w_preset variable to 1b and update the Upstream Port 64.0 GT/s Transmitter Preset field of the 64.0 GT/s Lane Equalization Control Register Entry with the values received in the eight consecutive 128b/130b EQ TS2 Ordered Sets for the corresponding Lane.

Any configured Lanes which do not receive EQ TS2 or 128b/130b EQ TS2 Ordered Sets meeting this criteria will use implementation dependent preset values when first operating at 8.0, 16.0, 32.0, or 64.0 GT/s prior to

performing link equalization. A Downstream Port must set the start_equalization_w_preset variable to 1b if any of the following are true:

- the equalization_done_8GT_data_rate variable is 0b
- 16.0 GT/s support is advertised by both ends and the equalization_done_16GT_data_rate variable is 0b
- 32.0 GT/s support is advertised by both ends and the equalization_done_32GT_data_rate variable is 0b
- 64.0 GT/s support is advertised by both ends and the equalization_done_64GT_data_rate variable is 0b
- the Perform Equalization bit in Link Control 3 Register is Set
- an implementation specific mechanism determined that equalization needs to be performed, following procedures described in § Section 4.2.4 .

A Downstream Port must record the 16.0 GT/s, 32.0 GT/s, or 64.0 GT/s Transmitter Preset settings advertised in the eight consecutive TS2 Ordered Sets received if they are 128b/130b EQ TS2 Ordered Sets, and 16.0 GT/s, 32.0 GT/s, or 64.0 GT/s support is advertised by both ends. The variable successful_speed_negotiation is set to 1b. Note that if the Link is already operating at the highest data rate supported by both Ports, Recovery.Speed is executed but the data rate is not changed. If 128b/130b or 1b/1b encoding is used and the Request Equalization bit is Set in the eight consecutive TS2 Ordered Sets, the Port must handle it as an equalization request as described in § Section 4.2.4 .

- Next state is Recovery.Idle if the following two conditions are both true:
 - Eight consecutive TS2 Ordered Sets are received on all configured Lanes with the same Link and Lane number that match what is being transmitted on those same Lanes (see § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding) with identical data rate identifiers within each Lane and one of the following two sub-conditions are true:
 - the speed_change bit is 0b in the received eight consecutive TS2 Ordered Sets
 - current data rate is 2.5 GT/s and either no 5.0 GT/s, or higher, data rate identifiers are set in the received eight consecutive TS2 Ordered Sets, or no 5.0 GT/s, or higher, data rate identifiers are being transmitted in the TS2 Ordered Sets
 - 16 TS2 Ordered Sets are sent after receiving one TS2 Ordered Set without being interrupted by any intervening EIEOS. The changed_speed_recovery variable and the directed_speed_change variable are reset to 0b on entry to Recovery.Idle.
 - In Flit Mode, if the received eight consecutive TS2 Ordered Sets have the Hot Reset bit, the Disable Link bit, or the Loopback bit set on any configured Lane, the corresponding directed bit must be set.

IMPLEMENTATION NOTE:

The above requirement ensures that both the components will immediately exit from Recovery.Idle to the corresponding Hot Reset/Disable/Loopback state without the follower having to send a data stream and waiting till the next scheduled SKP Ordered Set boundary.

- If the N_FTS value was changed, the new value must be used for future L0s states.
- When using 8b/10b encoding, Lane-to-Lane de-skew must be completed before leaving Recovery.RcvrCfg.
- The device must note the data rate identifier advertised on any configured Lane in the eight consecutive TS2 Ordered Sets described in this state transition. This will override any previously recorded value.

- When using 128b/130b or 1b/1b encoding and if the Request Equalization bit is Set in the eight consecutive TS2 Ordered Sets, the device must note it and follow the rules in § Section 4.2.4.
- Next state is Configuration in Non-Flit Mode if eight consecutive TS1 Ordered Sets are received on any configured Lanes with Link or Lane numbers that do not match what is being transmitted on those same Lanes and 16 TS2 Ordered Sets are sent after receiving one TS1 Ordered Set, either 8b/10b or 128b/130b encoding is used, and one of the following two conditions apply:
 - the speed_change bit is 0b on the received TS1 Ordered Sets
 - current data rate is 2.5 GT/s and either no 5.0 GT/s, or higher, data rate identifiers are set in the received eight consecutive TS1 Ordered Sets, or no 5.0 GT/s, or higher, data rate identifiers are being transmitted in the TS2 Ordered Sets

The changed_speed_recovery variable and the directed_speed_change variable are reset to 0b if the LTSSM transitions to Configuration.

- If the N_FTS value was changed, the new value must be used for future L0s states.
- Next state is Configuration in Flit Mode if all the following conditions are true:
 - 1 msec has elapsed after receiving one TS1 or TS2 Ordered Set in any configured Lane in this sub-state.
 - One of the following conditions is true:
 - Eight consecutive TS1 Ordered Sets are received after receiving a TS2 Ordered Set on any configured Lane
 - Eight consecutive TS1 Ordered Sets are received with the Link or Lane number set to PAD and no TS2 Ordered Set was received on any configured Lane
 - Eight consecutive TS2 Ordered Sets are received with Link number PAD on any configured Lane or a PAD is being transmitted in the TS2 Ordered Sets in any configured Lane (see § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding)
 - At least 16 TS2 Ordered Sets have been transmitted after receiving either of the following:
 - One TS1 Ordered Set with Link or Lane number set to PAD
 - One TS2 Ordered Set
 - The speed_change bit is 0b on the received TS1 or TS2 Ordered Sets.

The changed_speed_recovery variable and the directed_speed_change variable are reset to 0b if the LTSSM transitions to Configuration.

IMPLEMENTATION NOTE:

REDUCING LINK WIDTH DUE TO ERRORS IN FLIT MODE §

With Flit Mode, since there is no upconfig support, the reason to make the transition for Recovery → Configuration is to reduce the Link width due to errors. In that case, the Port that wants to reduce the Link width should send PAD in the Link Number field on those Lanes it does not want to be part of the configured Link.

- Next state is Recovery.Speed if the speed of operation has changed to a mutually negotiated data rate since entering Recovery from L0 or L1 (i.e., changed_speed_recovery = 1b) and an EIOS has been detected or an Electrical Idle condition has been inferred/detected on any of the configured Lanes and no configured Lane received a TS2 Ordered Set since entering this substate (Recovery.RcvrCfg). The new data rate to operate after leaving Recovery.Speed will be reverted back to the speed of operation during entry to Recovery from L0 or L1.

As described in § Section 4.2.5.4 , an Electrical Idle condition may be inferred if a TS1 or TS2 Ordered Set has not been received in a time interval specified in § Table 4-39.

- Next state is Recovery.Speed if the speed of operation has not changed to a mutually negotiated data rate since entering Recovery from L0 or L1 (i.e., changed_speed_recovery = 0b) and the current speed of operation is greater than 2.5 GT/s and an EIOS has been detected or an Electrical Idle condition has been detected/inferred on any of the configured Lanes and no configured Lane received a TS2 Ordered Set since entering this substate (Recovery.RcvrCfg). The new data rate to operate after leaving Recovery.Speed will be 2.5 GT/s if 8b/10b or 128b/130b encoding is used. The new data rate to operate after leaving Recovery.Speed will be 32.0 GT/s if 1b/1b encoding is used.

As described in § Section 4.2.5.4 , an Electrical Idle condition may be inferred if a TS1 or TS2 Ordered Set has not been received in a time interval specified in § Table 4-39.

Note: This transition implies that the other side was unable to achieve Symbol lock or Block alignment at the speed with which it was operating. Hence both sides will go back to the 2.5 GT/s speed of operation and neither device will attempt to change the speed again without exiting Recovery state. It should also be noted that even though a speed change is involved here, the changed_speed_recovery will be 0b.

- After a 48 ms timeout;
 - The next state is Detect if the current data rate is 2.5 GT/s or 5.0 GT/s.
 - The next state is Recovery.Idle if the idle_to_rlock_transitioned variable is less than FFh and the current data rate is 8.0 GT/s or higher.
 - i. The changed_speed_recovery variable and the directed_speed_change variable are reset to 0b on entry to Recovery.Idle.
 - Else the next state is Detect.

4.2.7.4.5 Recovery.Idle §

- Next state is Disabled if directed.
 - Note: “if directed” applies to a Downstream or optional crosslink Port that is instructed by a higher Layer to assert the Disable Link bit (TS1 and TS2) on the Link.

The clause, “if directed”, also applies to an Upstream Port in Flit Mode that transitioned to this state with the Disable Link bit set in the training control field in any configured Lane in the eight consecutive TS2 Ordered Sets that resulted in the transition to this state.
- Next state is Hot Reset if directed.
 - Note: “if directed” applies to a Downstream or optional crosslink Port that is instructed by a higher Layer to assert the Hot Reset bit (TS1 and TS2) on the Link.

The clause, “if directed”, also applies to an Upstream Port in Flit Mode that transitioned to this state with the Hot Reset bit set in the training control field in any configured Lane in the eight consecutive TS2 Ordered Sets that resulted in the transition to this state.
- Next state is Configuration if directed.
 - Note: “if directed” applies to a Port that is instructed by a higher Layer to optionally re-configure the Link (i.e., different width Link).
- Next state is Loopback if directed to this state, and the Transmitter is capable of being a Loopback Lead, which is determined by implementation specific means.
 - Note: “if directed” applies to a Port that is instructed by a higher Layer to assert the Loopback bit (TS1 and TS2) on the Link. and the Port becomes the Loopback Lead.

- Next state is Disabled immediately after any configured Lane has the Disable Link bit asserted in two consecutively received TS1 Ordered Sets.
 - Note: This is behavior only applicable to Upstream and optional crosslink Ports in Non-Flit Mode.
- Next state is Hot Reset immediately after any configured Lane has the Hot Reset bit asserted in two consecutive TS1 Ordered Sets.
 - Note: This is behavior only applicable to Upstream and optional crosslink Ports in Non-Flit Mode.
- Next state is Configuration if two consecutive TS1 Ordered Sets are received on any configured Lane with a Lane number set to PAD. See § Section 4.2.7 for more on Matching Link and Lane Numbers for 1b/1b Encoding.
 - Note: A Port that optionally transitions to Configuration to change the Link configuration is guaranteed to send Lane numbers set to PAD on all Lanes.
 - Note: It is recommended that in Non-Flit Mode, the LTSSM initiate a Link width up/downsizing using this transition to reduce the time it takes to change the Link width. In Flit Mode, the Recovery.RcvrCfg to Configuration transition should be used.
- Next state is Loopback if one of the following conditions is true:
 - The Port is operating in Non-Flit Mode and any configured Lane has the Loopback bit asserted in two consecutive TS1 Ordered Sets.
 - The port is operating in Flit Mode and the received eight consecutive TS2 Ordered Sets that resulted in the transition to this state had the Loopback bit set in the training control field in any configured Lane.
 - Note: The device receiving the Ordered Set with the Loopback bit set becomes the Loopback Follower.
- When using 8b/10b encoding, the Transmitter sends Idle data Symbols on all configured Lanes in Non-Flit Mode and IDLE Flits across all configured Lanes in Flit Mode.
- When using 128b/130b encoding in Non-Flit Mode:
 - If the data rate is 8.0 GT/s, the Transmitter sends one SDS Ordered Set on all configured Lanes to start a Data Stream and then sends Idle data Symbols on all configured Lanes. The first Idle data Symbol transmitted on Lane 0 is the first Symbol of the Data Stream.
 - If the data rate is 16.0 GT/s or higher, the Transmitter sends one Control SKP Ordered Set followed immediately by one SDS Ordered Set on all configured Lanes to start a Data Stream and then sends Idle data Symbols on all configured Lanes. The first Idle data Symbol transmitted on Lane 0 is the first Symbol of the Data Stream.
 - If directed to other states, Idle Symbols do not have to be sent, and must not be sent with 128b/130b encoding, before transitioning to the other states (i.e., Disabled, Hot Reset, Configuration, or Loopback)

IMPLEMENTATION NOTE:

EDS USAGE §

In 128b/130b encoding in Non-Flit Mode, on transition to Configuration or Loopback or Hot Reset or Disabled, an EDS must be sent if a Data Stream is active (i.e., an SDS Ordered Set has been sent). It is possible that the side that is not initiating Link Upconfigure has already transmitted SDS and transmitting Data Stream (Logical IDL) when it receives the TS1 Ordered Sets. In that situation, it will send EDS in the set of Lanes that are active before sending the TS1 Ordered Sets in Configuration.

- When using 1b/1b encoding or 128b/130b encoding in Flit Mode:

- Transmitter sends one SDS Ordered Set sequence followed by a Control SKP Ordered Set on all configured Lanes followed by IDLE Flits to start a Data Stream.
- If directed to other states, Idle Flits do not have to be sent, and must not be sent before transitioning to the other states (i.e., Disabled, Hot Reset, Configuration, or Loopback)
- When using 8b/10b encoding in Non-Flit Mode, next state is L0 if eight consecutive Symbol Times of Idle data are received on all configured Lanes and 16 Idle data Symbols are sent after receiving one Idle data Symbol.
 - If software has written a 1b to the Retrain Link bit in the Link Control Register since the last transition to L0 from Recovery or Configuration, the Downstream Port must set the Link Bandwidth Management Status bit of the Link Status Register to 1b.
- When using 128b/130b encoding in Non-Flit Mode, next state is L0 if eight consecutive Symbol Times of Idle data are received on all configured Lanes, 16 Idle data Symbols are sent after receiving one Idle data Symbol, and this state was not entered by a timeout from Recovery.RcvrCfg
 - The Idle data Symbols must be received in Data Blocks.
 - Lane-to-Lane de-skew must be completed before Data Stream processing starts.
 - If software has written a 1b to the Retrain Link bit in the Link Control Register since the last transition to L0 from Recovery or Configuration, the Downstream Port must set the Link Bandwidth Management Status bit of the Link Status Register to 1b.
 - The idle_to_rlock_transitioned variable is reset to 00h on transition to L0.
- In Flit Mode, the next state is L0 if two consecutive IDLE Flits are received and the minimum number of IDLE Flits are sent after receiving one IDLE Flit and this state was not entered by a timeout from Recovery.RcvrCfg. The minimum number of IDLE Flits to send is 4 with 8b/10b or 128b/130b encoding and 8 with 1b/1b encoding.
 - Lane-to-Lane de-skew must be completed before Data Stream processing starts.
 - If software has written a 1b to the Retrain Link bit in the Link Control Register since the last transition to L0 from Recovery or Configuration, the Downstream Port must set the Link Bandwidth Management Status bit of the Link Status Register to 1b.
 - The idle_to_rlock_transitioned variable is reset to 00h on transition to L0
- Otherwise, after a 2 ms timeout:
 - If the idle_to_rlock_transitioned variable is less than FFh, the next state is Recovery.RcvrLock.
 - If the data rate is 8.0 GT/s or higher, the idle_to_rlock_transitioned variable is incremented by 1b upon transitioning to Recovery.RcvrLock.
 - If the data rate is 5.0 GT/s (or, if supported in 2.5 GT/s), the idle_to_rlock_transitioned variable is set to FFh, upon transitioning to Recovery.RcvrLock.
 - Else the next state is Detect

Figure 4-53 Recovery Substate Machine §

4.2.7.5 L0 §

This is the normal operational state. It includes the L0p state, where some Lanes can be in idle state.

- LinkUp = 1b (status is set true).
 - On receipt of an STP or SDP Symbol, the idle_to_rlock_transitioned variable is reset to 00h.
- For an Upstream Port, the directed_speed_change variable must not be set to 1b if it has never recorded greater than 2.5 GT/s data rate support advertised in Configuration.Complete or Recovery.RcvrCfg substates by the Downstream Port since exiting the Detect state.
- For a Downstream Port, the directed_speed_change variable must not be set to 1b if it has never recorded greater than 2.5 GT/s data rate support advertised in Configuration.Complete or Recovery.RcvrCfg substates by the Upstream Port since exiting the Detect state. If greater than 2.5 GT/s data rate support has been noted, the Downstream Port must set the directed_speed_change variable to 1b if the Retrain Link bit of the Link Control Register is set to 1b and the Target Link Speed field in the Link Control 2 Register is not equal to the current Link speed.
- A Port supporting greater than 2.5 GT/s data rates must participate in the speed change even if the Link is not in DL_Active state if it is requested by the other side through the TS Ordered Sets.
- Next state is Recovery if directed to change speed (directed_speed_change variable = 1b) by a higher layer and any of the following three conditions are satisfied:
 - both sides support greater than 2.5 GT/s data rates and the Link is in DL_Active state
 - both sides support 8.0 GT/s or higher data rates, in order to perform Transmitter Equalization at a data rate supported by both sides, in which case the changed_speed_recovery bit is reset to 0b
 - an alternate protocol was selected by the Downstream Port and the current data rate of operation is not an operational data rate in the negotiated alternate protocol
- Next state is Recovery if directed to change Link width.
 - The upper layer must not direct a Port to increase the Link width if the other Port did not advertise the capability to upconfigure the Link width during the Configuration state or if the Link is currently operating at the maximum possible width it negotiated on initial entry to the L0 state.
 - Normally, the upper layer will not reduce width if upconfigure_capable is reset to 0b other than for reliability reasons, since the Link will not be able to go back to the original width if upconfigure_capable is 0b. A Port must not initiate reducing the Link width for reasons other than reliability if the Hardware Autonomous Width Disable bit in the Link Control Register is set to 1b.
 - The decision to initiate an increase or decrease in the Link width, as allowed by the specification, is implementation specific.
- Next state is Recovery if a TS1 or TS2 Ordered Set is received on any configured Lane or an EIEOS is received on any configured Lane in 128b/130b or 1b/1b encoding.
- Next state is Recovery if directed to this state. If Electrical Idle is detected/inferred on all Lanes without receiving an EIOS on any Lane, the Port may transition to the Recovery state or may remain in L0. In the event that the Port is in L0 and the Electrical Idle condition occurs without receiving an EIOS, errors may occur and the Port may be directed to transition to Recovery.
 - As described in § Section 4.2.5.4, an Electrical Idle condition may be inferred on all Lanes under any one of the following conditions: (i) absence of a Flow Control Update DLLP in any 128 μ s window, (ii) absence of a SKP Ordered Set in any of the configured Lanes in any 128 μ s window, or (iii) absence of a Flow Control Update DLLP, an Optimized_Update_FC, or a SKP Ordered Set in any of the configured Lanes in any 128 μ s window.

- Note: “if directed” applies to a Port that is instructed by a higher Layer to transition to Recovery including the Retrain Link bit in the Link Control Register being set.
- The Transmitter may complete any TLP or DLLP in progress.
- Next state is L0s for only the Transmitter if directed to this state and the Transmitter implements L0s. See § Section 4.2.7.6.2 .
 - Note: “if directed” applies to a Port that is instructed by a higher Layer to initiate L0s (see § Section 5.4.1.1.1).
 - Note: This is a point where the TX and RX may diverge into different LTSSM states.
- Next state is L0s for only the Receiver if an EIOS is received on any Lane, the Receiver implements L0s, and the Port is not directed to L1 or L2 states by any higher layers. See § Section 4.2.7.6.1 .
 - Note: This is a point where the TX and RX may diverge into different LTSSM states.
- Next state is Recovery if an EIOS is received on any Lane, the Receiver does not implement L0s, the Port is not directed to L1 or L2 states by any higher layers, and the EIOS is not expected as part of an L0p transition to a lower width. See § Section 4.2.7.6.1 and § Section 4.2.6.7 .
- Next state is L1:
 - i. If directed
and
 - ii. an EIOS is received on any Lane
and
 - iii. an EIOSQ is transmitted on all Lanes.
 - Note: “if directed” is defined as both ends of the Link having agreed to enter L1 immediately after the condition of both the receipt and transmission of the EIOS(s) is met. A transition to L1 can be initiated by PCI-PM (see § Section 5.3.2.1) or by ASPM (see § Section 5.4.1.3.1).
 - Note: When directed by a higher Layer one side of the Link always initiates and exits to L1 by transmitting the EIOS(s) on all Lanes, followed by a transition to Electrical Idle.⁸⁶ The same Port then waits for the receipt of an EIOS on any Lane, and then immediately transitions to L1. Conversely, the side of the Link that first receives the EIOS(s) on any Lane must send an EIOSQ on all Lanes and immediately transition to L1.
- Next state is L2:
 - i. If directed
and
 - ii. an EIOS is received on any Lane
and
 - iii. an EIOSQ is transmitted on all Lanes.
 - Note: “if directed” is defined as both ends of the Link having agreed to enter L2 immediately after the condition of both the receipt and transmission of the EIOS(s) is met (see § Section 5.3.2.3 for more details).
 - Note: When directed by a higher Layer, one side of the Link always initiates and exits to L2 by transmitting EIOS on all Lanes followed by a transition to Electrical Idle.⁸⁷ The same Port then waits

86. The common mode being driven must meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle ($V_{TX-CM-DC-ACTIVE-IDLE-DELTA}$) specification (see § Table 8-7).

87. The common mode being driven does not need to meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle ($V_{TX-CM-DC-ACTIVE-IDLE-DELTA}$) specification (see § Table 8-7).

for the receipt of EIOS on any Lane, and then immediately transitions to L2. Conversely, the side of the Link that first receives an EIOS on any Lane must send an EIOSQ on all Lanes and immediately transition to L2.

4.2.7.6 L0s §

The L0s substate machine is shown in § Figure 4-54.

4.2.7.6.1 Receiver L0s §

A Receiver must implement L0s if its Port advertises support for L0s, as indicated by the ASPM Support field in the Link Capabilities Register. It is permitted for a Receiver to implement L0s even if its Port does not advertise support for L0s.

4.2.7.6.1.1 Rx_L0s.Entry §

- Next state is Rx_L0s.Idle after a T_{TX-IDLE-MIN} (§ Table 8-7) timeout.
 - Note: This is the minimum time the Transmitter must be in an Electrical Idle condition.

4.2.7.6.1.2 Rx_L0s.Idle §

- Next state is Rx_L0s.FTS if the Receiver detects an exit from Electrical Idle on any Lane of the configured Link.
- Next state is Rx_L0s.FTS after a 100 ms timeout if the current data rate is 8.0 GT/s or higher and the Port's Receivers do not meet the Z_{RX-DC} specification for 2.5 GT/s (see § Table 8-12). All Ports are permitted to implement the timeout and transition to Rx_L0s.FTS when the data rate is 8.0 GT/s or higher.

4.2.7.6.1.3 Rx_L0s.FTS §

- The next state is L0 if a SKP Ordered Set is received in 8b/10b encoding or the SDS Ordered Set is received for 128b/130b encoding on all configured Lanes of the Link.
 - The Receiver must be able to accept valid data immediately after the SKP Ordered Set for 8b/10b encoding.
 - The Receiver must be able to accept valid data immediately after the SDS Ordered Set for 128b/130b encoding.
 - Lane-to-Lane de-skew must be completed before leaving Rx_L0s.FTS.
- Otherwise, next state is Recovery after the N_FTS timeout.
 - When using 8b/10b encoding: The N_FTS timeout shall be no shorter than $40 * [N_FTS + 3] * UI$ (The $3 * 40$ UI is derived from six Symbols to cover a maximum SKP Ordered Set + four Symbols for a possible extra FTS+2 Symbols of design margin), and no longer than twice this amount. When the Extended Synch bit is Set the Receiver N_FTS timeout must be adjusted to no shorter than $40 * [2048] * UI$ (2048 FTSs) and no longer than $40 * [4096] * UI$ (4096 FTSs). Implementations must take into account the worst case Lane to Lane skew, their design margins, as well as the four to eight consecutive EIE Symbols in speeds other than 2.5 GT/s when choosing the appropriate timeout value within the specification's defined range.

- When using 128b/130b encoding: The N_FTS timeout shall be no shorter than $130 * [N_FTS + 5 + 12 + \text{Floor}(N_FTS/32)] * UI$ and no longer than twice this amount for 8.0 GT/s and 16.0 GT/s data rates. For 32.0 GT/s and above data rates, the N_FTS timeout shall be no shorter than $130 * [N_FTS + 10 + 12 + 2 * \text{Floor}(N_FTS/32)] * UI$ and no longer than twice this amount. The $5 + \text{Floor}(N_FTS/32)$ accounts for the first EIEOS, the last EIEOS, the SDS, the periodic EIEOS and an additional EIEOS in case an implementation chooses to send two EIEOS followed by an SDS when N_FTS is divisible by 32 for 8.0 GT/s and 16.0 GT/s data rates and correspondingly doubled for the 32.0 GT/s and higher data rates. The 12 is there to account for the number of SKP Ordered Sets that will be transmitted if the Extended Synch bit is Set. When the Extended Synch bit is Set, the timeout should be the same as the normal case with N_FTS equal to 4096.
- The Transmitter must also transition to Recovery, but is permitted to complete any TLP or DLLP in progress.
- It is recommended that the N_FTS field be increased when transitioning to Recovery to prevent future transitions to Recovery from Rx_L0s.FTS.

4.2.7.6.2 Transmitter L0s §

A Transmitter must implement L0s if its Port advertises support for L0s, as indicated by the ASPM Support field in the Link Capabilities Register. It is permitted for a Transmitter to implement L0s even if its Port does not advertise support for L0s.

4.2.7.6.2.1 Tx_L0s.Entry §

- Transmitter sends an EIOSQ and enters Electrical Idle.
 - The DC common mode voltage must be within specification by T_{TX-IDLE-SET-TO-IDLE}.⁸⁸
- Next state is Tx_L0s.Idle after a T_{TX-IDLE-MIN} (§ Table 8-7) timeout.

4.2.7.6.2.2 Tx_L0s.Idle §

- Next state is Tx_L0s.FTS if directed.

IMPLEMENTATION NOTE: INCREASE OF N_FTS DUE TO TIMEOUT IN Rx_L0s.FTS §

The Transmitter sends the N_FTS Fast Training Sequences by going through Tx_L0s.FTS substate to enable the Receiver to reacquire its bit and Symbol lock or Block alignment. In the absence of the N_FTS Fast Training Sequence, the Receiver will timeout in Rx_L0s.FTS substate and may increase the N_FTS number it advertises in the Recovery state.

88. The common mode being driven must meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle (V_{TX-CM-DC-ACTIVE-IDLE-DELTA}) specification (see § Table 8-7).

4.2.7.6.2.3 Tx_L0s.FTS §

- Transmitter must send N_FTS Fast Training Sequences on all configured Lanes.
 - Four to eight EIE Symbols must be sent prior to transmitting the N_FTS (or 4096 if the Extended Synch bit is Set) number of FTS in 5.0 GT/s data rates. An EIEOSQ must be sent prior to transmitting the N_FTS (or 4096 if the Extended Synch bit is Set) number of FTS with 128b/130b encoding. In 2.5 GT/s speed, up to one full FTS may be sent before the N_FTS (or 4096 if the Extended Synch bit is Set) number of FTSs are sent.
 - SKP Ordered Sets must not be inserted before all FTSs as defined by the agreed upon N_FTS parameter are transmitted.
 - If the Extended Synch bit is Set, the Transmitter must send 4096 Fast Training Sequences, inserting SKP Ordered Sets according to the requirements in § Section 4.2.5.6 .
- When using 8b/10b encoding, the Transmitter must send a single SKP Ordered Set on all configured Lanes.
- When using 128b/130b encoding, the Transmitter must send one EIEOSQ followed by one SDS Ordered Set on all configured Lanes. Note: The first Symbol transmitted on Lane 0 after the SDS Ordered Set is the first Symbol of the Data Stream.
- Next state must be L0, after completing the above required transmissions.

IMPLEMENTATION NOTE: NO SKP ORDERED SET REQUIREMENT WHEN EXITING L0S AT 16.0 GT/S OR HIGHER DATA RATES §

Unlike in other LTSSM states, when exiting Tx_L0s.FTS no Control SKP Ordered Set is transmitted before transmitting the SDS. This results in the Data Parity information associated with the last portion of the previous datastream being discarded. Not sending the Control SKP Ordered Set reduces complexity and improves exit latency.

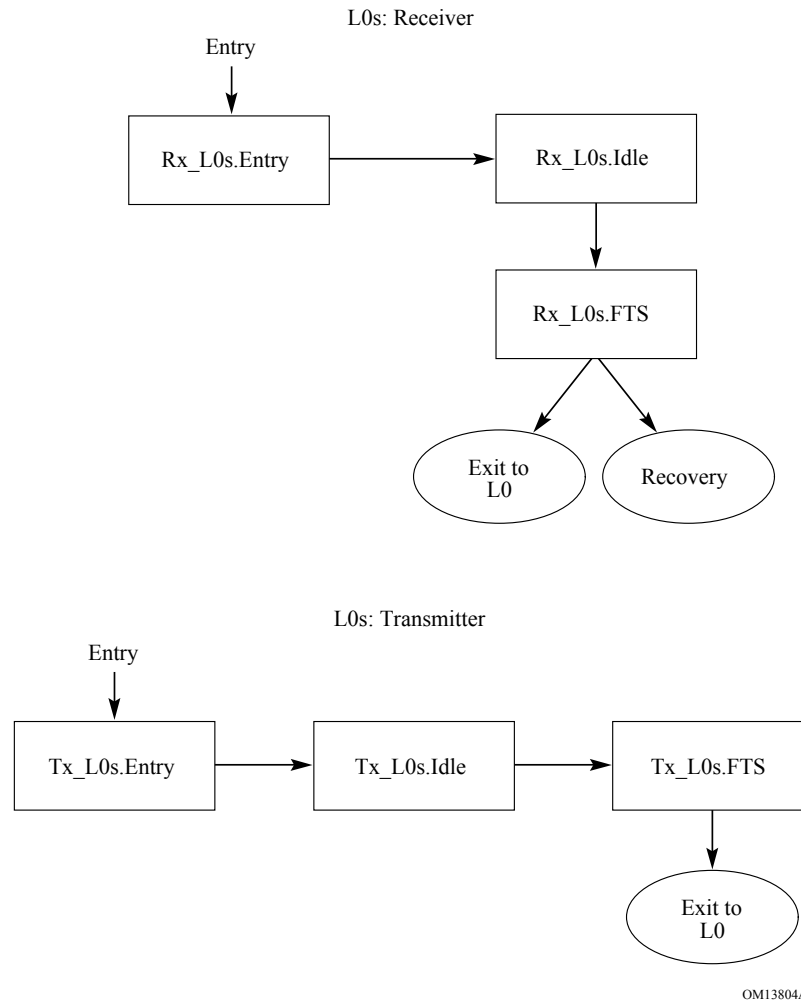

Figure 4-54 L0s Substate Machine §

4.2.7.7 L1 §

The L1 substate machine is shown in § Figure 4-55.

4.2.7.7.1 L1.Entry §

- All configured Transmitters are in Electrical Idle.
 - The DC common mode voltage must be within specification by $T_{TX-IDLE-SET-TO-IDLE}$.
- The next state is L1.Idle after a $T_{TX-IDLE-MIN}$ (§ Table 8-7) timeout.
 - Note: This guarantees that the Transmitter has established the Electrical Idle condition.

4.2.7.7.2 L1.Idle §

- Transmitter remains in Electrical Idle.

- The DC common mode voltage must be within specification, except as allowed by L1 PM Substates, when applicable.⁸⁹
- A substate of L1 is entered when the conditions for L1 PM Substates are satisfied (see § Section 5.5).
 - The L1 PM Substate must be L1.0 when L1.Idle is entered or exited.
- Next state is Recovery if exit from Electrical Idle is detected on any Lane of a configured Link, or directed after remaining in this substate for a minimum of 40 ns in speeds other than 2.5 GT/s.
 - Ports are not required to arm the Electrical Idle exit detectors on all Lanes of the Link.
 - Note: A minimum stay of 40 ns is required in this substate in speeds other than 2.5 GT/s to account for the delay in the logic levels to arm the Electrical Idle detection circuitry in case the Link enters L1 and immediately exits the L1 state.
 - A Port is allowed to set the directed_speed_change variable to 1b following identical rules described in L0 for setting this variable. When making such a transition, the changed_speed_recovery variable must be reset to 0b. A Port may also go through Recovery back to L0 and then set the directed_speed_change variable to 1b on the transition from L0 to Recovery.
 - A Port is also allowed to enter Recovery from L1 if directed to change the Link width. The Port must follow identical rules for changing the Link width as described in the L0 state.
- Next state is Recovery after a 100 ms timeout if the current data rate is 8.0 GT/s or higher and the Port's Receivers do not meet the Z_{RX-DC} specification for 2.5 GT/s. All Ports are permitted, but not encouraged, to implement the timeout and transition to Recovery when the data rate is 8.0 GT/s or higher.
 - This timeout is not affected by the L1 PM Substates mechanism.

IMPLEMENTATION NOTE:

100 MS TIMEOUT IN L1 §

Ports that meet the Z_{RX-DC} specification for 2.5 GT/s while in the L1.Idle state and are therefore not required to implement the 100 ms timeout and transition to Recovery should avoid implementing it, since it will reduce the power savings expected from the L1 state.

89. The common mode being driven must meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle ($V_{TX-CM-DC-ACTIVE-IDLE-DELTA}$) specification (see § Table 8-7).

Figure 4-55 L1 Substate Machine §

4.2.7.8 L2 §

The L2 substate machine is shown in § Figure 4-56.

4.2.7.8.1 L2.Idle §

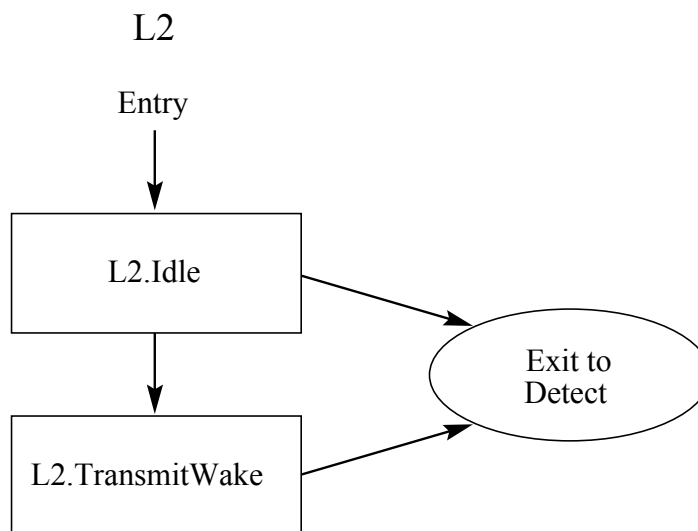

- All Receivers must meet the Z_{RX-DC} specification for 2.5 GT/s within 1 ms (see § Table 8-12).
- All configured Transmitters must remain in Electrical Idle for a minimum time of $T_{TX-IDLE-MIN}$.
 - The DC common mode voltage does not have to be within specification.
 - The Receiver needs to wait a minimum of $T_{TX-IDLE-MIN}$ to start looking for Electrical Idle Exit.
- For Downstream Lanes:
 - For all Downstream Ports, the next state is Detect if a Beacon is received on at least Lane 0 or if directed.
 - Main power must be restored before entering Detect.
 - Note: “if directed” is defined as a higher layer decides to exit to Detect.
 - For a Switch, if a Beacon is received on at least Lane 0 of any of its Downstream Ports and the Upstream Port is in L2.Idle, the Upstream Port must be directed to L2.TransmitWake.
- For Upstream Lanes:
 - The next state is Detect if Electrical Idle Exit is detected on any predetermined set of Lanes.
 - The predetermined set of Lanes must include but is not limited to any Lane which has the potential of negotiating to Lane 0 of a Link. For multi-Lane Links the number of Lanes in the predetermined set must be greater than or equal to two.
 - A Switch must transition any Downstream Lanes to Detect.
 - Next state is L2.TransmitWake for an Upstream Port if directed to transmit a Beacon.

- Note: Beacons may only be transmitted on Upstream Ports in the direction of the Root Complex.

4.2.7.8.2 L2.TransmitWake §

This state only applies to Upstream Ports.

- Transmit the Beacon on at least Lane 0.
- Next state is Detect if Electrical Idle exit is detected on any Upstream Port's Receiver that is in the direction of the Root Complex.
 - Note: Power is guaranteed to be restored when Upstream Receivers see Electrical Idle exited, but it may also be restored prior to Electrical Idle being exited.

OM13806A

Figure 4-56 L2 Substate Machine §

4.2.7.9 Disabled §

- It is recommended to Clear LinkUp upon entry to Disabled, without waiting for the EIOSQ to be transmitted or the EIOS to be received.
- All Lanes transmit 16 to 32 TS1 Ordered Sets with the Disable Link bit asserted and then transition to Electrical Idle.
 - An EIOSQ must be sent prior to entering Electrical Idle.
 - The DC common mode voltage does not have to be within specification.⁹⁰
- If an EIOSQ was transmitted and an EIOS was received on any Lane (even while transmitting TS1 with the Disable Link bit asserted), then:
 - LinkUp = 0b (False), unless already Cleared, as recommended above.

90. The common mode being driven does need to meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle (V_{TX-CM-DC-ACTIVE-IDLE-DELTA}) specification (see § Table 8-7).

- At this point, the Lanes are considered Disabled.
- For Upstream Ports: All Receivers must meet the Z_{RX-DC} specification for 2.5 GT/s within 1 ms (see § Table 8-12).
- For Upstream Ports: The next state is Detect when Electrical Idle exit is detected on at least one Lane.
- For Downstream Ports: The next state is Detect when directed (e.g., when the Link Disable bit is reset to 0b by software).
- For Upstream Ports: If no EIOS is received after a 2 ms timeout, the next state is Detect.

4.2.7.10 Loopback §

The Loopback substate machine is shown in § Figure 4-57.

4.2.7.10.1 Loopback.Entry §

- LinkUp = 0b (False)
- The Link and Lane numbers received in the TS1 or TS2 Ordered Sets are ignored by the Receiver while in this substate.
- Loopback Lead requirements:
 - If the Loopback Lead was directed, in an implementation specific manner, to perform a 64.0 GT/s equalization procedure on one active Lane, to be referred to as the ‘Lane under test’, before entering Loopback.Entry with LinkUp set to 0b, the perform_equalization_for_loopback_64GT variable must be set to 1b.
 - If Loopback.Entry was entered from Recovery.Equalization and the current data rate is 32.0 GT/s and perform_equalization_for_loopback_64GT is 1b and the equalization_done_64GT_data_rate variable is 0b, determine the highest common data rate of the data rates supported by the Lead and the highest data rates advertised by the Loopback Follower in the TS1s that it transmitted in Phase 1 of Recovery.Equalization on the ‘Lane Under Test’. If the highest common data rate is 64.0 GT/s, transmit 16 consecutive TS1 Ordered Sets with the Loopback bit asserted, followed by an EIOSQ, and then transition to Electrical Idle for 1 ms. During the period of Electrical Idle, change the data rate to 64.0 GT/s.

The 16 consecutive TS1 Ordered Sets transmitted on the Lane under test prior to the rate change to 64.0 GT/s must have the bits listed below as follows:

- The Enhanced Link Behavior Control bits must be set to 01b. The equalization procedure must be performed on the same ‘Lane under test’ for both equalization procedures.
- The Transmit Modified Compliance Pattern in Loopback bit must be set to 1b if the Loopback Follower is required to transmit the Modified Compliance Pattern on the Lanes that are not under test.
- If Loopback.Entry was entered from Configuration.Linkwidth.Start, the highest common data rate is 64.0 GT/s when LinkUp = 0b, the Loopback Lead intends to operate at 64.0 GT/s and the Loopback Lead has prior knowledge that the Loopback Follower also supports 64.0 GT/s. Otherwise, determine the highest common data rate of the data rates supported by the Lead and the data rates received in two consecutive TS1 or TS2 Ordered Sets on any active Lane at the time the transition to Loopback.Entry occurred. If the current data rate is not the highest common data rate:
 - Transmit 16 consecutive TS1 Ordered Sets with the Loopback bit asserted, followed by an EIOSQ, and then transition to Electrical Idle for 1 ms. During the period of Electrical Idle, if

the `perform_equalization_for_loopback_64GT` variable is 1b and the highest common data rate is 64.0 GT/s, change the data rate to 32.0 GT/s. Otherwise, change the data rate to the highest common data rate.

- If `LinkUp` is 0b, the Supported Link Speeds field of the Data Rate Identifier must use the Flit Mode data rate encoding if the Flit Mode Supported field in the PCI Express Capabilities Register is 1b and 64.0 GT/s is supported and the consecutive TS2 Ordered Sets received on the last transition from Polling.Configuration had the Flit Mode Supported bit set to 1b.
- The Loopback Lead may be directed, in an implementation specific manner, to perform a 32.0 GT/s equalization procedure on one active Lane, to be referred to as the ‘Lane under test’, before entering Loopback.Entry. If the highest common data rate is 32.0 GT/s, the `equalization_done_32GT_data_rate` variable is 0b, and the equalization procedure is to be executed, the 16 consecutive TS1 Ordered Sets transmitted on the Lane under test prior to the data rate change to the highest common data rate must have the bits listed below as follows:
 - The Enhanced Link Behavior Control bits must be set to 01b.
 - The Transmit Modified Compliance Pattern in Loopback bit must be set to 1b if the Loopback Follower is required to transmit the Modified Compliance Pattern on the Lanes that are not under test.

IMPLEMENTATION NOTE:

LANE UNDER TEST USAGE EXPECTATIONS §

The method whereby one active Lane is defined as the ‘Lane under test’ and is affected by the NEXT/FEXT aggressor Lanes (see § Section 8.5.1.1) so that measurements are performed on the Lane under test (after a speed change and completion of an equalization procedure at a rate of 32.0 GT/s or above) is defined for system configurations where a test apparatus, such as (but not limited to) a BERT, acts as the Loopback Lead. In such a system configuration, the expectation of this test method is that the Loopback Lead is able to provide the necessary stimulus for the state traversals and protocol negotiations required to establish and exercise the ‘Lane under test’ without any specific guidance from this specification.

This test mode is only defined for use while `LinkUp` = 0b (prior to entering Loopback.Entry). The test apparatus must be cognizant of the capabilities of the ‘Lane under test’. A mechanism to “re-do” equalization when this test procedure is performed is not defined. The Loopback Lead must only send TS1s with Flit Mode Encoding in Loopback if it received TS2s with the Flit Mode Supported bit set to 1b in Polling.Configuration - these TS2s indicate that the Loopback Follower will properly interpret TS1s with Flit Mode Data Rate Encoding.

- If the highest common data rate is 5.0 GT/s, the follower’s transmitter de-emphasis is controlled by setting the Selectable De-emphasis bit of the transmitted TS1 Ordered Sets to the desired value (1b = -3.5 dB, 0b = -6 dB).
- For data rates of 5.0 GT/s and above, the Lead is permitted to choose its own transmitter settings in an implementation specific manner, regardless of the settings it transmitted to the follower.
- Note: If Loopback is entered after LinkUp has been set to 1b, it is possible for one Port to enter Loopback from Recovery and the other to enter Loopback from Configuration. The

Port that entered from Configuration might attempt to change data rate while the other Port does not. If this occurs, the results are undefined. The test set-up must avoid such conflicting directed clauses.

- Transmit TS1 Ordered Sets with the Loopback bit asserted.
 - If Loopback.Entry was entered from Recovery.Equalization, the EC field of the transmitted TS1 Ordered Sets must be set to 00b.
 - The Lead is also permitted to assert the Compliance Receive bit of TS1 Ordered Sets transmitted in Loopback.Entry, including those transmitted before a data rate change. If it asserts the Compliance Receive bit, it must not deassert it again while in the Loopback.Entry state. This usage model might be helpful for test and validation purposes when one or both Ports have difficulty obtaining bit lock, Symbol lock, or Block alignment after a data rate change. The ability to set the Compliance Receive bit is implementation specific.
- Next state is Recovery.Equalization if the data rate was changed to 32.0 or 64.0 GT/s and 16 consecutive TS1 Ordered Sets were sent on any Lane with the Enhanced Link Behavior Control bits set to 01b.
 - The perform_equalization_for_loopback variable is set to 1b.
- Next state is Loopback.Active after 2 ms if the Compliance Receive bit of the transmitted TS1 Ordered Sets is asserted.
- Next state is Loopback.Active if Loopback.Entry was entered from Recovery.Equalization and the Lane under test receives two consecutive TS1 Ordered Sets with the Loopback bit asserted.
- Next state is Loopback.Active if the Compliance Receive bit of the transmitted TS1 Ordered Sets is deasserted and an implementation specific set of Lanes receive two consecutive TS1 Ordered Sets with the Loopback bit asserted.

If the data rate was changed and the equalization procedure was not performed at either 32.0 GT/s or 64.0 GT/s, the Lead must take into account the amount of time the follower can be in Electrical Idle and transmit a sufficient number of TS1 Ordered Sets for the follower to acquire Symbol lock or Block alignment before proceeding to Loopback.Active. These TS1 Ordered Sets may be used to specify Transmitter settings for the Loopback Follower when the data rate of operation is 8.0 GT/s or above by setting the value of the EC field appropriately for the follower's Port direction (10b or 11b) and requesting a preset or a set of valid coefficients.

IMPLEMENTATION NOTE: LANE NUMBERING WITH 128B/130B ENCODING IN LOOPBACK §

If the current data rate uses 128b/130b encoding and Lane numbers have not been negotiated, it is possible that the Lead and follower will not be able to decode received information because their Lanes are using different scrambling LFSR seed values (since the LFSR seed values are determined by the Lane numbers). This situation can be avoided by allowing the Lead and follower to negotiate Lane numbers before directing the Lead to Loopback, directing the Lead to assert the Compliance Receive bit during Loopback.Entry, or by using some other method of ensuring that the LFSR seed values match.

- Next state is Loopback.Exit after an implementation specific timeout of less than 100 ms.

- Loopback Follower requirements:
 - If Loopback.Entry was entered from Configuration.Linkwidth.Start with LinkUp set to 0b, the TS1 Ordered Sets that directed the follower to this state advertised 64.0 GT/s support and had Enhanced Link Behavior Control set to 01b and the follower intends to operate at 64.0 GT/s, perform_equalization_for_loopback_64GT must be set to 1b.
 - If Loopback.Entry was entered from Recovery.Equalization and the current data rate is 32.0 GT/s and perform_equalization_for_loopback_64GT is 1b and the equalization_done_64GT_data_rate variable is 0b, and 64.0 GT/s is advertised by the Loopback Follower in the TS1s that it transmitted in Phase 1 of Recovery.Equalization on the 'Lane under test':
 - Transmit an EIOSQ, and then transition to Electrical Idle for 2 ms. During the period of Electrical Idle, change the data rate to 64.0 GT/s.
 - If the Loopback Follower is a Downstream Port, transmit 16 consecutive TS1 Ordered Sets on the 'Lane under test' prior to transmitting the EIOSQ. The TS1 Ordered Sets must have the Equalization Control bits set to 00b.
 - Next state is Recovery.Equalization.
 - The 'Lane under test', perform_equalization_for_loopback variable, transmit_modified_compliance_pattern_in_loopback variable and the Link and Lane numbers for both the 32.0 GT/s and 64.0 GT/s equalization procedures must be the same.
 - If Loopback.Entry was entered from Configuration.Linkwidth.Start, determine the highest common data rate of the data rates supported by the follower and the data rates received in the two consecutive TS1 Ordered Sets that directed the follower to this state. If the current data rate is not the highest common data rate:
 - Transmit an EIOSQ, and then transition to Electrical Idle for 2 ms. During the period of Electrical Idle, if the perform_equalization_for_loopback_64GT variable is 1b and the highest common data rate is 64.0 GT/s, change the data rate to 32.0 GT/s. Otherwise, change the data rate to the highest common data rate.
 - If operating in full swing mode and the highest common data rate is 5.0 GT/s, set the transmitter's de-emphasis to the setting specified by the Selectable De-emphasis bit received in the TS1 Ordered Sets that directed the follower to this state. The de-emphasis is -3.5 dB if the Selectable De-emphasis bit was 1b, and it is -6 dB if the Selectable De-emphasis bit was 0b.
 - If the highest common data rate is 8.0 GT/s or higher and EQ TS1 Ordered Sets directed the follower to this state, set the transmitter to the settings specified by the Preset field of the EQ TS1 Ordered Sets. See § Section 4.2.4.2. If the highest common data rate is 8.0 GT/s or higher but standard TS1 Ordered Sets directed the follower to this state, the follower is permitted to use its default transmitter settings.
 - Next state is Recovery.Equalization if Loopback.Entry was entered from Configuration.Linkwidth.Start, the highest common data rate is 32.0 GT/s or higher and the Enhanced Link Behavior Control bits of the TS1 Ordered Sets that directed the follower to this state were 01b.
 - The ***perform_equalization_for_loopback*** variable is set to 1b.
 - The ***transmit_modified_compliance_pattern_in_loopback*** variable is set to 1b if the Transmit Modified Compliance Pattern in Loopback bit is Set to 1b in the TS1 Ordered Sets that directed the follower to this state.
 - When Recovery.Equalization is entered from Loopback.Entry, the Lane that received two consecutive TS1 Ordered Sets with the Enhanced Link Behavior Control bits set to 01b in Configuration.Linkwidth.Start is the Lane under test for the purposes of Loopback and Recovery.Equalization.

- The Loopback Follower must select a valid Link number in an implementation specific manner. (See § Section 4.2.2.4 for more on assigning Lane numbers and other Scrambler requirements.) The test measurement equipment that facilitates this state transition must ensure, in an implementation specific manner, that it uses a matching Lane number and LFSR seed value.
- Next state is Loopback.Active if the Compliance Receive bit of the TS1 Ordered Sets that directed the follower to this state was asserted.
 - The follower's transmitter does not need to transition to transmitting looped-back data on any boundary, and it is permitted to truncate any Ordered Set in progress.
- Else, the follower transmits TS1 Ordered Sets with Link and Lane numbers set to PAD.
 - If Loopback.Entry was entered from Recovery.Equalization:
 - The EC field of the transmitted TS1 Ordered Sets must be set to 00b.
 - The next state is Loopback.Active after two consecutive TS1 Ordered Sets with the Loopback bit asserted are received by the Lane under test.
 - Else, the next state is Loopback.Active if one of the following conditions is true:
 - The data rate is 2.5 GT/s or 5.0 GT/s and Symbol lock is obtained on all active Lanes.
 - The data rate is 8.0 GT/s or higher and two consecutive TS1 Ordered Sets are received on all active Lanes. The equalization settings specified by the received TS1 Ordered Sets must be evaluated and applied to the transmitter if the value of the EC field is appropriate for the follower's Port direction (10b or 11b) and the requested setting is a preset or a set of valid coefficients. (Note: This is the equivalent behavior for the Recovery.Equalization state.) Optionally, the follower can accept both EC field values. If the settings are applied, they must take effect within 500 ns of being received, and they must not cause the transmitter to violate any electrical specification for more than 1 ns. Unlike Recovery.Equalization, the new settings are not reflected in the TS1 Ordered Sets that the follower transmits.
- When using 8b/10b encoding, the follower's transmitter must transition to transmitting looped-back data on a Symbol boundary, but it is permitted to truncate any Ordered Set in progress. When using 128b/130b or 1b/1b encoding, the follower's transmitter does not need to transition to transmitting looped-back data on any boundary and is permitted to truncate any Ordered Set in progress.

4.2.7.10.2 Loopback.Active §

- The Loopback Lead must send valid encoded data. The Loopback Lead must not transmit EIOS as data until it wants to exit Loopback. When operating with 128b/130b encoding, Loopback Leads must follow the requirements of § Section 4.2.2.6 .
- When operating with 1b/1b encoding, the Loopback Lead must follow the requirements of § Section 4.2.3.1 , when it starts a Data Stream. The Loopback Lead is permitted to substitute the CRC and FEC bytes with any bytes of its choice. If the Link width has been negotiated by entering L0 since leaving the Detect State, that width is to be used; else the width must be assumed to be x1.
- A Loopback Follower that entered Loopback from Recovery.Equalization must transmit the Modified Compliance Pattern on all Lanes that detected Receivers in Detect.Active but are not under test if the transmit_modified_compliance_pattern_in_loopback variable is set to 1b, otherwise those Lanes must be

transitioned into Electrical Idle. The Lane under test must follow Loopback Follower rules described below. State transitions must be based only on Link activity on the Lane under test.

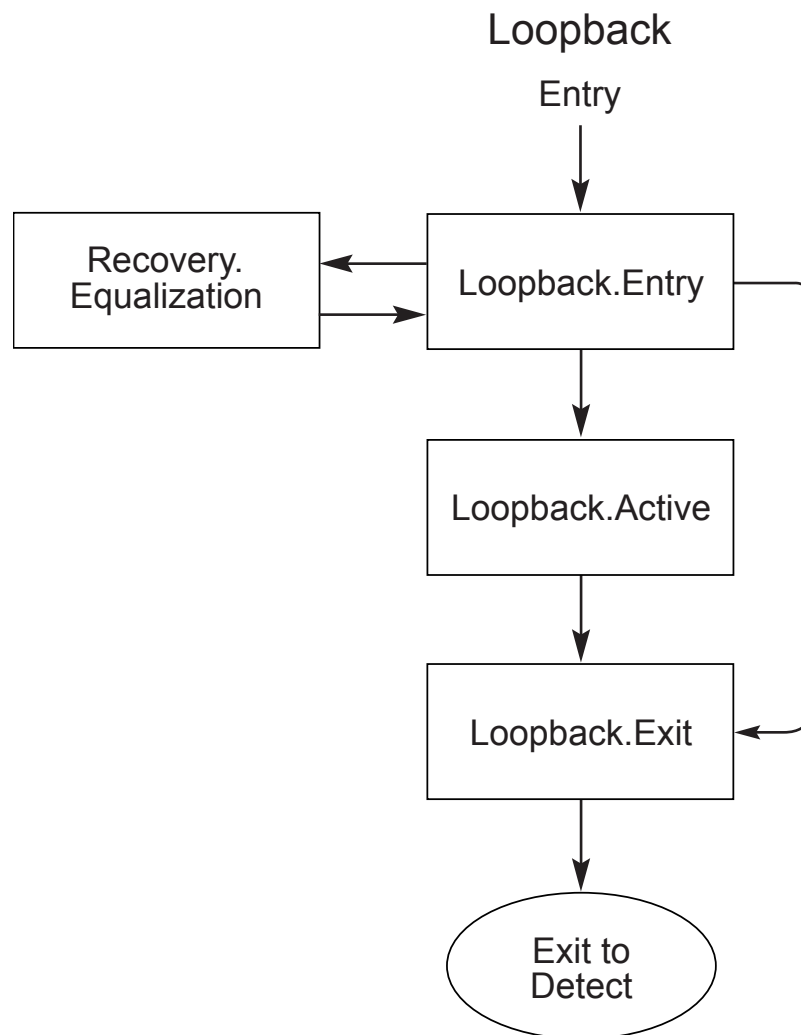

- A Loopback Follower is required to retransmit the received encoded information as received, with the polarity inversion determined in Polling applied, while continuing to perform clock tolerance compensation:
 - When operating with 1b/1b encoding: The Loopback Follower must track when the Data Stream transition happens and subsequently distinguish an Ordered Set from Data Stream bytes as defined in § Section 4.2.3.1, using the Ordered Set insertion interval of § Table 4-21 as follows:
 - If the Link width has been negotiated by entering L0 since leaving the Detect State, that width is to be used; else the width must be assumed to be x1
 - For Upstream Lanes, the SRIS mode is determined from the TS1 Ordered Set (Symbol 4, Bit 7) received in the Configuration state whereas for Downstream Lanes it comes from the SRIS Clocking bit in the Link Control Register.
 - SKPs must be added or deleted on a per-Lane basis as outlined in § Section 4.2.8 with the exception that SKPs do not have to be simultaneously added or removed across Lanes of a configured Link.
 - For 8b/10b encoding, if a SKP Ordered Set retransmission requires adding a SKP Symbol to accommodate timing tolerance correction, the SKP Symbol is inserted in the retransmitted Symbol stream anywhere adjacent to a SKP Symbol in the SKP Ordered Set following the COM Symbol. The inserted SKP Symbol must be of the same disparity as the received SKPs Symbol(s) in the SKP Ordered Set.
 - For 8b/10b encoding, if a SKP Ordered Set retransmission requires dropping a SKP Symbol to accommodate timing tolerance correction, the SKP Symbol is simply not retransmitted.
 - For 128b/130b encoding, if a SKP Ordered Set retransmission requires adding SKP Symbols to accommodate timing tolerance correction, four SKP Symbols are inserted in the retransmitted Symbol stream prior to the SKP_END Symbol in the SKP Ordered Set.
 - For 128b/130b encoding, if a SKP Ordered Set retransmission requires dropping SKP Symbols to accommodate timing tolerance correction, four SKP Symbols prior to the SKP_END Symbol in the SKP Ordered Set are simply not retransmitted.
 - For 1b/1b encoding, if a SKP Ordered Set retransmission requires adding SKP Symbols to accommodate timing tolerance correction, eight SKP Symbols are inserted in the retransmitted Symbol stream prior to the SKP_END Symbol in the SKP Ordered Set.
 - For 1b/1b encoding, if a SKP Ordered Set retransmission requires dropping SKP Symbols to accommodate timing tolerance correction, eight SKP Symbols prior to the SKP_END Symbol in the SKP Ordered Set are simply not retransmitted.
 - No modifications of the received encoded data (except for polarity inversion determined in Polling) are allowed by the Loopback Follower even if it is determined to be an invalid encoding (i.e., no legal translation to a control or data value possible for 8b/10b encoding or invalid Sync Header or invalid Ordered Set for 128b/130b encoding).
- Next state of the Loopback Follower is Loopback.Exit if one of the following conditions apply:
 - If directed or if four consecutive EIOSs are received on any Lane. The Requirements for detecting an EIOS are specified in § Section 4.2.5.3.
 - Optionally, if current Link speed is 2.5 GT/s and an EIOS is received or Electrical Idle is detected/ inferred on any Lane.
 - Note: As described in § Section 4.2.5.4, an Electrical Idle condition may be inferred if any of the configured Lanes remained electrically idle continuously for 128 μ s by not detecting an exit from Electrical Idle in the entire 128 μ s window.
 - A Loopback Follower must be able to detect an Electrical Idle condition on any Lane within 1 ms of the EIOS being received by the Loopback Follower.

- Note: During the time after an EIOS is received and before Electrical Idle is actually detected by the Loopback Follower, the Loopback Follower may receive a bit stream that is undefined by the encoding scheme, which may be looped back by the transmitter.
- The $T_{TX-IDLE-SET-TO-IDLE}$ parameter does not apply in this case since the Loopback Follower may not even detect Electrical Idle until as much as 1 ms after the EIOS.
- The next state of the Loopback Lead is Loopback.Exit if directed.

4.2.7.10.3 Loopback.Exit §

- The Loopback Lead sends an EIOS for Ports that support only the 2.5 GT/s data rate and eight consecutive EIOSs for Ports that support greater than 2.5 GT/s data rate, and optionally for Ports that only support the 2.5 GT/s data rate, irrespective of the current Link speed, and enters Electrical Idle on all Lanes for 2 ms.
 - The Loopback Lead must transition to a valid Electrical Idle condition⁹¹ on all Lanes within $T_{TX-IDLE-SET-TO-IDLE}$ after sending the last EIOS.
 - Note: The EIOS can be useful in signifying the end of transmit and compare operations that occurred by the Loopback Lead. Any data received by the Loopback Lead after any EIOS is received should be ignored since it is undefined.
- The Loopback Follower must enter Electrical Idle on all Lanes for 2 ms.
 - Before entering Electrical Idle the Loopback Follower must Loopback all Symbols that were received prior to detecting Electrical Idle. This ensures that the Loopback Lead may see the EIOS to signify the logical end of any Loopback send and compare operations.
- The next state of the Loopback Lead and Loopback Follower is Detect.

91. The common mode being driven does not need to meet the Absolute Delta Between DC Common Mode During L0 and Electrical Idle ($V_{TX-CM-DC-ACTIVE-IDLE-DELTA}$) specification (see § Table 8-7).

OM13807C

Figure 4-57 Loopback Substate Machine §

4.2.7.11 Hot Reset §

- Lanes that were directed by a higher Layer to initiate Hot Reset:
 - All Lanes in the configured Link transmit TS1 Ordered Sets with the Hot Reset bit asserted and the configured Link and Lane numbers.
 - If two consecutive TS1 Ordered Sets are received on any Lane with the Hot Reset bit asserted and configured Link and Lane numbers, then:
 - LinkUp = 0b (False)
 - If no higher Layer is directing the Physical Layer to remain in Hot Reset, the next state is Detect
 - Otherwise, all Lanes in the configured Link continue to transmit TS1 Ordered Sets with the Hot Reset bit asserted and the configured Link and Lane numbers.
 - Otherwise, after a 2 ms timeout next state is Detect.

- Lanes that were not directed by a higher Layer to initiate Hot Reset (i.e., received two consecutive TS1 Ordered Sets with the Hot Reset bit asserted on any configured Lanes):
 - LinkUp = 0b (False)
 - If any Lane of an Upstream Port of a Switch receives two consecutive TS1 Ordered Sets with the Hot Reset bit asserted, all configured Downstream Ports must transition to Hot Reset as soon as possible.
 - Any optional crosslinks on the Switch are an exception to this rule and the behavior is system specific.
 - All Lanes in the configured Link transmit TS1 Ordered Sets with the Hot Reset bit asserted and the configured Link and Lane numbers.
 - If two consecutive TS1 Ordered Sets were received with the Hot Reset bit asserted and the configured Link and Lane numbers, the state continues to be Hot Reset and the 2 ms timer is reset.
 - Otherwise, the next state is Detect after a 2 ms timeout.

Note: Generally, Lanes of a Downstream or optional crosslink Port will be directed to Hot Reset, and Lanes of an Upstream or optional crosslink Port will enter Hot Reset by receiving two consecutive TS1 Ordered Sets with the Hot Reset bit asserted on any configured Lanes, from Recovery.Idle state.

4.2.8 Clock Tolerance Compensation §

SKP Ordered Sets (defined in § Section 4.2.8.1 , § Section 4.2.8.2 , and § Section 4.2.8.3) are used to compensate for differences in frequencies between bit rates at two ends of a Link. The Receiver Physical Layer logical sub-block must include elastic buffering which performs this compensation. The interval between SKP Ordered Set transmissions is derived from the Transmit, Receiver, and Refclk specifications specified in § Table 8-6, § Table 8-12, and § Table 8-19.

The specification supports shared reference clocking architectures (common Refclk) where there is no difference between the Tx and Rx Refclk rates, and two kinds of reference clocking architectures where the Tx and Rx Refclk rates differ. Separate Reference Clocks With No SSC - **SRNS**, and Separate Reference Clocks with Independent SSC - **SRIS**. The maximum difference with SRNS is 600 ppm which can result in a clock shift once every 1666 clocks. The maximum difference with SRIS is 5600 ppm which can result in a clock shift every 178 clocks.

Specific form factor specifications are permitted to require the use of only SRIS, only SRNS, or to provide a mechanism for clocking architecture selection. Upstream Ports are permitted to implement support for any combination of SRIS and SRNS (including no support for either), but must conform to the requirements of any associated form factor specification. Downstream Ports supporting SRIS must also support SRNS unless the port is only associated with a specific form factor(s) which modifies these requirements. Port configuration to satisfy the requirements of a specific associated form factor is implementation specific. Specific guidance for form factor specifications is provided in § Section 8.6.8 .

If the receiver is capable of operating with SKP Ordered Sets being generated at the rate used in SRNS even though the Port is running in SRIS, the Port is permitted to Set its bit for the appropriate data rate in the Lower SKP OS Reception Supported Speeds Vector field of the Link Capabilities 2 Register. If the transmitter is capable of operating with SKP Ordered Sets being generated at the rate used in SRNS even though the Port is running in SRIS, the Port is permitted to Set its bit for the appropriate data rate in the Lower SKP OS Generation Supported Speeds Vector field of the Link Capabilities 2 register. System software must check that the bit is Set in the Lower SKP OS Reception Supported Speeds Vector field before setting the appropriate data rate's bit in the link partner's Enable Lower SKP OS Generation Vector field of the Link Control 3 Register. Any software transparent Extension Devices (such as a repeater) present on a Link must also support lower SKP OS Generation for system software to set the bit in the Enable Lower SKP OS Generation Vector field. Software determination of such support in such extension devices is implementation specific. When the bit for the data rate that the link is running in is Set in the Enable Lower SKP OS Generation Vector field, the transmitter schedules SKP Ordered Set generation in L0 at the rate used in SRNS, regardless of which clocking architecture the link is running in. In other LTSSM states, SKP Ordered Set scheduling is at the appropriate rate for the clocking architecture.

Components supporting SRIS may need more entries in their elastic buffers than designs supporting SRNS only. This requirement takes into account the extra time it may take to schedule a SKP Ordered Set if the latter falls immediately after a maximum payload sized packet.

4.2.8.1 SKP Ordered Set for 8b/10b Encoding §

When using 8b/10b encoding, a transmitted SKP Ordered Set is a COM Symbol followed by three SKP Symbols, except as is allowed for a Loopback Follower in the Loopback.Active LTSSM state. A received SKP Ordered Set is a COM Symbol followed by one to five SKP Symbols. See § Section 4.3.6.7 for Retimer rules on SKP Ordered Set modification.

4.2.8.2 SKP Ordered Set for 128b/130b Encoding §

When using 128b/130b encoding, a transmitted SKP Ordered Set is 16 Symbols, and a received SKP Ordered Set can be 8, 12, 16, 20, or 24 Symbols. See § Section 4.3.6.7 for Retimer rules on SKP Ordered Set modification.

There are two SKP Ordered Set formats defined for 128b/130b encoding as shown in § Table 4-52 and § Table 4-53. Both formats contain one to five groups of four SKP Symbols followed by a final group of four Symbols indicated by a SKP_END or SKP_END_CTL Symbol. When operating at 8.0 GT/s in Non-Flit Mode, only the Standard SKP Ordered Set is used. When operating at 16.0 GT/s or 32.0 GT/s in Non-Flit Mode, both the Standard and Control SKP Ordered Sets are used. When operating at 8.0, 16.0, 32.0 GT/s in Flit Mode, both the Standard SKP Ordered Sets and Control SKP Ordered Sets are used. All statements in this specification that do not refer to a specific SKP Ordered Set format apply to both formats. When a SKP Ordered Set is transmitted, all Lanes must transmit the same format of SKP Ordered Set - all Lanes must transmit the Standard SKP Ordered Set, or all Lanes must transmit the Control SKP Ordered Set.

The **Standard SKP Ordered Set** contains information following the SKP_END Symbol that is based on the LTSSM state and the sequence of Blocks. When in the Polling.Compliance state, the Symbols contain the Lane's error status information (see § Section 4.2.7.2.2 for more information). Otherwise, the Symbols contain the Lane's scrambling LFSR value, and a Data Parity bit when the SKP Ordered Set follows a Data Block. The **Control SKP Ordered Set** contains three Data Parity bits and additional information following the SKP_END_CTL Symbol.

When operating at 8.0 GT/s in Non-Flit Mode, the Data Parity bit of the Standard SKP Ordered Set is the even parity of the payload of all Data Blocks communicated by a Lane and is computed for each Lane independently⁹². Upstream and Downstream Port Transmitters compute the parity as follows:

- Parity is initialized when an SDS Ordered Set is transmitted.
- Parity is updated with each bit of a Data Block's payload after scrambling has been performed.
- The Data Parity bit of a Standard SKP Ordered Set transmitted immediately following a Data Block is set to the current parity.
- Parity is initialized after a Standard SKP Ordered Set is transmitted.

Upstream and Downstream Port Receivers compute and act on the parity as follows:

- Parity is initialized when an SDS Ordered Set is received.
- Parity is updated with each bit of a Data Block's payload before de-scrambling has been performed.
- When a Standard SKP Ordered Set is received immediately following a Data Block, each Lane compares the received Data Parity bit to its calculated parity. If a mismatch is detected, the receiver must set the bit of the Port's Lane Error Status register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.

92. The requirements for 8.0 GT/s operation documented here are identical to those in [PCIe-3.1].

- Parity is initialized when a Standard SKP Ordered Set is received.

When operating at a data rate of 16.0 or 32.0 GT/s in Non-Flit Mode or 8.0, 16.0m or 32.0 GT/s in Flit Mode, the Data Parity bits of both the Standard SKP Ordered Set in non-Flit-Mode and the Control SKP Ordered Set is the even parity of the payload of all Data Blocks communicated by a Lane and is computed for each Lane independently. Upstream and Downstream Port Transmitters compute the parity as follows:

- Parity is initialized when the LTSSM is in Recovery.Speed.
- Parity is initialized when an SDS Ordered Set is transmitted.
- Parity is updated with each bit of a Data Block's payload after scrambling has been performed.
- Thus, in Flit Mode, Parity is computed post FEC.
- The Data Parity bit of a Standard SKP Ordered Set transmitted immediately following a Data Block is set to the current parity.
- The Data Parity, First Retimer Data Parity, and Second Retimer Data Parity bits of a Control SKP Ordered Set are all set to the current parity.
- Parity is initialized after a Control SKP Ordered Set is transmitted. However, parity is not initialized when a Standard SKP Ordered Set is transmitted.

Upstream and Downstream Port Receivers compute and act on the parity as follows:

- Parity is initialized when the LTSSM is in Recovery.Speed.
- Parity is initialized when an SDS Ordered Set is received.
- Parity is updated with each bit of a Data Block's payload before de-scrambling has been performed.
- Thus, in Flit Mode, Parity is compared prior to FEC decoding.
- When a Control SKP Ordered Set is received, each Lane compares the received Data Parity bit to its calculated parity. It is strongly recommended that this check be performed for Control SKP Ordered Sets immediately following a Data Block only. If a mismatch is detected, the receiver must set the bit of the Port's Local Data Parity Mismatch Status Register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.
- When a Control SKP Ordered Set is received, each Lane compares the received First Retimer Data Parity bit to its calculated parity. It is strongly recommended that this check be performed for Control SKP Ordered Sets immediately following a Data Block only. If a mismatch is detected, the receiver must set the bit of the Port's First Retimer Data Parity Mismatch Status Register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.
- When a Control SKP Ordered Set is received, each Lane compares the received Second Retimer Data Parity bit to its calculated parity. It is strongly recommended that this check be performed for Control SKP Ordered Sets immediately following a Data Block only. If a mismatch is detected, the receiver must set the bit of the Port's Second Retimer Data Parity Mismatch Status Register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.
- When a Standard SKP Ordered Set is received immediately following a Data Block, the receiver is permitted to compare the received Data Parity bit to its calculated parity bit. However, the results of such a comparison must not affect the state of the Lane Error Status Register.
- Parity is initialized when a Control SKP Ordered Set is received. However, parity is not initialized when a Standard SKP Ordered Set is received.

See § Section 4.3.6.7 for the definition of First Retimer and Second Retimer, and for Retimer Pseudo Port requirements for parity computation and modification of the First Retimer Data Parity and Second Retimer Data Parity bits of Control SKP Ordered Sets.

IMPLEMENTATION NOTE: LFSR IN STANDARD SKP ORDERED SET §

The LFSR value is transmitted to enable trace tools to be able to function even if they need to reacquire block alignment in the midst of a bit stream. Since trace tools cannot force the link to enter Recovery, they can reacquire bit lock, if needed, and monitor for the SKP Ordered Set to obtain Block alignment and perform Lane-to-Lane de-skew. The LFSR value from the SKP Ordered Set can be loaded into its LFSR to start interpreting the bit stream. It must be noted that with a bit stream one may alias to a SKP Ordered Set on a non-Block boundary. The trace tools can validate their Block alignment by using implementation specific means such as receiving a fixed number of valid packets or Sync Headers or subsequent SKP Ordered Sets.

Table 4-52 Standard SKP Ordered Set with 128b/130b Encoding §

Symbol Number	Value	Description
0 through (4*N-1) [N can be 1 through 5]	AAh for 8.0 GT/s and 16.0 GT/s data rates 99h for 32.0 GT/s and higher data rates	SKP Symbol. Symbol 0 is the SKP Ordered Set identifier.
4*N	E1h	SKP_END Symbol Signifies the end of the SKP Ordered Set after three more Symbols.
4*N + 1	00-FFh	(i) If LTSSM state is <u>Polling.Compliance</u> : AAh (ii) Else if prior block was a Data Block: Bit[7] = Data Parity Bit[6:0] = LFSR[22:16] (iii) Else: Bit[7] = ~LFSR[22] Bit[6:0] = LFSR[22:16]
4*N + 2	00-FFh	(i) If the LTSSM state is <u>Polling.Compliance</u> : Error_Status[7:0] (ii) Else LFSR[15:8]
4*N + 3	00-FFh	(i) If the LTSSM state is <u>Polling.Compliance</u> : ~Error_Status[7:0] (ii) Else: LFSR[7:0]

The Control SKP Ordered Set is different from the Standard SKP Ordered Set in the last 4 Symbols. It is used to communicate the parity bits, as computed by each Retimer, in addition to the Data Parity bit computed by the Upstream/ Downstream Port. It may also be used for Lane Margining at a Retimer's Receiver, as described below.

Table 4-53 Control SKP Ordered Set with 128b/130b Encoding §

Symbol Number	Value	Description
0 through (4*N-1) [N can be 1 through 5]	AAh for 8.0 GT/s and 16.0 GT/s data rates 99h for 32.0 GT/s and higher data rates	SKP Symbol. Symbol 0 is the <u>SKP Ordered Set</u> identifier.
4*N	78h	SKP_END_CTL Symbol. Signifies the end of the <u>Control SKP Ordered Set</u> after three more Symbols.
4*N + 1	00-FFh	Bit 7: Data Parity Bit 6: First Retimer Data Parity Bit 5: Second Retimer Parity Bits [4:0]: Margin CRC [4:0]
4*N + 2	00-FFh	Bit 7: Margin Parity Bits [6:0]: Refer to § Section 4.2.18.1
4*N + 3	00-FFh	Bits [7:0]: Refer to § Section 4.2.18.1

The 'Margin CRC[4:0]' is computed from Bits [6:0] in Symbols 4N+2 (referred to as d[6:0] in the equations below, where d[0] is Bit 0 of Symbol 4N+2, d[1] is Bit 1 of Symbol 4N+2, ... d[6] is Bit 6 of Symbol 4N+2) and Bits [7:0] of Symbol 4N+3 (referred to as d[14:7], where d[7] is Bit 0 of Symbol 4N+3, d[8] is Bit 1 of Symbol 4N+3, .. d[14] is Bit 7 of Symbol 4N+3) as follows:

$$\text{Margin CRC}[0] = d[0] \wedge d[3] \wedge d[5] \wedge d[6] \wedge d[9] \wedge d[10] \wedge d[11] \wedge d[12] \wedge d[13]$$

$$\text{Margin CRC}[1] = d[1] \wedge d[4] \wedge d[6] \wedge d[7] \wedge d[10] \wedge d[11] \wedge d[12] \wedge d[13] \wedge d[14]$$

$$\text{Margin CRC}[2] = d[0] \wedge d[2] \wedge d[3] \wedge d[6] \wedge d[7] \wedge d[8] \wedge d[9] \wedge d[10] \wedge d[14]$$

$$\text{Margin CRC}[3] = d[1] \wedge d[3] \wedge d[4] \wedge d[7] \wedge d[8] \wedge d[9] \wedge d[10] \wedge d[11]$$

$$\text{Margin CRC}[4] = d[2] \wedge d[4] \wedge d[5] \wedge d[8] \wedge d[9] \wedge d[10] \wedge d[11] \wedge d[12]$$

'Margin Parity' is the even parity of Bits [4:0] of Symbol 4N+1, Bits [6:0] of Symbol 4N+2, and Bits [7:0] of Symbol 4N+3 (i.e., Margin Parity = Margin CRC[0] ^ Margin CRC[1] ^ Margin CRC[2] ^ Margin CRC[3] ^ Margin CRC[4] ^ d[0] ^ d[1] ^ d[2] ^ d[3] ^ d[4] ^ d[5] ^ d[6] ^ d[7] ^ d[8] ^ d[9] ^ d[10] ^ d[11] ^ d[12] ^ d[13] ^ d[14]).

'Margin Parity' only applies to 128b/130b encoding. 1b/1b Control SKP Ordered Sets do not contain a 'Margin Parity' field.

The rules for generating and checking the Margin CRC and Margin Parity are described in § Section 4.2.1.3 .

IMPLEMENTATION NOTE:

ERROR PROTECTION IN CONTROL SKP ORDERED SET §

The 21 bits in Symbol 4N+1 (Bits [4:0]), Symbol 4N+2 (Bits[7:0]) and Symbol 4N+3 (Bits[7:0]) is protected by 5 bits of CRC and one bit of parity, leaving 15 bits for information passing. The parity bit provides detection against odd number of bit-flips (e.g., 1-bit, 3-bit), whereas the CRC provides guaranteed detection of 1-bit and 2-bit flips; thus resulting in a triple bit flip detection guarantee over the 21 bits as well as guaranteed detection of burst errors of length 5. The 5-bit CRC is derived from the primitive polynomial: $x^5 + x^2 + 1$.

Since these 21 bits are not part of a TLP, repeated delivery of the same content provides delivery guarantee. This is achieved through architected registers. Downstream commands are sent from the Downstream Port, reflecting the contents of an architected register whereas the upstream status that passes the error checking is updated into a status register in the Downstream Port. Software thus has a mechanism to issue a command and wait for the status to be reflected back before issuing a new command. Thus, these 15 bits of information act as a micro-packet.

4.2.8.3 SKP Ordered Set for 1b/1b Encoding §

- Only Control SKP Ordered Sets are transmitted in 1b/1b Encoding.
- A transmitted SKP Ordered Set is 40 symbols (40B), and a received SKP Ordered Set can be 24, 32, 40, 48 or 56 symbols (24B, 32B, 40B, 48B or 56B).
- The transmitted SKP Ordered Set consists of the SKPs (**F00F_F00F**), followed by a SKP_END (**FFF0_00F0**), followed by PHY Payload (8B), as shown in § Table 4-54.
- The PHY Payload field of the 1b/1b SKP Ordered Set is illustrated in § Table 4-55, § Figure 4-58, § Figure 4-59, and § Figure 4-60.
- The Payload Type and Parity fields are replicated four times, spaced more than 16 bits apart.
 - The Receiver can implement a majority voting to correct these fields if three or more sets match. If two sets of value are 0b and two sets are 1b, there is a tie. A tie in the parity can be considered to mismatch. A tie in the Payload Type results in ignoring the PHY payload field.
- The Payload field is replicated twice.
- For Margin payload with its own CRC, the Receiver can choose whichever copy passes CRC (and if both pass CRC, can perform a comparison before acting on it).

The Data Parity bit is the even parity of the payload of all Data Blocks communicated by a Lane and is computed for each Lane independently. Upstream and Downstream Port Transmitters compute the parity as follows:

- Parity is initialized when the LTSSM is in Recovery.Speed.
- Parity is initialized when an SDS Ordered Set is transmitted.
- Parity is initialized after a SKP Ordered Set is transmitted.
- Parity is updated with each bit of a Data Block's payload after scrambling has been performed. Thus, gray coding and precoding, if any, does not affect the Parity calculation and Parity is computed post FEC.
- The Data Parity bit of a SKP Ordered Set transmitted immediately following a Data Block is set to the current parity.

- The Data Parity, First Retimer Data Parity, and Second Retimer Data Parity bits of a SKP Ordered Set are all set to the current parity.

Upstream and Downstream Port Receivers compute and act on the parity as follows:

- Parity is initialized when the LTSSM is in Recovery.Speed.
- Parity is initialized when an SDS Ordered Set is received.
- Parity is updated with each bit of a Data Block's payload before de-scrambling has been performed. Thus, this is performed after gray coding and precoding, if any, by the Receiver and Parity is compared pre FEC.
- When a SKP Ordered Set is received, each Lane compares the received Data Parity bit to its calculated parity. It is strongly recommended that this check be performed for Control SKP Ordered Sets immediately following a Data Block only. If a mismatch is detected, the receiver must set the bit of the Port's Local Data Parity Mismatch Status Register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.
- When a SKP Ordered Set is received, each Lane compares the received First Retimer Data Parity bit to its calculated parity. It is strongly recommended that this check be performed for Control SKP Ordered Sets immediately following a Data Block only. If a mismatch is detected, the receiver must set the bit of the Port's First Retimer Data Parity Mismatch Status Register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.
- When a SKP Ordered Set is received, each Lane compares the received Second Retimer Data Parity bit to its calculated parity. It is strongly recommended that this check be performed for Control SKP Ordered Sets immediately following a Data Block only. If a mismatch is detected, the receiver must set the bit of the Port's Second Retimer Data Parity Mismatch Status Register that corresponds to the Lane's default Lane number. The mismatch is not a Receiver Error and must not cause a Link retrain.
- Parity is initialized when a SKP Ordered Set is received. See § Section 4.3.6.7 for the definition of First Retimer and Second Retimer, and for Retimer Pseudo Port requirements for parity computation and modification of the First Retimer Data Parity and Second Retimer Data Parity bits of Control SKP Ordered Sets.

Table 4-54 Control SKP Ordered Set with 1b/1b Encoding §

Symbol Number	Value	Description
0, 4, 8, 12, 16, 20	F0h	SKP Symbol
1, 5, 9, 13, 17, 21	0Fh	
2, 6, 10, 14, 18, 22	F0h	
3, 7, 11, 15, 19, 23	0Fh	
24, 28	FFh	SKP_END
25, 29	F0h	
26, 30	00h	
27, 31	F0h	
32	F0h if TS0 Ordered Sets are being transmitted, as defined in § Section 4.2.7.4.2, else Phy Payload[7:0] See § Table 4-55, § Figure 4-58, § Figure 4-59, and § Figure 4-60.	PHY Payload

Symbol Number	Value	Description

Table 4-55 PHY Payload for Control SKP Ordered Set with 1b/1b Encoding §

Field	Bit Position(s) (Replicated Bit Position(s))	Description
Phy Payload Type	0 (20) (40) (60)	<p>If the LTSSM state is <u>Polling.Compliance</u>: this bit is Set to 1b</p> <p>Else: 0b Margin Payload 1b LFSR</p> <p>See § Section 4.2.8.4 for Phy Payload Type field usage.</p>
Port Parity	1 (21) (41) (61)	<p>If the LTSSM state is <u>Polling.Compliance</u>: this bit is Set to 1b</p> <p>Else: even parity of all the bits in the Data Blocks on that Lane from the last SKP Ordered Set</p>
Retimer 1 Parity	2 (22) (42) (62)	<p>If the LTSSM state is <u>Polling.Compliance</u>: this bit is Set to 1b</p> <p>Else: Port sets this bit with Port Parity; First Retimer, if present, overwrites with its own calculated even parity of all the bits in the Data Blocks on that Lane from the last SKP ordered Set</p>
Retimer 2 Parity	3 (23) (43) (63)	<p>If the LTSSM state is <u>Polling.Compliance</u>: this bit is Set to 1b</p> <p>Else: Port sets this bit with Port Parity; Second Retimer, if present, overwrites with its own calculated even parity of all the bits in the Data Blocks on that Lane from the last SKP Ordered Set</p>
Payload [23:0]	{31:24, 19:4} {59:44, 39:32}	<p>If the LTSSM state is <u>Polling.Compliance</u>: { Error_Status[7:0], ~Error_Status[7], Error_Status[6], ~Error_Status[5], Error_Status[4], ~Error_Status[3], Error_Status[2], ~Error_Status[1], Error_Status[0], 22h }</p> <p>Else If PHY Payload Type == 0b Margin: { Margin Payload[7:0], Usage Model, Margin Type[2:0], Receiver Number[2:0], Margin CRC[4:0], Reserved[3:0] }</p> <p>Else: { Even Parity of LFSR[22:0], LFSR[22:0] }</p> <p>All of these are in little-endian format. Thus, for example, the 8 bits of Margin Payload occupies bits 31:24 and 59:52</p>

4.2.8.4 Rules for Transmitters §

- All Lanes shall transmit Symbols at the same frequency (the difference between bit rates is 0 ppm within all multi-Lane Links).
- When transmitted, all Lanes of a multi-Lane Link must simultaneously transmit SKP Ordered Sets of the same length and type (Control or Standard), except as allowed for a Loopback Follower in the Loopback.Active LTSSM State (see § Section 4.2.5.11 and § Table 8-7 for the definition of simultaneous in this context).
- The transmitted SKP Ordered Set when using 8b/10b encoding must follow the definition in § Section 4.2.8.1.

- The transmitted SKP Ordered Set when using 128b/130b encoding must follow the definition in § Section 4.2.8.2.
- The transmitted SKP Ordered Set when using 1b/1b-encoding must follow the definition in § Section 4.2.8.3.
- When using 8b/10b encoding:
 - If the Link is not operating in SRIS, or the bit corresponding to the current Link speed is Set in the Enable Lower SKP OS Generation Vector field and the LTSSM is in L0, a SKP Ordered Set must be scheduled for transmission at an interval between 1180 and 1538 Symbol Times.
 - If the Link is operating in SRIS and either the bit corresponding to the current Link speed is Clear in the Enable Lower SKP OS Generation Vector field or the LTSSM is not in L0, a SKP Ordered Set must be scheduled for transmission at an interval of less than 154 Symbol Times.
- When using 128b/130b encoding:
 - If the Link is not operating in SRIS, or the bit corresponding to the current Link speed is Set in the Enable Lower SKP OS Generation Vector field and the LTSSM is in L0, a SKP Ordered Set must be scheduled for transmission at an interval between 370 and 375 Blocks, in Non-Flit Mode or while not sending Data Stream in Flit Mode. Loopback Followers must meet this requirement until they start looping back the incoming bit stream.
 - If the Link is operating in SRIS and either the bit corresponding to the current Link speed is Clear in the Enable Lower SKP OS Generation Vector field or the LTSSM is not in L0, a SKP Ordered Set must be scheduled for transmission at an interval less than 38 Blocks, in Non-Flit Mode or while not sending Data Stream in Flit Mode. Loopback Followers must meet this requirement until they start looping back the incoming bit stream.
 - When the LTSSM is in the Loopback state and the Link is not operating in SRIS, the Loopback Lead must schedule two SKP Ordered Sets to be transmitted, at most two Blocks apart from each other, at an interval between 370 to 375 blocks. For 32.0 GT/s, the Loopback Lead is permitted to have an EIEOSQ between the two SKP Ordered Sets.
 - When the LTSSM is in the Loopback state and the Link is operating in SRIS, the Loopback Lead must schedule two SKP Ordered Sets to be transmitted, at most two Blocks apart from each other, at an interval of less than 38 Blocks. For 32.0 GT/s, the Loopback Lead is permitted to have an EIEOSQ between the two SKP Ordered Sets.
 - When operating in Flit Mode during a Data Stream or just prior to transitioning to transmitting the Data Stream, SKP Ordered Set transmission rules as specified in § Section 4.2.3.1.5.
 - The Control SKP Ordered Set is transmitted only at the following times:
 - In Non-Flit Mode when the data rate is 16.0 or 32.0 GT/s and in Flit Mode when the data rate is 8.0, 16.0, or 32.0 GT/s and one of the following conditions is met:
 - A Data Stream is being transmitted.
SKP Ordered Sets transmitted within a Data Stream must alternate between the Standard SKP Ordered Set and the Control SKP Ordered Set except for when undergoing an L0p upsize. In L0p when an inactive Lane is transitioning to active the Link must send a Control SKP Ordered Set on all Lanes prior to transmitting the Data Stream on the transitioning Lanes. During an L0p upsize, active lanes are permitted to transmit Control SKP Ordered Sets instead of Standard SKP Ordered Sets to reduce the latency of the that L0p upsize.
 - The LTSSM enters the Configuration.Idle state or Recovery.Idle state.
 See § Section 4.2.7.3.6 and § Section 4.2.7.4.5 for more information. Transmission of this instance of the Control SKP Ordered Set is not subject to any minimum scheduling interval requirements described above. Transmitters are permitted,

but not required, to reset their SKP Ordered Set scheduling interval timer after transmitting this instance of the Control SKP Ordered Set.

- The first SKP Ordered Set is being sent after an L0p upsizing.

A Control SKP Ordered Set must be transmitted on all Lanes - the Lanes that are active and the Lanes that are being activated.

- When using 1b/1b encoding: only Control SKP Ordered Sets are sent. The following rules must be followed, except when transmitting Compliance Modified Compliance patterns:
 - If the Link is not operating in SRIS, or the bit corresponding to the current Link speed is Set in the Enable Lower SKP OS Generation Vector field and the LTSSM is in L0, a SKP Ordered Set must be scheduled for transmission at an interval of 740 to 750 Blocks from the prior SKP Ordered Set, while a Data Stream is not in progress. Loopback Followers must meet this requirement until they start looping back the incoming bit stream.
 - Behavior is undefined if the Enable Lower SKP OS Generation Vector field setting is changed in FM at a data rate other than 2.5 GT/s.
 - If the Link is operating in SRIS and either the bit corresponding to the current Link speed is Clear in the Enable Lower SKP OS Generation Vector field or the LTSSM is not in L0, a SKP Ordered Set must be scheduled for transmission at an interval of less than 76 Blocks, while a Data Stream is not in progress. Loopback Followers must meet this requirement until they start looping back the incoming bit stream.
 - When the LTSSM is in the Loopback state and the Link is not operating in SRIS, the Loopback Lead must schedule two back-to-back SKP Ordered Sets to be transmitted. The SKP Ordered Sets must be sent, at an interval of 740 to 750 blocks from the prior SKP Ordered Set when not in a Data Stream.
 - When the LTSSM is in the Loopback state and the Link is operating in SRIS, the Loopback Lead must schedule two back-to-back SKP Ordered Sets to be transmitted. The SKP Ordered Sets must be sent at an interval of less than 76 Blocks, when not in a Data Stream.
 - During the Data Stream, just prior to transitioning to transmitting the Data Stream, or immediately after terminating the Data Stream, SKP Ordered Set transmission rules must be followed as specified in § Section 4.2.3.1.5.
 - Phy Payload Type must be set as follows:
 - If the LTSSM state is Polling.Compliance: 1b.
 - Else: For Lane 0, alternate between 0b and 1b in consecutive Control SKP OS, with any starting value after an exit from electrical idle. Any other Lane must send the same value as Lane 0. Receivers must not depend on this alternation.
- Scheduled SKP Ordered Sets shall be transmitted if a packet or Ordered Set is not already in progress, otherwise they are accumulated and then inserted consecutively at the next packet or Ordered Set boundary. Note: When using 128b/130b or 1b/1b encoding, SKP Ordered Sets cannot be transmitted in consecutive Blocks within a Data Stream. See § Section 4.2.2.3.2 for more information.
- SKP Ordered Sets do not count as an interruption when monitoring for consecutive Symbols or Ordered Sets (e.g., eight consecutive TS1 Ordered Sets in Polling.Active).
- When using 8b/10b encoding: SKP Ordered Sets must not be transmitted while the Compliance Pattern or the Modified Compliance Pattern (see § Section 4.2.9) is in progress during Polling.Compliance if the Compliance SOS bit of the Link Control 2 register is 0b. If the Compliance SOS bit of the Link Control 2 register is 1b, two consecutive SKP Ordered Sets must be sent (instead of one) for every scheduled SKP Ordered Set time interval while the Compliance Pattern or the Modified Compliance Pattern is in progress when using 8b/10b encoding.

- When using 128b/130b or 1b/1b encoding: The Compliance SOS register bit has no effect. While in Polling.Compliance, Transmitters must not transmit any SKP Ordered Sets other than those specified as part of the Modified Compliance Pattern in § Section 4.2.12 .
- Any and all time spent in a state when the Transmitter is electrically idle does not count in the scheduling interval used to schedule the transmission of SKP Ordered Sets.
- It is recommended that any counter(s) or other mechanisms used to schedule SKP Ordered Sets be reset any time when the Transmitter is electrically idle.

4.2.8.5 Rules for Receivers §

- Receivers shall recognize received SKP Ordered Sets as defined in § Section 4.2.8.1 when using 8b/10b encoding, as defined in § Section 4.2.8.2 when using 128b/130b encoding, and as defined in § Section 4.2.8.3 when using the 1b/1b encoding.
 - The length of the received SKP Ordered Sets shall not vary from Lane-to-Lane in a multi-Lane Link, except as may occur during Loopback.Active.
- Receivers must be tolerant to receive and process SKP Ordered Sets sent by a transmitter, as defined by the appropriate rules in § Section 4.2.4.1 , § Section 4.2.8.1 , § Section 4.2.8.2 , and § Section 4.2.8.3
 - Note: Since Transmitters in electrical idle are not required to reset their mechanism for time-based scheduling of SKP Ordered Sets, Receivers shall be tolerant to receive the first time-scheduled SKP Ordered Set following electrical idle in less than the average time interval between SKP Ordered Sets.
- For 8.0, 16.0, and 32.0 GT/s data rates, in L0 state, Receivers must check that each SKP Ordered Set is preceded by a Data Block with an EDS token.
- Receivers shall be tolerant to receive and process consecutive SKP Ordered Sets in 2.5 GT/s and 5.0 GT/s data rates.
 - Receivers shall be tolerant to receive and process SKP Ordered Sets that have a maximum separation dependent on the largest Rx_MPS_Limit a component supports. For 2.5 GT/s and 5.0 GT/s data rates, the formula for the maximum number of Symbols (N) between SKP Ordered Sets is:

$$N = 1538 + \text{Rx_MPS_Limit (in bytes)} + 28.$$
 For example, if Rx_MPS_Limit is 4096 bytes, $N = 1538 + 4096 + 28 = 5662$.
- When using 1b/1b encoding, each Receiver is permitted to insert or delete 8 Bytes of SKP at an aligned 8 byte boundary. Thus, a received SKP Ordered Set can be 24, 32, 40, 48 or 56 bytes.

IMPLEMENTATION NOTE:

SKP ORDERED SETS IN A DATA STREAM IN FLIT MODE §

- For 1b/1b, Receivers can predict when SKP OS will occur.
- For 128b/130b, Receivers can predict when SKP OS will occur. This is needed since the EDS Token is not used in Flit Mode.
- For 8b/10b, Receivers need to look for COM SKP. SKP OS will occur at a period specified in [§ Section 4.2.8.4](#).

When upconfiguring Lanes in [L0p](#):

- For 8b/10b, there is no CTL SKP OS but there also is no retimer parity bits that need to be initialized.
- For 128b/130b, the CTL SKP OS is needed to restart the parity computations
- For 1b/1b, CTL SKP OS are always sent to restart the parity computations. Identical values in Phy Payload type are required for simplicity (see [Section 4.2.8.4](#))

4.2.9 Compliance Pattern in 8b/10b Encoding §

During Polling, the Polling.Compliance substate must be entered from Polling.Active based on the conditions described in [§ Section 4.2.7.2.1](#). The compliance pattern consists of the sequence of 8b/10b Symbols [K28.5](#), [D21.5](#), [K28.5](#), and [D10.2](#) repeating. The Compliance sequence is as follows:

Symbol	K28.5	D21.5	K28.5	D10.2
Current Disparity	Negative	Positive	Positive	Negative
Pattern	0011111010	1010101010	1100000101	0101010101

The first Compliance sequence Symbol must have negative disparity. It is permitted to create a disparity error to align the running disparity to the negative disparity of the first Compliance sequence Symbol.

For any given device that has multiple Lanes, every eighth Lane is delayed by a total of four Symbols. A two Symbol delay occurs at both the beginning and end of the four Symbol Compliance Pattern sequence. A x1 device, or a xN device operating a Link in x1 mode, is permitted to include the Delay Symbols with the Compliance Pattern.

This delay sequence on every eighth Lane is then:

Symbol:	D	D	K28.5	D21.5	K28.5	D10.2	D	D

Where D is a [K28.5](#) Symbol. The first D Symbol has negative disparity to align the delay disparity with the disparity of the Compliance sequence.

After the eight Symbols are sent, the delay Symbols are advanced to the next Lane, until the delay Symbols have been sent on all eight lanes. Then the delay Symbols cycle back to Lane 0, and the process is repeated. It is permitted to advance the delay sequence across all eight lanes, regardless of the number of lanes detected or supported. An illustration of this process is shown below:

Lane 0	D	D	K28.5-	D21.5	K28.5+	D10.2	D	D	K28.5-	D21.5	K28.5+	D10.2

Lane 1	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	D	D	<u>K28.5-</u>	D21.5
Lane 2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2
Lane 3	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2
Lane 4	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2
Lane 5	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2

Lane 9	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	<u>K28.5-</u>	D21.5	<u>K28.5+</u>	D10.2	D	D	<u>K28.5-</u>	D21.5
Key:	<u>K28.5-</u>	COM when disparity is negative, specifically: “0011111010”										
	<u>K28.5+</u>	COM when disparity is positive, specifically: “1100000101”										
	D21.5	Out of phase data Symbol, specifically: “1010101010”										
	D10.2	Out of phase data Symbol, specifically: “0101010101”										
	D	Delay Symbol K28.5 (with appropriate disparity)										

This sequence of delays ensures interference between adjacent Lanes, enabling measurement of the compliance pattern under close to worst-case Inter-Symbol Interference and cross-talk conditions.

4.2.10 Modified Compliance Pattern in 8b/10b Encoding §

The Modified Compliance Pattern consists of the same basic Compliance Pattern sequence (see § Section 4.2.9) with one change. Two identical error status Symbols followed by two K28.5 are appended to the basic Compliance sequence of 8b/10b Symbols (K28.5, D21.5, K28.5, and D10.2) to form the Modified Compliance Sequence of (K28.5, D21.5, K28.5, D10.2, error status Symbol, error status Symbol, K28.5, K28.5). The first Modified Compliance Sequence Symbol must have negative disparity. It is permitted to create a disparity error to align the running disparity to the negative disparity of the first Modified Compliance Sequence Symbol. For any given device that has multiple Lanes, every eighth Lane is moved by a total of eight Symbols. Four Symbols of K28.5 occurs at the beginning and another four Symbols of K28.7 occurs at the end of the eight Symbol Modified Compliance Pattern sequence. The first D Symbol has negative disparity to align the delay disparity with the disparity of the Modified Compliance Sequence. After the 16 Symbols are sent, the delay Symbols are advanced to the next Lane, until the delay Symbols have been sent on all eight lanes. Then the delay Symbols cycle back to Lane 0, and the process is repeated. It is permitted to advance the delay sequence across all eight lanes, regardless of the number of lanes detected or supported. A x1 device, or a xN device operating a Link in x1 mode, is permitted to include the Delay symbols with the Modified Compliance Pattern.

An illustration of the Modified Compliance Pattern is shown in § Table 4-59. Note: This table was “wrapped” to allow it to fit on the page.

<i>prev row</i> →										

The reason two identical error Symbols are inserted instead of one is to ensure disparity of the 8b/10b sequence is not impacted by the addition of the error status Symbol.

All other Compliance Pattern rules are identical (i.e., the rules for adding delay Symbols) so as to preserve all the crosstalk characteristics of the Compliance Pattern.

The error status Symbol is an 8b/10b data Symbol, maintained on a per-Lane basis, and defined in 8-bit domain in the following way:

- Receiver Error Count (Bits 6:0) - Incremented on every Receiver error after the Pattern Lock bit becomes asserted.
- Pattern Lock (Bit 7) - Asserted when the Lane locks to the incoming Modified Compliance Pattern.

4.2.11 Compliance Pattern in 128b/130b Encoding §

The compliance pattern consists of the following repeating sequence of 36 or 37 Blocks:

1. One block with a Sync Header of 01b followed by a 128-bit unscrambled payload of 64 1's followed by 64 0's
2. One block with a Sync Header of 01b followed by a 128-bit unscrambled payload of the following:

	Lane No modulo 8 = 0	Lane No modulo 8 = 1	Lane No modulo 8 = 2	Lane No modulo 8 = 3	Lane No modulo 8 = 4	Lane No modulo 8 = 5	Lane No modulo 8 = 6	Lane No modulo 8 = 7
Symbol 0	55h	FFh	FFh	FFh	55h	FFh	FFh	FFh
Symbol 1	55h	FFh	FFh	FFh	55h	FFh	FFh	FFh

Symbol 13	FFh	FFh	FFh	55h	FFh	FFh	FFh	55h
Symbol 14	FFh	FFh	FFh	55h	FFh	FFh	FFh	55h
Symbol 15	FFh	FFh	FFh	55h	FFh	FFh	FFh	55h
Key:	P Indicates the 4-bit encoding of the Transmitter preset being used. ~P Indicates the bit-wise inverse of P.							

4. One EIEOSQ
5. 32 Data Blocks, each with a payload of 16 Idle data Symbols (00h) scrambled

IMPLEMENTATION NOTE: FIRST TWO BLOCKS OF THE COMPLIANCE PATTERN §

The first block is a very low frequency pattern to help with measurement of the preset settings. The second block is to notify the Lane number and preset encoding the compliance pattern is using along with ensuring the entire compliance pattern is DC Balanced.

The payload in each Data Block is the output of the scrambler in that Lane (i.e., input data is 0b). The Lane numbers used to determine the scrambling LFSR seed value depend on how Polling.Compliance is entered. (See § Section 4.2.2.4 for more on assigning Lane numbers and other Scrambler requirements.) The Data Blocks of the compliance pattern do not form a Data Stream and hence are exempt from the requirement of transmitting an SDS Ordered Set or EDS Token during Ordered Set Block to Data Block transition and vice-versa.

IMPLEMENTATION NOTE: ORDERED SETS IN COMPLIANCE AND MODIFIED COMPLIANCE PATTERNS IN 128B/130B ENCODING §

The various Ordered Sets (e.g., EIEOS and SKP OS) follow the Ordered Set definition corresponding to the current Data Rate of operation. For example, at 32.0 GT/s Data Rate, the EIEOS is the 32.0 GT/s EIEOS; at 16.0 GT/s Data Rate, the EIEOS is the 16.0 GT/s EIEOS; whereas at 8.0 GT/s Data Rate, the EIEOS is the 8.0 GT/s EIEOS defined earlier. As defined in § Section 4.2.8, the SKP Ordered Set is the Standard SKP Ordered Set.

4.2.12 Modified Compliance Pattern in 128b/130b Encoding §

The modified compliance pattern, when not operating in SRIS, consists of repeating the following sequence of 65792 or 65793 Blocks:

1. One EIEOSQ
2. 256 Data Blocks, each with a payload of 16 Idle data Symbols (00h), scrambled
3. 255 sets of the following sequence:
 - i. One SKP Ordered Set
 - ii. 256 Data Blocks, each with a payload of 16 Idle data Symbols (00h), scrambled

The modified compliance pattern, when operating in SRIS, consists of repeating the following sequence of 67585 or 67586 Blocks:

1. One EIEOSQ
2. 2048 sets of the following sequence:
 - i. One SKP Ordered Set
 - ii. 32 Data Blocks, each with a payload of 16 Idle data Symbols (00h), scrambled

The payload in each Data Block is the output of the scrambler in that Lane (i.e., input data is 0b). The Lane numbers used to determine the scrambling LFSR seed value depend on how Polling.Compliance is entered. (See § Section 4.2.2.4 for more on assigning Lane numbers.) The Data Blocks of the modified compliance pattern do not form a Data Stream and hence are exempt from the requirement of transmitting an SDS Ordered Set or EDS Token during Ordered Set Block to Data Block transition and vice-versa.

4.2.13 Jitter Measurement Pattern in 128b/130b §

The jitter measurement pattern consists of repeating the following Block:

- Sync Header of 01b followed by a 128-bit unscrambled payload of 16 Symbols of 55h

This generates a pattern of alternating 1s and 0s for measuring the transmitter's jitter.

4.2.14 Compliance Pattern in 1b/1b Encoding §

The Compliance Pattern consists of the following repeating sequence of 137 Blocks. Gray-coding and precoding are not performed during the compliance pattern.

1. One block, unscrambled: 64 UIs of 11b each (voltage level 3 throughout)
2. One block, unscrambled: 64 UIs of 00b each (voltage level 0 throughout)
3. Two unscrambled blocks of Toggle Pattern (Ch repeated 32 times for each block)
4. Two blocks with an unscrambled payload of the following: This is in hex format starting with the most significant Symbol. For example, in Lane 1, Block 5 (38_DA_CC_C4_E2_3F_1D_35_3B_25_63_CC_B2_CC_FF_FF), Symbol 0 is FFh and Symbol 15 is 38. Note that these are inserted for establishing DC balance.

Lane 0, 8:

Block 5: FF_FF_FF_FF_FF_FF_FF_FF_FF_FF_FF_FF_FF_FF_FF_FF

Block 6: 5F_26_CC_65_C2_3B_C5_3F_FF_FF_FF_FF_FF_FF_FF_FF_FF

Lane 1, 9:

Block 5: 38_DA_CC_C4_E2_3F_1D_35_3B_25_63_CC_B2_CC_FF_FF

Block 6: B1_CB_0D_33_C5_D4_EC_32_A2_AC_CC_53_DC_C6_38_B4

Lane 2, 10:

Lane 6, 14:

Block 5: 00_00_00_00_00_00_00_00_00_00_00_00_00_00_00

Block 6: 63_6B_31_37_20_00_00_00_00_00_00_00_00_00_00

Lane 7, 15:

Block 5: D9_C3_33_CC_A0_D3_DC_FF_FF_FF_FF_FF_FF_FF_FF_FF

Block 6: 5D_2D_CD_0E_C3_23_E1_F0_8F_1D_32_8E_B3_31_39_C2

5. One EIEOSQ (unscrambled) – this resets the scrambler
6. 64 Blocks, each comprising of 16 Symbols of 00h scrambled.
7. One block, unscrambled: 64 UIs of 10b each (voltage level 2 throughout). The scrambler does not advance.
8. One block, unscrambled: 64 UIs of 01b each (voltage level 1 throughout). The scrambler does not advance.
9. 64 Blocks, each comprising of 16 Symbols of 00h scrambled.

The payload in each scrambled Block is the output of the scrambler in that Lane (i.e., input data is 0b), which are then gray-coded, and precoded, if performed, as shown in § Figure 4-22. The Lane numbers used to determine the scrambling LFSR seed value depend on how `Polling.Compliance` is entered. (See § Section 4.2.2.4 for more on assigning Lane numbers and other Scrambler requirements.) The scrambled Blocks of the compliance pattern do not form a Data Stream and hence are exempt from the requirement of transmitting an SDS Ordered Set or the FEC / CRC / Flit formation requirements.

4.2.15 Modified Compliance Pattern in 1b/1b Encoding §

The modified compliance pattern, when not operating in SRIS, consists of repeating the following sequence of 65792 Blocks:

1. One EIEOSQ (that resets the scrambler)
2. 256 Blocks, each comprising of 16 Symbols of 00h scrambled
3. 255 sets of the following sequence:
 - a. One SKP Ordered Set
 - b. 256 Data Blocks, each comprising of 16 Symbols of 00h scrambled

The modified compliance pattern, when operating in SRIS, consists of repeating the following sequence of 67585 Blocks:

1. One EIEOSQ (that resets the scrambler)
2. 2048 sets of the following sequence:
 - a. One SKP Ordered Set
 - b. 32 Blocks, each comprising of 16 Symbols of 00h scrambled

The payload in each scrambled Block is the output of the scrambler in that Lane (i.e., input data is 0b), which are then gray-coded, and precoded, if performed, as shown in § Figure 4-22. The Lane numbers used to determine the scrambling LFSR seed value depend on how `Polling.Compliance` is entered. (See § Section 4.2.2.4 for more on assigning Lane numbers.) The scrambled Blocks of the modified compliance pattern do not form a Data Stream and hence are exempt from the requirement of transmitting an SDS Ordered Set or the FEC / CRC / Flit formation requirements.

4.2.16 Jitter Measurement Pattern in 1b/1b Encoding §

The jitter measurement pattern consists of repeating the following 52 UI, consisting of the following 4 sets of 13 UI each:

```
{ 00b, 01b, 00b, 11b, 00b, 10b, 01b, 10b, 11b, 01b, 11b, 10b, 10b,
  00b, 01b, 00b, 11b, 00b, 10b, 01b, 10b, 11b, 01b, 11b, 10b, 00b,
  00b, 01b, 00b, 11b, 00b, 10b, 01b, 10b, 11b, 01b, 11b, 10b,
  00b, 01b, 00b, 11b, 00b, 10b, 01b, 10b, 11b, 01b, 11b, 10b }
```

IMPLEMENTATION NOTE:

JITTER PATTERN RATIONALE §

The base pattern used above for voltage levels is: { 0, 1, 0, 3, 0, 2, 1, 2, 3, 1, 3, 2 }. This pattern, when repeated, covers all 12 voltage level transitions while being fully DC balanced and using the minimum number of UI.

However, for implementations that use interleaved bit streams, this 12 UI base pattern may not test all the circuits during all the transitions. To address this, a 13th UI is introduced to ensure coverage even with interleaved bitstreams (13 is a prime number). This insertion is done by keeping the same set of transitions and cycling across the 4 sets of values over 52 UI, as shown above. Thus:

- Voltage level 2 (10b) is repeated in the 12th and 13th UI of the first row;
- voltage level 0 (00b) is repeated in the 13th UI of the second row and the 1st UI of the third row;
- voltage level 3 (11b) is repeated in the 11th and 12th UI of the third row; and
- voltage level 1 (01b) is repeated in the 10th and 11th UI of the last row.

Across these 52 UI, DC balance is maintained and the DC imbalance between the rows has been minimized by the choice of the sequence of the repeated voltage level.

4.2.17 Toggle Patterns in 1b/1b encoding §

Two types of Toggle Patterns are defined for the best single edge jitter measurement accuracy:

High Swing Toggle Pattern

This comprises of alternating UIs between 00b and 11b (i.e., back to back symbols of 33h unscrambled, effectively alternating between voltage levels 0 and 3 in successive UIs).

Low Swing Toggle Pattern

This comprises of alternating UIs between 01b and 10b (i.e., back to back symbols of 66h unscrambled, effectively alternating between voltage levels 1 and 2 in successive UIs).

4.2.18 Lane Margining at Receiver §

Lane Margining at Receiver, as defined in this section, is mandatory for all Ports supporting a data rate of 16.0 GT/s or higher, including Pseudo Ports (Retimers). Lane Margining at Receiver enables system software to obtain the margin information of a given Receiver while the Link is in the L0 state. The margin information includes both voltage and time, in either direction from the current Receiver position. For all Ports that implement Lane Margining at Receiver, Lane Margining at Receiver for timing is required, while support of Lane Margining at Receiver for voltage is optional at 16.0 GT/s and required at 32.0 GT/s and higher data rates.

Lane Margining at Receiver begins when a Margin Command is received, the Link is operating at 16.0 GT/s Data Rate or higher, and the Link is in L0 state. Lane Margining at Receiver ends when either a Go to Normal Settings command is received, the Link changes speed, or the Link exits either the L0 or Recovery states. Lane Margining at Receiver optionally ends when certain error thresholds are exceeded. Lane Margining at Receiver is permitted to be suspended while the Link is in Recovery for independent samplers.

Lane Margining at Receiver is not supported by Links operating at 2.5 GT/s, 5.0 GT/s, or 8.0 GT/s.

Software uses the per-Lane Margining Lane Control Register and Margining Lane Status Register in each Port (Downstream or Upstream) for sending Margin Commands and obtaining margin status information for the corresponding Receiver associated with the Port. For the Retimers, the commands to get information about the Receiver's capabilities and status and the commands to margin the Receiver are conveyed in the Control SKP Ordered Sets in the Downstream direction. The status and error reporting of the target Retimer Receiver is conveyed in the Control SKP Ordered Sets in the Upstream direction. Software controls margining in the Receiver of a Retimer by writing to the appropriate bits in the Margining Lane Control Register in the Downstream Port. The Downstream Port also updates the status information conveyed by the Retimer(s) in the Link through the Control SKP Ordered Set into its Margining Lane Status Register.

4.2.18.1 Receiver Number, Margin Type, Usage Model, and Margin Payload Fields §

The contents of the four command fields of the Margining Lane Control Register in the Downstream Port are always reflected in the identical fields in the Downstream Control SKP Ordered Sets. The contents of the Upstream Control SKP Ordered Set received in the Downstream Port is always reflected in the corresponding status fields of the Margining Lane Status Register in the Downstream Port. The following table provides the bit placement of these fields in the Control SKP Ordered Set.

Table 4-62 Margin Command Related Fields in the Control SKP Ordered Set §

Symbol	Description	
	Usage Model = 0b	Usage Model = 1b
4*N + 2	Bit 7: <u>Margin Parity</u> (see § Table 4-53)	Reserved
	Bit 6: Usage Model = 0b: Lane Margining at Receiver	
	Bits [5:3]: Margin Type	
	Bits [2:0]: Receiver Number	
4*N + 3	Bits [7:0]: Margin Payload	Reserved

Usage Model: An encoding of 0b indicates that the usage model is Lane Margining at Receiver. An encoding of 1b in this field is reserved for future usages.

If the Usage Model field is 1b, Bits [5:0] of Symbol 4N+2 and Bits [7:0] of Symbol 4N+3 are Reserved.

When evaluating received Control SKP Ordered Set for Margin Commands, all Receivers that do not comprehend the usage associated with Usage Model = 1b are required to ignore Bits[5:0] of Symbol 4N+2 and Bits[7:0] of Symbol 4N+3 of the Control SKP Ordered Set, if the Usage Model field is 1b.

IMPLEMENTATION NOTE: POTENTIAL FUTURE USAGE OF CONTROL SKP ORDERED SET §

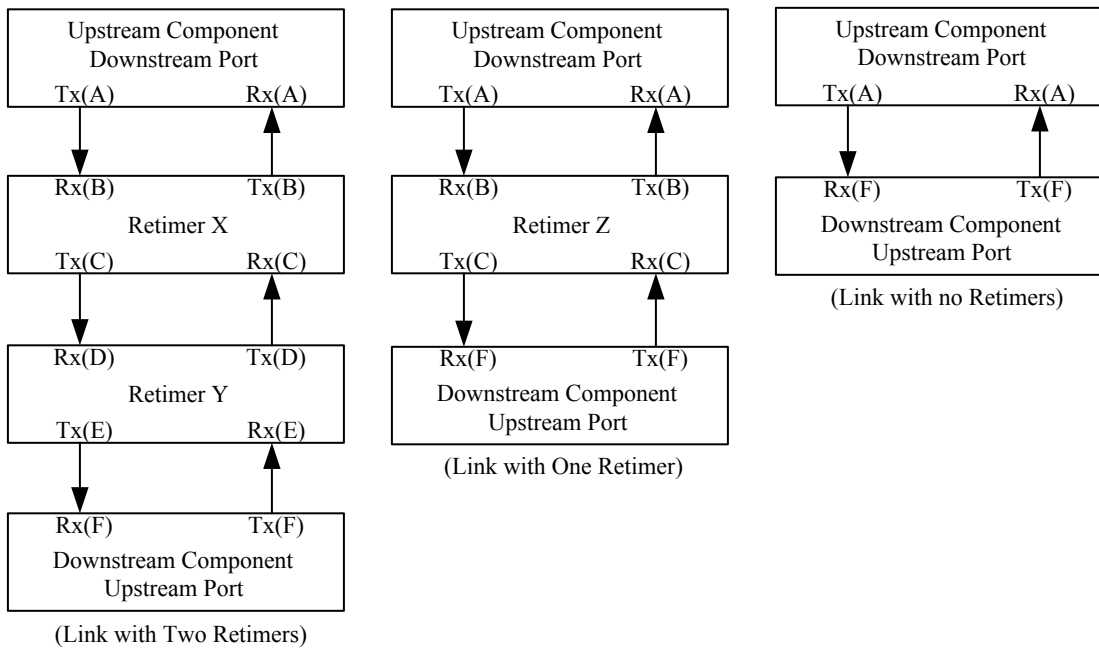

The intended usage for the 15 bits of information in the Control SKP Ordered Set, as defined in § Table 4-62 is Lane Margining at Receiver. However a single bit (Bit 7 of Symbol 4N+2) is Reserved for any future usage beyond Lane Margining at Receiver. If such a usage is defined in the future, this bit will be set to 1b and the remaining 14 bits can be defined as needed by the new usage model. Alternatively, Symbol 4N could use a different encoding than 78h for any future usage, permitting all bits in Symbols 4N+1, 4N+2, and 4N+3 to be defined for that usage model.

Receiver Number: Receivers are identified in § Figure 4-61. The following Receiver Number encodings are used in the Downstream Port for Margin Commands targeting that Downstream Port or a Retimer below that Downstream Port:

- 000b**
Broadcast (Downstream Port Receiver and all Retimer Pseudo Port Receivers)
- 001b**
Rx(A) (Downstream Port Receiver)
- 010b**
Rx(B) (Retimer X or Z Upstream Pseudo Port Receiver)
- 011b**
Rx(C) (Retimer X or Z Downstream Pseudo Port Receiver)
- 100b**
Rx(D) (Retimer Y Upstream Pseudo Port Receiver)
- 101b**
Rx(E) (Retimer Y Downstream Pseudo Port Receiver)
- 110b**
Reserved
- 111b**
Reserved

The following Receiver Number encodings are used in the Upstream Port for Margin Commands targeting that Upstream Port:

- 000b** Broadcast (Upstream Port Receiver)
- 001b** Reserved
- 010b** Reserved
- 011b** Reserved
- 100b** Reserved
- 101b** Reserved
- 110b** Rx (F) (Upstream Port Receiver)
- 111b** Reserved

(Various System Topologies with or without Retimers)

Figure 4-61 Receiver Number Assignment §

Margin Type and Margin Payload: The Margin Type field together with a valid Receiver Number(s), associated with the Margin Type encoding, and specific Margin Payload field define various commands used for margining (referred to as **Margin Command**). § Table 4-63 defines the encodings of valid Margin Commands along with the corresponding responses, used in both the Control SKP Ordered Sets as well as the Margining Lane Control Register and Margining Lane Status Register. Margin commands that are always broadcast will use the broadcast encoding for the Receiver Number, even when only one Receiver is the target (e.g., UP or a DP in a Link with no Retimers). The Receiver Number field in the response to a Margin Command other than No Command reflects the number of the Receiver that is responding, even for a Margin Command that is broadcast. The Margin Commands go Downstream whereas the responses go Upstream in the Control SKP Ordered Sets. The responses reflect the Margin Type to which the target Receiver is responding. The Receiver Number field of the response corresponds to the target Receiver that is responding. All unused encodings in § Table 4-63 are Reserved and must not be considered to be a valid Margin Command.

The parameters used here (e.g., $M_{\text{SampleCount}}$) are defined in § Section 8.4.4. Each data rate has an independent set of parameters and the values in § Table 4-63 reflect the current data rate. Any relationship between values for different data rates is implementation specific. For example, the timing/voltage step sizes might differ between 64.0 GT/s in PAM-4 mode and 16.0 GT/s or 32.0 GT/s in NRZ mode; N voltage steps at 64.0 GT/s is likely to be a different eye height from N voltage steps at 16.0 GT/s or 32.0 GT/s.

In PAM-4 mode, the Step Margin commands apply to all 3 eyes simultaneously.

Table 4-63 Margin Commands and Corresponding Responses §

Command				Response	
Margin Command	Margin Type[2:0]	Valid Receiver Number(s) [2:0]	Margin Payload[7:0]	Margin Type[2:0]	Margin Payload[7:0]
No Command	111b	000b	9Ch (No Command is also an independent command in Upstream direction. The expected Response is No Command with the Receiver Number = 000b.)		
Access Retimer Register	001b	010b, 100b	Register offset in bytes: 00h - 87h, A0h - FFh	001b	Register value, if supported. It is recommended that the Target Receiver on Retimer return 00h if it does not support accessing its registers. It is permitted that the Retimer not respond.
Report Margin Control Capabilities	001b	001b through 110b	88h	001b	Margin Payload[7:5] = Reserved; Margin Payload[4:0] = { <u>MIndErrorSampler</u> , <u>MSampleReportingMethod</u> , <u>MIndLeftRightTiming</u> , <u>MIndUpDownVoltage</u> , <u>MVoltageSupported</u> }
Report MNumVoltageSteps	001b	001b through 110b	89h	001b	Margin Payload[7] = Reserved Margin Payload[6:0] = <u>MNumVoltageSteps</u>
Report MNumTimingSteps	001b	001b through 110b	8Ah	001b	Margin Payload[7:6] = Reserved Margin Payload[5:0] = <u>MNumTimingSteps</u>
Report MMaxTimingOffset	001b	001b through 110b	8Bh	001b	Margin Payload[7] = Reserved Margin Payload[6:0] = <u>MMaxTimingOffset</u>
Report MMaxVoltageOffset	001b	001b through 110b	8Ch	001b	Margin Payload[7] = Reserved Margin Payload[6:0] = <u>MMaxVoltageOffset</u>
Report MSamplingRateVoltage	001b	001b through 110b	8Dh	001b	Margin Payload[7:6] = Reserved Margin Payload[5:0] = { <u>MSamplingRateVoltage</u> [5:0]}
Report MSamplingRateTiming	001b	001b through 110b	8Eh	001b	Margin Payload[7:6] = Reserved Margin Payload[5:0] = { <u>MSamplingRateTiming</u> [5:0]}

Command				Response	
<u>Margin Command</u>	<u>Margin Type</u> [2:0]	<u>Valid Receiver Number(s)</u> [2:0]	<u>Margin Payload</u> [7:0]	<u>Margin Type</u> [2:0]	<u>Margin Payload</u> [7:0]
Report $M_{SampleCount}$	001b	001b through 110b	8Fh	001b	<u>Margin Payload</u> [7] = Reserved <u>Margin Payload</u> [6:0] = $M_{SampleCount}$
Report $M_{MaxLanes}$	001b	001b through 110b	90h	001b	<u>Margin Payload</u> [7:5] = Reserved <u>Margin Payload</u> [4:0] = $M_{MaxLanes}$
Report Reserved	001b	001b through 110b	91-9Fh	001b	<u>Margin Payload</u> [7:0] = Reserved
Set Error Count Limit	010b	001b through 110b	<u>Margin Payload</u> [7:6] = 11b <u>Margin Payload</u> [5:0] = Error Count Limit	010b	<u>Margin Payload</u> [7:6] = 11b <u>Margin Payload</u> [5:0] = <u>Error Count Limit</u> registered by the target Receiver
Go to Normal Settings	010b	000b through 110b	0Fh	010b	0Fh
Clear Error Log	010b	000b through 110b	55h	010b	55h
Step Margin to timing offset to right/left of default	011b	001b through 110b	See § Section 4.2.18.1.2	011b	<u>Margin Payload</u> [7:6] = Step Margin Execution Status (see § Section 4.2.18.1.1) <u>Margin Payload</u> [5:0] = $M_{ErrorCount}$
Step Margin to voltage offset to up/down of default	100b	001b through 110b	See § Section 4.2.18.1.2	100b	<u>Margin Payload</u> [7:6] = Step Margin Execution Status (see § Section 4.2.18.1.1) <u>Margin Payload</u> [5:0] = $M_{ErrorCount}$
Vendor Defined	101b	001b through 110b	Vendor Defined	101b	Vendor Defined

Note:

Command				Response	
<u>Margin Command</u>	<u>Margin Type</u> [2:0]	<u>Valid Receiver Number(s)</u> [2:0]	<u>Margin Payload</u> [7:0]	<u>Margin Type</u> [2:0]	<u>Margin Payload</u> [7:0]

1. The term **Step Margin** command is used to refer to either a Step Margin to timing offset to right/left of default or a Step Margin to voltage offset to up/down of default command.

4.2.18.1.1 Step Margin Execution Status §

The **Step Margin Execution Status** used in § Table 4-63 is a 2-bit field defined as follows:

11b

NAK. Indicates that an unsupported Lane Margining command was issued. For example, timing margin beyond ± 0.2 UI. M_{ErrorCount} is 0.

10b

Margining in progress. The Receiver is executing a Step Margin command. M_{ErrorCount} reflects the number of errors detected as defined in § Section 8.4.4 .

01b

Set up for margin in progress. This indicates the Receiver is getting ready but has not yet started executing a Step Margin command. M_{ErrorCount} is 0.

00b

Too many errors - Receiver autonomously went back to its default settings. M_{ErrorCount} reflects the number of errors detected as defined in § Section 8.4.4 . Note that M_{ErrorCount} might be greater than Error Count Limit.

4.2.18.1.2 Margin Payload for Step Margin Commands §

For the Step Margin to timing offset to right/left of default command, the Margin Payload field is defined as follows:

- Margin Payload [7]: Reserved.
- If M_{IndLeftRightTiming} for the targeted Receiver is Set:
 - Margin Payload [6] indicates whether the Margin Command is right vs. left. A 0b indicates to move the Receiver to the right of the normal setting whereas a 1b indicates to move the Receiver to the left of the normal setting.
 - Margin Payload [5:0] indicates the number of steps to the left or right of the normal setting.
- If M_{IndLeftRightTiming} for the targeted Receiver is Clear:
 - Margin Payload [6]: Reserved
 - Margin Payload [5:0] indicates the number of steps beyond the normal setting.

For the Step Margin to voltage offset to up/down of default command, the Margin Payload field is defined as follows:

- If M_{IndUpDownVoltage} for the targeted Receiver is Set:

- Margin Payload [7] indicates whether the Margin Command is up vs. down. A 0b indicates to move the Receiver up from the normal setting whereas a 1b indicates to move the Receiver down from the normal setting.
- Margin Payload [6:0] indicates the number of steps up or down from the normal setting.
- If M_{IndUpDownVoltage} for the targeted Receiver is Clear:
 - Margin Payload [7]: Reserved
 - Margin Payload [6:0] indicates the number of steps beyond the normal setting.

4.2.18.2 Margin Command and Response Flow §

Each Receiver advertises its capabilities as defined in § Section 8.4.4 . The Receiver being margined must report the number of errors that are consistent with data samples occurring at the indicated location for margining. For simplicity, the Margin Commands and requirements are described in terms of moving the data sampler location though the actual margining method may be implementation specific. For example, the timing margin could be implemented on the actual data sampler or an independent error sampler. Further, the timing margin can be implemented by injecting an appropriate amount of stress/jitter to the data sample location, or by actually moving the data/error sample location. When an independent data/error sampler is used, the errors encountered with the independent data/error sampler must be reported in M_{ErrorCount} even though the Link may not experience any errors. To margin a Receiver, Software moves the target Receiver to a voltage/timing offset from its default sampling position.

The following rules must be followed:

- Every Retimer Upstream Pseudo Port Receiver and the Downstream Port Receiver must compute the Margin CRC and Margin Parity bits and compare against the received Margin CRC and Margin Parity bits. Any mismatch must result in ignoring the contents of Symbols 4N+2 and 4N+3. A Downstream Port Receiver must report Margin CRC and Margin Parity errors in the Lane Error Status Register (see § Section 7.7.3.3).
- The Upstream Port Receiver is permitted to ignore the Margin CRC bits, Margin Parity bits, and all bits in the Symbols 4N+2 and 4N+3 of the Control SKP Ordered Set. If it checks Margin CRC and Margin Parity, any mismatch must be reported in the Lane Error Status Register.
- The Downstream Port must transmit Control SKP Ordered Sets in each Lane, with the Margin Type, Receiver Number, Usage Model, and Margin Payload fields reflecting the corresponding control fields in the Margining Lane Control Register. Any Control SKP Ordered Set transmitted more than 10 μ s after the Configuration Write Completion must reflect the Margining Lane Control Register values written by that Configuration Write.
 - This requirement applies regardless of the values in the Margining Lane Control Register.
 - This requirement applies regardless of the number of Retimer(s) in the Link.
- For Control SKP Ordered Sets received by the Upstream Pseudo Port, a Retimer Receiver is the target of a valid Margin Command, if all of the following conditions are true:
 - the Margin Type is not No Command
 - the Receiver Number is the number assigned to the Receiver, or Margin Type is either Clear Error Log or Go to Normal Settings and the Receiver Number is 'Broadcast'.
 - the Usage Model field is 0b
 - the Margin Type, Receiver Number, and Margin Payload fields are consistent with the definitions in § Table 4-62 and § Table 4-63
 - the Margin CRC check and Margin Parity check pass.
- For Upstream and Downstream Ports, a Receiver is the target of a valid Margin Command, if all of the following conditions are true for its Margining Lane Control Register:

- the Margin Type is not No Command
- the Receiver Number is the number assigned to the Receiver or Margin Type is either Clear Error Log or Go to Normal Settings and the Receiver Number is 'Broadcast'
- the Usage Model field is 0b
- the Margin Type, the Receiver Number, and Margin Payload fields are consistent with the definitions in § Table 4-62 and § Table 4-63
- The Upstream Port must transmit the Control SKP Ordered Set with No Command.
- A target Receiver must apply and respond to the Margin Command within 1 ms of receiving the valid Margin Command if the Link is still in L0 state and operating at 16.0 GT/s or higher Data Rate.
 - A target Receiver in a Retimer must send a response in the Control SKP Ordered Set in the Upstream Direction within 1 ms of receiving the Margin Command.
 - A target Receiver in the Upstream Port must update the Status field of the Lane Margin Command and Status register within 1 ms of receiving the Margin Command.
 - A target Receiver in the Downstream Port must update the Status field of the Lane Margin Command and Status register within 1 ms of receiving the Margin Command if the command is not broadcast or no Retimer(s) are present
- For a valid Margin Type, other than No Command, that is broadcast and received by a Retimer:
 - A Retimer, in position X (see § Figure 4-61), forwards the response unmodified in the Upstream Control SKP Ordered Set, if the command has been applied, else it sends the No Command.
 - The Receiver Number field of the response must be set to an encoding of one of the Retimer's Pseudo Ports.
 - The Retimer must respond only after both Pseudo Ports have completed the Margin Command.
- The Retimer must overwrite Bits [4:0] of Symbol 4N+1, Bits[7, 5:0] of Symbol 4N+2 and Bits [7:0] in Symbol 4N+3 as it forwards the Control SKP Ordered Set in the Upstream direction if it is the target Receiver of a Margin Command and is executing the command.
- On receipt of a Control SKP Ordered Set, the Downstream Port must reflect the Margining Lane Status Register from the corresponding fields in the received Control SKP Ordered Set within 1 μ s, if it passes the Margin CRC and Margin Parity checks and one of the following conditions apply:
 - In the Margining Lane Control Register: Receiver Number is 010b through 101b
 - In the Margining Lane Control Register: Receiver Number is 000b, Margin Command is Clear Error Log, No Command, or Go to Normal Settings, and there are Retimer(s) in the Link
 - Optionally, if the Margining Lane Control Register Usage Model field is 1b
 - Optionally, if the Margining Lane Control Register Receiver Number field is 110b or 111b

The Margining Lane Status Register fields are updated regardless of the Usage Model bit in the received Control SKP Ordered Set.
- A component must advertise the same value for each parameter defined in § Table 8-13 in § Section 8.4.4 across all its Receivers. A component must not change any parameter value except for M_{SampleCount} and M_{ErrorCount} defined in § Table 8-13 in § Section 8.4.4 while LinkUp = 1b.
- A target Receiver that receives a valid Step Margin command must continue to apply that offset until any of the following occur:
 - it receives a valid Go to Normal Settings command
 - it receives a subsequent valid Step Margin command with different Margin Type or Margin Payload field

- M_{IndErrorSampler} is 0b and M_{ErrorCount} exceeds Error Count Limit
- Optionally, M_{IndErrorSampler} is 1b and M_{ErrorCount} exceeds Error Count Limit.
- If a Step Margin command terminates because M_{ErrorCount} exceeds Error Count Limit, the target Receiver must automatically return to its default sample position and indicate this in the Margin Payload field (Step Margin Execution Status = 00b). Note: termination for this reason is optional if M_{IndErrorSampler} is 1b.
- If M_{IndErrorSampler} is 0b, an error is detected when:
 - The target Receiver is a Port that enters Recovery or detects a Data Parity mismatch while in L0
 - The target Receiver is a Pseudo Port that enters Forwarding training sets or detects a Data Parity mismatch while forwarding non-training sets.
- If M_{IndErrorSampler} is 1b, an error is detected when:
 - The target Receiver is a Port and a bit error is detected while in L0
 - The target Receiver is a Pseudo Port and a bit error is detected while the Retimer is forwarding non-training sets
- If M_{IndErrorSampler} is 0b and either (1) the target Receiver is a Port that enters Recovery or (2) the target Receiver is a Pseudo Port that enters Forwarding training sets:
 - The target Receiver must go back to the default sample position
 - If the target Receiver is a Port that is still performing margining, it must resume the margin position within 128 μs of entering L0
 - If the target Receiver is a Pseudo Port that is still performing margining, it must resume the margin position within 128 μs of Forwarding non-training sets
- A target Receiver is required to clear its accumulated error count on receiving Clear Error Log command, while it continues to margin (if it is the target Receiver of a Step Margin command still in progress), if it was doing so.
- For a target Receiver of a Set Error Count Limit command, the new value is used for all future Step Margin commands until a new Set Error Count Limit command is received.
- If no Set Error Count Limit is received by a Receiver since entering L0, the default value is 4.
- Behavior is undefined if a Set Error Count Limit command is received while a Step Margin command is in effect.
- Once a target Receiver reports a Step Margin Execution Status of 11b (NAK) or 00b ('Too many errors'), it must continue to report the same status as long as the Step Margin command is in effect.
- A target Receiver must not report a Step Margin Execution Status of 01b ('Set up for margin in progress') for more than 100 ms after it receives a new valid Step Margin command
- A target Receiver that reports a Step Margin Execution Status other than 01b, cannot report 01b subsequently unless it receives a new valid Step Margin command.
- Reserved bits in the Margin Payload field must follow these rules:
 - The Downstream or Upstream Port must transmit 0s for Reserved bits
 - The retimer must forward Reserved bits unmodified
 - All Receivers must ignore Reserved bits
- Reserved encodings of the Margin Type, Receiver Number, or Margin Payload fields must follow these rules:
 - The retimer must forward Reserved encodings unmodified
 - All Receivers must treat Reserved encodings as if they are not the target of the Margin Command
- A Vendor Defined Margin Command or response, that is not defined by a retimer is ignored and forwarded normally.

- A target Receiver on a Retimer must return 00h on the response payload on Access Retimer Register command, if it does not support register access. If a Retimer supports Access Retimer Register command, the following must be observed:
 - It must return a non-zero value for the DWORD at locations 80h and 84h respectively.
 - It must not place any registers corresponding to Margin Payload locations 88h through 9Fh.

4.2.18.3 Flit Mode 8.0 GT/s Margining Behavior §

Lane Margining is defined for 16.0 GT/s and higher data rates. Lane Margining is not supported at 2.5, 5.0, and 8.0 GT/s. In Non-Flit Mode, Control SKP Ordered Sets only present at 16.0 GT/s and higher data rates so margin commands at slower speeds are not possible. In Flit Mode, Control SKP Ordered Sets are also used at 8.0 GT/s.

The following behavior is recommended in Flit Mode at 8.0 GT/s:

- Upstream and Downstream Ports must send Control SKP Ordered Sets as defined, but the margin command should always be No Command, regardless of the contents of the Margining Lane Control Register.
- Upstream Ports, Downstream Ports, and Retimer Upstream Ports should ignore the margin command in received Control SKP Ordered Sets.
 - The Margining Lane Status Register value is unpredictable.
 - Upstream and Downstream Ports are permitted to compute the Margin CRC and Margin Parity bits and compare against the received Margin CRC and Margin Parity bits. If checked, any mismatch must be reported as Margin CRC and Margin Parity errors in the Lane Error Status Register (see § Section 7.7.3.3).

4.2.18.4 Receiver Margin Testing Requirements §

Software must ensure that the following conditions are met before performing Lane Margining at Receiver:

- The current Link data rate must be 16.0 GT/s or higher.
- The current Link width must include the Lanes that are to be tested.
- The Upstream Port's Function(s) must be programmed to a D-state that prevents the Port from entering the L1 Link state. See § Section 5.2 for more information.
- The ASPM Control field of the Link Control register must be set to 00b (Disabled) in both the Downstream Port and Upstream Port.
- The state of the Hardware Autonomous Speed Disable bit of the Link Control 2 register and the Hardware Autonomous Width Disable bit of the Link Control register must be saved to be restored later in this procedure.
- If writeable, the Hardware Autonomous Speed Disable bit of the Link Control 2 register must be Set in both the Downstream Port and Upstream Port. (If hardwired to 0b, the autonomous speed change mechanism is not implemented and is therefore inherently disabled.)
- If writeable, the Hardware Autonomous Width Disable bit of the Link Control register must be Set in both the Downstream Port and Upstream Port. (If hardwired to 0b, the autonomous width change mechanism is not implemented and is therefore inherently disabled.)

While margining, software must ensure the following:

- All Margin Commands must have the Usage Model field in the Margining Lane Control Register set to 0b. While checking for the status of an outstanding Margin Command, software must check that the Usage Model field of the status part of the Margining Lane Status Register is set to 0b.
- Software must read the capabilities offered by a Receiver and margin it within the constraints of the capabilities it offers. The commands issued and the process followed to determine the margin must be consistent with the definitions provided in § Section 4.2.18 and § Section 8.4.4 . For example, if the Port does not support voltage testing, then software must not initiate a voltage test. In addition, if a Port supports testing of 2 Lanes simultaneously, then software must test only 1 or 2 Lanes at the same time and not more than 2 Lanes.
- For Receivers where M_{IndErrorSampler} is 1b, any combination of such Receivers are permitted to be margined in parallel.
- For Receivers where M_{IndErrorSampler} is 0b, at most one such Receiver is permitted to be margined at a time. However, margining may be performed on multiple Lanes simultaneously, as long as it is within the maximum number of Lanes the device supports.
- Software must ensure that the Margin Command it provides in the Margining Lane Control Register is a valid one, as defined in § Section 4.2.18.1 . For example, the Margin Type must have a defined encoding and the Receiver Number and Margin Payload consistent with it.
- After issuing a command by writing to the Margining Lane Control Register atomically, software must check for the completion of this command. This is done by atomically reading the Margining Lane Status Register and checking that the status fields match the expected response for the issued command (see § Table 4-62 and § Table 4-63). It is strongly recommended that software continue to reread the Margining Lane Status Register if it does not find the expected Receiver Number. If 10 ms has elapsed after a new Margin Command was issued and the values read do not match the expected response, software is permitted to assume that the Receiver will not respond, and declare that the target Receiver failed margining. For a broadcast command other than No Command the Receiver Number in the response must correspond to one of the Pseudo Ports in Retimer Y or Retimer Z, if Retimers are present, or the Downstream Port if they are not, as described in § Figure 4-61.
- Any two reads of the Margining Lane Status Register should be spaced at least 10 μs apart to make sure they are reading results from different Control SKP Ordered Sets.
- Software must broadcast No Command and wait for it to complete, or for 10 ms to elapse without observing that completion, prior to issuing a new Margin Type or Receiver Number or Margin Payload in the Margining Lane Control Register.
- At the end of margining in a given direction (voltage/ timing and up/down/left/right), software must broadcast Go to Normal Settings, No Command, Clear Error Log, and No Command in series in the Downstream and Upstream Ports, after ensuring each command has been acknowledged by the target Receiver.
- If the Data Rate has changed during margining, margining results (if any) are not accurate and software must exit the margining procedure. Software must set the Margining Lane Control Register to No Command to avoid starting margining if the Data Rate later changes to 16.0 GT/s or higher.
- Software is permitted to issue a Clear Error Log command periodically while margining is in progress, to gather error information over a long period of time.
- Software must not attempt to margin both timing and voltage of a target Receiver simultaneously. Results are undefined if a Receiver receives commands that would place both voltage and timing margin locations away from the default sample position at the same time.
- Software should allow margining to run for at least 10⁸ bits margined by the Receiver under test before switching to the next margin step location (unless the error limit is exceeded).
- Software must account for the 'set up for margin in progress' status while measuring the margin time or the number of bits sampled by the Receiver.

- If a target Receiver is reporting 'set up for margin in progress' for 200 ms after issuing one of the Step Margin commands, Software is permitted to assume that the Receiver will not respond and declare that the target Receiver failed margining.
- If a Receiver reports a 'NAK' in the Margin Payload status field and the corresponding Step Margin command was valid and within the allowable range (as defined in § Section 4.2.18 and § Section 8.4.4), Software is permitted to declare that the target Receiver failed margining.
- When the margin testing procedure is completed, the state of the Hardware Autonomous Speed Disable bit and the Hardware Autonomous Width Disable bit must be restored to the previously saved values.

IMPLEMENTATION NOTE: EXAMPLE SOFTWARE FLOW FOR LANE MARGINING AT RECEIVER §

For getting the invariant parameters the following steps may be followed. Once obtained, the same parameters can be used across multiple sets of margining tests as long as LinkUp=1b continues to be true. For each component in the Link, do the following Steps. Software can do these steps in parallel for different components on different Lanes of the Link.

Step A1:

Issue Report Margin Control Capabilities (Margin Type = 001b, Margin Payload = 88h, Receiver Number = target device in the Margining Lane Control Register)

Step A2:

Read the Margining Lane Status Register.

- a. If Margin Type = 001b and Receiver Number = target Receiver: Go to Step A3
- b. Else: If 10 ms has expired since command issued, declare Receiver failed margining and exit; else wait for >10 μ s and Go to Step A2

Step A3:

Store the information provided Marging Payload status field for use during margining.

Step A4:

Broadcast No Command (Margin Type = 111b, Receiver Number = 000b, and Margin Payload = 9Ch in the Margining Lane Control Register) and wait for those to be reflected back in the Margining Lane Status Register. If 10 ms expires without getting the command completion handshake, declare the Receiver failed margining and exit.

Step A5:

Repeat Step A1 through Step A4 for Report $M_{NumVoltageSteps}$, Report $M_{NumTimingSteps}$, Report $M_{MaxTimingOffset}$, Report $M_{MaxVoltageOffset}$, Report $M_{SamplingRateVoltage}$, and Report $M_{SamplingRateTiming}$. It may be noted that this step can be executed in parallel across different Lanes for different Margin Type.

Margining on each Lane across the Link can be a sequence of separate commands. Prior to launching the sequence, software should read the maximum number of Lanes it is allowed to run margining simultaneously. The steps would be similar to Step A1 through Step A4 above with the Report $M_{MaxLanes}$ command. After that software can simultaneously margin up to that many Lanes of the Link. On each Link, each Receiver is margined based on its capability, subject to the constraints described here, after ensuring the Link is operating at full width in 16.0 GT/s or higher Data Rate and the hardware autonomous width and speed change as well as ASPM power states have been disabled.

If software desires to set an Error Count Limit value different than default of 4 or whatever was programmed last, it executes the following Steps prior to going to Step C1 below.

Step B1:

Issue Set Error Count Limit (Margin Type = 010b, the target Receiver Number, and Margin Payload = {11b, Error Count Limit} in the Margining Lane Control Register)

Step B2:

Read the Margining Lane Status Register.

- a. If Margin Type = 010b, Receiver Number = target Receiver, and Margin Payload = Margin Payload control field (Bits [14:7]), go to Step B4
- b. Else: If 10 ms has expired since command issued, go to Step B3; else wait for >10 μ s and Go to Step B2

Step B3:

Margining has failed. Invoke the system checks to find out if the Link degraded in width/speed due to reliability reasons.

Step B4:

Broadcast No Command and wait for those to be reflected back in the status fields. If 10 ms expires without getting the command completion handshake, declare the Receiver failed margining and exit.

The following steps is an example flow of one margin point for a given Receiver executing Step Margin to timing offset to right/left of default starting with 15 steps to the right:

Step C1:

Write Margin Type = 011b, the target Receiver Number, and Margin Payload = {0000b, 1111b} in the Margining Lane Control Register

Step C2:

Read the Margining Lane Status Register.

- a. If Margin Type = 011b and Receiver Number = target Receiver, Go to Step C3
- b. Else If 10 ms has expired since command issued, declare Receiver has failed margining and go to Step C7
- c. Wait for >10 μ s and Go to Step C2

Step C3:

In the Margining Lane Status Register:

- a. If Margin Payload[7:6] = 11b:
 - i. If we exceeded the 0.2 UI, that is the margin;
 - ii. Else report margin failure at this point and go to Step C7;
- b. Else if Margin Payload[7:6] = 00b:
 - i. report margin failure at this point and go to Step C7
- c. Else if Margin Payload[7:6] = 01b:
 - i. If 200 ms has elapsed since entering Step C3, report that the Receiver failed margining test and exit;
 - ii. else wait 1 ms, read the Margining Lane Status Register and go to Step C3
- d. Else go to Step C4

Step C4:

Wait for the desired amount of time for margining to happen while sampling the Margining Lane Status Register periodically for the number of errors reported in the Margin Payload field (Bits [5:0] - MErrorCount).

For longer runs, issue the No Command followed by the Clear Error Log commands, (using procedures similar to Step B1 through Step B4, with the corresponding expected status field) if the length of time will cause the error count to exceed the Set Error Count Limit even when staying within the expected BER target.

If the aggregate error count remains within the expected error count and the Margin Payload[7:6] in the status field remains 10b till the end, the Receiver has the required Margin at the timing margin step; else it fails that timing margin step go to [Step C7](#).

Step C5:

Broadcast No Command and wait for those to be reflected back in the status fields. If 10 ms expires without getting the command completion handshake, declare the Receiver failed margining and exit.

Step C6:

Go to [Step C1](#), incrementing the number of timing steps through the Margin Payload control field (Bits[5:0]) if we want to test against a higher margin amount; else go to [Step C8](#) noting the margin value that the Receiver passed

Step C7:

Margin failed; The previous margin step the Receiver passed in [Step C6](#) is the margin of the Receiver

Step C8:

Broadcast No Command, Clear Error Log, No Command, Go to Normal Settings series of commands (using a procedure similar to [Step B1](#) through [Step B4](#) with the corresponding expected status fields)

4.3 Retimers §

This Section defines the requirements for Retimers that are Physical Layer protocol aware and that interoperate with any pair of components with any compliant channel on each side of the Retimer. An important capability of a Physical Layer protocol aware Retimer is to execute the Phase 2/3 of the equalization procedure in each direction. A maximum of two Retimers are permitted between an Upstream and a Downstream Port.

The two Retimer limit is based on multiple considerations, most notably limits on modifying SKP Ordered Sets and limits on the time spent in Phase 2/3 of the equalization procedure. To ensure interoperability, platform designers must ensure that the two Retimer limit is honored for all PCI Express Links, including those involving form factors as well as those involving active cables. Form factor specifications may define additional Retimer rules that must be honored for their form factors. Assessing interoperability with any Extension Device not based on the Retimer definition in this section is outside the scope of this specification.

Many architectures of Extension Devices are possible, i.e., analog only Repeater, protocol unaware Retimer, etc. This specification describes a Physical Layer protocol aware Retimer. It may be possible to use other types of Extension Devices in closed systems if proper analysis is done for the specific channel, Extension Device, and end-device pair - but a specific method for carrying out this analysis is outside the scope of this specification.

Retimers have two Pseudo Ports, one facing Upstream, and the other facing Downstream. The Transmitter of each Pseudo Port must derive its clock from a 100 MHz reference clock. The reference clock(s) must meet the requirements of § Section 8.6 . A Retimer supports one or more reference clocking architectures as defined in § Section 8.6 Electrical Sub-block.

In most operations Retimers simply forward received Ordered Sets, DLLPs, TLPs, Logical Idle, and Electrical Idle. Retimers are completely transparent to the Data Link Layer and Transaction Layer. System software shall not enable [L0s](#) on any Link where a Retimer is present. Support of beacon by Retimers is optional and beyond the scope of this specification.

When using 128b/130b encoding the Retimer executes the protocol so that each Link Segment undergoes independent Link equalization as described in [§ Section 4.3.6](#) .

The Pseudo Port orientation (Upstream or Downstream) is determined dynamically, while the Link partners are in Configuration. Both crosslink and regular Links are supported.

4.3.1 Retimer Requirements §

The following is a high level summary of Retimer requirements:

- Retimers are required to comply with all the electrical specification described in § Chapter 8. Electrical Sub-block. Retimers must operate in one of two modes:
 - Retimers' Receivers operate at 8.0 GT/s and above with an impedance that meets the range defined by the Z_{RX-DC} parameter for 2.5 GT/s.
 - Retimers' Receivers operate at 8.0 GT/s and above with an impedance that does not meet the range defined by the Z_{RX-DC} parameter for 2.5 GT/s. In this mode the Z_{RX-DC} parameter for 2.5 GT/s must be met within 1 ms of receiving an EIOS or inferring Electrical Idle and while the Receivers remain in Electrical Idle.
- Forwarded Symbols must always be de-skewed when more than one Lane is forwarding Symbols (including upconfigure cases).
- Determine Port orientation dynamically.
- Determine Data Stream Mode (Flit Mode or Non-Flit Mode) dynamically.
- Perform Lane polarity inversion (if needed).
- Interoperate with the Link equalization procedure for Phase 2 and Phase 3, when using 128b/130b or 1b/1b encoding, on each Link Segment.
- Interoperate with de-emphasis negotiation at 5.0 GT/s, on each Link Segment.
- Interoperate with Link Upconfigure.
- Interoperate with L0p.
- Pass loopback data between the Loopback Lead and Loopback Follower.
 - Optionally execute Follower Loopback on one Pseudo Port when using 8b/10b or 128b/130b encoding
 - Execute Follower Loopback on one Pseudo Port when using 1b/1b
- Generate the Compliance Pattern on each Pseudo Port.
 - Load board method (i.e., time out in Polling.Active).
- Forward Modified Compliance Pattern when the Link enters Polling.Compliance via Compliance Receive bit in TS1 Ordered Sets.
- Forward Compliance or Modified Compliance Patterns when Ports enter Polling.Compliance via the Enter Compliance bit in the Link Control 2 register is set to 1b in both the Upstream Port and the Downstream Port and Retimer Enter Compliance is set to 1b (accessed in an implementation specific manner) in the Retimer.
- Adjust the data rate of operation in concert with the Upstream and Downstream Ports of the Link.
- Adjust the Link width in concert with the Upstream and Downstream Ports of the Link.
- Capture Lane numbers during Configuration.
 - Lane numbers are required when using 128b/130b and 1b/1b encoding for the scrambling seed.
- Capture the Flit Mode Supported bit during Polling and Configuration during Link training.
 - The Flit Mode Supported bit is used to determine the Data Stream Mode.
- Dynamically adjust Retimer Receiver impedance to match end Component Receiver impedance.

- Infer entering Electrical Idle at all data rates.
- Modify certain fields of Ordered Sets while forwarding.
- Perform clock compensation via addition or removal of SKP Symbols.
- Support L1.
 - Optionally Support L1 PM Substates.
- If 32.0 GT/s capable, then interoperate with Link equalization to the highest data rate.
- If 32.0 GT/s capable, then interoperate with No Equalization Needed mode.
 - If 32.0 GT/s capable, then interoperate with the use of Modified TS1/TS2 Ordered Sets.
- Forward 1b/1b Control SKP Ordered Sets that have Phy Payload Type equal to 0b. Thus, 1b/1b Control SKP Ordered Sets with Margin Payload will be forwarded.

4.3.2 Supported Retimer Topologies §

§ Figure 4-62 shows the topologies supported by Retimers defined in this specification. There may be one or two Retimers between the Upstream and Downstream Ports on a Link. Each Retimer has two Pseudo Ports, which determine their Downstream/Upstream orientation dynamically. Each Retimer has an Upstream Path and a Downstream Path. Both Pseudo Ports must always operate at the same data rate, when in Forwarding mode. Thus, each Path will also be at the same data rate. A Retimer is permitted to support any width option defined by this specification as its maximum width. The behavior of the Retimer in each high level operating mode is:

- Forwarding mode:
 - Symbols, Electrical Idle, and exit from Electrical Idle; are forwarded on each Upstream and Downstream Path.
- Execution mode:
 - The Upstream Pseudo Port acts as an Upstream Port of a Component. The Downstream Pseudo Port acts as a Downstream Port of a Component. This mode is used in the following cases:
 - Polling, Compliance.
 - Phase 2 and Phase 3 of the Link equalization procedure.
 - Optionally Follower Loopback.

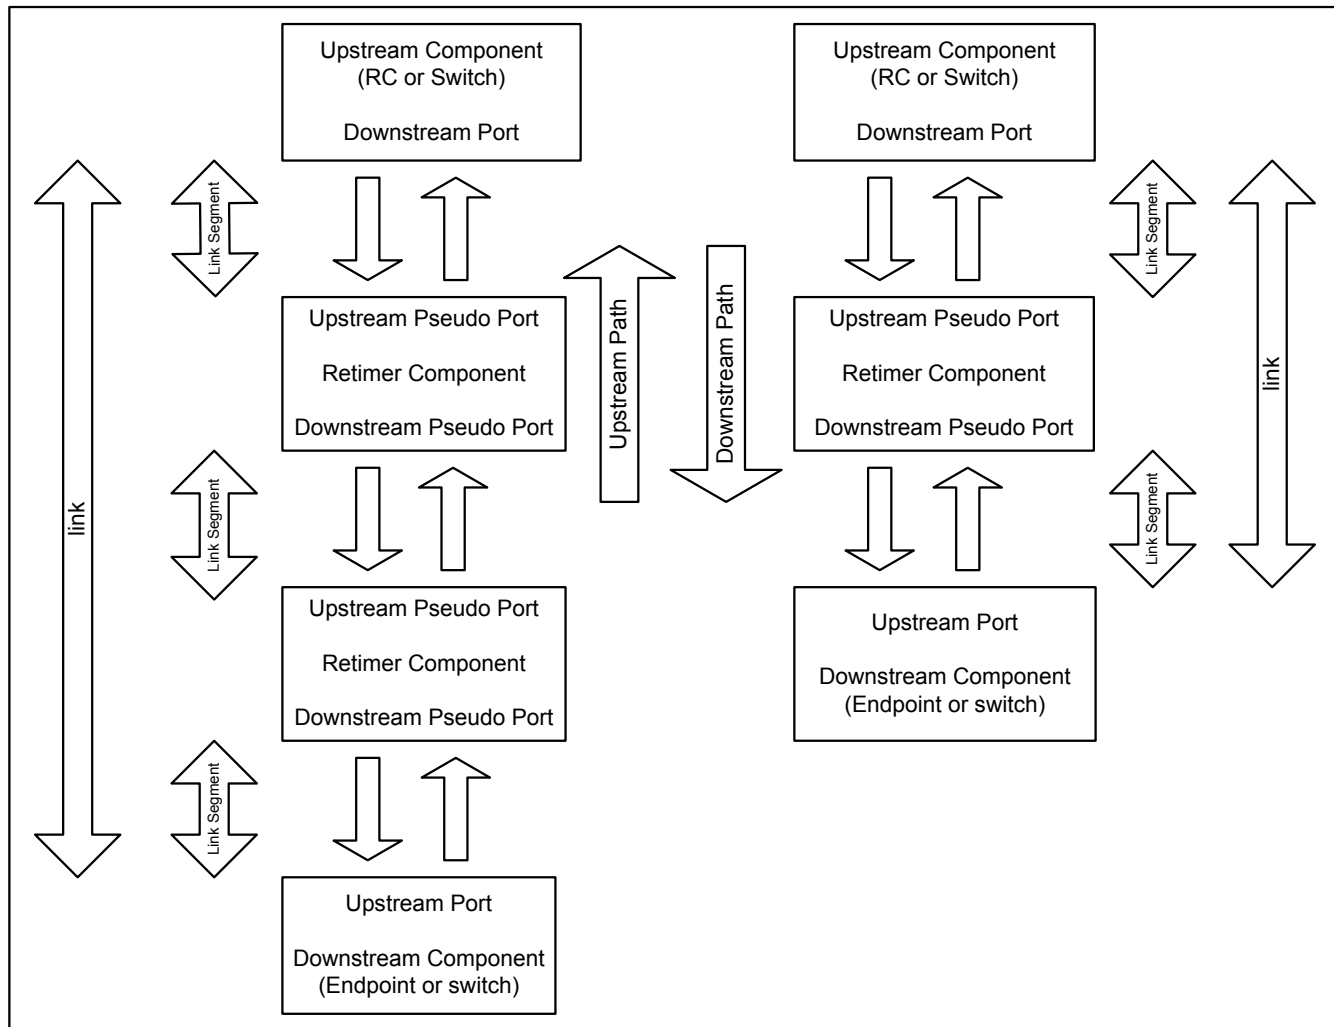

Figure 4-62 Supported Retimer Topologies §

4.3.3 Variables §

The following variables are set to the following specified values following a Fundamental Reset or whenever the Retimer receives Link and Lane number equal to PAD on two consecutive TS2 Ordered Sets on all Lanes that are receiving TS2 Ordered Sets on both Upstream and Downstream Pseudo Ports within a 1 μ s time window from the last Symbol of the second TS2 Ordered Set on the first Lane to the last Symbol of the second TS2 Ordered Set on the last Lane.

- ***RT_port_orientation*** = undefined
- ***RT_captured_lane_number*** = PAD
- ***RT_captured_link_number*** = PAD
- ***RT_G3_EQ_complete*** = 0b
- ***RT_G4_EQ_complete*** = 0b
- ***RT_G5_EQ_complete*** = 0b
- ***RT_G6_EQ_complete*** = 0b

- ***RT_LinkUp*** = 0b
- ***RT_number*** = undefined
- ***RT_next_data_rate*** = 2.5 GT/s
- ***RT_error_data_rate*** = 2.5 GT/s
- ***RT_flit_mode_enabled*** = 0b

4.3.4 Receiver Impedance Propagation Rules §

The Retimer Transmitters and Receivers shall meet the requirements in § Section 4.2.5.9.1 while Fundamental Reset is asserted. When Fundamental Reset is deasserted the Retimer is permitted to take up to 100 ms to begin active determination of its Receiver impedance. A Retimer that supports only Link speeds 5.0 GT/s or less must do this within 20 ms. During this interval the Receiver impedance remains as required during Fundamental Reset. Once this interval has expired Receiver impedance on Retimer Lanes is determined as follows:

- Within 1.0 ms of the Upstream or Downstream Port's Receiver meeting the Z_{RX-DC} parameter, the low impedance is back propagated, (i.e., the Retimer's Receiver shall meet the Z_{RX-DC} parameter on the corresponding Lane on the other Pseudo Port). Each Lane operates independently and this requirement applies at all times.
- The Retimer must keep its Transmitter in Electrical Idle until the Z_{RX-DC} condition has been detected. This applies on an individual Lane basis.

4.3.5 Switching Between Modes §

The Retimer operates in two basic modes, Forwarding mode or Execution mode. When switching between these modes the switch must occur on an Ordered Set boundary for all Lanes of the Transmitter at the same time. No other Symbols shall be between the last Ordered Set transmitted in the current mode and the first Symbol transmitted in the new mode.

When using 128b/130b or 1b/1b the Transmitter must maintain the correct scrambling seed and LFSR value when switching between modes.

When switching between Forwarding and Execution modes, the Retimer must ensure that at least 16 TS1 Ordered Sets and at most 64 TS1 Ordered Sets are transmitted between the last EIEOS transmitted in the previous mode and the first EIEOS transmitted in the new mode.

When switching to and from the Execution Link Equalization mode the Retimer must ensure a Transmitter does not send two SKP Ordered Sets in a row, and that the maximum allowed interval is not exceeded between SKP Ordered Sets, see § Section 4.2.8.4 .

4.3.6 Forwarding Rules §

These rules apply when the Retimer is in Forwarding mode. The Retimer is in Forwarding mode after the deassertion of Fundamental Reset.

- If the Retimer's Receiver detects an exit from Electrical Idle on a Lane the Retimer must enter Forwarding mode and forward the Symbols on that Lane to the opposite Pseudo Port as described in § Section 4.3.6.3 .

- The Retimer must continue to forward the received Symbols on a given Lane until it enters Execution mode or until an EIOS is received, or until Electrical Idle is inferred on that Lane. This requirement applies even if the Receiver loses Symbol lock or Block Alignment. See § Section 4.3.6.5 for rules regarding Electrical Idle entry.
- A Retimer shall forward all Symbols unchanged, except as described in § Section 4.3.6.9 and § Section 4.3.6.7 .
- When operating at 64.0 GT/s data rate, a Retimer must follow the requirements of § Section 4.2.3.2 in order to identify SKP OS, EIEOS, and EIOS received.
- When operating at 2.5 GT/s data rate, if any Lane of a Pseudo Port receives TS1 Ordered Sets with Link and Lane numbers set to PAD for 5 ms or longer, and the other Pseudo Port does not detect an exit from Electrical Idle on any Lane in that same window, and either of the following occurs:
 - The following sequence occurs:
 - An EIOS is received on any Lane that was receiving TS1 Ordered Sets
 - followed by a period of Electrical Idle, for less than 5 ms
 - followed by Electrical Idle Exit that cannot be forwarded according to § Section 4.3.6.3
 - Note: this is interpreted as the Port attached to the Receiver going into Electrical Idle followed by a data rate change for a Compliance Pattern above 2.5 GT/s.
 - Compliance Pattern at 2.5 GT/s is received on any Lane that was receiving TS1 Ordered Sets.

Then the Retimer enters the Execution mode CompLoadBoard state, and follows § Section 4.3.7.1 .

- If any Lane on the Upstream Pseudo Port receives two consecutive TS1 Ordered Sets with the EC field equal to 10b, when using 128b/130b or 1b/1b encoding, then the Retimer enters Execution mode Equalization, and follows § Section 4.3.7.2 .
- If the Retimer is configured to support Execution mode Follower Loopback and if any Lane on either Pseudo Port receives two consecutive TS1 Ordered Sets or two consecutive TS2 Ordered Sets with the Loopback bit set to 1b then the Retimer enters Execution mode Follower Loopback, and follows § Section 4.3.7.3 .

4.3.6.1 Forwarding Type Rules §

A Retimer must determine what type of Symbols it is forwarding. The rules for inferring Electrical Idle are a function of the type of Symbols the Retimer is forwarding. If a Path forwards two consecutive TS1 Ordered Sets or two consecutive TS2 Ordered Sets, on any Lane, then the Path is forwarding training sets. If a Path forwards eight consecutive Symbol Times of Idle data on all Lanes that are forwarding Symbols then the Path is forwarding non-training sets. When a Retimer transitions from forwarding training sets to forwarding non-training sets, the variable RT_error_data_rate is set to 2.5 GT/s.

4.3.6.2 Orientation, Lane Numbers, and Data Stream Mode Rules §

The Retimer must determine the Port orientation, Lane assignment, Lane polarity, and Data stream Mode dynamically as the Link trains.

- When RT_LinkUp=0, the first Pseudo Port to receive two consecutive TS1 Ordered Sets with a non-PAD Lane number on any Lane, has its RT_port_orientation variable set to Upstream Port, and the other Pseudo Port has its RT_port_orientation variable set to Downstream Port.
- The Retimer plays no active part in Lane number determination. The Retimer must capture the Lane numbers with the RT_captured_lane_number variable at the end of the Configuration state, between the Link Components. This applies on the first time through Configuration, i.e., when the RT_LinkUp variable is set to 0b. Subsequent trips through Configuration during Link width configure must not change the Lane numbers.

Lane numbers are required for the scrambling seed when using 128b/130b or 1b/1b. Link numbers are required in some cases when the Retimer is in Execution mode. Link numbers and Lane numbers are captured with the `RT_captured_lane_number`, and `RT_captured_link_number` variables whenever the first two consecutive TS2 Ordered Sets that contain non-PAD Lane and non-PAD Link numbers are received after the `RT_LinkUp` variable is set to 0b. A Retimer must function normally if Lane reversal occurs. When the Retimer has captured the Lane numbers and Link numbers the `RT_LinkUp` variable is set to 1b. In addition, if the Disable Scrambling bit in the TS2 Ordered Sets is set to 1b, in either case above, then the Retimer determines that scrambling is disabled when using 8b/10b encoding.

- Lane polarity is determined any time the Lane exits Electrical Idle, and achieves Symbol lock at 2.5 GT/s as described in § Section 4.2.5.5 :
 - If polarity inversion is determined the Receiver must invert the received data. The Transmitter must never invert the transmitted data.
- The Retimer plays an active part of Data Stream Mode determination. If the Retimer supports Flit Mode operation, for each Pseudo Port, it must capture the value of the `Flit Mode Supported bit` of the Data Rate Identifier field in the eight consecutive TS2 Ordered Sets received with Link and Lane numbers set to PAD when the `RT_LinkUp` variable is set to 0b. If the `Flit Mode Supported bit` is 1b in eight consecutive TS2 Ordered Sets received by both Pseudo Ports, the `RT_flit_mode_enabled` variable must be set to 1b and each Pseudo Port must follow Flit Mode rules (as specified in § Section 4.2) to identify transitions between Ordered Set Data and Data Streams. If the Retimer does not support Flit Mode operation, its `RT_flit_mode_enabled` variable must remain set to 0b and it must set bit 0 of the Data Rate Identifier (Symbol 0) to 0b in all TS Ordered Sets that it forwards (as described in § Section 4.3.6.7).
 - When using 8b/10b with Flit Mode, `NOP Flits` (instead of Idle data) identify the start of the data stream.
 - When using 128b/130b or 1b/1b with Flit Mode, `SDS Ordered Sets` identify the start of the data stream.
- The Retimer's place in the system topology is determined when eight consecutive TS2 Ordered Sets are received with (non-PAD) matching Link and Lane numbers and identical data rate identifiers. If the Retimer Present bits are set to 01b on the Upstream Pseudo Port, the `RT_number` must be set to 10b, otherwise `RT_number` must be set to 01b. The `RT_number` is used to determine Pseudo Ports B, C, D and E. This identification is needed for Execution Mode Follower Loopback with 1b/1b encoding.

4.3.6.3 Electrical Idle Exit Rules §

At data rates other than 2.5 GT/s, EIEOS are sent within the training sets to ensure that the analog circuit detects an exit from Electrical Idle. Receiving an EIEOS is required when using 128b/130b or 1b/1b encoding to achieve Block Alignment. When the Retimer starts forwarding data after detecting an Electrical Idle exit, the Retimer starts transmitting on a training set boundary. The first training sets it forwards must be an EIEOS, when operating at data rates higher than 2.5 GT/s. The first EIEOS sent will be in place of the `TS1` or `TS2` Ordered Set that it would otherwise forward.

If no Lanes meet Z_{RX-DC} on a Pseudo Port, and the following sequence occurs:

- An exit from Electrical Idle is detected on any Lane of that Pseudo Port.
- And then if not all Lanes infer Electrical Idle, via absence of exit from Electrical Idle in a 12 ms window on that Pseudo Port and the other Pseudo Port is not receiving Ordered Sets on any Lane in that same 12 ms window.

Then the same Pseudo Port, where no Lanes meet Z_{RX-DC} , sends the Electrical Idle Exit pattern described below for 5 μ s on all Lanes.

If operating at 2.5 GT/s and the following occurs:

- any Lane detects an exit from Electrical Idle
- and then receives two consecutive TS1 Ordered Sets with Lane and Link numbers equal to PAD
- and the other Pseudo Port is not receiving Ordered Sets on any Lane

Then Receiver Detection is performed on all Lanes of the Pseudo Port that is not receiving Ordered Sets. If no Receivers were detected then:

- The result is back propagated as described in § Section 4.3.4 , within 1.0 ms.
- The same Pseudo Port that received the TS1 Ordered Sets with Lane and Link numbers equal to PAD, sends the Electrical Idle Exit pattern described below for 5 μ s on all Lanes.

If a Lane detects an exit from Electrical Idle then the Lane must start forwarding when all of the following are true:

- Data rate is determined, see § Section 4.3.6.4 , current data rate is changed to RT_next_data_rate if required.
- Lane polarity is determined, see § Section 4.3.6.2 .
- Two consecutive TS1 Ordered Sets or two consecutive TS2 Ordered Sets are received.
- Two consecutive TS1 Ordered Sets or two consecutive TS2 Ordered Sets are received on all Lanes that detected an exit from Electrical Idle or the max Retimer Exit Latency has occurred, see § Table 4-64.
- Lane De-skew is achieved on all Lanes that received two consecutive TS1 or two consecutive TS2 Ordered Sets.
- If a data rate change has occurred then 6 μ s has elapsed since Electrical Idle Exit was detected.

All Ordered Sets used to establish forwarding must be discarded. Only Lanes that have detected a Receiver on the other Pseudo Port, as described in § Section 4.3.4 , are considered for forwarding.

Otherwise after a 3.0 ms timeout, if the other Pseudo Port is not receiving Ordered Sets then Receiver Detection is performed on all Lanes of the Pseudo Port that is not receiving Ordered Sets, the result is back propagated as described in § Section 4.3.4 , and if no Receivers were detected:

- Then the same Pseudo Port that was unable to receive two consecutive TS1 or TS2 Ordered Sets on any Lane sends the Electrical Idle Exit pattern described below for 5 μ s on all Lanes.
- Else the Electrical Idle Exit pattern described below is forwarded on all Lanes that detected an exit from Electrical Idle.
- When using 8b/10b encoding:
 - The Modified Compliance Pattern with the error status Symbol set to 00h.
- When using 128b/130b encoding:
 - One EIEOS or one EIEOSQ (recommended).
 - 32 Data Blocks, each with a payload of 16 Idle data Symbols (00h), scrambled, for Symbols 0 to 13.
 - Symbol 14 and 15 of each Data Block either contain Idle data Symbols (00h), scrambled, or DC Balance, determined by applying the same rules in § Section 4.2.5.1 to these Data Blocks.
- When using 1b/1b encoding:
 - Four consecutive EIEOS, uninterrupted by any other Ordered Set including the Control SKP Ordered Set.
 - 32 Data Blocks, each with a payload of 16 Idle data Symbols (00h), scrambled, for Symbols 0-6, 8-14.
 - Symbol 7 and 15 of each Data Block either contain Idle data Symbols (00h), scrambled, or DC Balance, determined by applying the same rules in § Section 4.2.5.1 to these Data Blocks.

- This Path now is forwarding the Electrical Idle Exit pattern. In this state Electrical Idle is inferred by the absence of Electrical Idle Exit, see § Table 4-65. The Path continues forwarding the Electrical Idle Exit pattern until Electrical Idle is inferred on any lane, or a 48 ms time out occurs. If a 48 ms time out occurs then:
 - The `RT_LinkUp` variable is set to 0b.
 - The Pseudo Port places its Transmitter in Electrical Idle
 - The `RT_next_data_rate` and the `RT_error_data_rate` must be set to 2.5 GT/s for both Pseudo Ports
 - Receiver Detection is performed on the Pseudo Port that was sending the Electrical Idle Exit pattern and timed out, the result is back propagated as described in § Section 4.3.4 .

The Transmitter, on the opposite Pseudo Port that was sending the Electrical Idle Exit Pattern and timed out, sends the Electrical Idle Exit Pattern described above for 5 μ s.

IMPLEMENTATION NOTE: ELECTRICAL IDLE EXIT §

Forwarding Electrical Idle Exit occurs in error cases where a Retimer is unable to decode training sets. Upstream and Downstream Ports use Electrical Idle Exit (without decoding any Symbols) during Polling, Compliance, and Recovery, Speed. If the Retimer does not forward Electrical Idle Exit then the Upstream and Downstream Ports will misbehave in certain conditions. For example, this may occur after a speed change to a higher data rate. In this event forwarding Electrical Idle Exit is required to keep the Upstream and Downstream Ports in lock step at Recovery, Speed, so that the data rate will return to the previous data rate, rather than a Link Down condition from a time out to Detect.

When a Retimer detects an exit from Electrical Idle and starts forwarding data, the time this takes is called the Retimer Exit Latency, and allows for such things as data rate change (if required), clock and data recovery, Symbol lock, Block Alignment, Lane-to-Lane de-skew, Receiver tuning, etc. The Maximum Retimer Exit Latency is specified below for several conditions:

- The data rate before and after Electrical Idle and Electrical Idle exit detect does not change.
- Data rate change to a data rate that uses 8b/10b encoding.
- Data rate change to a data rate that uses 128b/130b encoding for the first time.
- Data rate change to a data rate that uses 128b/130b encoding not for the first time.
- Data rate change to a data rate that uses 1b/1b encoding for the first time.
- Data rate change to a data rate that uses 1b/1b encoding not for the first time.
- How long both transmitters have been in Electrical Idle when a data rate change occurs.

Retimers are permitted to change their data rate while in Electrical Idle, and it is recommended that Retimers start the data rate change while in Electrical Idle to minimize Retimer Exit latency.

Table 4-64 Maximum Retimer Exit Latency §

Condition	Link in Electrical Idle for X μ s, where:	
	X < 500 μ s	X \geq 500 μ s
No data rate change, 2.5 GT/s	8 μ s	8 μ s
No data rate change, 5.0 GT/s or higher	4 μ s	4 μ s

Condition	Link in Electrical Idle for X μ s, where:	
	X < 500 μ s	X \geq 500 μ s
When forwarding <u>TS1</u> Ordered Sets at 2.5 GT/s with Lane and Link number equal to PAD.	1 ms	1 ms
Any data rate change to 8b/10b encoding data rate	504 – X μ s	4 μ s
First data rate change to 128b/130b encoding data rate	1.5 – X ms	1 ms
Subsequent data rate change to 128b/130b encoding data rate	504 – X μ s	4 μ s
First data rate change to 1b/1b encoding data rate	1.5 – X ms	1 ms
Subsequent data rate change to 1b/1b encoding data rate	504 – X μ s	4 μ s

4.3.6.4 Data Rate Change and Determination Rules §

The data rate of the Retimer is set to 2.5 GT/s after deassertion of Fundamental Reset.

Both Pseudo Ports of the Retimer must operate at the same data rate. If a Pseudo Port places its Transmitter in Electrical Idle, then the Symbols that it has just completed transmitting determine the variables RT_next_data_rate and RT_error_data_rate. Only when both Pseudo Ports have all Lanes in Electrical Idle shall the Retimer change the data rate. If both Pseudo Ports do not make the same determination of these variables, then both variables must be set to 2.5 GT/s.

- If both Pseudo Ports were forwarding non-training sequences, then the RT_next_data_rate must be set to the current data rate. The RT_error_data_rate must be set to 2.5 GT/s if 8b/10b or 128b/130b encoding is being used. The RT_error_data_rate is set to 32.0 GT/s if 1b/1b encoding is being used. Note: this covers the case where the Link has entered L1 from L0.
- If both Pseudo Ports were forwarding TS2 Ordered Sets with the speed_change bit set to 1b and either:
 - the data rate, when forwarding those TS2s, is greater than 2.5 GT/s or,
 - the highest common data rate received in the data rate identifiers in both directions is greater than 2.5 GT/s,
then RT_next_data_rate must be set to the highest common data rate and the RT_error_data_rate is set to current data rate. Note: this covers the case where the Link has entered Recovery.Speed from Recovery.RcvrCfg and is changing the data rate according to the highest common data rate.
- Else the RT_next_data_rate must be set to the RT_error_data_rate. The RT_error_data_rate is set to 2.5 GT/s if 8b/10b or 128b/130b encoding is being used. The RT_error_data_rate is set to 32.0 GT/s if 1b/1b encoding is being used. Note this covers the two error cases:
 - This indicates that the Link was unable to operate at the current data rate (greater than 2.5 GT/s) and the Link will operate at either the 2.5 GT/s data rate or the 32.0 GT/s data rate or
 - This indicates that the Link was unable to operate at the new negotiated data rate and will revert back to the old data rate with which it entered Recovery from L0 or L1.

4.3.6.5 Electrical Idle Entry Rules §

The Rules for Electrical Idle entry in Forwarding mode are a function of whether the Retimer is forwarding training sets or non-training sets. The determination of this is described in § Section 4.3.6.1 .

Before a Transmitter enters Electrical Idle, it must always send the Electrical Idle Ordered Set Sequence (EIOSQ), unless otherwise specified.

If the Retimer is forwarding training sets then:

- If an EIOS is received on a Lane, then the EIOSQ is forwarded on that Lane and only that Lane places its Transmitter in Electrical Idle.
- If Electrical Idle is inferred on a Lane, then that Lane places its Transmitter in Electrical Idle, after EIOSQ is transmitted on that Lane.

Else if the Retimer is forwarding non-training sets then:

- If operating in Flit Mode and EIOS are received on some Lanes while some other Lanes receive SKP OS (i.e., L0p Link width down-size), then Lanes that are receiving EIOS must forward the EIOSQ and must place their Transmitters into Electrical Idle. Lanes that are forwarding Symbols, but are not receiving EIOS, must continue forwarding Symbols and must not place their Transmitters into Electrical Idle. Else if an EIOS is received on any Lane, then the EIOSQ is forwarded on all Lanes that are currently forwarding Symbols and all Lanes place their Transmitters in Electrical Idle.
- If Electrical Idle is inferred on a Lane, then that Lane places its Transmitter in Electrical Idle, and EIOSQ is not transmitted on that Lane.
- When operating at 64.0 GT/s, a Retimer must follow the requirements of § Section 4.2.3.2 in order to identify SKP OS, EIEOS, and EIOS received.

The Retimer is required to infer Electrical Idle. The criteria for a Retimer inferring Electrical Idle are described in § Table 4-65.

Table 4-65 Inferring Electrical Idle §

State	2.5 GT/s	5.0 GT/s	8.0 GT/s	16.0 GT/s or higher
Forwarding: Non Training Sequence	Absence of a SKP Ordered Set in a 128 μ s window	Absence of a SKP Ordered Set in a 128 μ s window	Absence of a SKP Ordered Set in a 128 μ s window	Absence of a SKP Ordered Set in a 128 μ s window
Forwarding: Training Sequence	Absence of a TS1 or TS2 Ordered Set in a 1280 UI interval	Absence of a TS1 or TS2 Ordered Set in a 1280 UI interval	Absence of a TS1 or TS2 Ordered Set in a 4680 UI interval	Absence of a TS1 or TS2 Ordered Set in a 4680 UI interval
Forwarding: Electrical Idle Exit Executing: Force Timeout	Absence of an exit from Electrical Idle in a 2000 UI interval	Absence of an exit from Electrical Idle in a 16000 UI interval	Absence of an exit from Electrical Idle in a 16000 UI interval	Absence of an exit from Electrical Idle in a 16000 UI interval
Forwarding: Loopback Executing: Loopback Follower	Absence of an exit from Electrical Idle in a 128 μ s window	N/A	N/A	N/A

4.3.6.6 Transmitter Settings Determination Rules §

When a data rate change to 64.0 GT/s occurs the Retimer transmitter settings are determined as follows:

- If the RT_G6_EQ_complete variable is set to 1b:
 - The Transmitter must use the coefficient settings agreed upon at the conclusion of the last equalization procedure applicable to 64.0 GT/s operation.
- Else:
 - An Upstream Pseudo Port must use the 128b/130b Transmitter preset values it registered from the eight consecutive 128b/130b EQ TS2 Ordered Sets received while operating at 32.0 GT/s in its Transmitter preset setting as soon as it starts transmitting at the 64.0 GT/s data rate and must ensure that it meets the preset definition in § Section 4.2.4.2 . Lanes that received a Reserved or unsupported Transmitter preset value must use an implementation specific method to choose a supported Transmitter preset setting for use as soon it starts transmitting at 64.0 GT/s.
 - A Downstream Pseudo Port determines its Transmitter Settings in an implementation specific manner when it starts transmitting at 64.0 GT/s.

The RT_G6_EQ_complete variable is set to 1b when:

- Two consecutive TS0 Ordered Sets are received with EC = 01b at 64.0 GT/s and RT_port_orientation is set to Downstream Port.
- Two consecutive TS1 Ordered Sets are received with EC = 01b at 64.0 GT/s and RT_port_orientation is set to Upstream Port.

The RT_G6_EQ_complete variable is set to 0b when any of the following occur:

- The RT_LinkUp variable is set to 0b.
- The Pseudo Port is operating at 32.0 GT/s and eight consecutive 128b/130b EQ TS2 Ordered Sets are received on any Lane of the Upstream Pseudo Port. The value in the 128b/130b Transmitter Preset field is registered for later use at 64.0 GT/s for that Lane.

When a data rate change to 32.0 GT/s occurs the Retimer transmitter settings are determined as follows:

- If the RT_G5_EQ_complete variable is set to 1b:
 - The Transmitter must use the coefficient settings agreed upon at the conclusion of the last equalization procedure applicable to 32.0 GT/s operation.
- Else:
 - An Upstream Pseudo Port must use the 128b/130b Transmitter preset values it registered from the eight consecutive 128b/130b EQ TS2 Ordered Sets received while operating at 16.0 GT/s in its Transmitter preset setting as soon as it starts transmitting at the 32.0 GT/s data rate and must ensure that it meets the preset definition in § Section 4.2.4.2 . Lanes that received a Reserved or unsupported Transmitter preset value must use an implementation specific method to choose a supported Transmitter preset setting for use as soon it starts transmitting at 32.0 GT/s.
 - A Downstream Pseudo Port determines its Transmitter Settings in an implementation specific manner when it starts transmitting at 32.0 GT/s.

The RT_G5_EQ_complete variable is set to 1b when:

- Two consecutive TS1 Ordered Sets are received with EC = 01b at 32.0 GT/s.

The RT_G5_EQ_complete variable is set to 0b when any of the following occur:

- RT_LinkUp variable is set to 0b.
- The Pseudo Port is operating at 16.0 GT/s and eight consecutive 128b/130b EQ TS2 Ordered Sets are received on any Lane of the Upstream Pseudo Port. The value in the 128b/130b Transmitter Preset field is registered for later use at 32.0 GT/s for that Lane.

When a data rate change to 16.0 GT/s occurs the Retimer transmitter settings are determined as follows:

- If the RT_G4_EQ_complete variable is set to 1b:
 - The Transmitter must use the coefficient settings agreed upon at the conclusion of the last equalization procedure applicable to 16.0 GT/s operation.
- Else:
 - An Upstream Pseudo Port must use the 128b/130b Transmitter preset values it registered from the received eight consecutive 128b/130b EQ TS2 Ordered Sets in its Transmitter preset setting as soon as it starts transmitting at the 16.0 GT/s data rate and must ensure that it meets the preset definition in § Section 8.3.3.3 . Lanes that received a Reserved or unsupported Transmitter preset value must use an implementation specific method to choose a supported Transmitter preset setting for use as soon it starts transmitting at 16.0 GT/s.
 - A Downstream Pseudo Port determines its Transmitter Settings in an implementation specific manner when it starts transmitting at 16.0 GT/s.

The RT_G4_EQ_complete variable is set to 1b when:

- Two consecutive TS1 Ordered Sets are received with EC = 01b at 16.0 GT/s.

The RT_G4_EQ_complete variable is set to 0b when any of the following occur:

- The RT_LinkUp variable is set to 0b.
- Eight consecutive 128b/130b EQ TS2 Ordered Sets are received on any Lane of the Upstream Pseudo Port. The value in the 128b/130b Transmitter Preset field is registered for later use at 16.0 GT/s for that Lane.

When a data rate change to 8.0 GT/s occurs the Retimer transmitter settings are determined as follows:

- If the RT_G3_EQ_complete variable is set to 1b:
 - The Transmitter must use the coefficient settings agreed upon at the conclusion of the last equalization procedure applicable to 8.0 GT/s operation.
- Else:
 - An Upstream Pseudo Port must use the 8.0 GT/s Transmitter preset values it registered from the received eight consecutive EQ TS2 Ordered Sets in its Transmitter preset setting as soon as it starts transmitting at the 8.0 GT/s data rate and must ensure that it meets the preset definition in § Section 8.3.3 . Lanes that received a Reserved or unsupported Transmitter preset value must use an implementation specific method to choose a supported Transmitter preset setting for use as soon it starts transmitting at 8.0 GT/s. The Upstream Pseudo Port may optionally use the 8.0 GT/s Receiver preset hint values it registered in those EQ TS2 Ordered Sets.
 - A Downstream Pseudo Port determines its Transmitter preset settings in an implementation specific manner when it starts transmitting at 8.0 GT/s.

The RT_G3_EQ_complete variable is set to 1b when:

- Two consecutive TS1 Ordered Sets are received with EC = 01b at 8.0 GT/s.

The RT_G3_EQ_complete variable is set to 0b when any of the following occur:

- The RT_LinkUp variable is set to 0b.
- Eight consecutive EQ TS1 or eight consecutive EQ TS2 Ordered Sets are received on any Lane of the Upstream Pseudo Port. The value in the 8.0 GT/s Transmitter Preset and optionally the 8.0 GT/s Receiver Preset Hint fields are registered for later use at 8.0 GT/s for that Lane.

When a data rate change to 5.0 GT/s occurs the Retimer transmitter settings are determined as follows:

- The Upstream Pseudo Port must set its Transmitters to either -3.5 dB or -6.0 dB, according to the Selectable De-emphasis bit (bit 6 of Symbol 4) received in eight consecutive TS2 Ordered Sets, in the most recent series of TS2 Ordered sets, received prior to entering Electrical Idle.
- The Downstream Pseudo Port sets its Transmitters to either -3.5 dB or -6.0 dB in an implementation specific manner.

4.3.6.7 Ordered Set Modification Rules §

Ordered Sets are forwarded, and certain fields are modified according to the following rules:

- The Retimer shall not modify any fields except those specifically allowed/required for modification in this specification.
- LF: the Retimer shall overwrite the LF field in TS1 Ordered Sets transmitted in both directions. The new value is determined in an implementation specific manner by the Retimer.
- FS: the Retimer shall overwrite the FS field in TS1 Ordered Sets transmitted in both directions. The new value is determined in an implementation specific manner by the Retimer.
- Pre-Cursor Coefficient: the Retimer shall overwrite the Pre-Cursor Coefficient field in TS1 Ordered Sets transmitted in both directions. The new value is determined by the current Transmitter settings.
- Cursor Coefficient: the Retimer shall overwrite the Cursor Coefficient field in TS1 Ordered Sets transmitted in both directions. The new value is determined by the current Transmitter settings.
- Post-Cursor Coefficient: the Retimer shall overwrite the Post-Cursor Coefficient field in the TS1 Ordered Sets transmitted in both directions. The new value is determined by the current Transmitter settings.
- Parity: the Retimer shall overwrite the Parity bit of forwarded TS1 Ordered Sets. This bit is the even parity of all bits of Symbols 6, 7, and 8 and bits 6:0 of Symbol 9.
- Transmitter Preset: the Retimer shall overwrite the Transmitter Preset field in TS1 Ordered Sets transmitted in both directions. If the Transmitter is using a Transmitter preset setting then the value is equal to the current setting, else it is recommended that the Transmitter Preset field be set to the most recent Transmitter preset setting that was used for the current data rate.

The Retimer is permitted to do the following:

- overwrite the Transmitter Preset field in EQ TS1 Ordered Sets in either direction
- overwrite the 8.0 GT/s Transmitter Preset field in EQ TS2 Ordered Sets in the Downstream direction.
- overwrite the 128b/130b Transmitter Preset field in 128b/130b EQ TS2 Ordered Sets, in the Downstream direction.

The new values for the 8.0 GT/s Transmitter Preset and 128b/130b Transmitter Preset fields are determined in an implementation specific manner by the Retimer.

During phase 0 of Equalization to 16.0 GT/s (i.e., the current Data Rate is 8.0 GT/s), phase 0 of Equalization to 32.0 GT/s (i.e., the current Data Rate is 16.0 GT/s), or phase 0 of Equalization to 64.0 GT/s (i.e., the current Data Rate is 32.0 GT/s) the Retimer is permitted to do the following in the Upstream direction:

- Forward received TS2 Ordered Sets.
- Convert TS2 Ordered Sets to 128b/130b EQ TS2 Ordered Sets, the value for the 128b/130b Transmitter Preset field is determined in an implementation specific manner by the Retimer.
- Forward received 128b/130b EQ TS2 Ordered Sets with modification, the value for the 128b/130b Transmitter Preset field is determined in an implementation specific manner by the Retimer.
- Convert 128b/130b EQ TS2 Ordered Sets to TS2 Ordered Sets.
- Receiver Preset Hint: the Retimer is permitted to do the following:
 - overwrite the Receiver Preset Hint field in EQ TS1 Ordered Sets in either direction
 - overwrite the 8.0 GT/s Receiver Preset Hint field in EQ TS2 Ordered Sets in the Downstream direction.

The new values, for the Receiver Preset Hint and 8.0 GT/s Receiver Preset Hint fields are determined in an implementation specific manner by the Retimer.
- SKP Ordered Set: The Retimer is permitted to adjust the length of SKP Ordered Sets transmitted in both directions. The Retimer must perform the same adjustment on all Lanes. When operating with 8b/10b encoding, the Retimer is permitted to add or remove one SKP Symbol of a SKP Ordered Set. When operating with 128b/130b encoding, a Retimer is permitted to add or remove 4 SKP Symbols of a SKP Ordered Set. When operating with 1b/1b encoding, only Control SKP Ordered Sets are sent.
- Control SKP Ordered Set: The Retimer must modify the First Retimer Data Parity, or the Second Retimer Data Parity, of the Control SKP Ordered Set when the Retimer is in forwarding mode at 16.0 GT/s or above, according to its received parity. The received even parity is computed independently on each Lane as follows:
 - Parity is initialized when a data rate change occurs.
 - Parity is initialized when a SDS Ordered Set is received.
 - Parity is updated with each bit of a Data Block's payload before de-scrambling has been performed.
 - Parity is initialized when a Control SKP Ordered Set is received. However, parity is NOT initialized when a Standard SKP Ordered Set is received.

If a Pseudo Port detects the Retimer Present bit was 0b in the most recently received two consecutive TS2 or EQ TS2 Ordered Sets received by that Pseudo Port when operating at 2.5 GT/s then that Pseudo Port receiver modifies the First Retimer Data Parity as it forwards the Control SKP Ordered Set, else that Pseudo Port receiver modifies the Second Retimer Data Parity as it forwards the Control SKP Ordered Set.

The Retimer must modify symbols $4*N+1$, $4*N+2$, and $4*N+3$ of the Control SKP Ordered Set in the Upstream direction as described in § Section 4.2.18 .

See § Section 4.2.8.2 for Control SKP Ordered Set definition.

 - When operating with 1b/1b encoding, a Retimer is permitted to add or remove 8 Bytes of SKP at an aligned 8 byte boundary.
- Selectable De-emphasis: the Retimer is permitted to overwrite the Selectable De-emphasis field in the TS1 or TS2 Ordered Set in both directions. The new value is determined in an implementation specific manner by the Retimer.
- The Data Rate Identifier: The Retimer must set the Data Rate Supported bits of the Data Rate Identifier Symbol consistent with the data rates advertised in the received Ordered Sets and its own max supported Data Rate, i.e., it clears to 0b all Symbol 4 bits[5:0] Data Rates that it does not support. A Retimer must support all data

rates below and including its maximum supported data rate. A Retimer makes its determination of maximum supported Data Rate once, after fundamental reset. A Retimer that does not support Flit Mode must set Symbol 4, bit 0 to 0b.

- DC Balance: When operating with 128b/130b encoding, the Retimer tracks the DC Balance of its Pseudo Port transmitters and transmits DC Balance Symbols as described in § Section 4.2.5.1 .
- Retimer Present: When operating at 2.5 GT/s, the Retimer must Set the Retimer Present bit in all forwarded Ordered Sets with a defined Retimer Present bit.
- Two Retimers Present: If the Retimer supports 16.0 GT/s or higher, then when operating at 2.5 GT/s, the Retimer must Set the Two Retimers Present bit in all forwarded Ordered Sets with a defined Two Retimers Present bit, if it receives an Ordered Set that has a defined Retimer Present bit and the Retimer Present bit is Set. If the Retimer does not support 16.0 GT/s or higher, then when operating at 2.5 GT/s, the Retimer is permitted to Set the Two Retimers Present bit of all forwarded Ordered Sets with a defined Two Retimers Present bit, if it receives an Ordered Set that has a defined Retimer Present bit and the Retimer Present bit is Set.
- Loopback: When optionally supporting Follower Loopback in Execution mode at 8b/10b or 128b/130b encoding, the Loopback bit must be cleared to 0b when forwarding training sets. When Follower Loopback in Execution mode at 1b/1b encoding is enabled, the Assert Loopback bits (Training Control bits 2:0) must be cleared to 000b when forwarding training sets.
- Enhanced Link Behavior Control: If the Retimer supports 32.0 GT/s or higher, then when operating at 2.5GT/s, the Retimer must set the Enhanced Link Behavior Control bits of all forwarded TS1, TS2, EQ TS1 and EQ TS2 Ordered Sets as follows:
 - Set to 11b when Retimer supports Modified TS1/TS2 Ordered Sets and the Enhanced Link Behavior Control bits set to 11b in the Ordered Sets received for forwarding.
 - Set to 10b when Retimer supports no equalization and the Enhanced Link Behavior Control bits is set to 10b in the Ordered Sets received for forwarding.
 - Set to 01b when Retimer supports Equalization Bypass to Highest NRZ Rate and the Enhanced Link Behavior Control field is set to 01b in the Ordered Sets received for forwarding.
 - Otherwise, set to 00b.

4.3.6.8 DLLP, TLP, Logical Idle, and Flit Modification Rules §

DLLPs, TLPs, Logical Idle, and Flits are forwarded with no modifications to any of the Symbols unless otherwise specified.

4.3.6.9 8b/10b Encoding Rules §

The Retimer shall meet the requirements in § Section 4.2.1.1.3 except as follows:

- When the Retimer is forwarding and an 8b/10b decode error or a disparity error is detected in the received data, the Symbol with an error is replaced with the D21.3 Symbol with incorrect disparity in the forwarded data.

IMPLEMENTATION NOTE:**FORWARDING D21.3 SYMBOL WITH INCORRECT DISPARITY §**

Detection of 8b/10b decode errors and disparity errors takes place in the Receiver. Whether replacement of the Symbol in error takes place in the Receiver or in the Transmitter, the Symbol forwarded by the Retimer after Scrambling will be the D21.3 Symbol with incorrect disparity.

- This clause in § Section 4.2.1.1.3 does not apply: If a received Symbol is found in the column corresponding to the incorrect running disparity or if the Symbol does not correspond to either column, the Physical Layer must notify the Data Link Layer that the received Symbol is invalid. This is a Receiver Error, and is a reported error associated with the Port (see § Section 6.2).

IMPLEMENTATION NOTE:**RETIMER TRANSMITTER DISPARITY §**

The Retimer must modify certain fields of the TS1 and TS2 Ordered Sets (e.g., Receiver Preset Hint, Transmitter Preset), therefore the Retimer must recalculate the running disparity. Simply using the disparity of the received Symbol may lead to an error in the running disparity. For example, some 8b/10b codes have 6 ones and 4 zeros for positive disparity, while other codes have 5 ones and 5 zeros.

4.3.6.10 8b/10b Scrambling Rules §

A Retimer is required to determine if scrambling is disabled when using 8b/10b encoding as described in § Section 4.3.6.2.

4.3.6.11 Hot Reset Rules §

If any Lane of the Upstream Pseudo Port receives two consecutive TS1 Ordered Sets with the Hot Reset bit set to 1b and both the Disable Link bit and the Loopback bit set to 0b, and then both Pseudo Ports either receive an EIOS or infer Electrical Idle on any Lane, that is receiving TS1 Ordered Sets, the Retimer does the following:

- Clears variable RT_LinkUp = 0b.
- Places its Transmitters in Electrical Idle on both Pseudo Ports.
- Set the RT_next_data_rate variable to 2.5 GT/s.
- Set the RT_error_data_rate variable to 2.5 GT/s.
- Waits for an exit from Electrical Idle on any Lane on either Pseudo Port.

The Retimer does not perform Receiver Detection on either Pseudo Port.

4.3.6.12 Disable Link Rules §

If any Lane of the Upstream Pseudo Port receives two consecutive TS1 Ordered Sets with the Disable Link bit set to 1b and both the Hot Reset bit and the Loopback bit set to 0b, and then both Pseudo Ports either receive an EIOS or infer Electrical Idle on any Lane, that is receiving TS1 Ordered Sets, the Retimer does the following:

- Clears variable RT_LinkUp = 0b.
- Places its Transmitters in Electrical Idle on both Pseudo Ports.
- Set the RT_next_data_rate variable to 2.5 GT/s.
- Set the RT_error_data_rate variable to 2.5 GT/s.
- Waits for an exit from Electrical Idle on any Lane on either Pseudo Port.

The Retimer does not perform Receiver Detection on either Pseudo Port.

4.3.6.13 Loopback §

The Retimer must operate in Follower Loopback Execution mode when operating at 8b/10b or 128b/130b encoding and any Lane receives two consecutive TS1 Ordered Sets with the Loopback bit equal to 1b and both the Hot Reset and Disable Link bits set to 0b and the ability to execute Follower Loopback is configured in an implementation specific way.

The Retimer must operate in Follower Loopback Execution mode when operating at 1b/1b encoding and any Lane receives two consecutive TS1 Ordered Sets with Training Control bits [3:2] set to 01b (Assert Loopback) and with Training Control bits [1:0] matching the RT_number. See § Section 4.3.7.3 for Follower Loopback in Execution mode.

- When RT_number is 01b, the Retimer represents Pseudo-Ports B and C of the system topology (which are the ports being targeted for Follower Loopback Execution mode when Training Control = 0101b).
- When RT_number is 10b, the Retimer represents Pseudo-Ports D and E of the system topology (which are the ports being targeted for Follower Loopback Execution mode when Training Control = 0110b).

The Retimer follows these additional rules if one of the following conditions is met:

- Retimer is operating at 8b/10b or 128b/130b encoding and any Lane receives two consecutive TS1 Ordered Sets with the Loopback bit equal to 1b and both the Hot Reset bit and the Disable Link bit set to 0b and the ability to execute Follower Loopback is not configured in an implementation specific way.
- Retimer is operating at 1b/1b encoding and any Lane receives two consecutive TS1 Ordered Sets with the Assert Loopback bit (Training Control bits 2) set to 1b and the conditions to enable Follower Loopback in Execution mode are not met. The setting does not configure Follower Loopback.

The purpose of these rules is to allow interoperation when a Retimer (or two Retimers) exist between a Loopback Lead and a Loopback Follower

- The Pseudo Port that received the TS1 Ordered Sets with the Loopback bit set to 1b acts as the Loopback Follower (the other Pseudo Port acts as Loopback Lead). The Upstream Path is defined as the Pseudo Port that is the Loopback Lead to the Pseudo Port that is the Loopback Follower. The other Path is the Downstream Path.
- Once established, if a Lane loses the ability to maintain Symbol Lock or Block alignment, then the Lane must continue to transmit Symbols while in this state.
- When using 8b/10b encoding and Symbol lock is lost, the Retimer must attempt to re-achieve Symbol Lock.

- When using 128b/130b encoding and Block Alignment is lost, the Retimer must attempt to re-achieve Block Alignment via SKP Ordered Sets.
- When using 1b/1b encoding and Block or Flit Alignment is lost, the Retimer must attempt to re-achieve Block and Flit Alignment via SKP Ordered Sets.
- If Loopback was entered while the Link Components were in Configuration.Linkwidth.Start, then determine the highest common data rate of the data rates supported by the Link via the data rates received in two consecutive TS1 Ordered Sets or two consecutive TS2 Ordered Sets on any Lane, that was receiving TS1 or TS2 Ordered Sets, at the time the transition to Forwarding.Loopback occurred. If the current data rate is not the highest common data rate, then:
 - Wait for any Lane to receive EIOS, and then place the Transmitters in Electrical Idle for that Path.
 - When all Transmitters are in Electrical Idle, adjust the data rate as previously determined.
 - If the new data rate is 5.0 GT/s, then the Selectable De-emphasis is determined the same as way as described in § Section 4.2.7.10.1 .
 - If the new data rate uses 128b/130b or 1b/1b encoding, then the Transmitter preset setting is determined the same as way as described in § Section 4.2.7.10.1 .
 - In the Downstream Path; wait for Electrical Idle exit to be detected on each Lane and then start forwarding when two consecutive TS1 Ordered Sets have been received, on a Lane by Lane basis. This is considered the first time to this data rate for the Retimer Exit Latency.
 - In the Upstream Path; if the Compliance Receive bit of the TS1 Ordered Sets that directed the follower to this state was not asserted, then wait for Electrical Idle exit to be detected on each Lane, and start forwarding when two consecutive TS1 Ordered Sets have been received, on a Lane by Lane basis. This is considered the first time to this data rate for the Retimer Exit Latency.
- In the Upstream Path; if the Compliance Receive bit of the TS1 Ordered Sets that directed the follower to this state was set to 1b, then wait for Electrical Idle exit to be detected on each Lane, and start forwarding immediately, on a Lane by Lane basis. This is considered the first time to this data rate for the Retimer Exit Latency.
- If four EIOS (one EIOS if the current data rate is 2.5 GT/s) are received on any Lane then:
 - Transmit eight EIOS on every Lane that is transmitting TS1 Ordered Sets on the Pseudo Port that did not receive the EIOS and place the Transmitters in Electrical Idle.
- When both Pseudo Ports have placed their Transmitters in Electrical Idle then:
 - Set the RT_next_data_rate variable to 2.5 GT/s.
 - Set the RT_error_data_rate variable to 2.5 GT/s.
 - The additional rules for Loopback no longer apply unless the rules for entering this section are met again.

4.3.6.14 Compliance Receive Rules §

The Retimer follows these additional rules if any Lane receives eight consecutive TS1 Ordered Sets (or their complement) with the Compliance Receive bit set to 1b and the Loopback bit set to 0b. The purpose of the following rules is to support Link operation with a Retimer when the Compliance Receive bit is Set and the Loopback bit is Clear in TS1 Ordered Sets, transmitted by the Upstream or Downstream Port, while the Link is in Polling.Active.

- Pseudo Port A is defined as the first Pseudo Port that receives eight consecutive TS1 Ordered Sets (or their complement) with the Compliance Receive bit is Set and the Loopback bit is Clear. Pseudo Port B is defined as the other Pseudo Port.

- The Retimer determines the highest common data rate of the Link by examining the data rate identifiers in the TS1 Ordered Sets received on each Pseudo Port, and the maximum data rate supported by the Retimer.
- If the highest common data rate is equal to 5.0 GT/s then:
 - The Retimer must change its data rate to 5.0 GT/s as described in § Section 4.3.6.4 .
 - The Retimer Pseudo Port A must set its de-emphasis according to the selectable de-emphasis bit received in the eight consecutive TS1 Ordered Sets.
 - The Retimer Pseudo Port B must set its de-emphasis in an implementation specific manner.
- If the highest common data rate is equal to 8.0 GT/s or higher then:
 - The Retimer must change its data rate to as applicable, as described in § Section 4.3.6.4 .
 - Lane numbers are determined as described in § Section 4.2.12 .
 - The Retimer Pseudo Port A must set its Transmitter coefficients on each Lane to the Transmitter preset value advertised in Symbol 6 of the eight consecutive TS1 Ordered Sets and this value must be used by the Transmitter (use of the Receiver preset hint value advertised in those TS1 Ordered Sets is optional). If the common data rate is 8.0 GT/s or higher, any Lanes that did not receive eight consecutive TS1 Ordered Sets with Transmitter preset information can use any supported Transmitter preset setting in an implementation specific manner.
 - The Retimer Pseudo Port B must set its Transmitter and Receiver equalization in an implementation specific manner.
- The Retimer must forward the Modified Compliance Pattern when it has locked to the pattern. This occurs independently on each Lane in each direction. If a Lane's Receiver loses Symbol Lock or Block Alignment, the associated Transmitter (i.e., same Lane on opposite Pseudo Port) Continues to forward data.
- Once locked to the pattern, the Retimer keeps an internal count of received Symbol errors, on a per-Lane basis. The pattern lock and Lane error is permitted to be readable in an implementation specific manner, on a per-Lane basis.
- When operating with 128b/130b or 1b/1b encoding, Symbols with errors are forwarded unmodified by default, or may optionally be corrected to remove error pollution. The default behavior must be supported and the method of selecting the optional behavior, if supported, is implementation specific.
- When operating with 8b/10b encoding, Symbols with errors are replaced with the D21.3 Symbol with incorrect disparity by default, or may optionally be corrected to remove error pollution. The default behavior must be supported and the method of selecting the optional behavior, if supported, is implementation specific.
- The error status Symbol when using 8b/10b encoding or the Error_Status field when using 128b/130b or 1b/1b encoding is forwarded unmodified by default, or may optionally be redefined as it is transmitted by the Retimer. The default behavior must be supported and the method of selecting the optional behavior, if supported, is implementation specific.
- If any Lane receives an EIOS on either Pseudo Port then:
 - Transmit EIOSQ on every Lane of the Pseudo Port that did not receive EIOS and place the Transmitters in Electrical Idle. Place the Transmitters of the other Pseudo Port in Electrical Idle; EIOS is not transmitted by the other Pseudo Port.
 - Set the RT_next_data_rate variable to 2.5 GT/s.
 - Set the RT_error_data_rate variable to 2.5 GT/s.
 - The Compliance Receive additional rules no longer apply unless the rules for entering this section are met again.

4.3.6.15 Enter Compliance Rules §

The Retimer follows these additional rules if the Retimer is exiting Electrical Idle after entering Electrical Idle as a result of Hot Reset, and the Retimer Enter Compliance bit is Set in the Retimer. The purpose of the following rules is to support Link operation with a Retimer when the Link partners enter compliance as a result of the Enter Compliance bit in the Link Control 2 Register set to 1b in both Link Components and a Hot Reset occurring on the Link. Retimers do not support Link operation if the Link partners enter compliance when they exit detect if the entry into detect was not caused by a Hot Reset.

Retimers must support the following register fields in an implementation specific manner:

- Retimer Target Link Speed
 - One field per Retimer
 - Type = RWS
 - Size = 3 bits
 - Default = 001b
 - Encoding:
 - 001b = 2.5 GT/s
 - 010b = 5.0 GT/s
 - 011b = 8.0 GT/s
 - 100b = 16.0 GT/s
 - 101b = 32.0 GT/s
 - 110b = 64.0 GT/s
- Retimer Transmit Margin
 - One field per Pseudo Port
 - Type = RWS
 - Size = 3 bits
 - Default = 000b
 - Encoding:
 - 000b = Normal Operating Range
 - 001b-111b = As defined in § Section 8.3.4 , not all encodings are required to be implemented
- Retimer Enter Compliance
 - One bit per Retimer
 - Type = RWS
 - Size = 1 bit
 - Default = 0b
 - Encoding:
 - 0b = do not enter compliance
 - 1b = enter compliance
- Retimer Enter Modified Compliance
 - One bit per Retimer

- Type = RWS
- Size = 1 bit
- Default = 0b
- Encoding:
 - 0b = do not enter modified compliance
 - 1b = enter modified compliance
- Retimer Compliance SOS
 - One bit per Retimer
 - Type = RWS
 - Size = 1 bit
 - Default = 0b
 - Encoding:
 - 0b = Send no SKP Ordered Sets between sequences when sending the Compliance Pattern or Modified Compliance Pattern with 8b/10b encoding.
 - 1b = Send two SKP Ordered Sets between sequences when sending the Compliance Pattern or Modified Compliance Pattern with 8b/10b encoding.
- Retimer Compliance Preset/De-emphasis
 - One field per Pseudo Port
 - Type = RWS
 - Size = 4 bits
 - Default = 0000b
 - Encoding when Retimer Target Link Speed is 5.0 GT/s:
 - 0000b -6.0 dB
 - 0001b -3.5 dB
 - Encoding when Retimer Target Link Speed is 8.0 GT/s or higher: the Transmitter Preset.

A Retimer must examine the values in the above registers when the Retimer exits from Hot Reset. If the Retimer Enter Compliance bit is Set the following rules apply:

- The Retimer adjusts its data rate as defined by Retimer Target Link Speed. No data is forwarded until the data rate change has occurred.
- The Retimer configures its Transmitters according to Retimer Compliance Preset/De-emphasis on a per Pseudo Port basis.
- The Retimer must forward the Compliance or Modified Compliance Pattern when it has locked to the pattern. The Retimer must search for the Compliance Pattern if the Retimer Enter Modified Compliance bit is Clear or search for the Modified Compliance Pattern if the Retimer Enter Modified Compliance bit is Set. This occurs independently on each Lane in each direction.
- When using 8b/10b encoding, a particular Lane's Receiver independently determines a successful lock to the incoming Modified Compliance Pattern or Compliance Pattern by looking for any one occurrence of the Modified Compliance Pattern or Compliance Pattern.
 - An occurrence is defined above as the sequence of 8b/10b Symbols defined in § Section 4.2.9 .
 - In the case of the Modified Compliance Pattern, the error status Symbols are not to be used for the lock process since they are undefined at any given moment.

- Lock must be achieved within 1.0 ms of receiving the Modified Compliance Pattern.
- When using 128b/130b or 1b/1b encoding each Lane determines Pattern Lock independently when it achieves Block Alignment as described in § Section 4.2.2.2.1 .
 - Lock must be achieved within 1.5 ms of receiving the Modified Compliance Pattern or Compliance Pattern.
- When 128b/130b or 1b/1b encoding is used, Symbols with errors are forwarded unmodified by default, or may optionally be corrected to remove error pollution. The default behavior must be supported and the method of selecting the optional behavior, if supported, is implementation specific.
- When 8b/10b encoding is used, Symbols with errors are replaced with the D21.3 Symbol with incorrect disparity by default, or may optionally be corrected to remove error pollution. The default behavior must be supported.
- Once locked, the Retimer keeps an internal count of received Symbol errors, on a per-Lane basis. If the Retimer is forwarding the Modified Compliance Pattern then the error status Symbol when using 8b/10b encoding or the Error_Status field when using 128b/130b encoding is forwarded unmodified by default, or may optionally be redefined as it is transmitted by the Retimer. The default behavior must be supported and the method of selecting the optional behavior, if supported, is implementation specific. The Retimer is permitted to make the pattern lock and Lane error information available in an implementation specific manner, on a per-Lane basis.
- If an EIOS is received on any Lane then:
 - All Lanes in that direction transmit 8 EIOS and then all Transmitters in that direction are placed in Electrical Idle.
 - When both directions have sent 8 EIOS and placed their Transmitters in Electrical Idle the data rate is changed to 2.5 GT/s.
 - Set the RT_next_data_rate variable to 2.5 GT/s.
 - Set the RT_error_data_rate variable to 2.5 GT/s.
 - The Retimer Enter Compliance bit and Retimer Enter Modified Compliance bit are both set to 0b.
 - The above additional rules no longer apply unless the rules for entering this section and clause are met again.

4.3.7 Execution Mode Rules §

In Execution mode, Retimers directly control all information transmitted by the Pseudo Ports rather than forwarding information.

4.3.7.1 CompLoadBoard Rules §

While the Retimer is in the CompLoadBoard (Compliance Load Board) state both Pseudo Ports are executing the protocol as regular Ports, generating Symbols as specified in the following sub-sections on each Port, rather than forwarding from one Pseudo Port to the other.

IMPLEMENTATION NOTE:

PASSIVE LOAD ON TRANSMITTER §

This state is entered when a passive load is placed on one Pseudo Port, and the other Pseudo Port is receiving traffic.

4.3.7.1.1 CompLoadBoard.Entry §

- RT_LinkUp = 0b.
- The Pseudo Port that received Compliance Pattern (Pseudo Port A) does the following:
 - The data rate remains at 2.5 GT/s.
 - The Transmitter is placed in Electrical Idle.
 - The Receiver ignores incoming Symbols.
- The other Pseudo Port (Pseudo Port B) does the following:
 - The data rate remains at 2.5 GT/s.
 - The Transmitter is placed in Electrical Idle. Receiver Detection is performed on all Lanes as described in § Section 8.4.5.7 .
 - The Receiver ignores incoming Symbols.
- If Pseudo Port B's Receiver Detection determines there are no Receivers attached on any Lanes, then the next state for both Pseudo Ports is CompLoadBoard.Exit.
- Else the next state for both Pseudo Ports is CompLoadBoard.Pattern.

4.3.7.1.2 CompLoadBoard.Pattern §

When The Retimer enters CompLoadBoard.Pattern the following occur:

- Pseudo Port A does the following:
 - The Transmitter remains in Electrical Idle.
 - The Receiver ignores incoming Symbols.
- Pseudo Port B does the following:
 - The Transmitter sends out the Compliance Pattern on all Lanes that detected a Receiver at the data rate and de-emphasis/preset level determined as described in § Section 4.2.7.2.2 , (i.e., each consecutive entry into CompLoadBoard advances the pattern), except that the Setting is not set to Setting #1 during Polling.Configuration. Setting #26 and later are not used if Pseudo Port B has received a TS1 or TS2 Ordered Set (or their complement) since the exit of Fundamental Reset. If the new data rate is not 2.5 GT/s, the Transmitter is placed in Electrical Idle prior to the data rate change. The period of Electrical Idle must be greater than 1 ms but it is not to exceed 2 ms.
- If Pseudo Port B detects an Electrical Idle exit of any Lane that detected a Receiver, then the next state for both Pseudo Ports is CompLoadBoard.Exit.

4.3.7.1.3 CompLoadBoard.Exit §

When The Retimer enters CompLoadBoard.Exit the following occur:

- The Pseudo Port A:
 - Data rate remains at 2.5 GT/s.
 - The Transmitter sends the Electrical Idle Exit pattern described in § Section 4.3.6.3 , on the Lane(s) where Electrical Idle exit was detected on Pseudo Port B for 1 ms. Then the Transmitter is placed in Electrical Idle.
 - The Receiver ignores incoming Symbols.
- Pseudo Port B:
 - If the Transmitter is transmitting at a rate other than 2.5 GT/s the Transmitter sends eight consecutive EIOS.
 - The Transmitter is placed in Electrical Idle. If the Transmitter was transmitting at a rate other than 2.5 GT/s the period of Electrical Idle must be at least 1.0 ms.
 - Data rate is changed to 2.5 GT/s, if not already at 2.5 GT/s.
- Both Pseudo Ports are placed in Forwarding mode.

IMPLEMENTATION NOTE: TS1 ORDERED SETS IN FORWARDING MODE §

Once in Forwarding mode one of two things will likely occur:

- TS1 Ordered Sets are received and forwarded from Pseudo Port's B Receiver to Pseudo Port's A Transmitter. Link training continues.
- Or: TS1 Ordered Sets are not received because 100 MHz pulses are being received on a lane from the compliance load board, advancing the Compliance Pattern. In this case the Retimer must transition from Forwarding mode to CompLoadBoard when the device attached to Pseudo Port A times out from Polling.Active to Polling.Compliance. The Retimer advances the Compliance Pattern on each entry to CompLoadBoard.

4.3.7.2 Link Equalization Rules §

When in the Execution mode performing Link Equalization, the Pseudo Ports act as regular Ports, generating Symbols on each Port rather than forwarding from one Pseudo Port to the other. When the Retimer is in Execution mode it must use the Lane and Link numbers stored in RT_captured_lane_number and RT_captured_link_number.

This mode is entered while the Upstream and Downstream Ports on the Link are in negotiation to enter Phase 2 of the Equalization procedure following the procedure for switching to Execution mode described in § Section 4.3.5 .

4.3.7.2.1 Downstream Lanes §

The LF and FS values received in two consecutive TS0 or TS1 Ordered Sets when the Upstream Port is in Phase 1 must be stored for use during Phase 3, if the Downstream Pseudo Port wants to adjust the Upstream Port's Transmitter.

4.3.7.2.1.1 Phase 1 §

Transmitter behaves as described in § Section 4.2.7.4.2.1.1 except as follows:

- If the data rate of operation is 64.0 GT/s or above, the Retimer Equalization Extend bit of the transmitted TS0 Ordered Sets is set to 1b when the Upstream Pseudo Port state is Phase 0. The EC field is initially set to 00b. After two consecutive TS0 Ordered Sets are received with Retimer Equalization Extend bit set to 0b, the EC field is set to 01b. The Retimer Equalization Extend bit of the transmitted TS0 Ordered Sets it is set to 0b when the Upstream Pseudo Port state is Phase 1. The 24 ms timeout is decreased to 22 ms.

4.3.7.2.1.2 Phase 2 §

Transmitter behaves as described in § Section 4.2.7.4.2.1.2 except as follows:

- If the data rate of operation is 16.0 GT/s or above, the Retimer Equalization Extend bit of the transmitted TS1 Ordered Sets is set to 1b when the Upstream Pseudo Port state is Phase 2 Active, and it is set to 0b when the Upstream Pseudo Port state is Phase 2 Passive.
- Next phase is Phase 3 Active if all configured Lanes receive two consecutive TS1 Ordered Sets with EC=11b.
- Else, if the data rate of operation is less than 64.0 GT/s: next state is Force Timeout after a 32 ms timeout with a tolerance of -0 ms and +4 ms.
- Else, if the data rate of operation is 64.0 GT/s: next state is Force Timeout after a 64 ms timeout with a tolerance of -0 ms and +4 ms.

4.3.7.2.1.3 Phase 3 Active §

If the data rate of operation is 8.0 GT/s then the transmitter behaves as described in § Section 4.2.7.4.2.1.3 except the 24 ms timeout is 2.5 ms and as follows:

- Next phase is Phase 3 Passive if all configured Lanes are operating at their optimal settings.
- Else, next state is Force Timeout after a timeout of 2.5 ms with a tolerance of -0 ms and +0.1 ms

If the data rate of operation is 16.0 GT/s or 32.0 GT/s then the transmitter behaves as described in § Section 4.2.7.4.2.1.3 except the 24 ms timeout is 22 ms and as follows:

- The Retimer Equalization Extend bit of transmitted TS0 or TS1 Ordered Sets is set to 0b.
- Next phase is Phase 3 Passive if all configured Lanes are operating at their optimal settings and all configured Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b.
- Else, next state is Force Timeout after a timeout of 22 ms with a tolerance of -0 ms and +1.0 ms.

If the data rate of operation is 64.0 GT/s then the transmitter behaves as described in § Section 4.2.7.4.2.1.3 except the 48 ms timeout is 46 ms and as follows:

- The Retimer Equalization Extend bit of transmitted TS0 or TS1 Ordered Sets is set to 0b.
- Next phase is Phase 3 Passive if all configured Lanes are operating at their optimal settings and all configured Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b.
- Else, next state is Force Timeout after a timeout of 46 ms with a tolerance of -0 ms and +1.0 ms.

4.3.7.2.1.4 Phase 3 Passive §

- Transmitter sends TS1 Ordered Sets with EC = 11b, Retimer Equalization Extend = 0b, and the Transmitter Preset field and the Coefficients fields must not be changed from the final value transmitted in Phase 3 Active.
- The transmitter switches to Forwarding mode when the Upstream Pseudo Port exits Phase 3.

4.3.7.2.2 Upstream Lanes §

The LF and FS values received in two consecutive TS1 Ordered Sets when the Downstream Port is in Phase 1 must be stored for use during Phase 2, if the Upstream Pseudo Port wants to adjust the Downstream Port's Transmitter.

4.3.7.2.2.1 Phase 0 §

Transmitter follows Phase 0 rules for Upstream Lanes in § Section 4.2.7.4.2.2.1 except as follows:

- If the data rate of operation is 64.0 GT/s or above, the Retimer Equalization Extend bit of the transmitted TS0 Ordered Sets is set to 1b when the Downstream Pseudo Port state is Phase 1 and is transmitting TS0 Ordered Sets with the EC = 00b otherwise it is set to 0b; the 12 ms timeout is 10 ms.

4.3.7.2.2.2 Phase 1 Active §

Transmitter follows Phase 1 rules for Upstream Lanes in § Section 4.2.7.4.2.2.2 .

4.3.7.2.2.3 Phase 2 Active §

If the data rate of operation is 8.0 GT/s then the transmitter behaves as described in § Section 4.2.7.4.2.2.3 except the 24 ms timeout is decreased to 2.5 ms and as follows:

- Next state is Phase 2 Passive if all configured Lanes are operating at their optimal settings.
- Else, next state is Force Timeout after a 2.5 ms timeout with a tolerance of -0 ms and +0.1 ms

If the data rate of operation is 16.0 GT/s or 32.0 GT/s then the transmitter behaves as described in § Section 4.2.7.4.2.2.3 except the 24 ms timeout is 22 ms and as follows:

- The Retimer Equalization Extend bit of transmitted TS1 Ordered Sets is set to 0b.
- Next phase is Phase 2 Passive if all configured Lanes are operating at their optimal settings and all configured Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b.
- Else, next state is Force Timeout after a 22 ms timeout with a tolerance of -0 ms and +1.0 ms.

If the data rate of operation is 64.0 GT/s then the transmitter behaves as described in § Section 4.2.7.4.2.2.3 except the 48 ms timeout is 46 ms and as follows:

- The Retimer Equalization Extend bit of transmitted TS1 Ordered Sets is set to 0b.
- Next phase is Phase 2 Passive if all configured Lanes are operating at their optimal settings and all configured Lanes receive two consecutive TS1 Ordered Sets with the Retimer Equalization Extend bit set to 0b.
- Else, next state is Force Timeout after a 46 ms timeout with a tolerance of -0 ms and +1.0 ms.

4.3.7.2.2.4 Phase 2 Passive §

- Transmitter sends TS1 Ordered Sets with EC = 10b, Retimer Equalization Extend = 0b, and the Transmitter Preset field and the Coefficients fields must not be changed from the final value transmitted in Phase 2 Active.
- If the data rate of operation is 8.0 GT/s, the next state is Phase 3 when the Downstream Pseudo Port has completed Phase 3 Active.
- If the data rate of operation is 16.0 GT/s or above, the next state is Phase 3 when the Downstream Pseudo Port has started Phase 3 Active.

4.3.7.2.2.5 Phase 3 §

Transmitter follows Phase 3 rules for Upstream Lanes in § Section 4.2.7.4.2.2.4 except as follows:

- If the data rate of operation is 16.0 GT/s or above, the Retimer Equalization Extend bit of the transmitted TS1 Ordered Sets is set to 1b when the Downstream Pseudo Port state is Phase 3 Active, and it is set to 0b when the Downstream Pseudo Port state is Phase 3 Passive.
- If all configured Lanes receive two consecutive TS1 Ordered Sets with EC=00b then the Retimer switches to Forwarding mode.
- Else, if the data rate of operation is less than 64.0 GT/s: next state is Force Timeout after a timeout of 32 ms with a tolerance of -0 ms and +4 ms.
- Else, if the data rate of operation is 64.0 GT/s: next state is Force Timeout after a timeout of 64 ms with a tolerance of -0 ms and +4 ms.

4.3.7.2.3 Force Timeout §

- The Electrical Idle Exit Pattern described in § Section 4.3.6.3 is transmitted by both Pseudo Ports at the current data rate for a minimum of 1.0 ms.
- If on any Lane, a Receiver receives an EIOS or infers Electrical Idle via not detecting an exit from Electrical Idle (see § Table 4-65) then, the Transmitters on all Lanes of the opposite Pseudo Port send an EIOSQ and are then placed in Electrical Idle.
- If both Paths have placed their Transmitters in Electrical Idle then, the RT_next_data_rate is set to the RT_error_data_rate, and the RT_error_data_rate is set to 2.5 GT/s, on both Pseudo Ports, and the Retimer enters Forwarding mode.
 - The Transmitters of both Pseudo Ports must be in Electrical Idle for at least 6 μ s, before forwarding data.
- Else after a 48 ms timeout, the RT_next_data_rate is set to 2.5 GT/s and the RT_error_data_rate is set to 2.5 GT/s, on both Pseudo Ports, and the Retimer enters Forwarding mode.

IMPLEMENTATION NOTE: PURPOSE OF FORCE TIMEOUT STATE §

The purpose of this state is to ensure both Link Components are in Recovery.Speed at the same time so they go back to the previous data rate.

4.3.7.3 Follower Loopback §

Retimers optionally support Follower Loopback in Execution mode at 8b/10b and 128b/130b encoding. Follower Loopback in Execution mode must be supported at 1b/1b. By default, Retimers are configured to forward loopback between Loopback Lead and Loopback Follower. At 8b/10b and 128b/130b, Retimers are permitted to allow configuration in an implementation specific manner to act as a Loopback Follower on either Pseudo Port; at 1b/1b Loopback Follower on either Pseudo Port is mandatory. The other Pseudo Port that is not the Loopback Follower, places its Transmitter in Electrical Idle, and ignores any data on its Receivers.

4.3.7.3.1 Follower Loopback.Entry §

The Pseudo Port that is not operating as the Loopback bit Follower does the following:

- The Transmitter is placed in Electrical Idle.
- The Receiver ignores incoming Symbols.

The Pseudo Port that is operating as the Loopback Follower behaves as the Loopback Follower as described in § Section 4.2.7.10.1 with the following exceptions:

- The statement “LinkUp = 0b (False)” is replaced by “RT_LinkUp = 0b”.
- The statement “If Loopback.Entry was entered from Configuration.Linkwidth.Start” is replaced by “If Follower.Loopback.Entry was entered when RT_LinkUp = 0b”.
- References to Loopback.Active become Follower Loopback.Active.

4.3.7.3.2 Follower Loopback.Active §

The Pseudo Port that is not operating as the Loopback Follower does the following:

- The Transmitter remains in Electrical Idle.
- The Receiver continues to ignore incoming Symbols.

The Pseudo Port that is operating the Loopback Follower behaves as the Loopback Follower as described in § Section 4.2.7.10.2 with the following exception:

- References to Loopback.Exit become Follower Loopback.Exit.

4.3.7.3.3 Follower Loopback.Exit §

The Pseudo Port that is not operating as the Loopback Follower must do the following:

- Maintain the Transmitter in Electrical Idle.
- Set the data rate to 2.5 GT/s.
- The Receiver continues to ignore incoming Symbols.

The Pseudo Port that is operating as the Loopback Follower must behave as the Loopback Follower as described in § Section 4.2.7.10.3 with the following exception:

- The clause “The next state of the Loopback Lead and Loopback Follower is Detect” becomes “The Data rate is set to 2.5 GT/s and then both Pseudo Ports are placed in Forwarding mode”.

4.3.8 Retimer Latency §

This Section defines the requirements on allowed Retimer Latency.

4.3.8.1 Measurement §

Latency must be measured when the Retimer is in Forwarding mode and the Link is in L0, and is defined as the time from when the last bit of a Symbol is received at the input pins of one Pseudo Port to when the equivalent bit is transmitted on the output pins of the other Pseudo Port.

Retimer vendors are strongly encouraged to specify the latency of the Retimer in their data sheets.

Retimers are permitted to have different latencies at different data rates, and when this is the case the latency *MUST@FLIT* be specified per data rate.

4.3.8.2 Maximum Limit on Retimer Latency §

Retimer latency shall be less than the following limit, when not operating in SRIS.

Table 4-66 Retimer Latency Limit not SRIS (Symbol times) §

	2.5 GT/s	5.0 GT/s	8.0 GT/s	16.0 GT/s	32.0 GT/s	64.0 GT/s
Maximum Latency	32	32	64	128	256	512

4.3.8.3 Impacts on Upstream and Downstream Ports §

Retimers will add to the channel latency. The round trip delay is 4 times the specified latency when two Retimers are present. It is recommended that designers of Upstream and Downstream Ports consider Retimer latency when determining the following characteristics:

- Data Link Layer Retry Buffer size
- Transaction Layer Receiver buffer size and Flow Control Credits

- Data Link Layer REPLAY_TIMER Limits

Additional buffering (replay or FC) may be required to compensate for the additional channel latency.

4.3.9 SRIS §

Retimers are permitted but not required to support SRIS. Retimers that support SRIS must provide a mechanism for enabling the higher rate of SKP Ordered Set transmission, as Retimers must generate SKP Ordered Sets while in Execution mode. Retimers that are enabled to support SRIS will incur additional latency in the elastic store between receive and transmit clock domains. The additional latency is required to handle the case where a Tx_MPS_Limit TLP is transmitted and SKP Ordered Sets, which are scheduled, are not sent. The additional latency is a function of Link width and Max_Payload_Size. This additional latency is not included in § Table 4-66.

A SRIS capable Retimer must provide an implementation specific mechanism to configure its supported Max_Payload_Size while in SRIS, which must be greater than or equal to the largest Tx_MPS_Limit for the Transmitter in the Port that the Pseudo Port is receiving. Retimer latency must be less than the following limit for the current supported Max_Payload_Size, with SRIS.

Table 4-67 Retimer Latency Limit SRIS (Symbol times) §

<u>Max_Payload_Size</u>	2.5 GT/s	5.0 GT/s	8.0 GT/s	16.0 GT/s	32.0 GT/s	64.0 GT/s
128 Bytes	34 (max)	34 (max)	66 (max)	130 (max)	258 (max)	514 (max)
256 Bytes	36 (max)	36 (max)	68 (max)	132 (max)	260 (max)	516 (max)
512 Bytes	39 (max)	39 (max)	71 (max)	135 (max)	263 (max)	519 (max)
1024 Bytes	46 (max)	46 (max)	78 (max)	142 (max)	270 (max)	526 (max)
2048 Bytes	59 (max)	59 (max)	91 (max)	155 (max)	283 (max)	539 (max)
4096 Bytes	86 (max)	86 (max)	118 (max)	182 (max)	310 (max)	566 (max)

IMPLEMENTATION NOTE: RETIMER LATENCY WITH SRIS CALCULATION: §

§ Table 4-67 is calculated assuming that the link is operating at x1 Link width. The max Latency is the sum of § Table 4-66 and the additional latency required in the elastic store for SRIS clock compensation. The SRIS additional latency in symbol times required for SRIS clock compensation is described in the following equation:

$$2 * \left(\frac{((\text{SRIS Link Payload Size} + \text{TLP Overhead}) / \text{Link Width})}{\text{SKP_rate}} \right)$$

Equation 4-3 Retimer Latency with SRIS §

Where:

SRIS Link Payload Size

is the value programmed in the Retimer.

TLP Overhead

Represents the additional TLP components which consume Link bandwidth (TLP Prefix, header, LCRC, framing Symbols) and is treated here as a constant value of 28 Symbols.

Link Width

The operating width of the Link.

SKP_rate

The rate that a transmitter schedules SKP Ordered Sets when using 8b/10b encoding, 154, see § Section 4.2.8.4 . When using the 128b/130b encoding the effective rate is the same.

The nominal latency would be ½ of the SRIS additional latency, and is the nominal fill of the elastic store. This makes a worse case assumption that every blocked SKP Ordered Set requires an additional symbol of latency in the elastic store. When an Rx_MPS_Limit size TLP is transmitted, the actual fill of the elastic store could go to zero, or two times the nominal fill depending on the relative clock frequencies. Link width down configure may occur at any time, a lane fails for example, and this down configure may occur faster than the Retimer is able to adjust its nominal elastic store. By default Retimer's will configure its nominal fill based on x1 link width, regardless of the actual current link width.

Retimers that optionally support SRIS, may optionally support a dynamic elastic store. Dynamic elastic store changes the nominal buffer fill as the link width changes. Retimers are permitted to delay the Link LTSSM transitions, only while the Link down configures, in Configuration, for up to 40 µs. Retimers are permitted to delay the TS1 Order Set to TS2 Ordered Set transition between Configuration.Lanenum.Accept and Configuration.Complete to increase their elastic store.

4.3.10 L1 PM Substates Support §

The following Section describes the Retimer's requirements to support the optional L1 PM Substates.

The Retimer enters L1.1 when CLKREQ# is sampled as deasserted. The following occur:

- REFCLK to the Retimer is turned off.
- The PHY remains powered.
- The Retimer places all Transmitters in Electrical Idle on both Pseudo Ports (if not already in Electrical Idle, the expected state). Transmitters maintain their common mode voltage.
- The Retimer must ignore any Electrical Idle exit from all Receivers on both Pseudo Ports.

The Retimer exits L1.1 when CLKREQ# is sampled as asserted. The following occur:

- REFCLK to the Retimer is enabled.
- Normal operation of the Electrical Idle exit circuit is resumed on all Lanes of both Pseudo Ports of the Retimer.
- Normal exit from Electrical Idle exit behavior is resumed, See § Section 4.3.6.3.

Retimers do not support L1.2, but if they support L1.1 and the removal of the reference clock then they must not interfere with the attached components' ability to enter L1.2.

Retimer vendors must document specific implementation requirements applying to CLKREQ#. For example, a Retimer implementation that does not support the removal of the reference clock might require an implementation to pull CLKREQ# low.

IMPLEMENTATION NOTE: CLKREQ# CONNECTION TOPOLOGY WITH A RETIMER SUPPORTING L1 PM SUBSTATES §

In this platform configuration Downstream Port (A) has only a single CLKREQ# signal. The Upstream and Downstream Ports' CLKREQ# (A and C), and the Retimer's CLKREQ# signals are connected to each other. In this case, Downstream Port (A), must assert CLKREQ# signal whenever it requires a reference clock. Component A, Component B, and the Retimer have their REFCLKs removed/restored at the same time.

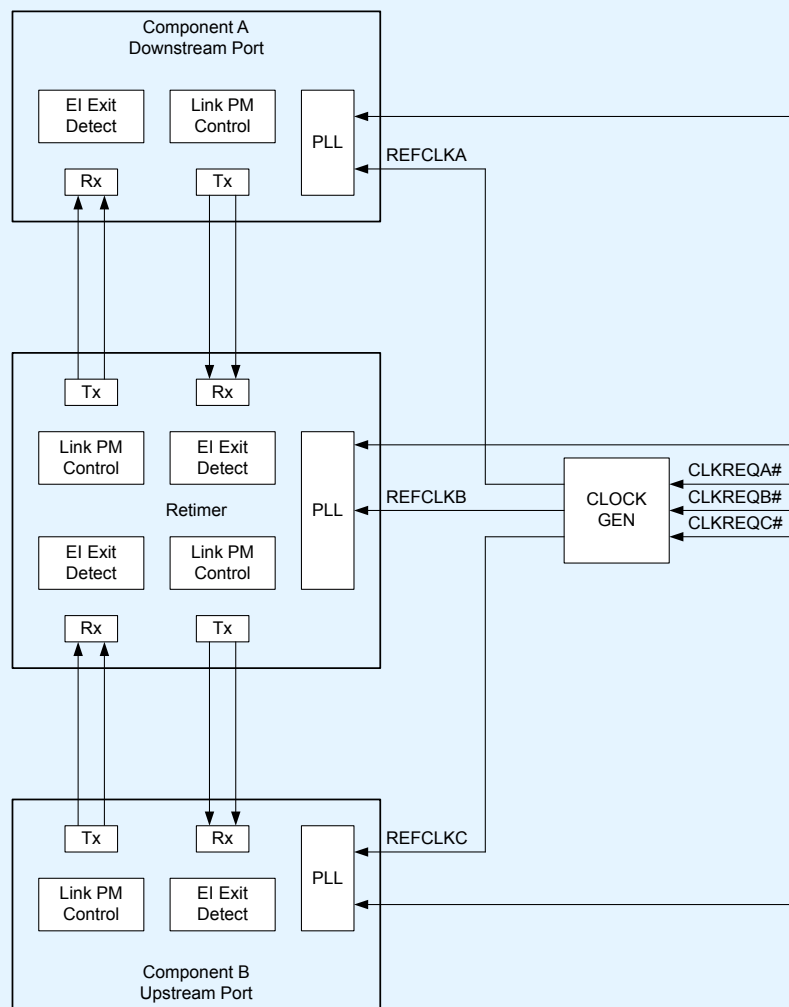

Figure 4-63 Retimer CLKREQ# Connection Topology §

4.3.11 Retimer Configuration Parameters §

Retimers must provide an implementation specific mechanism to configure each of the parameters in this section.

The parameters are split into two groups: parameters that are configurable globally for the Retimer and parameters that are configurable for each physical Retimer Pseudo Port.

If a per Pseudo Port parameter only applies to an Upstream or a Downstream Pseudo Port the Retimer is not required to provide an implementation specific mechanism to configure the parameter for the other type of Pseudo Port.

4.3.11.1 Global Parameters §

- **Port Orientation Method.** This controls whether the Port Orientation is determined dynamically as described in § Section 4.3.6.2 , or statically based on vendor assignment of Upstream and Downstream Pseudo Ports. If the Port Orientation is set to static the Retimer is not required to dynamically adjust the Port Orientation as described in § Section 4.3.6.2 . The default behavior is for the Port Orientation to be dynamically determined.
- **Maximum Data Rate.** This controls the maximum data rate that the Retimer sets in the Data Rate Identifier field of training sets that the Retimer transmits. Retimers that support only the 2.5 GT/s speed are permitted not to provide this configuration parameter.
- **SRIS Enable.** This controls whether the Retimer is configured for SRIS and transmits SKP Ordered Sets at the SRIS mode rate when in Execution mode. Retimers that do not support SRIS and at least one other clocking architecture are not required to provide this configuration parameter.
- **SRIS Link Payload Size.** This controls the maximum payload size the Retimer supports while in SRIS. The value must be selectable from all the Maximum Payload Sizes shown in § Table 4-67. The default value of this parameter is to support a maximum payload size of 4096 bytes. Retimers that do not support SRIS are not required to provide this configuration parameter.

The following are examples of cases where it might be appropriate to configure the SRIS Link Payload Size to a smaller value than the default:

- A Retimer is part of a motherboard connected to Root Port that supports a maximum payload size less than 4096 bytes.
- A Retimer is part of an adapter connected to an Upstream Port (e.g., Endpoint) that supports a maximum payload size less than 4096 bytes.
- A Retimer is located Downstream of the Downstream Port of a Switch integrated as part of a system, the Root Port supports a maximum payload size less than 4096 bytes and the system does not support peer to peer traffic.
- **Enhanced Link Behavior Control.** This controls the ability for the Retimer to either bypass equalization to the highest data rate or completely bypass equalization when it supports 32.0 GT/s.

4.3.11.2 Per Physical Pseudo Port Parameters §

- **Port Orientation.** This is applicable only when the Port Orientation Method is configured for static determination. This is set for either Upstream or Downstream. Each Pseudo Port must be configured for a different orientation, or the behavior is undefined.
- **Selectable De-emphasis.** When the Downstream Pseudo Port is operating at 5.0 GT/s this controls the transmit de-emphasis of the Link to either -3.5 dB or -6 dB in specific situations and the value of the Selectable De-emphasis field in training sets transmitted by the Downstream Pseudo Port. See § Section 4.2.7 for detailed usage information. When the Link Segment is not operating at the 5.0 GT/s speed, the setting of this bit has no effect. Retimers that support only the 2.5 GT/s speed are permitted not to provide this configuration parameter.
- **Rx Impedance Control.** This controls whether the Retimer dynamically applies and removes 50 Ω terminations or statically has 50 Ω terminations present. The value must be selectable from Dynamic, Off, and On. The default behavior is Dynamic.

- **Tx Compliance Disable.** This controls whether the Retimer transmits the Compliance Pattern in the `CompLoadBoard.Pattern` state. The default behavior is for the Retimer to transmit the Compliance Pattern in the `CompLoadBoard.Pattern` state. If TX Compliance Pattern is set to disabled, the Retimer Transmitters remain in Electrical Idle and do not transmit Compliance Pattern in `CompLoadBoard.Pattern` - all other behavior in the `CompLoadBoard` state is the same.
- **Pseudo Port Follower Loopback.** This controls whether the Retimer operates in a Forwarding mode during loopback on the Link or enters Follower Loopback on the Pseudo Port. The default behavior is for the Retimer to operate in Forwarding mode during loopback. Retimers that do not support optional Follower Loopback are permitted not to provide this configuration parameter. This configuration parameter shall only be enabled for one physical Port. Retimer behavior is undefined if the parameter is enabled for more than one physical Port.
- **Downstream Pseudo Port 8GT TX Preset.** This controls the initial TX preset used by the Downstream Pseudo Port transmitter for 8.0 GT/s transmission. The default value is implementation specific. The value must be selectable from all applicable values in § Table 4-23.
- **Downstream Pseudo Port 16GT TX Preset.** This controls the initial TX preset used by the Downstream Pseudo Port transmitter for 16.0 GT/s transmission. The default value is implementation specific. The value must be selectable from all applicable values in § Table 4-23.
- **Downstream Pseudo Port 32GT TX Preset.** This controls the initial TX preset used by the Downstream Pseudo Port transmitter for 32.0 GT/s transmission. The default value is implementation specific. The value must be selectable for all applicable values in § Table 4-23.
- **Downstream Pseudo Port 64GT TX Preset.** This controls the initial TX preset used by the Downstream Pseudo Port transmitter for 64.0 GT/s transmission. The default value is implementation specific. The value must be selectable for all applicable values in § Table 4-23.
- **Downstream Pseudo Port 8GT Requested TX Preset.** This controls the initial transmitter preset value used in the EQ TS2 Ordered Sets transmitted by the Downstream Pseudo Port for use at 8.0 GT/s. The default value is implementation specific. The value must be selectable from all values in § Table 4-23.
- **Downstream Pseudo Port 16GT Requested TX Preset.** This controls the initial transmitter preset value used in the 128b/130b EQ TS2 Ordered Sets transmitted by the Downstream Pseudo Port for use at 16.0 GT/s. The default value is implementation specific. The value must be selectable from all values in § Table 4-23.
- **Downstream Pseudo Port 32GT Requested TX Preset.** This controls the initial transmitter preset value used in the 128b/130b EQ TS2 Ordered Sets transmitted by the Downstream Pseudo Port for use at 32.0 GT/s. The default value is implementation specific. The value must be selectable from all values in § Table 4-23.
- **Downstream Pseudo Port 64GT Requested TX Preset.** This controls the initial transmitter preset value used in the 128b/130b EQ TS2 Ordered Sets transmitted by the Downstream Pseudo Port for use at 64.0 GT/s. The default value is implementation specific. The value must be selectable from all values in § Table 4-23.
- **Downstream Pseudo Port 8GT RX Hint.** This controls the Receiver Preset Hint value used in the EQ TS2 Ordered Sets transmitted by the Downstream Pseudo Port for use at 8.0 GT/s. The default value is implementation specific. The value must be selectable from all values in § Table 4-24.

4.3.12 In Band Register Access §

- Retimers operating at 16.0 GT/s or higher may optionally support inband read only access. Control SKP Ordered Sets at 16.0 GT/s or higher provide the mechanism via the Margin Command 'Access Retimer Register', see § Table 4-63. Retimers that support inband read only access must return a non-zero value for the DWORD at Registers offsets 80h and 84h. Retimers that do not support inband read only access must return a zero value.
- Register offsets between A0h and FFh are designated as Vendor Defined register space.
- Register offsets from 00h to 7Fh and 85H to 9Fh are Reserved for PCI-SIG future use.

5. Power Management §

This chapter describes power management (PM) capabilities and protocols.

5.1 Overview §

Power Management states are as follows:

- D states are associated with a particular Function
 - D0 is the operational state and consumes the most power
 - D1 and D2 are intermediate power saving states
 - D3_{Hot} is a very low power state
 - D3_{Cold} is the power off state
- L states are associated with a particular Link
 - L0 is the operational state
 - L0p is a reduced power sub-state of L0 (see § Section 4.2.6.7)
 - L0s, L1, L1.0, L1.1, and L1.2 are various lower power states

Other specifications define related power states (e.g., S states). This specification does not describe relationships between those states and D/L states.

PM provides the following services:

- A mechanism to identify power management capabilities of a given Function
- The ability to transition a Function into a certain power management state
- Notification of the current power management state of a Function
- The option to wakeup the system on a specific event

PM is compatible with the *PCI Bus Power Management Interface Specification* and the *Advanced Configuration and Power Interface Specification*. This chapter also defines PCI Express Native Power Management extensions.

PM defines Link power management states that a PCI Express physical Link is permitted to enter in response to either software driven D-state transitions or active state Link power management activities. PCI Express Link states are not visible directly to legacy bus driver software, but are derived from the power management state of the components residing on those Links. Defined Link states are L0, L0s, L1, L2, and L3. The power savings increase as the Link state transitions from L0 through L3.

Components may wakeup the system using a wakeup mechanism followed by a power management event (PME) Message. PCI Express systems may provide the optional auxiliary power supply (Vaux) needed for wakeup operation from states where the main power supplies are off.

The specific definition and requirements associated with **Vaux** are form-factor specific, and throughout this document the terms “auxiliary power” and “Vaux” should be understood in reference to the specific form factor in use.

Unlike earlier mechanisms, the PCI Express-PM PME mechanism separates the following two PME tasks:

- Reactivation (wakeup) of the associated resources (i.e., re-establishing reference clocks and main power rails to the PCI Express components)
- Sending a PME Message to the Root Complex to provide the source of the wakeup event

Active State Power Management (ASPM) is an autonomous hardware-based, active state mechanism that enables power savings even when the connected components are in the D0 state. After a period of idle Link time, an ASPM Physical-Layer protocol places the idle Link into a lower power state. Once in the lower-power state, transitions to the fully operative L0 state are triggered by traffic appearing on either side of the Link. ASPM may be disabled by software. Refer to § Section 5.4.1 for more information on ASPM.

5.2 Link State Power Management §

PCI Express defines Link power management states, replacing the bus power management states that were defined by the *PCI Bus Power Management Interface Specification*. Link states are not visible to PCI-PM legacy compatible software, and are either derived from the power management D-states of the corresponding components connected to that Link or by ASPM protocols (see § Section 5.4.1).

Note that the PCI Express Physical Layer may define additional intermediate states. Refer to § Chapter 4 for more detail on each state and how the Physical Layer handles transitions between states.

PCI Express-PM defines the following Link power management states:

- L0 (including the L0p sub-state) - Active state.

L0 support is required for both ASPM and PCI-PM compatible power management.

All PCI Express transactions and other operations are enabled.

- L0s - A low resume latency, energy saving “standby” state.

L0s support is optional for ASPM unless the applicable form factor specification for the Link explicitly requires L0s support.

All main power supplies, component reference clocks, and components' internal PLLs must be active at all times during L0s. TLP and DLLP transmission is disabled for a Port whose Link is in Tx_L0s.

The Physical Layer provides mechanisms for quick transitions from this state to the L0 state. When common (distributed) reference clocks are used on both sides of a Link, the transition time from L0s to L0 is desired to be less than 100 Symbol Times.

It is possible for the Transmit side of one component on a Link to be in L0s while the Transmit side of the other component on the Link is in L0.

- L1 - Higher latency, lower power “standby” state.

L1 support is required for PCI-PM compatible power management. L1 is optional for ASPM unless specifically required by a particular form factor.

When L1 PM Substates is enabled by setting one or more of the enable bits in the L1 PM Substates Control 1 Register this state is referred to as the L1.0 substate.

All main power supplies must remain active during L1. As long as they adhere to the advertised L1 exit latencies, implementations are explicitly permitted to reduce power by applying techniques such as, but not limited to, periodic rather than continuous checking for Electrical Idle exit, checking for Electrical Idle exit on only one Lane, and powering off of unneeded circuits. All platform-provided component reference clocks must remain active during L1, except as permitted by Clock Power Management (using CLKREQ#) and/or L1 PM

Substates when enabled. A component's internal PLLs may be shut off during L1, enabling greater power savings at a cost of increased exit latency.⁹³

The L1 state is entered whenever all Functions of a Downstream component on a given Link are programmed to a D-state other than D0. The L1 state also is entered if the Downstream component requests L1 entry (ASPM) and receives positive acknowledgement for the request.

Exit from L1 is initiated by an Upstream-initiated transaction targeting a Downstream component, or by the Downstream component's initiation of a transaction heading Upstream. Transition from L1 to L0 is desired to be a few microseconds.

TLP and DLLP transmission is disabled for a Link in L1.

- **L1 PM Substates** - optional L1.1 and L1.2 substates of the L1 low power Link state for PCI-PM and ASPM.

In the L1.1 substate, the Link common mode voltages are maintained. The L1.1 substate is entered when the Link is in the L1.0 substate and conditions for entry into L1.1 substate are met. See § Section 5.5.1 for details.

In the L1.2 substate, the Link common mode voltages are not required to be maintained. The L1.2 substate is entered when the Link is in the L1.0 substate and conditions for entry into L1.2 substate are met. See § Section 5.5.1 . for details.

Exit from all L1 PM Substates is initiated when the CLKREQ# signal is asserted (see § Section 5.5.2.1 and § Section 5.5.3.3).

- **L2/L3 Ready** - Staging point for L2 or L3.

L2/L3 Ready transition protocol support is required.

L2/L3 Ready is a pseudo-state (corresponding to the LTSSM L2 state) that a given Link enters when preparing for the removal of power and clocks from the Downstream component or from both attached components. This process is initiated after PM software transitions a device into a D3 state, and subsequently calls power management software to initiate the removal of power and clocks. After the Link enters the L2/L3 Ready state the component(s) are ready for power removal. After main power has been removed, the Link will either transition to L2 if Vaux is provided and used, or it will transition to L3 if no Vaux is provided or used. Note that these are PM pseudo-states for the Link; under these conditions, the LTSSM will in, general, operate only on main power, and so will power off with main power removal.

The L2/L3 Ready state entry transition process must begin as soon as possible following the acknowledgment of a PME_Turn_Off Message, (i.e., the injection of a PME_TO_Ack TLP). The Downstream component initiates L2/L3 Ready entry by sending a PM_Enter_L23 DLLP. Refer to § Section 5.7 for further detail on power management system Messages.

TLP and DLLP transmission is disabled for a Link in L2/L3 Ready.

Note: Exit from L2/L3 Ready back to L0 will be through intermediate LTSSM states. Refer to § Chapter 4. for detailed information.

- L2 - Auxiliary-powered Link, deep-energy-saving state.

L2 support is optional, and dependent upon the presence of auxiliary power.

A component may only consume auxiliary power if enabled to do so as described in § Section 5.6 .

In L2, the component's main power supply inputs and reference clock inputs are shut off.

When in L2, any Link reactivation wakeup logic (Beacon or WAKE#), PME context, and any other “keep alive” logic is powered by auxiliary power.

93. For example, disabling the internal PLL may be something that is desirable when in D3Hot, but not so when in D1 or D2.

TLP and DLLP transmission is disabled for a Link in L2.

- **L3** - Link Off state.

When no power is present, the component is in the L3 state.

- **LDn** - A transitional Link Down pseudo-state prior to L0.

This pseudo-state is associated with the LTSSM states Detect, Polling, and Configuration, and, when applicable, Disabled, Loopback, and Hot Reset.

Refer to § Section 4.2 for further detail relating to entering and exiting each of the L-states between L0 and L2/L3 Ready (L2.Idle from the § Chapter 4. perspective). The L2 state is an abstraction for PM purposes distinguished by the presence of auxiliary power, and should not be construed to imply a requirement that the LTSSM remain active.

The electrical section specifies the electrical properties of drivers and Receivers when no power is applied. This is the L3 state but the electrical section does not refer to L3.

§ Figure 5-1 shows an overview of L-state transitions that may occur.

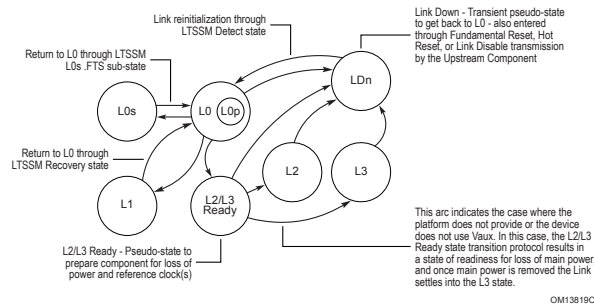

Figure 5-1 Link Power Management State Flow Diagram §

The L1 and L2/L3 Ready entry negotiations happen while in the L0 state. L1 and L2/L3 Ready are entered only after the negotiation completes. Link Power Management remains in L0 until the negotiation process is completed, unless LDn occurs. Note that these states and state transitions do not correspond directly to the actions of the Physical Layer LTSSM. For example in § Figure 5-1, L0 encompasses the LTSSM L0, Recovery, and, during LinkUp, Configuration states. Also, the LTSSM is typically powered by main power (not Vaux), so LTSSM will not be powered in either the L2 or the L3 state.

The following example sequence illustrates the multi-step Link state transition process leading up to entering a system sleep state:

1. System software directs all Functions of a Downstream component to D3Hot.
2. The Downstream component then initiates the transition of the Link to L1 as required.
3. System software then causes the Root Complex to broadcast the PME_Turn_Off Message in preparation for removing the main power source.
4. This Message causes the subject Link to transition back to L0 in order to send it and to enable the Downstream component to respond with PME_TO_Ack.
5. After sending the PME_TO_Ack, the Downstream component initiates the L2/L3 Ready transition protocol.

L0 → L1 → L0 → L2/L3 Ready

As the following example illustrates, it is also possible to remove power without first placing all Functions into D3Hot:

1. System software causes the Root Complex to broadcast the PME_Turn_Off Message in preparation for removing the main power source.
2. The Downstream components respond with PME_TO_Ack.
3. After sending the PME_TO_Ack, the Downstream component initiates the L2/L3 Ready transition protocol.

L0 → L2/L3 Ready

The L1 entry negotiation (whether invoked via PCI-PM or ASPM mechanisms) and the L2/L3 Ready entry negotiation map to a state machine which corresponds to the actions described later in this chapter. This state machine is reset to an idle state. For a Downstream component, the first action taken by the state machine, after leaving the idle state, is to start sending the appropriate entry DLLPs depending on the type of negotiation. If the negotiation is interrupted, for example by a trip through Recovery, the state machine in both components is reset back to the idle state. The Upstream component must always go to the idle state, and wait to receive entry DLLPs. The Downstream component must always go to the idle state and must always proceed to sending entry DLLPs to restart the negotiation.

§ Table 5-1 summarizes each L-state, describing when they are used, and the platform and component behaviors that correspond to each.

A “Yes” entry indicates that support is required (unless otherwise noted). “On” and “Off” entries indicate the required clocking and power delivery. “On/Off” indicates an optional design choice.

Table 5-1 Summary of PCI Express Link Power Management States §

	L-State Description	Used by S/W Directed PM	Used by ASPM	Platform Reference Clocks	Platform Main Power	Component Internal PLL	Platform <u>Vaux</u>
<u>L0 / L0p</u>	Fully active Link	Yes (<u>D0</u>)	Yes (<u>D0</u>)	On	On	On	On/Off
<u>L0s</u>	Standby state	No	Yes ¹ (opt., <u>D0</u>)	On	On	On	On/Off
<u>L1</u>	Lower power standby	Yes (<u>D1-D3Hot</u>)	Yes (opt., <u>D0</u>)	On/Off ⁶	On	On/Off ²	On/Off
<u>L2/L3 Ready</u> (pseudo-state)	Staging point for power removal	Yes ³	No	On/Off ⁶	On	On/Off	On/Off
<u>L2</u>	Low power sleep state (all clocks, main power off)	Yes ⁴	No	Off	Off	Off	On ⁵
<u>L3</u>	Off (zero power)	n/a	n/a	Off	Off	Off	Off
<u>LDn</u> (pseudo-state)	Transitional state preceding <u>L0</u>	Yes	N/A	On	On	On/Off	On/Off

Notes:

1. L0s exit latency will be greatest in Link configurations with independent reference clock inputs for components connected to opposite ends of a given Link (vs. a common, distributed reference clock).
2. L1 exit latency will be greatest for components that internally shut off their PLLs during this state.
3. L2/L3 Ready entry sequence is initiated at the completion of the PME_Turn_Off/PME_TO_Ack protocol handshake. It is not directly affiliated with either a D-State transition or a transition in accordance with ASPM policies and procedures.
4. Depending upon the platform implementation, the system's sleep state may use the L2 state, transition to fully off (L3), or it may leave Links in the L2/L3 Ready state. L2/L3 Ready state transition protocol is initiated by the Downstream component following reception and TLP acknowledgement of the PME_Turn_Off TLP Message. While platform support for

	L-State Description	Used by S/W Directed PM	Used by ASPM	Platform Reference Clocks	Platform Main Power	Component Internal PLL	Platform Vaux
--	---------------------	-------------------------	--------------	---------------------------	---------------------	------------------------	---------------

an L2 sleep state configuration is optional (depending on the availability of Vaux), component protocol support for transitioning the Link to the L2/L3 Ready state is required.

- L2 is distinguished from the L3 state only by the presence and use of Vaux. After the completion of the L2/L3 Ready state transition protocol and before main power has been removed, the Link has indicated its readiness for main power removal.
- Low-power mobile or handheld devices may reduce power by clock gating the reference clock(s) via the “clock request” (CLKREQ#) mechanism. As a result, components targeting these devices should be tolerant of the additional delays required to re-energize the reference clock during the low-power state exit.

5.3 PCI-PM Software Compatible Mechanisms §

5.3.1 Device Power Management States (D-States) of a Function §

While the concept of these power states is universal for all Functions in the system, the meaning, or intended functional behavior when transitioned to a given power management state, is dependent upon the type (or class) of the Function.

The D0 power management state is the normal operation state of the Function. Other states are various levels of reduced power, where the Function is either not operating or supports a limited set of operations. D1 and D2 are intermediate states that are intended to afford the system designer more flexibility in balancing power savings, restore time, and low power feature availability tradeoffs for a given device class. The D1 state could, for example, be supported as a slightly more power consuming state than D2, however one that yields a quicker restore time than could be realized from D2.

The D3 power management state constitutes a special category of power management state in that a Function could be transitioned into D3 either by software or by physically removing its power. In that sense, the two D3 variants have been designated as **D3_{Hot}** and **D3_{Cold}** where the subscript refers to the presence or absence of main power respectively. Functions in D3_{Hot} are permitted to be transitioned to the D0 state via software by writing to the Function's PMCSR register. Functions in the D3_{Cold} state are permitted to be transitioned to the D0_{uninitialized} state by reapplying main power and asserting Fundamental Reset.

All Functions must support the D0 and D3 states (both D3_{Hot} and D3_{Cold}). The D1 and D2 states are optional.

IMPLEMENTATION NOTE: SWITCH AND ROOT PORT VIRTUAL BRIDGE BEHAVIOR IN NON-D0 STATES §

When a Type 1 Function associated with a Switch/Root Port (a “virtual bridge”) is in a non-D0 power state, it will emulate the behavior of a conventional PCI bridge in its handling of Memory, I/O, and Configuration Requests and Completions. All Memory and I/O requests flowing Downstream are terminated as Unsupported Requests. All Type 1 Configuration Requests are terminated as Unsupported Requests, however Type 0 Configuration Request handling is unaffected by the virtual bridge D state. Completions flowing in either direction across the virtual bridge are unaffected by the virtual bridge D state.

Note that the handling of Messages is not affected by the PM state of the virtual bridge.

5.3.1.1 D0 State §

All Functions must support the D0 state. D0 is divided into two distinct substates, the “un-initialized” substate and the “active” substate. When a component comes out of Conventional Reset all Functions of the component enter the **D0_{uninitialized}** state. When a Function completes FLR, it enters the D0_{uninitialized} state. After configuration is complete a Function enters the D0_{active} state, the fully operational state for a PCI Express Function. A Function enters the **D0_{active}** state whenever any single or combination of the Function's Memory Space Enable, I/O Space Enable, or Bus Master Enable bits have been Set⁹⁴.

5.3.1.2 D1 State §

D1 support is optional. While in the D1 state, a Function must not initiate any Request TLPs on the Link with the exception of Messages as defined in § Section 2.2.8 . Configuration and Message Requests are the only TLPs accepted by a Function in the D1 state. All other received Requests must be handled as Unsupported Requests, and all received Completions may optionally be handled as Unexpected Completions. If an error caused by a received TLP (e.g., an Unsupported Request) is detected while in D1, and reporting is enabled, the Link must be returned to L0 if it is not already in L0 and an error Message must be sent. If an error caused by an event other than a received TLP (e.g., a Completion Timeout) is detected while in D1, an error Message must be sent when the Function is programmed back to the D0 state.

Note that a Function's software driver participates in the process of transitioning the Function from D0 to D1. It contributes to the process by saving any functional state (if necessary), and otherwise preparing the Function for the transition to D1. As part of this quiescence process the Function's software driver must ensure that any mid-transaction TLPs (i.e., Requests with outstanding Completions), are terminated prior to handing control to the system configuration software that would then complete the transition to D1.

5.3.1.3 D2 State §

D2 support is optional. When a Function is not currently being used and probably will not be used for some time, it may be put into D2. This state requires the Function to provide significant power savings while still retaining the ability to fully recover to its previous condition. While in the D2 state, a Function must not initiate any Request TLPs on the Link with the exception of Messages as defined in § Section 2.2.8 . Configuration and Message requests are the only TLPs

94. A Function remains in D0_{active} even if these enable bits are subsequently cleared.

accepted by a Function in the D2 state. All other received Requests must be handled as Unsupported Requests, and all received Completions may optionally be handled as Unexpected Completions. If an error caused by a received TLP (e.g., an Unsupported Request) is detected while in D2, and reporting is enabled, the Link must be returned to L0 if it is not already in L0 and an error Message must be sent. If an error caused by an event other than a received TLP (e.g., a Completion Timeout) is detected while in D2, an error Message must be sent when the Function is programmed back to the D0 state.

Note that a Function's software driver participates in the process of transitioning the Function from D0 to D2. It contributes to the process by saving any functional state (if necessary), and otherwise preparing the Function for the transition to D2. As part of this quiescence process the Function's software driver must ensure that any mid-transaction TLPs (i.e., Requests with outstanding Completions), are terminated prior to handing control to the system configuration software that would then complete the transition to D2.

System software must restore the Function to the D0_{active} state before memory or I/O space can be accessed. Initiated actions such as bus mastering and interrupt request generation can only commence after the Function has been restored to D0_{active}.

There is a minimum recovery time requirement of 200 μ s between when a Function is programmed from D2 to D0 and the next Request issued to the Function. Behavior is undefined for Requests received in this recovery time window (see § Section 7.9.16).

5.3.1.4 D3 State §

D3 support is required, (both the D3_{Cold} and the D3_{Hot} states).

Functional context is required to be maintained by Functions in the D3_{Hot} state if the No_Soft_Reset field in the PMCSR is Set. In this case, System Software is not required to re-initialize the Function after a transition from D3_{Hot} to D0 (the Function will be in the D0_{active} state). If the No_Soft_Reset bit is Clear, functional context is not required to be maintained by the Function in the D3_{Hot} state, however it is not guaranteed that functional context will be cleared and software must not depend on such behavior. As a result, in this case System Software is required to fully re-initialize the Function after a transition to D0 as the Function will be in the D0_{uninitialized} state.

The Function will be reset if the Link state has transitioned to the L2/L3 Ready state regardless of the value of the No_Soft_Reset bit.

IMPLEMENTATION NOTE: TRANSITIONING TO L2/L3 READY §

As described in § Section 5.2, transition to the L2/L3 Ready state is initiated by platform power management software in order to begin the process of removing main power and clocks from the device. As a result, it is expected that a device will transition to D3_{Cold} shortly after its Link transitions to L2/L3 Ready, making the No_Soft_Reset bit, which only applies to D3_{Hot}, irrelevant. While there is no guarantee of this correlation between L2/L3 Ready and D3_{Cold}, system software should ensure that the L2/L3 Ready state is entered only when the intent is to remove device main power. Device Functions, including those that are otherwise capable of maintaining functional context while in D3_{Hot} (i.e., set the No_Soft_Reset bit), are required to re-initialize internal state as described in § Section 2.9.1 when exiting L2/L3 Ready due to the required DL_Down status indication.

Unless the Immediate_Readiness_on_Return_to_D0 bit in the PCI-PM Power Management Capabilities register is Set, System Software must allow a minimum recovery time following a D3_{Hot} → D0 transition of at least 10 ms (see § Section 7.9.16), prior to accessing the Function. This recovery time may, for example, be used by the D3_{Hot} → D0 transitioning

component to bootstrap any of its component interfaces (e.g., from serial ROM) prior to being accessible. Attempts to target the Function during the recovery time (including configuration request packets) will result in undefined behavior.

5.3.1.4.1 D3_{Hot} State §

Configuration and Message requests are the only TLPs accepted by a Function in the D3_{Hot} state. All other received Requests must be handled as Unsupported Requests, and all received Completions may optionally be handled as Unexpected Completions. If an error caused by a received TLP (e.g., an Unsupported Request) is detected while in D3_{Hot}, and reporting is enabled, the Link must be returned to L0 if it is not already in L0 and an error Message must be sent. If an error caused by an event other than a received TLP (e.g., a Completion Timeout) is detected while in D3_{Hot}, an error Message may optionally be sent when the Function is programmed back to the D0 state. Once in D3_{Hot} the Function can later be transitioned into D3_{Cold} (by removing power from its host component).

Note that a Function's software driver participates in the process of transitioning the Function from D0 to D3_{Hot}. It contributes to the process by saving any functional state that would otherwise be lost with removal of main power, and otherwise preparing the Function for the transition to D3_{Hot}. As part of this quiescence process the Function's software driver must ensure that any outstanding transactions (i.e., Requests with outstanding Completions), are terminated prior to handing control to the system configuration software that would then complete the transition to D3_{Hot}.

Note that D3_{Hot} is also a useful state for reducing power consumption by idle components in an otherwise running system.

Functions that are in D3_{Hot} are permitted to be transitioned by software (writing to their PMCSR PowerState field) to the D0_{active} state or the D0_{uninitialized} state. Functions that are in D3_{Hot} must respond to Configuration Space accesses as long as power and clock are supplied so that they can be returned to D0 by software. Note that the Function is not required to generate an internal hardware reset during or immediately following its transition from D3_{Hot} to D0 (see usage of the No_Soft_Reset bit in the PMCSR).

If not requiring an internal reset, upon completion of the D3_{Hot} to D0_{active} state, no additional operating system intervention is required beyond writing the PowerState field. If the internal reset is required, devices return to D0_{uninitialized} and a full reinitialization is required on the device. The full reinitialization sequence returns the device to D0_{active}.

If the device supports PME events, and PME_En is Set, PME context must be preserved in D3_{Hot}. PME context must also be preserved in a PowerState command transition back to D0.

IMPLEMENTATION NOTE:

DEVICES NOT PERFORMING AN INTERNAL RESET §

Bus controllers to non-PCIe buses and resume from D3_{Hot} bus controllers on PCIe buses that serve as interfaces to non-PCIe buses, (e.g., CardBus, USB, and IEEE 1394) are examples of bus controllers that would benefit from not requiring an internal reset upon resume from D3_{Hot}. If this internal reset is not required, the bus controller would not need to perform a downstream bus reset upon resume from D3_{Hot} on its secondary (non-PCIe) bus.

IMPLEMENTATION NOTE:

MULTI-FUNCTION DEVICE ISSUES WITH SOFT RESET §

With Multi-Function Devices (MFDs), certain control settings affecting overall device behavior are determined either by the collective settings in all Functions or strictly off the settings in Function 0. Here are some key examples:

- With non-ARI MFDs, certain controls in the Device Control register and Link Control registers operate off the collective settings of all Functions (see § Section 7.5.3.4 and § Section 7.5.3.7).
- With ARI Devices, certain controls in the Device Control register and Link Control registers operate strictly off the settings in Function 0 (see § Section 7.5.3.4 and § Section 7.5.3.7).
- With all MFDs, certain controls in the Device Control 2 and Link Control 2 registers operate strictly off the settings in Function 0 (see § Section 7.5.3.16 and § Section 7.5.3.19).

Performing a soft reset on any Function (especially Function 0) may disrupt the proper operation of other active Functions in the MFD. Since some Operating Systems transition a given Function between $D3_{Hot}$ and $D0$ with the expectation that other Functions will not be impacted, it is strongly recommended that every Function in an MFD be implemented with the `No_Soft_Reset` bit Set in the Power Management Control/Status register. This way, transitioning a given Function from $D3_{Hot}$ to $D0$ will not disrupt the proper operation of other active Functions. For Functions that support Flit Mode, the `No_Soft_Reset` bit is required to be Set (see § Table 7-15).

It is also strongly recommended that every Endpoint Function in an MFD implement Function Level Reset (FLR) (i.e., Function Level Reset Capability is Set). FLR can be used to reset an individual Endpoint Function without impacting the settings that might affect other Functions, particularly if those Functions are active. As a result of FLR's quiescing, error recovery, and cleansing for reuse properties, FLR is also recommended for single-Function Endpoint devices.

5.3.1.4.2 $D3_{Cold}$ State §

A Function transitions to the $D3_{Cold}$ state when its main power is removed. A power-on sequence with its associated Cold Reset transitions a Function from the $D3_{Cold}$ state to the $D0_{uninitialized}$ state, and the power-on defaults will be restored to the Function by hardware just as at initial power up. At this point, software must perform a full initialization of the Function in order to re-establish all functional context, completing the restoration of the Function to its $D0_{active}$ state.

When `PME_En` is Set, Functions that support wakeup functionality from $D3_{Cold}$ must maintain their PME context in the PMCSR for inspection by PME service routine software during the course of the resume process. Retention of additional context is implementation specific.

IMPLEMENTATION NOTE:

PME CONTEXT §

Examples of PME context include, but are not limited to, a Function's `PME_Status` bit, the requesting agent's Requester ID, Caller ID if supported by a modem, IP information for IP directed network packets that trigger a resume event, etc.

A Function's PME assertion is acknowledged when system software performs a “write 1 to clear” configuration transaction to the asserting Function's PME_Status bit of its PCI-PM compatible PMCSR.

An auxiliary power source must be used to support PME event detection within a Function, Link reactivation, and to preserve PME context from within D3Cold. Note that once the I/O Hierarchy has been brought back to a fully communicating state, as a result of the Link reactivation, the waking agent then propagates a PME Message to the root of the Hierarchy indicating the source of the PME event. Refer to § Section 5.3.3 for further PME specific detail.

5.3.2 PM Software Control of the Link Power Management State §

The power management state of a Link is determined by the D-state of its Downstream component.

§ Table 5-2 depicts the relationships between the power state of a component (with an Upstream Port) and its Upstream Link.

Table 5-2 Relation Between Power Management States of Link and Components §

Downstream Component D-State	Permissible Upstream Component D-State	Permissible Interconnect State
<u>D0</u>	<u>D0</u>	<u>L0, L0s, L1⁽¹⁾, L2/L3 Ready</u>
<u>D1</u>	<u>D0-D1</u>	<u>L1, L2/L3 Ready</u>
<u>D2</u>	<u>D0-D2</u>	<u>L1, L2/L3 Ready</u>
<u>D3Hot</u>	<u>D0- D3Hot</u>	<u>L1, L2/L3 Ready</u>
<u>D3Cold</u>	<u>D0- D3Cold</u>	<u>L2⁽²⁾, L3</u>

Notes:

1. Requirements for ASPM L0s and ASPM L1 support are form factor specific.
2. If Vaux is provided by the platform, the Link sleeps in L2. In the absence of Vaux, the L-state is L3.

The following rules relate to PCI-PM compatible power management:

- Devices in D0, D1, D2, and D3Hot must respond to the receipt of a PME_Turn_Off Message by the transmission of a PME_TO_Ack Message.
- In any device D state, following the execution of a PME_Turn_Off/PME_TO_Ack handshake sequence, a Downstream component must request a Link transition to L2/L3 Ready using the PM_Enter_L23 DLLP. Following the L2/L3 Ready entry transition protocol the Downstream component must be ready for loss of main power and reference clock.
- The Upstream Port of a single-Function device must initiate a Link state transition to L1 based solely upon its Function being programmed to D1, D2, or D3Hot. In the case of the Switch, system software bears the responsibility of ensuring that any D-state programming of a Switch's Upstream Port is done in a compliant manner with respect to hierarchy-wide PM policies (i.e., the Upstream Port cannot be programmed to a D-state that is any less active than the most active Downstream Port and Downstream connected component/Function(s)).
- The Upstream Port of a non-ARI Multi-Function Device must not initiate a Link state transition to L1 (on behalf of PCI-PM) until all of its Functions have been programmed to a non-D0 D-state.

- The Upstream Port of an ARI Device must not initiate a Link state transition to L1 (on behalf of PCI-PM) until at least one of its Functions has been programmed to a non-D0 state, and all of its Functions are either in a non-D0 state or the D0_{uninitialized} state.
- With SR-IOV devices, the Link Power State is controlled solely by the setting in the PFs, regardless of the VFs' D-states. VF Power States do not affect the Link Power State.

5.3.2.1 Entry into the L1 State §

§ Figure 5-2 depicts the process by which a Link transitions into the L1 state as a direct result of power management software programming the Downstream connected component into a lower power state, (either D1, D2, or D3_{Hot} state). This figure and the subsequent description outline the transition process for a single -Function Downstream component that is being programmed to a non-D0 state.

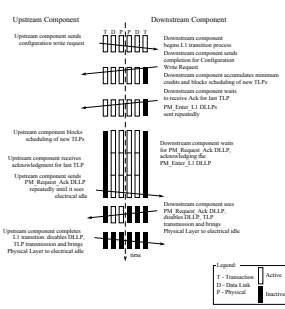

Figure 5-2 Entry into the L1 Link State §

The following text provides additional detail for the Link state transition process shown in § Figure 5-2.

PM Software Request:

1. PM software sends a Configuration Write Request TLP to the Downstream Function's PMCSR to change the Downstream Function's D-state (from D0 to D1 for example).

Downstream Component Link State Transition Initiation Process:

2. The Downstream component schedules the Completion corresponding to the Configuration Write Request to its PMCSR PowerState field and accounts for the completion credits required.
3. The Downstream component must then wait until it accumulates at least the minimum number of credits required to send the largest possible packet for any FC type for all enabled VCs (if it does not already have such credits). All Transaction Layer TLP scheduling is then suspended.
4. The Downstream component then waits until it receives an acknowledgement for the PMCSR Write Completion, and any other TLPs it had previously sent. The component must retransmit a TLP out of its appropriate Retry Buffer if required to do so by the Data Link Layer rules (when operating in Non Flit Mode) or the Flit Ack/Nak rules (when operating in Flit Mode).
5. Once all of the Downstream components' TLPs have been acknowledged, the Downstream component starts to transmit PM_Enter_L1 DLLPs. The Downstream component sends this DLLP repeatedly with no more than eight (when using 8b/10b encoding) or 32 (when using 128b/130b encoding) Symbol times of idle between subsequent transmissions of the PM_Enter_L1 DLLP, in Non-Flit Mode. The transmission of other DLLPs and SKP Ordered Sets is permitted at any time between PM_Enter_L1 transmissions, and do not contribute to this idle time limit.

The Downstream component continues to transmit the PM_Enter_L1 DLLP as described above until it receives a response from the Upstream component⁹⁵ (PM_Request_Ack).

The Downstream component must continue to accept TLPs and DLLPs from the Upstream component, and continue to respond with DLLPs, including FC update DLLPs and Ack/Nak DLLPs, as required. Any TLPs that are blocked from transmission (including responses to TLP(s) received) must be stored for later transmission, and must cause the Downstream component to initiate L1 exit as soon as possible following L1 entry.

Upstream Component Link State Transition Process:

6. Upon receiving the PM_Enter_L1 DLLP, the Upstream component blocks the scheduling of all TLP transmissions.
7. The Upstream component then must wait until it receives an acknowledgement for the last TLP it had previously sent. The Upstream component must retransmit a TLP from its appropriate Retry Buffer if required to do so by the Data Link Layer rules (when operating in Non Flit Mode) or the Flit Ack/Nak rules (when operating in Flit Mode).
8. Once all of the Upstream component's TLPs have been acknowledged, the Upstream component must send PM_Request_Ack DLLPs Downstream, regardless of any outstanding Requests. The Upstream component sends this DLLP repeatedly with no more than eight (when using 8b/10b encoding) or 32 (when using 128b/130b encoding) Symbol times of idle between subsequent transmissions of the PM_Request_Ack DLLP, in Non-Flit Mode. The transmission of SKP Ordered Sets is permitted at any time between PM_Request_Ack transmissions, and does not contribute to this idle time limit.

The Upstream component continues to transmit the PM_Request_Ack DLLP as described above until it observes its receive Lanes enter into the Electrical Idle state. Refer to § Chapter 4. for more details on the Physical Layer behavior.

Completing the L1 Link State Transition:

9. Once the Downstream component has captured the PM_Request_Ack DLLP on its Receive Lanes (signaling that the Upstream component acknowledged the transition to L1 request), it then disables DLLP transmission and brings the Upstream directed physical Link into the Electrical Idle state.
10. When the Receive Lanes on the Upstream component enter the Electrical Idle state, the Upstream component stops sending PM_Request_Ack DLLPs, disables DLLP transmission, and brings its Transmit Lanes to Electrical Idle completing the transition of the Link to L1.

When two components' interconnecting Link is in L1 as a result of the Downstream component being programmed to a non-D0 state, both components suspend the operation of their Flow Control Update and, if implemented, Update FCP Timer (see § Section 2.6.1.2) counter mechanisms. Refer to § Chapter 4. for more detail on the Physical Layer behavior.

Refer to § Section 5.2 if the negotiation to L1 is interrupted.

Components on either end of a Link in L1 may optionally disable their internal PLLs in order to conserve more energy. Note, however, that platform supplied main power and reference clocks must continue to be supplied to components on both ends of an L1 Link in the L1.0 substate of L1.

Refer to § Section 5.5 for entry into the L1 PM Substates.

95. If at this point the Downstream component needs to initiate a transfer on the Link, it must first complete the transition to L1. Once in L1 it is then permitted to initiate an exit L1 to handle the transfer.

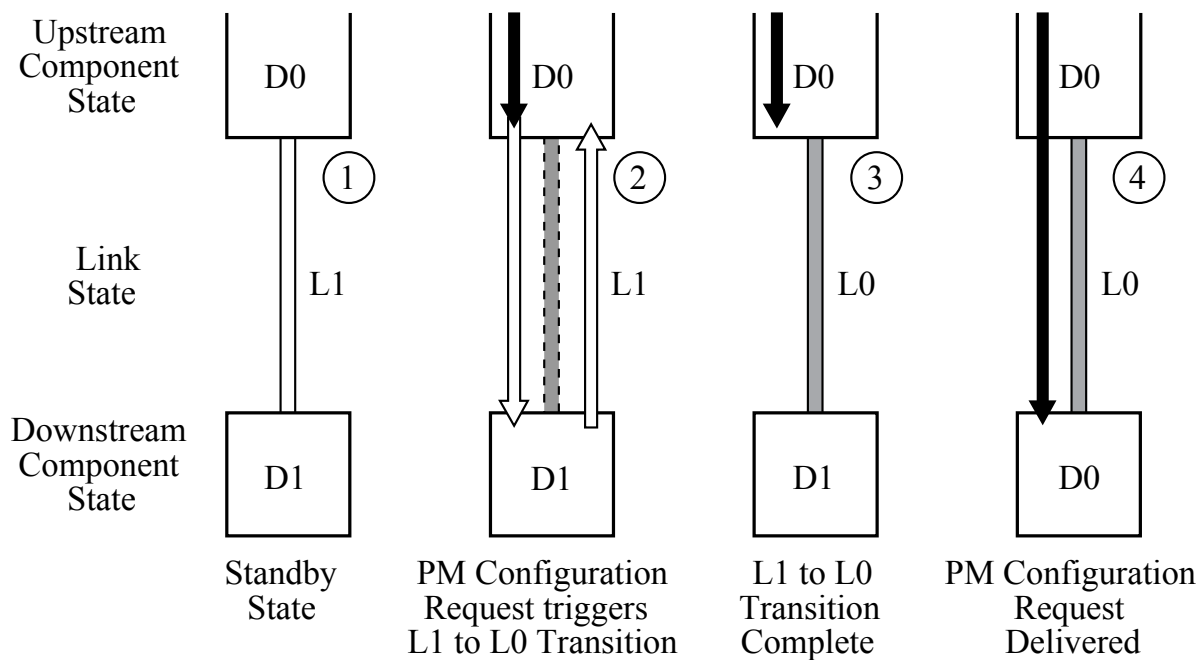

5.3.2.2 Exit from L1 State §

L1 exit can be initiated by the component on either end of a Link.

Upon exit from L1, it is recommended that the Downstream component send flow control update DLLPs for all enabled VCs and FC types starting within 1 μ s of L1 exit.

The physical mechanism for transitioning a Link from L1 to L0 is described in detail in § Chapter 4. .

L1 exit must be initiated by a component if that component needs to transmit a TLP on the Link. An Upstream component must initiate L1 exit on a Downstream Port even if it does not have the flow control credits needed to transmit the TLP that it needs to transmit. Following L1 exit, the Upstream component must wait to receive the needed credit from the Downstream component. § Figure 5-3 outlines an example sequence that would trigger an Upstream component to initiate transition of the Link to the L0 state.

OM13821

Figure 5-3 Exit from L1 Link State Initiated by Upstream Component §

Sequence of events:

1. Power management software initiates a configuration cycle targeting a PM configuration register (the PowerState field of the PMCSR in this example) within a Function that resides in the Downstream component (e.g., to bring the Function back to the D0 state).
2. The Upstream component detects that a configuration cycle is intended for a Link that is currently in a low power state, and as a result, initiates a transition of that Link into the L0 state.
3. If the Link is in either L1.1 or L1.2 substates of L1, then the Upstream component initiates a transition of the Link into the L1.0 substate of L1.
4. In accordance with the § Chapter 4. definition, both directions of the Link enter into Link training, resulting in the transition of the Link to the L0 state. The L1 \rightarrow L0 transition is discussed in detail in § Chapter 4. .

- Once both directions of the Link are back to the active L0 state, the Upstream Port sends the configuration Packet Downstream.

5.3.2.3 Entry into the L2/L3 Ready State §

Transition to the L2/L3 Ready state follows a process that is similar to the L1 entry process. There are some minor differences between the two that are spelled out below.

- L2/L3 Ready entry transition protocol does not immediately result in an L2 or L3 Link state. The transition to L2/L3 Ready is effectively a handshake to establish the Downstream component's readiness for power removal. L2 or L3 is ultimately achieved when the platform removes the components' power and reference clock.
- The time for L2/L3 Ready entry transition is indicated by the completion of the PME_Turn_Off/PME_TO_Ack handshake sequence. Any actions on the part of the Downstream component necessary to ready itself for loss of power must be completed prior to initiating the transition to L2/L3 Ready. Once all preparations for loss of power and clock are completed, L2/L3 Ready entry is initiated by the Downstream component by sending the PM_Enter_L23 DLLP Upstream.
- L2/L3 Ready entry transition protocol uses the PM_Enter_L23 DLLP.

Note that the PM_Enter_L23 DLLPs are sent continuously until an acknowledgement is received or power is removed.

- Refer to § Section 5.2 if the negotiation to L2/L3 Ready is interrupted.

5.3.3 Power Management Event Mechanisms §

5.3.3.1 Motivation §

The PCI Express PME mechanism is software compatible with the [PCI] PME mechanism. Power Management Events are generated by Functions as a means of requesting a PM state change. Power Management Events are typically utilized to revive the system or an individual Function from a low power state.

Power management software may transition a Hierarchy into a low power state, and transition the Upstream Links of these devices into the non-communicating L2 state.⁹⁶ The PCI Express PME generation mechanism is, therefore, broken into two components:

- Waking a non-communicating Hierarchy (wakeup). This step is required only if the Upstream Link of the device originating the PME is in the non-communicating L2 state, since in that state the device cannot send a PM_PME Message Upstream.
- Sending a PM_PME Message to the root of the Hierarchy

PME indications that originate from PCI Express Endpoints or PCI Express Legacy Endpoints are propagated to the Root Complex in the form of TLP messages. PM_PME Messages identify the requesting agent within the Hierarchy (via the Requester ID of the PM_PME Message header). Explicit identification within the PM_PME Message is intended to facilitate quicker PME service routine response, and hence shorter resume time.

If an RCiEP is associated with a Root Complex Event Collector, any PME indications that originate from that RCiEP must be reported by that Root Complex Event Collector.

PME indications that originate from a Root Port itself are reported through the same Root Port.

96. The L2 state is defined as “non-communicating” since component reference clock and main power supply are removed in that state.

5.3.3.2 Link Wakeup §

The Link wakeup mechanisms provide a means of signaling the platform to re-establish power and reference clocks to the components within its domain. There are two defined wakeup mechanisms: Beacon and WAKE#. The Beacon mechanism uses in-band signaling to implement wakeup functionality. For components that support wakeup functionality, the form factor specification(s) targeted by the implementation determine the support requirements for the wakeup mechanism. Switch components targeting applications where Beacon is used on some Ports of the Switch and WAKE# is used for other Ports must translate the wakeup mechanism appropriately (see the implementation note entitled “Example of WAKE# to Beacon Translation” in Section, 5.3.3.2). In applications where WAKE# is the only wakeup mechanism used, the Root Complex is not required to support the receipt of Beacon.

The WAKE# mechanism uses sideband signaling to implement wakeup functionality. WAKE# is an “open drain” signal asserted by components requesting wakeup and observed by the associated power controller. WAKE# is only defined for certain form factors, and the detailed specifications for WAKE# are included in the relevant form factor specifications. Specific form factor specifications may require the use of either Beacon or WAKE# as the wakeup mechanism.

When WAKE# is used as a wakeup mechanism, once WAKE# has been asserted, the asserting Function must continue to drive the signal low until main power has been restored to the component as indicated by Fundamental Reset going inactive.

The system is not required to route or buffer WAKE# in such a way that an Endpoint is guaranteed to be able to detect that the signal has been asserted by another Function.

Before using any wakeup mechanism, a Function must be enabled by software to do so by setting the Function's PME_En bit in the PMCSR. The PME_Status bit is sticky, and Functions must maintain the value of the PME_Status bit through reset if auxiliary power is available and they are enabled for wakeup events (this requirement also applies to the PME_En bit in the PMCSR and the Aux Power PM Enable bit in the Device Control Register).

Systems that allow PME generation from D3Cold state must provide auxiliary power to support Link wakeup when the main system power rails are off. A component may only consume auxiliary power if software has enabled it to do so as described in § Section 5.6 . Software is required to enable auxiliary power consumption in all components that participate in Link wakeup, including all components that must propagate the Beacon signal. In the presence of legacy system software, this is the responsibility of system firmware.

Regardless of the wakeup mechanism used, once the Link has been re-activated and trained, the requesting agent then propagates a PM_PME Message Upstream to the Root Complex. From a power management point of view, the two wakeup mechanisms provide the same functionality, and are not distinguished elsewhere in this chapter.

IMPLEMENTATION NOTE: EXAMPLE OF WAKE# TO BEACON TRANSLATION §

Switch components targeting applications that connect “Beacon domains” and “WAKE# domains” must translate the wakeup mechanism appropriately. § Figure 5-4 shows two example systems, each including slots that use the WAKE# wakeup mechanism. In Case 1, WAKE# is input directly to the Power Management Controller, and no translation is required. In Case 2, WAKE# is an input to the Switch, and in response to WAKE# being asserted the Switch must generate a Beacon that is propagated to the Root Complex/Power Management Controller.

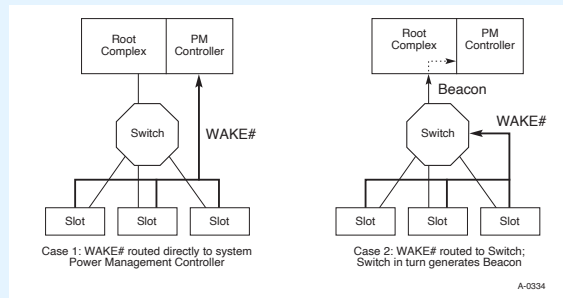

Figure 5-4 Conceptual Diagrams Showing Two Example Cases of WAKE# Routing §

5.3.3.2.1 PME Synchronization §

PCI Express-PM introduces a fence mechanism that serves to initiate the power removal sequence while also coordinating the behavior of the platform's power management controller and PME handling by PCI Express agents.

PME_Turn_Off Broadcast Message

Before main component power and reference clocks are turned off, the Root Complex or Switch Downstream Port must issue a broadcast Message that instructs all agents Downstream of that point within the hierarchy to cease initiation of any subsequent PM_PME Messages, effective immediately upon receipt of the PME_Turn_Off Message.

Each PCI Express agent is required to respond with a TLP “acknowledgement” Message, PME_TO_Ack that is always routed Upstream. In all cases, the PME_TO_Ack Message must terminate at the PME_Turn_Off Message's point of origin.

97

A Switch must report an “aggregate” acknowledgement only after having received PME_TO_Ack Messages from each of its Downstream Ports. Once a PME_TO_Ack Message has arrived on each Downstream Port, the Switch must then send a PME_TO_Ack packet on its Upstream Port. The occurrence of any one of the following must reset the aggregation mechanism: the transmission of the PME_TO_Ack Message from the Upstream Port, the receipt of any TLP at the Upstream Port, the removal of main power to the Switch, or Fundamental Reset.

All components with an Upstream Port must accept and acknowledge the PME_Turn_Off Message regardless of the D state of the associated device or any of its Functions for a Multi-Function Device. Once a component has sent a PME_TO_Ack Message, it must then prepare for removal of its power and reference clocks by initiating a transition to the L2/L3 Ready state.

97. Point of origin for the PME_Turn_Off Message could be all of the Root Ports for a given Root Complex (full platform sleep state transition), an individual Root Port, or a Switch Downstream Port.

A Switch must transition its Upstream Link to the L2/L3 Ready state after all of its Downstream Ports have entered the L2/L3 Ready state.

The Links attached to the originator of the PME_Turn_Off Message are the last to assume the L2/L3 Ready state. This state transition serves as an indication to the power delivery manager⁹⁸ that all Links within that portion of the Hierarchy have successfully retired all in flight PME Messages to the point of PME_Turn_Off Message origin and have performed any necessary local conditioning in preparation for power removal.

In order to avoid deadlock in the case where one or more devices do not respond with a PME_TO_Ack Message and then put their Links into the L2/L3 Ready state, the power manager must implement a timeout after waiting for a certain amount of time, after which it proceeds as if the Message had been received and all Links put into the L2/L3 Ready state. The recommended limit for this timer is in the range of 1 ms to 10 ms.

The power delivery manager must wait a minimum of 100 ns after observing all Links corresponding to the point of origin of the PME_Turn_Off Message enter L2/L3 Ready before removing the components' reference clock and main power. This requirement does not apply in the case where the above mentioned timer triggers.

IMPLEMENTATION NOTE:

PME_TO_ACK MESSAGE PROXY BY SWITCHES §

One of the PME_Turn_Off/PME_TO_Ack handshake's key roles is to ensure that all in flight PME Messages are flushed from the PCI Express fabric prior to sleep state power removal. This is guaranteed to occur because PME Messages and the PME_TO_Ack Messages both use the posted request queue within VC0 and so all previously injected PME Messages will be made visible to the system before the PME_TO_Ack is received at the Root Complex. Once all Downstream Ports of the Root Complex receive a PME_TO_Ack Message the Root Complex can then signal the power manager that it is safe to remove power without loss of any PME Messages.

Switches create points of hierarchical expansion and, therefore, must wait for all of their connected Downstream Ports to receive a PME_TO_Ack Message before they can send a PME_TO_Ack Message Upstream on behalf of the sub-hierarchy that it has created Downstream. This can be accomplished very simply using common score boarding techniques. For example, once a PME_Turn_Off broadcast Message has been broadcast Downstream of the Switch, the Switch simply checks off each Downstream Port having received a PME_TO_Ack. Once the last of its active Downstream Ports receives a PME_TO_Ack, the Switch will then send a single PME_TO_Ack Message Upstream as a proxy on behalf of the entire sub-hierarchy Downstream of it. Note that once a Downstream Port receives a PME_TO_Ack Message and the Switch has scored its arrival, the Port is then free to drop the packet from its internal queues and free up the corresponding posted request queue FC credits.

5.3.3.3 PM_PME Messages §

PM_PME Messages are posted Transaction Layer Packets (TLPs) that inform the power management software which agent within the Hierarchy requests a PM state change. PM_PME Messages, like all other Power Management system Messages, must use the general purpose Traffic Class, TC0.

PM_PME Messages are always routed in the direction of the Root Complex. To send a PM_PME Message on its Upstream Link, a device must transition the Link to the L0 state (if the Link was not in that state already). Unless otherwise noted, the device will keep the Link in the L0 state following the transmission of a PM_PME Message.

98. Power delivery control within this context relates to control over the entire Link hierarchy, or over a subset of Links ranging down to a single Link and associated Endpoint for sub hierarchies supporting independently managed power and clock distribution.

5.3.3.3.1 PM_PME “Backpressure” Deadlock Avoidance §

A Root Complex is typically implemented with local buffering to store temporarily a finite number of PM_PME Messages that could potentially be simultaneously propagating through the Hierarchy. Given a limited number of PM_PME Messages that can be stored within the Root Complex, there can be backpressure applied to the Upstream directed posted queue in the event that the capacity of this temporary PM_PME Message buffer is exceeded.

Deadlock can occur according to the following example scenario:

1. Incoming PM_PME Messages fill the Root Complex's temporary storage to its capacity while there are additional PM_PME Messages still in the Hierarchy making their way Upstream.
2. The Root Complex, on behalf of system software, issues a Configuration Read Request targeting one of the PME requester's PMCSR (e.g., reading its PME_Status bit).
3. The corresponding split completion Packet is required, as per producer/consumer ordering rules, to push all previously posted PM_PME Messages ahead of it, which in this case are PM_PME Messages that have no place to go.
4. The PME service routine cannot make progress; the PM_PME Message storage situation does not improve.
5. Deadlock occurs.

Precluding potential deadlocks requires the Root Complex to always enable forward progress under these circumstances. This must be done by accepting any PM_PME Messages that posted queue flow control credits allow for, and discarding any PM_PME Messages that create an overflow condition. This required behavior ensures that no deadlock will occur in these cases; however, PM_PME Messages will be discarded and hence lost in the process.

To ensure that no PM_PME Messages are lost permanently, all agents that are capable of generating PM_PME must implement a PME Service Timeout mechanism to ensure that their PME requests are serviced in a reasonable amount of time.

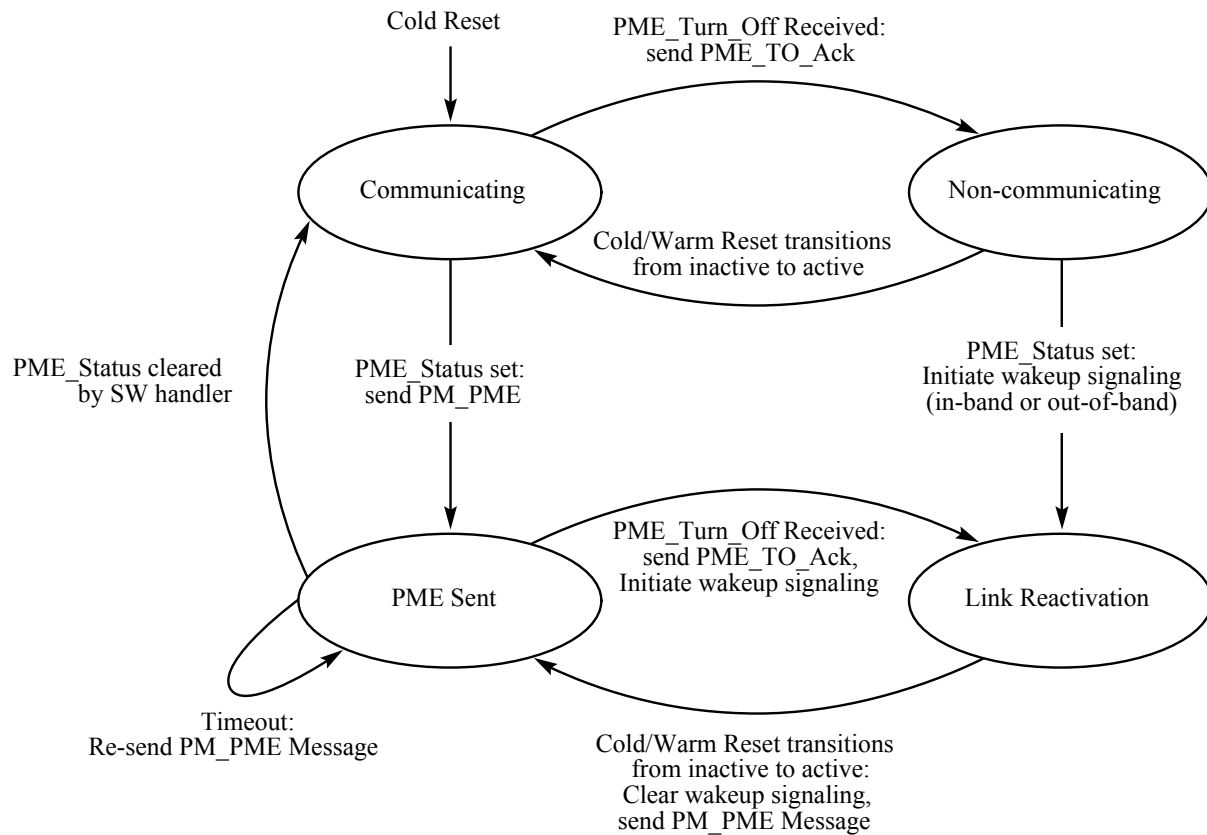

If after 100 ms (+50%/-5%), the PME_Status bit of a requesting agent has not yet been cleared, the PME Service Timeout mechanism expires triggering the PME requesting agent to re-send the temporarily lost PM_PME Message. If at this time the Link is in a non-communicating state, then, prior to re-sending the PM_PME Message, the agent must reactivate the Link as defined in § Section 5.3.3.2 .

5.3.3.4 PME Rules §

- All device Functions must implement the PCI-PM Power Management Capabilities (PMC) register and the PMCSR in accordance with the PCI-PM specification. These registers reside in the PCI-PM compliant PCI Capability List format.
 - PME capable Functions must implement the PME_Status bit, and underlying functional behavior, in their PMCSR.
 - When a Function initiates Link wakeup, or issues a PM_PME Message, it must set its PME_Status bit.
- Switches must route a PM_PME received on any Downstream Port to their Upstream Port
- On receiving a PME_Turn_Off Message, the device must block the transmission of PM_PME Messages and transmit a PME_TO_Ack Message Upstream. The component is permitted to send a PM_PME Message after the Link is returned to an L0 state through LDn.
- Before a Link or a portion of a Hierarchy is transferred into a non-communicating state (i.e., a state from which it cannot issue a PM_PME Message), a PME_Turn_Off Message must be broadcast Downstream.

5.3.3.5 PM_PME Delivery State Machine §

The following diagram conceptually outlines the PM_PME delivery control state machine. This state machine determines the ability of a Link to service PME events by issuing PM_PME immediately vs. requiring Link wakeup.

OM13822A

Figure 5-5 A Conceptual PME Control State Machine §

Communicating State:

At initial power-up and associated reset, the Upstream Link enters the Communicating state

- If PME_Status is asserted (assuming PME delivery is enabled), a PM_PME Message will be issued Upstream, terminating at the root of the Hierarchy. The next state is the PME Sent state
- If a PME_Turn_Off Message is received, the Link enters the Non-communicating state following its acknowledgment of the Message and subsequent entry into the L2/L3 Ready state.

Non-communicating State:

- Following the restoration of power and clock, and the associated reset, the next state is the Communicating state.
- If PME_Status is asserted, the Link will transition to the Link Reactivation state, and activate the wakeup mechanism.

PME Sent State

- If PME_Status is cleared, the Function becomes PME Capable again. Next state is the Communicating state.
- If the PME_Status bit is not Clear by the time the PME service timeout expires, a PM_PME Message is re-sent Upstream. Refer to § Section 5.3.3.3.1 for an explanation of the timeout mechanism.
- If a PME Message has been issued but the PME_Status has not been cleared by software when the Link is about to be transitioned into a messaging incapable state (a PME_Turn_Off Message is received), the Link transitions into Link Reactivation state after sending a PME_TO_Ack Message. The device also activates the wakeup mechanism.

Link Reactivation State

- Following the restoration of power and clock, and the associated reset, the Link resumes a transaction-capable state. The device clears the wakeup signaling, if necessary, and issues a PM_PME Upstream and transitions into the PME Sent state.

5.4 Native PCI Express Power Management Mechanisms §

The following sections define power management features that require new software. While the presence of these features in new PCI Express designs will not break legacy software compatibility, taking the full advantage of them requires new code to manage them.

These features are enumerated and configured using PCI Express native configuration mechanisms as described in § Chapter 7. of this specification. Refer to § Chapter 7. for specific register locations, bit assignments, and access mechanisms associated with these PCI Express-PM features.

5.4.1 Active State Power Management (ASPM) §

All Ports not associated with an Internal Root Complex Link or system Egress Port are required to support the minimum requirements defined herein for Active State Link PM. This feature must be treated as being orthogonal to the PCI-PM software compatible features from a minimum requirements perspective. For example, the Root Complex is exempt from the PCI-PM software compatible features requirements; however, it must implement the minimum requirements of ASPM.

Components in the D0 state (i.e., fully active state) normally keep their Upstream Link in the active L0 state, as defined in § Section 5.3.2 . ASPM defines a protocol for components in the D0 state to reduce Link power by placing their Links into a low power state and instructing the other end of the Link to do likewise. This capability allows hardware-autonomous, dynamic Link power reduction beyond what is achievable by software-only controlled (i.e., PCI-PM software driven) power management.

In Non-Flit Mode there are two low power “standby” Link states defined for ASPM, L0s and L1. In Flit Mode L0p effectively replaces L0s, and L1 remains as a “standby” Link state for ASPM.

The L0s low power Link state is optimized for short entry and exit latencies, while providing substantial power savings. If the L0s state is enabled in a device, it is recommended that the device bring its Transmit Link into the L0s state whenever that Link is not in use (refer to § Section 5.4.1.1.1 for details relating to the L0s invocation policy). Component support of the L0s Link state from within the D0 device state is optional unless the applicable form factor specification for the Link explicitly requires it.

The L0p low power Link state is optimized for short entry and longer exit latencies, while providing substantial power savings and supporting Link operation while a Link width change is in progress.

The L1 Link state is optimized for maximum power savings at a cost of longer entry and exit latencies. L1 reduces Link power beyond the L0s state for cases where very low power is required and longer transition times are acceptable. ASPM support for the L1 Link state is optional unless specifically required by a particular form factor.

Optional L1 PM Substates L1.1 and L1.2 are defined. These substates can further reduce Link power for cases where very low idle power is required, and longer transition times are acceptable.

Each component must report its level of support for ASPM in the ASPM Support field. As applicable, each component shall also report its L0s and L1 exit latency (the time that it requires to transition from the L0s or L1 state to the L0 state). Endpoint Functions must also report the worst-case latency that they can withstand before risking, for example, internal FIFO overruns due to the transition latency from L0s or L1 to the L0 state. Power management software can use the provided information to then enable the appropriate level of ASPM.

The L1 exit latency also applies to L0p, but when used for L0p, indicates the time required to widen the Link. The Link remains operational during this time period, but at lower bandwidth.

NOTE: L0p and ASPM §

A future draft of this specification may define a mechanism to report the worst case latency an Endpoint can withstand at L0p reduced bandwidth. This may involve multiple latency requirement values depending on the beginning and ending Link widths. Power management software could use this information to enable appropriate L0p Link widths for ASPM.

The L0s exit latency may differ significantly if the reference clock for opposing sides of a given Link is provided from the same source, or delivered to each component from a different source. PCI Express-PM software informs each device of its clock configuration via the Common Clock Configuration bit in its Capability structure's Link Control register. This bit serves as the determining factor in the L0s exit latency value reported by the device. ASPM may be enabled or disabled by default depending on implementation specific criteria and/or the requirements of the associated form factor specification(s). Software can enable or disable ASPM using a process described in § Section 5.4.1.4.1 .

Power management software enables or disables ASPM in each Port of a component by programming the ASPM Control field. Note that new BIOS code can effectively enable or disable ASPM functionality when running with a legacy operating system, but a PCI Express-aware operating system might choose to override ASPM settings configured by the BIOS.

IMPLEMENTATION NOTE: ISOCHRONOUS TRAFFIC AND ASPM §

Isochronous traffic requires bounded service latency. ASPM may add latency to isochronous transactions beyond expected limits. A possible solution would be to disable ASPM for devices that are configured with an Isochronous Virtual Channel.

For ARI Devices, ASPM Control is determined solely by the setting in Function 0, regardless of Function 0's D-state. The ASPM Control settings in other Functions are ignored by the component.

An Upstream Port of a non-ARI Multi-Function Device may be programmed with different values in their respective ASPM Control fields of each Function. The policy for such a component will be dictated by the most active common denominator among all D0 Functions according to the following rules:

- Functions in a non-D0 state (D1 and deeper) are ignored in determining the ASPM policy

- If any of the Functions in the D0 state has its ASPM disabled (ASPM Control field = 00b) or if at least one of the Functions in the D0 state is enabled for L0s only (ASPM Control field = 01b) and at least one other Function in the D0 state is enabled for L1 only (ASPM Control field = 10b), then ASPM is disabled for the entire component
- Else, if at least one of the Functions in the D0 state is enabled for L0s only (ASPM Control field = 01b), then ASPM is enabled for L0s only
- Else, if at least one of the Functions in the D0 state is enabled for L1 only (ASPM Control field = 10b), then ASPM is enabled for L1 only
- Else, ASPM is enabled for both L0s and L1 states

Note that the components must be capable of changing their behavior during runtime as device Functions enter and exit low power device states. For example, if one Function within a Multi-Function Device is programmed to disable ASPM, then ASPM must be disabled for that device while that Function is in the D0 state. Once the Function transitions to a non-D0 state, ASPM can be enabled if all other Functions are enabled for ASPM.

5.4.1.1 L0s ASPM State §

IMPLEMENTATION NOTE: L0S ONLY WORKS IN NON-FLIT MODE WITH NO RETIMERS §

Flit Mode does not support L0s.

Retimers do not support L0s.

Device support of the L0s low power Link state is optional unless the applicable form factor specification for the Link explicitly requires it.

IMPLEMENTATION NOTE: POTENTIAL ISSUES WITH LEGACY SOFTWARE WHEN L0S IS NOT SUPPORTED §

In earlier versions of this specification, device support of L0s was mandatory, and software could legitimately assume that all devices support L0s. Newer hardware components that do not support L0s may encounter issues with such “legacy software”. Such software might not even check the ASPM Support field in the Link Capabilities register, might not recognize the subsequently defined values (00b and 10b) for the ASPM Support field, or might not follow the policy of enabling L0s only if components on both sides of the Link each support L0s.

Legacy software (either operating system or firmware) that encounters the previously reserved value 00b (No ASPM Support), will most likely refrain from enabling L1, which is intended behavior. Legacy software will also most likely refrain from enabling L0s for that component's Transmitter (also intended behavior), but it is unclear if such software will also refrain from enabling L0s for the component on the other side of the Link. If software enables L0s on one side when the component on the other side does not indicate that it supports L0s, the result is undefined. Situations where the resulting behavior is unacceptable may need to be handled by updating the legacy software, establishing a list of configurations for which the legacy software is directed not to enable L0s, or simply not supporting the problematic system configurations.

On some platforms, firmware controls ASPM, and the operating system may either preserve or override the ASPM settings established by firmware. This will be influenced by whether the operating system supports controlling ASPM, and in some cases by whether the firmware permits the operating system to take control of ASPM. Also, ASPM control with hot-plug operations may be influenced by whether native PCI Express hot-plug versus ACPI hot-plug is used. Addressing any legacy software issues with L0s may require updating the firmware, the operating system, or both.

When a component does not advertise that it supports L0s, as indicated by its ASPM Support field value being 00b or 10b, it is recommended that the component's L0s Exit Latency field return a value of 111b, indicating the maximum latency range. Advertising this maximum latency range may help discourage legacy software from enabling L0s if it otherwise would do so, and thus may help avoid problems caused by legacy software mistakenly enabling L0s on this component or the component on the other side of the Link.

Transaction Layer and Link Layer timers are not affected by a transition to the L0s state (i.e., they must follow the rules as defined in their respective chapters).

IMPLEMENTATION NOTE: MINIMIZING L0S EXIT LATENCY §

L0s exit latency depends mainly on the ability of the Receiver to quickly acquire bit and Symbol synchronization. Different approaches exist for high-frequency clocking solutions which may differ significantly in their L0s exit latency, and therefore in the efficiency of ASPM. To achieve maximum power savings efficiency with ASPM, L0s exit latency should be kept low by proper selection of the clocking solution.

5.4.1.1.1 Entry into the L0s State §

Entry into the L0s state is managed separately for each direction of the Link. It is the responsibility of each device at either end of the Link to initiate an entry into the L0s state on its transmitting Lanes. Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined.

A Port that is disabled for the L0s state must not transition its transmitting Lanes to the L0s state. However, if the Port advertises that it supports L0s, Port must be able to tolerate having its Receiver Port Lanes enter L0s, (as a result of the device at the other end bringing its transmitting Lanes into L0s state), and then later returning to the L0 state.

L0s Invocation Policy

Ports that are enabled for L0s entry generally should transition their Transmit Lanes to the L0s state if the defined idle conditions (below) are met for a period of time, recommended not to exceed 7 μ s. Within this time period, the policy used by the Port to determine when to enter L0s is implementation specific. It is never mandatory for a Transmitter to enter L0s.

Definition of Idle

The definition of an “idle” Upstream Port varies with device Function category. An Upstream Port of a Multi-Function Device is considered idle only when all of its Functions are idle.

A non-Switch Port is determined to be idle if the following conditions are met:

- No TLP is pending to transmit over the Link, or no FC credits are available to transmit any TLPs
- No DLLPs are pending for transmission

A Switch Upstream Port Function is determined to be idle if the following conditions are met:

- None of the Switch's Downstream Port Receive Lanes are in the L0, Recovery, or Configuration state
- No pending TLPs to transmit, or no FC credits are available to transmit anything
- No DLLPs are pending for transmission

A Switch's Downstream Port is determined to be idle if the following conditions are met:

- The Switch's Upstream Port's Receive Lanes are not in the L0, Recovery, or Configuration state
- No pending TLPs to transmit on this Link, or no FC credits are available
- No DLLPs are pending for transmission

Refer to § Section 4.2 for details on L0s entry by the Physical Layer.

5.4.1.1.2 Exit from the L0s State §

A component with its Transmitter in L0s must initiate L0s exit when it has a TLP or DLLP to transmit across the Link. Note that a transition from the L0s Link state does not depend on the status (or availability) of FC credits. The Link must be able to reach the L0 state, and to exchange FC credits across the Link. For example, if all credits of some type were consumed when the Link entered L0s, then any component on either side of the Link must still be able to transition the Link to the L0 state when new credits need to be sent across the Link. Note that it may be appropriate for a component to anticipate the end of the idle condition and initiate L0s transmit exit; for example, when an NP request is received.

Downstream Initiated Exit

The Upstream Port of a component is permitted to initiate an exit from the L0s low-power state on its Transmit Link, (Upstream Port Transmit Lanes in the case of a Downstream Switch), if it needs to communicate through the Link. The component initiates a transition to the L0 state on Lanes in the Upstream direction as described in § Section 4.2 .

If the Upstream component is a Switch (i.e., it is not the Root Complex), then it must initiate a transition on its Upstream Port Transmit Lanes (if the Upstream Port's Transmit Lanes are in a low-power state) as soon as it detects an exit from L0s on any of its Downstream Ports.

Upstream Initiated Exit

A Downstream Port is permitted to initiate an exit from L0s low power state on any of its Transmit Links if it needs to communicate through the Link. The component initiates a transition to the L0 state on Lanes in the Downstream direction as described in § Chapter 4 . .

If the Downstream component contains a Switch, it must initiate a transition on all of its Downstream Port Transmit Lanes that are in L0s at that time as soon as it detects an exit from L0s on its Upstream Port. Links that are already in the L0 state are not affected by this transition. Links whose Downstream component is in a low-power state (i.e., D1- D3_{Hot} states) are also not affected by the exit transitions.

For example, consider a Switch with an Upstream Port in L0s and a Downstream device in a D1 state. A configuration request packet travels Downstream to the Switch, intending ultimately to reprogram the Downstream device from D1 to D0. The Switch's Upstream Port Link must transition to the L0 state to allow the packet to reach the Switch. The Downstream Link connecting to the device in D1 state will not transition to the L0 state yet; it will remain in the L1 state. The captured packet is checked and routed to the Downstream Port that shares a Link with the Downstream device that is in D1. As described in § Section 4.2 , the Switch now transitions the Downstream Link to the L0 state. Note that the transition to the L0 state was triggered by the packet being routed to that particular Downstream L1 Link, and not by the transition of the Upstream Port's Link to the L0 state. If the packet's destination was targeting a different Downstream Link, then that particular Downstream Link would have remained in the L1 state.

5.4.1.2 ASPM L0p State §

L0p is a substate of L0 that provides power savings with short entry latency and a longer exit latency. Local L0p exit latency and remote L0p exit latency are visible to software and are reported in the Local L0p Exit Latency and Remote L0p Exit Latency fields of the Data Link Feature Extended Capability.

L0p is supported in Flit Mode only and can be used only when supported by both Link partners. When supported, ASPM L0p is controlled by the Hardware Autonomous Width Disable bit in the Link Control Register and by several Device Control 3 Register fields. See § Section 4.2.6.7 for more detail on L0p.

5.4.1.3 ASPM L1 State §

A component may optionally support the ASPM L1 state; a state that provides greater power savings at the expense of longer exit latency. L1 exit latency is visible to software, and reported via the L1 Exit Latency field.

IMPLEMENTATION NOTE: POTENTIAL ISSUES WITH LEGACY SOFTWARE WHEN ONLY L1 IS SUPPORTED §

In earlier versions of this specification, device support of L0s was mandatory, and there was no architected ASPM Support field value to indicate L1 support without L0s support. Newer hardware components that support only L1 may encounter issues with “legacy software”, i.e., software that does not recognize the subsequently defined value for the ASPM Support field.

Legacy software that encounters the previously reserved value 10b (L1 Support), may refrain from enabling both L0s and L1, which unfortunately avoids using L1 with new components that support only L1. While this may result in additional power being consumed, it should not cause any functional misbehavior. However, the same issues with respect to legacy software enabling L0s exist for this 10b case as are described in the Implementation Note “Potential Issues With Legacy Software When L0s is Not Supported” in § Section 5.4.1.1 .

When supported, L1 entry is controlled by the ASPM Control field. Software must enable ASPM L1 on the Downstream component only if it is supported by both components on a Link. Software must sequence the enabling and disabling of ASPM L1 such that the Upstream component is enabled before the Downstream component and disabled after the Downstream component.

5.4.1.3.1 ASPM Entry into the L1 State §

An Upstream Port on a component enabled for L1 ASPM entry may initiate entry into the L1 Link state.

See § Section 5.5.1 for details on transitions into either the L1.1 or L1.2 substates.

IMPLEMENTATION NOTE: INITIATING L1 §

This specification does not dictate when a component with an Upstream Port must initiate a transition to the L1 state. The interoperable mechanisms for transitioning into and out of L1 are defined within this specification; however, the specific ASPM policy governing when to transition into L1 is left to the implementer.

One possible approach would be for the Downstream device to initiate a transition to the L1 state once the device has both its Receiver and Transmitter in the L0s state (RxL0s and TxL0s) for a set amount of time. Another approach would be for the Downstream device to initiate a transition to the L1 state once the Link has been idle in L0 for a set amount of time. This is particularly useful if L0s entry is not enabled. Still another approach would be for the Downstream device to initiate a transition to the L1 state if it has completed its assigned tasks. Note that a component's L1 invocation policy is in no way limited by these few examples.

Three power management Messages provide support for the ASPM L1 state:

- PM_Active_State_Request_L1 (DLLP)
- PM_Request_Ack (DLLP)
- PM_Active_State_Nak (TLP)

Downstream components enabled for ASPM L1 entry negotiate for L1 entry with the Upstream component on the Link.

A Downstream Port must accept a request to enter L1 if all of the following conditions are true:

- The Port supports ASPM L1 entry, and ASPM L1 entry is enabled.⁹⁹
- No TLP is scheduled for transmission
- No Ack or Nak DLLP is scheduled for transmission (Non-Flit Mode)
- No Flit Ack or Nak is scheduled for transmission (Flit Mode)

A Switch Upstream Port may request L1 entry on its Link provided all of the following conditions are true:

- The Upstream Port supports ASPM L1 entry and it is enabled
- All of the Switch's Downstream Port Links are in the L1 state (or deeper)
- No pending TLPs to transmit
- No pending DLLPs to transmit
- The Upstream Port's Receiver is idle for an implementation specific set amount of time

Note that it is legitimate for a Switch to be enabled for the ASPM L1 Link state on any of its Downstream Ports and to be disabled or not even supportive of ASPM L1 on its Upstream Port. In that case, Downstream Ports may enter the L1 Link state, but the Switch will never initiate an ASPM L1 entry transition on its Upstream Port.

ASPM L1 Negotiation Rules (see § Figure 5-6 and § Figure 5-7):

- In Non-Flit Mode, the Downstream component must not initiate ASPM L1 entry until it accumulates at least the minimum number of credits required to send the largest possible packet for any FC type.
- In Flit Mode, for any FC/VC that was initialized with non-zero and non-infinite dedicated credits, the Downstream component must not initiate ASPM L1 entry until it accumulates at least the minimum number of dedicated credits on that VC required to send the largest possible packet for that FC type.
- In Flit Mode, for any FC/VC that was initialized with zero dedicated credits, the Downstream component must not initiate ASPM L1 entry until it accumulates at least the minimum number of shared credits required to send the largest possible packet for that FC type.
- Upon deciding to enter a low-power Link state, the Downstream component must block movement of all TLPs from the Transaction Layer to the Data Link Layer for transmission (including completion packets). If any TLPs become available from the Transaction Layer for transmission during the L1 negotiation process, the transition to L1 must first be completed and then the Downstream component must initiate a return to L0. Refer to § Section 5.2 if the negotiation to L1 is interrupted.
- In Non-Flit Mode, the Downstream component must wait until it receives a Link Layer acknowledgement for the last TLP it had previously sent (i.e., the retry buffer is empty). The component must retransmit a TLP out of its Data Link Layer Retry buffer if required by the Data Link Layer rules.
- In Flit Mode, the Downstream component must wait until it receives a Flit acknowledgement for the last Flit of the last TLP it had previously sent (i.e., the retry buffer is empty). The component must retransmit Flit(s) out of its Retry buffer if required by the Flit Ack/Nak rules.
- The Downstream component then initiates ASPM negotiation by sending a PM_Active_State_Request_L1 DLLP onto its Transmit Lanes. The Downstream component sends this DLLP repeatedly with no more than eight (when using 8b/10b encoding) or 32 (when using 128b/130b encoding) Symbol times of idle between subsequent transmissions of the PM_Active_State_Request_L1 DLLP in Non-Flit Mode. The transmission of other DLLPs and SKP Ordered Sets must occur as required at any time between PM_Active_State_Request_L1

99. Software must enable ASPM L1 for the Downstream component only if it is also enabled for the Upstream component.

transmissions, and do not contribute to this idle time limit. Transmission of SKP Ordered Sets during L1 entry follows the clock tolerance compensation rules in § Section 4.2.8.

- The Downstream component continues to transmit the PM_Active_State_Request_L1 DLLP as described above until it receives a response from the Upstream device (see below). The Downstream component remains in this loop waiting for a response from the Upstream component.

During this waiting period, the Downstream component must not initiate any Transaction Layer transfers. It must still accept TLPs and DLLPs from the Upstream component, storing for later transmission any TLP responses required. It continues to respond with DLLPs, including FC update DLLPs, as needed by the Link Layer protocol.

If the Downstream component for any reason needs to transmit a TLP on the Link, it must first complete the transition to the low-power Link state. Once in a lower power Link state, the Downstream component must then initiate exit of the low-power Link state to handle the transfer. Refer to § Section 5.2 if the negotiation to L1 is interrupted.

- The Upstream component must immediately (while obeying all other rules in this specification) respond to the request with either an acceptance or a rejection of the request.
If the Upstream component is not able to accept the request, it must immediately (while obeying all other rules in this specification) reject the request.
- Refer to § Section 5.2 if the negotiation to L1 is interrupted.

Rules in case of rejection:

- In the case of a rejection, the Upstream component must schedule, as soon as possible, a rejection by sending the PM_Active_State_Nak Message to the Downstream component. Once the PM_Active_State_Nak Message is sent, the Upstream component is permitted to initiate any TLP or DLLP transfers.
- If the request was rejected, it is generally recommended that the Downstream component immediately transition its Transmit Lanes into the L0s state, provided L0s is enabled and that conditions for L0s entry are met.
- Prior to transmitting a PM_Active_State_Request_L1 DLLP associated with a subsequent ASPM L1 negotiation sequence, the Downstream component must either enter and exit L0s on its Transmitter, or it must wait at least 10 μ s from the last transmission of the PM_Active_State_Request_L1 DLLP associated with the preceding ASPM L1 negotiation. This 10 μ s timer must count only time spent in the LTSSM L0 and L0s states. The timer must hold in the LTSSM Recovery state. If the Link goes down and comes back up, the timer is ignored and the component is permitted to issue new ASPM L1 request after the Link has come back up.

IMPLEMENTATION NOTE:

ASPM L1 ACCEPT/REJECT CONSIDERATIONS FOR THE UPSTREAM COMPONENT §

When the Upstream component has responded to the Downstream component's ASPM L1 request with a `PM_Request_Ack` DLLP to accept the L1 entry request, the ASPM L1 negotiation protocol clearly and unambiguously ends with the Link entering L1. However, if the Upstream component responds with a `PM_Active_State_Nak` Message to reject the L1 entry request, the termination of the ASPM L1 negotiation protocol is less clear. Therefore, both components need to be designed to unambiguously terminate the protocol exchange. If this is not done, there is the risk that the two components will get out of sync with each other, and the results may be undefined. For example, consider the following case:

- The Downstream component requests ASPM L1 entry by transmitting a sequence of `PM_Active_State_Request_L1` DLLPs.
- Due to a temporary condition, the Upstream component responds with a `PM_Active_State_Nak` Message to reject the L1 request.
- The Downstream component continues to transmit the `PM_Active_State_Request_L1` DLLPs for some time before it is able to respond to the `PM_Active_State_Nak` Message.
- Meanwhile, the temporary condition that previously caused the Upstream component to reject the L1 request is resolved, and the Upstream component erroneously sees the continuing `PM_Active_State_Request_L1` DLLPs as a new request to enter L1, and responds by transmitting `PM_Request_Ack` DLLPs Downstream.

At this point, the result is undefined, because the Downstream component views the L1 request as rejected and finishing, but the Upstream component views the situation as a second L1 request being accepted.

To avoid this situation, the Downstream component needs to provide a mechanism to distinguish between one ASPM L1 request and another. The Downstream component does this by entering L0s (when supported and enabled), or by waiting a minimum of 10 μ s from the transmission of the last `PM_Active_State_Request_L1` DLLP associated with the first ASPM L1 request before starting transmission of the `PM_Active_State_Request_L1` DLLPs associated with the second request (as described above).

If the Upstream component is capable of exhibiting the behavior described above, then it is necessary for the Upstream component to recognize the end of an L1 request sequence by detecting a transition to L0s on its Receiver (when supported and enabled) or a break in the reception of `PM_Active_State_Request_L1` DLLPs of 9.5 μ s measured while in L0/L0s or more as a separation between ASPM L1 requests by the Downstream component.

If there is a possibility of ambiguity, the Upstream component should reject the L1 request to avoid potentially creating the ambiguous situation outlined above.

Rules in case of acceptance:

- If the Upstream component is ready to accept the request, it must block scheduling of any TLPs from the Transaction Layer.
- In Non-Flit Mode, the Upstream component then must wait until it receives a Data Link Layer acknowledgement for the last TLP it had previously sent. The Upstream component must retransmit a TLP if required by the Data Link Layer rules.

- In Flit Mode, the Upstream component then must wait until it receives a Data Link Layer acknowledgement for the last Flit of the last TLP it had previously sent. The Upstream component must retransmit Flit(s) if required by the Data Link Layer rules.
- Once all TLPs/Flits have been acknowledged, the Upstream component sends a PM_Request_Ack DLLP Downstream. The Upstream component sends this DLLP repeatedly with no more than eight (when using 8b/10b encoding) or 32 (when using 128b/130b encoding) Symbol times of idle between subsequent transmissions of the PM_Request_Ack DLLP in Non-Flit Mode. The transmission of SKP Ordered Sets must occur as required at any time between PM_Request_Ack transmissions, and do not contribute to this idle time limit. Transmission of SKP Ordered Sets during L1 entry follows the clock tolerance compensation rules in § Section 4.2.8.
- The Upstream component continues to transmit the PM_Request_Ack DLLP as described above until it observes its Receive Lanes enter into the Electrical Idle state. Refer to § Chapter 4. for more details on the Physical Layer behavior.
- If the Upstream component needs, for any reason, to transmit a TLP on the Link after it sends a PM_Request_Ack DLLP, it must first complete the transition to the low-power state, and then initiate an exit from the low-power state to handle the transfer once the Link is back to L0. Refer to § Section 5.2 if the negotiation to L1 is interrupted.
 - The Upstream component must initiate an exit from L1 in this case even if it does not have the required flow control credit to transmit the TLP(s).
- When the Downstream component detects a PM_Request_Ack DLLP on its Receive Lanes (signaling that the Upstream device acknowledged the transition to L1 request), the Downstream component then ceases sending the PM_Active_State_Request_L1 DLLP, disables DLLP, TLP transmission and brings its Transmit Lanes into the Electrical Idle state.
- When the Upstream component detects an Electrical Idle on its Receive Lanes (signaling that the Downstream component has entered the L1 state), it then ceases to send the PM_Request_Ack DLLP, disables DLLP, TLP transmission and brings the Downstream direction of the Link into the Electrical Idle state.

Notes:

1. The transaction Layer Completion Timeout mechanism is not affected by transition to the L1 state (i.e., it must keep counting).
2. Flow Control Update timers are frozen while the Link is in L1 state to prevent a timer expiration that will unnecessarily transition the Link back to the L0 state.

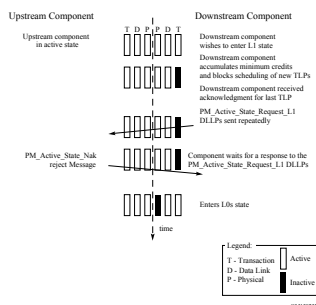

Figure 5-6 L1 Transition Sequence Ending with a Rejection (L0s Enabled) §

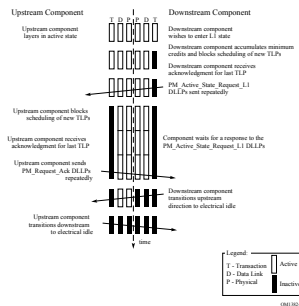

Figure 5-7 L1 Successful Transition Sequence §

5.4.1.3.2 Exit from the L1 State §

Components on either end of a Link may initiate an exit from the L1 Link state.

See § Section 5.5.1 for details on transitions into either the L1.1 or L1.2 substates.

Upon exit from L1, it is recommended that the Downstream component send flow control update DLLPs for all enabled VCs and FC types starting within 1 μ s of L1 exit.

Downstream Component Initiated Exit

An Upstream Port must initiate an exit from L1 on its Transmit Lanes if it needs to communicate through the Link. The component initiates a transition to the L0 state as described in § Chapter 4. . The Upstream component must respond by initiating a similar transition of its Transmit Lanes.

If the Upstream component is a Switch Downstream Port, (i.e., it is not a Root Complex Root Port), the Switch must initiate an L1 exit transition on its Upstream Port's Transmit Lanes, (if the Upstream Port's Link is in the L1 state), as soon as it detects the L1 exit activity on any of its Downstream Port Links. Since L1 exit latencies are relatively long, a Switch must not wait until its Downstream Port Link has fully exited to L0 before initiating an L1 exit transition on its Upstream Port Link. Waiting until the Downstream Link has completed the L0 transition will cause a Message traveling through several Switches to experience accumulating latency as it traverses each Switch.

A Switch is required to initiate an L1 exit transition on its Upstream Port Link after no more than 1 μ s from the beginning of an L1 exit transition on any of its Downstream Port Links. Refer to § Section 4.2 for details of the Physical Layer signaling during L1 exit.

Consider the example in § Figure 5-8. The numbers attached to each Port represent the corresponding Port's reported Transmit Lanes L1 exit latency in units of microseconds.

Links 1, 2, and 3 are all in the L1 state, and Endpoint C initiates a transition to the L0 state at time T. Since Switch B takes 32 μ s to exit L1 on its Ports, Link 3 will transition to the L0 state at T+32 (longest time considering T+8 for the Endpoint C, and T+32 for Switch B).

Switch B is required to initiate a transition from the L1 state on its Upstream Port Link (Link 2) after no more than 1 μ s from the beginning of the transition from the L1 state on Link 3. Therefore, transition to the L0 state will begin on Link 2 at T+1. Similarly, Link 1 will start its transition to the L0 state at time T+2.

Following along as above, Link 2 will complete its transition to the L0 state at time T+33 (since Switch B takes longer to transition and it started at time T+1). Link 1 will complete its transition to the L0 state at time T+34 (since the Root Complex takes 32 μ s to transition and it started at time T+2).

Therefore, among Links 1, 2, and 3, the Link to complete the transition to the L0 state last is Link 1 with a 34 μ s delay. This is the delay experienced by the packet that initiated the transition in Endpoint C.

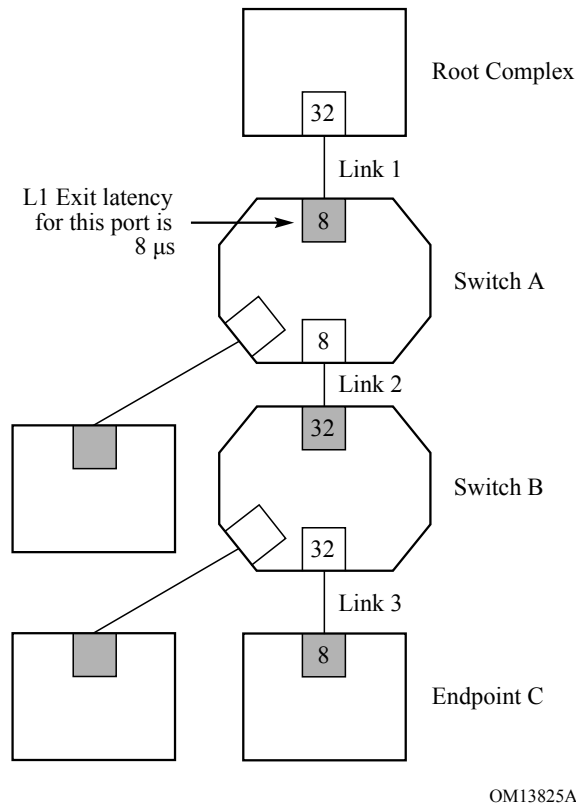

Figure 5-8 Example of L1 Exit Latency Computation §

Switches are not required to initiate an L1 exit transition on any other of their Downstream Port Links.

Upstream Component Initiated Exit

A Root Complex, or a Switch must initiate an exit from L1 on any of its Root Ports, or Downstream Port Links if it needs to communicate through that Link. The Switch or Root Complex must be capable of initiating L1 exit even if it does not have the flow control credits needed to transmit a given TLP. The component initiates a transition to the L0 state as described in § Chapter 4. . The Downstream component must respond by initiating a similar transition on its Transmit Lanes.

If the Downstream component contains a Switch, it must initiate a transition on all of its Downstream Links (assuming the Downstream Link is in an ASPM L1 state) as soon as it detects an exit from L1 state on its Upstream Port Link. Since L1 exit latencies are relatively long, a Switch must not wait until its Upstream Port Link has fully exited to L0 before initiating an L1 exit transition on its Downstream Port Links. If that were the case, a Message traveling through multiple Switches would experience accumulating latency as it traverses each Switch.

A Switch is required to initiate a transition from L1 state on all of its Downstream Port Links that are currently in L1 after no more than 1 μ s from the beginning of a transition from L1 state on its Upstream Port. Refer to § Section 4.2 for details of the Physical Layer signaling during L1 exit. Downstream Port Links that are already in the L0 state do not participate in the exit transition. Downstream Port Links whose Downstream component is in a low power D-state (D1-D3_{Hot}) are also not affected by the L1 exit transitions (i.e., such Links must not be transitioned to the L0 state).

5.4.1.4 ASPM Configuration §

All Functions must implement the following configuration bits in support of ASPM. Refer to [§ Chapter 7](#) for configuration register assignment and access mechanisms.

Each component reports its level of support for ASPM in the ASPM Support field below.

Table 5-3 Encoding of the ASPM Support Field §

Field	Description
ASPM Support	00b No ASPM support
	01b L0s supported
	10b L1 supported
	11b L0s and L1 supported

Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined.

Each component reports the source of its reference clock in its Slot Clock Configuration bit located in its Capability structure's Link Status register.

Table 5-4 Description of the Slot Clock Configuration Bit §

Bit	Description
Slot Clock Configuration	<p>This bit, when Set, indicates that the component uses the same physical reference clock that the platform provides on the connector.</p> <p>This bit, when Clear, indicates the component uses an independent clock irrespective of the presence of a reference on the connector.</p> <p>For Root and Switch Downstream Ports, this bit, when Set, indicates that the Downstream Port is using the same reference clock as the Downstream component or the slot.</p> <p>For Switch and Bridge Upstream Ports, this bit when Set, indicates that the Upstream Port is using the same reference clock that the platform provides.</p> <p>Otherwise it is Clear.</p>

Each component must support the Common Clock Configuration bit in its Capability structure's Link Control register. Software writes to this register bit to indicate to the device whether it is sharing the same clock source as the device on the other end of the Link.

Table 5-5 Description of the Common Clock Configuration Bit §

Bit	Description
Common Clock Configuration	<p>This bit, when Set, indicates that this component and the component at the opposite end of the Link are operating with a common clock source.</p> <p>This bit, when Clear, indicates that this component and the component at the opposite end of the Link are operating with separate reference clock sources.</p> <p>Default value of this bit is 0b.</p>

Bit	Description
	Components utilize this common clock configuration information to report the correct <u>L0s</u> and <u>L1</u> Exit Latencies.

Each Port reports the L0s and L1 exit latency (the time that they require to transition their Receive Lanes from the L0s or L1 state to the L0 state) in the L0s Exit Latency and the L1 Exit Latency configuration fields, respectively. If a Port does not support L0s or ASPM L1, the value of the respective exit latency field is undefined.

Table 5-6 Encoding of the L0s Exit Latency Field §

Field	Description
<u>L0s</u> Exit Latency>	000b Less than 64 ns
	001b 64 ns to less than 128 ns
	010b 128 ns to less than 256 ns
	011b 256 ns to less than 512 ns
	100b 512 ns to less than 1 μ s
	101b 1 μ s to less than 2 μ s
	110b 2 μ s to 4 μ s
	111b More than 4 μ s

Table 5-7 Encoding of the L1 Exit Latency Field §

Field	Description
<u>L1</u> Exit Latency	000b Less than 1 μ s
	001b 1 μ s to less than 2 μ s
	010b 2 μ s to less than 4 μ s
	011b 4 μ s to less than 8 μ s
	100b 8 μ s to less than 16 μ s
	101b 16 μ s to less than 32 μ s
	110b 32 μ s to 64 μ s
	111b More than 64 μ s

Endpoints also report the additional latency that they can absorb due to the transition from L0s state or L1 state to the L0 state. This is reported in the Endpoint L0s Acceptable Latency and Endpoint L1 Acceptable Latency fields, respectively.

Power management software, using the latency information reported by all components in the Hierarchy, can enable the appropriate level of ASPM by comparing exit latency for each given path from Root to Endpoint against the acceptable latency that each corresponding Endpoint can withstand.

*Table 5-8 Encoding of the Endpoint L0s
Acceptable Latency Field §*

Field	Description
Endpoint L0s Acceptable Latency	000b Maximum of 64 ns
	001b Maximum of 128 ns
	010b Maximum of 256 ns
	011b Maximum of 512 ns
	100b Maximum of 1 μ s
	101b Maximum of 2 μ s
	110b Maximum of 4 μ s
	111b No limit

*Table 5-9 Encoding of the Endpoint L1
Acceptable Latency Field §*

Field	Description
Endpoint L1 Acceptable Latency	000b Maximum of 1 μ s
	001b Maximum of 2 μ s
	010b Maximum of 4 μ s
	011b Maximum of 8 μ s
	100b Maximum of 16 μ s
	101b Maximum of 32 μ s
	110b Maximum of 64 μ s
	111b No limit

Power management software enables or disables ASPM in each component by programming the ASPM Control field.

*Table 5-10 Encoding of the ASPM Control
Field §*

Field	Description
ASPM Control	00b Disabled
	01b L0s Entry Enabled
	10b L1 Entry Enabled

Field	Description
	11b L0s and L1 Entry enabled

ASPM Control = 00b

Port's Transmitter must not enter L0s.

Ports connected to the Downstream end of the Link must not issue a PM_Active_State_Request_L1 DLLP on its Upstream Link.

Ports connected to the Upstream end of the Link receiving a L1 request must respond with negative acknowledgement.

ASPM Control = 01b

Port must bring a Link into L0s state if all conditions are met.

Ports connected to the Downstream end of the Link must not issue a PM_Active_State_Request_L1 DLLP on its Upstream Link.

Ports connected to the Upstream end of the Link receiving a L1 request must respond with negative acknowledgement.

ASPM Control = 10b

Port's Transmitter must not enter L0s.

Ports connected to the Downstream end of the Link may issue PM_Active_State_Request_L1 DLLPs.

Ports connected to the Upstream end of the Link must respond with positive acknowledgement to a L1 request and transition into L1 if the conditions for the Root Complex Root Port or Switch Downstream Port in § Section 5.4.1.3.1 are met.

ASPM Control = 11b

Port must bring a Link into the L0s state if all conditions are met.

Ports connected to the Downstream end of the Link may issue PM_Active_State_Request_L1 DLLPs.

Ports connected to the Upstream end of the Link must respond with positive acknowledgement to a L1 request and transition into L1 if the conditions for the Root Complex Root Port or Switch Downstream Port in § Section 5.4.1.3.1 are met.

5.4.1.4.1 Software Flow for Enabling or Disabling ASPM §

Following is an example software algorithm that highlights how to enable or disable ASPM in a component.

- PCI Express components power up with an appropriate value in their Slot Clock Configuration bit. The method by which they initialize this bit is device-specific.
- PCI Express system software scans the Slot Clock Configuration bit in the components on both ends of each Link to determine if both are using the same reference clock source or reference clocks from separate sources. If the Slot Clock Configuration bits in both devices are Set, they are both using the same reference clock source, otherwise they're not.
- PCI Express software updates the Common Clock Configuration bits in the components on both ends of each Link to indicate if those devices share the same reference clock and triggers Link retraining by writing 1b to the Retrain Link bit in the Link Control register of the Upstream component.

- Devices must reflect the appropriate L0s/L1 exit latency in their L0s/L1 Exit Latency fields, per the setting of the Common Clock Configuration bit.
- PCI Express system software then reads and calculates the L0s/L1 exit latency for each Endpoint based on the latencies reported by each Port. Refer to § Section 5.4.1.3.2 for an example.
- For each component with one or more Endpoint Functions, PCI Express system software examines the Endpoint L0s Acceptable Latency /Endpoint L1 Acceptable Latency, as reported by each Endpoint Function in its Link Capabilities Register, and enables or disables L0s /L1 entry (via the ASPM Control field in the Link Control Register) accordingly in some or all of the intervening device Ports on that hierarchy.

5.5 L1 PM Substates §

L1 PM Substates establish a Link power management regime that creates lower power substates of the L1 Link state (see § Figure 5-9), and associated mechanisms for using those substates. The L1 PM Substates are:

- **L1.0** substate
 - The L1.0 substate corresponds to the conventional L1 Link state. This substate is entered whenever the Link enters L1. The L1 PM Substate mechanism defines transitions from this substate to and from the L1.1 and L1.2 substates.
 - The Upstream and Downstream Ports must be enabled to detect Electrical Idle exit as required in § Section 4.2.7.7.2 .
- **L1.1** substate
 - Link common mode voltages are maintained.
 - Uses a bidirectional open-drain clock request (CLKREQ#) signal for entry to and exit from this state.
 - The Upstream and Downstream Ports are not required to be enabled to detect Electrical Idle exit.
- **L1.2** substate
 - Link common mode voltages are not required to be maintained.
 - Uses a bidirectional open-drain clock request (CLKREQ#) signal for entry to and exit from this state.
 - The Upstream and Downstream Ports are not required to be enabled to detect Electrical Idle exit.

Ports that support L1 PM Substates must not require a reference clock while in L1 PM Substates other than L1.0.

Ports that support L1 PM Substates and also support SRIS mode are required to support L1 PM Substates while operating in SRIS mode. In such cases the CLKREQ# signal is used by the L1 PM Substates protocol as defined in this section, but has no defined relationship to any local clocks used by either Port on the Link, and the management of such local clocks is implementation specific.

Ports that support the L1.2 substate for ASPM L1 must support Latency Tolerance Reporting (LTR).

Figure 5-9 State Diagram for L1 PM Substates §

- When enabled, the L1 PM Substates mechanism applies the following additional requirements to the CLKREQ# signal: The CLKREQ# signal must be supported as a bi-directional open drain signal by both the Upstream and Downstream Ports of the Link. Each Port must have a unique instance of the signal, and the Upstream and Downstream Port CLKREQ# signals must be connected.
- It is permitted for the Upstream Port to deassert CLKREQ# when the Link is in the PCI-PM L1 or ASPM L1 states, or when the Link is in the L2/L3 Ready pseudo-state; CLKREQ# must be asserted by the Upstream Port when the Link is in any other state.
- All other specifications related to the CLKREQ# signal that are not specifically defined or modified by L1 PM Substates continue to apply.

If these requirements cannot be satisfied in a particular system, then L1 PM Substates must not be enabled.

IMPLEMENTATION NOTE: CLKREQ# CONNECTION TOPOLOGIES §

For an Upstream component the connection topologies for the CLKREQ# signal can vary. A few examples of CLKREQ# connection topologies are described below. For the Downstream component these cases are essentially the same, however from the Upstream component's perspective, there are some key differences that are described below.

Example 1: Single Downstream Port with a single PLL connected to a single Upstream Port (see § Figure 5-10).

In this platform configuration the Upstream component (A) has only a single CLKREQ# signal. The Upstream and Downstream Ports' CLKREQ# (A and B) signals are connected to each other. In this case, Upstream component (A), must assert CLKREQ# signal whenever it requires a reference clock.

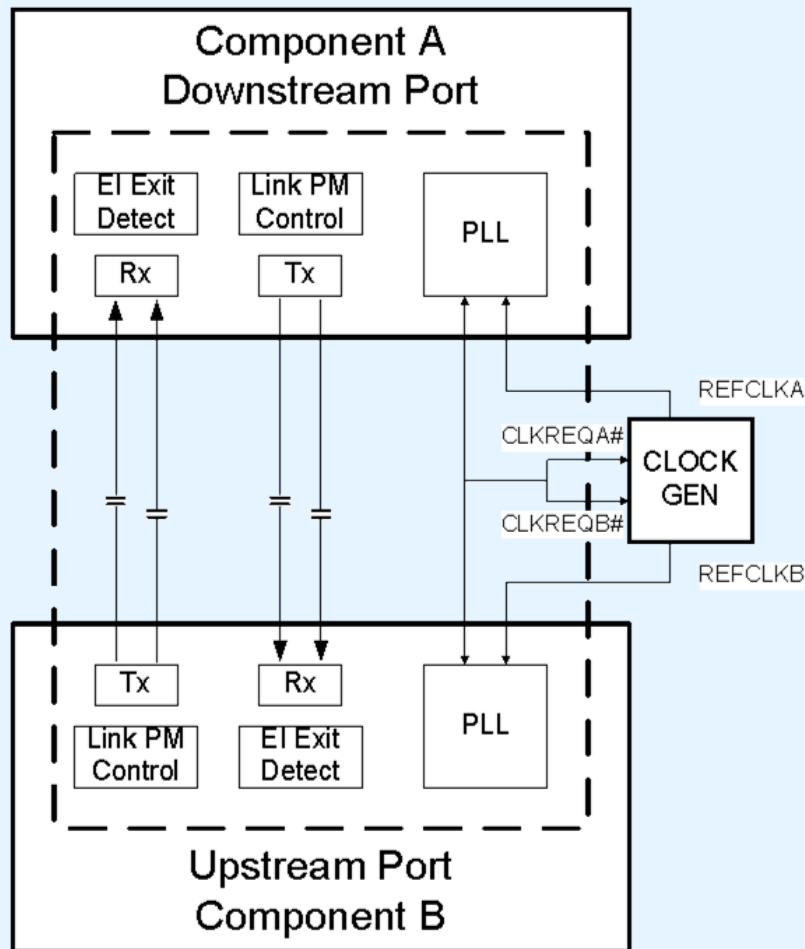

Figure 5-10 Downstream Port with a Single PLL §

Example 2: Upstream component with multiple Downstream Ports, with a common shared PLL, connected to separate Downstream components (see § Figure 5-11).

In this example configuration, there are three instances of CLKREQ# signal for the Upstream component (A), one per Downstream Port and a common shared CLKREQ# signal for the Upstream component (A). In this topology the Downstream Port CLKREQ# (CLKREQB#, CLKREQC#) signals are used to connect to the CLKREQ# signal of the Upstream Port of the Downstream components (B and C). The common shared CLKREQ# (CLKREQA#) signal for the Upstream component is used to request the reference clock for the shared PLL. The PLL control logic in Upstream component (A) can only be turned off and CLKREQA# be deasserted when both the Downstream Ports are in L1.1 or L1.2 Substates, and all internal (A) consumers of the PLL don't require a clock.

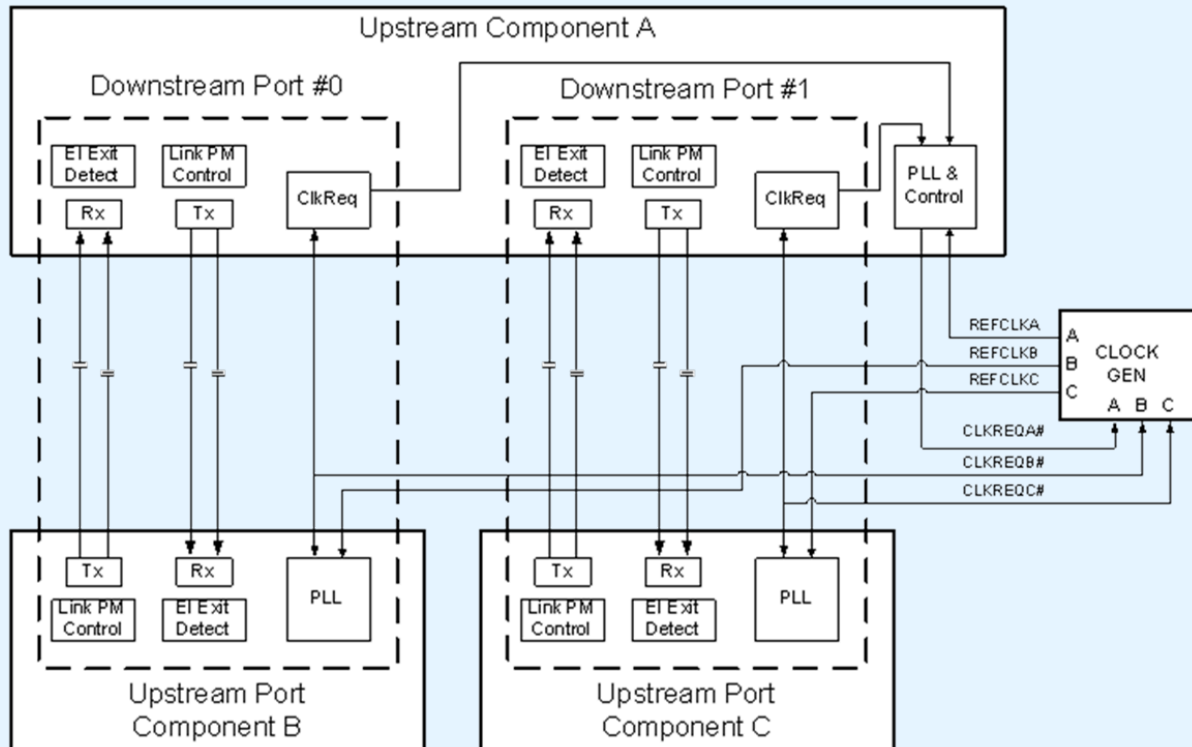

Figure 5-11 Multiple Downstream Ports with a shared PLL §

It is necessary for board implementers to consider what CLKREQ# topologies will be supported by components in order to make appropriate board level connections to support L1 PM Substates and for the reference clock generation.

IMPLEMENTATION NOTE: AVOIDING UNINTENDED INTERACTIONS BETWEEN L1 PM SUBSTATES AND THE LTSSM §

It is often the case that implementation techniques which save power will also increase the latency to return to normal operation. When implementing L1 PM Substates, it is important for the implementer to ensure that any added delays will not negatively interact with other elements of the platform. It is particularly important to ensure that LTSSM timeout conditions are not unintentionally triggered. Although typical implementations will not approach the latencies that would cause such interactions, the responsibility lies with the implementer to ensure that correct overall operation is achieved.

5.5.1 Entry conditions for L1 PM Substates and L1.0 Requirements §

The Link is considered to be in PCI-PM L1.0 when the L1 PM Substate is L1.0 and the LTSSM entered L1 through PCI-PM compatible power management. The Link is considered to be in ASPM L1.0 when the L1 PM Substate is in L1.0 and LTSSM entered L1 through ASPM.

The following rules define how the L1.1 and L1.2 substates are entered:

- Both the Upstream and Downstream Ports must monitor the logical state of the CLKREQ# signal.
- When in PCI-PM L1.0 and the PCI-PM L1.2 Enable bit is Set, the L1.2 substate must be entered when CLKREQ# is deasserted.
- When in PCI-PM L1.0 and the PCI-PM L1.1 Enable bit is Set, the L1.1 substate must be entered when CLKREQ# is deasserted and the PCI-PM L1.2 Enable bit is Clear.
- When in ASPM L1.0 and the ASPM L1.2 Enable bit is Set, the L1.2 substate must be entered when CLKREQ# is deasserted and all of the following conditions are true:
 - The reported snooped LTR value last sent or received by this Port is greater than or equal to the value set by the LTR_L1.2_THRESHOLD Value and Scale fields, or there is no snoop service latency requirement.
 - The reported non-snooped LTR last sent or received by this Port value is greater than or equal to the value set by the LTR_L1.2_THRESHOLD Value and Scale fields, or there is no non-snoop service latency requirement.
- When in ASPM L1.0 and the ASPM L1.1 Enable bit is Set, the L1.1 substate must be entered when CLKREQ# is deasserted and the conditions for entering the L1.2 substate are not satisfied.

When the entry conditions for L1.2 are satisfied, the following rules apply:

- Both the Upstream and Downstream Ports must monitor the logical state of the CLKREQ# input signal.
- An Upstream Port must not deassert CLKREQ# until the Link has entered L1.0.
- It is permitted for either Port to assert CLKREQ# to prevent the Link from entering L1.2.
- A Downstream Port intending to block entry into L1.2 must assert CLKREQ# before the Link enters L1.
- When CLKREQ# is deasserted the Ports enter the L1.2.Entry substate of L1.2.

If a Downstream Port is in PCI-PM L1.0 and PCI-PM L1.1 Enable and/or PCI-PM L1.2 Enable are Set, or if a Downstream Port is in ASPM L1.0 and ASPM L1.1 Enable and/or ASPM L1.2 Enable are Set, and the Downstream Port initiates an exit to Recovery without having entered L1.1 or L1.2, the Downstream Port must assert CLKREQ# until the Link exits Recovery.

5.5.2 L1.1 Requirements §

Both Upstream and Downstream Ports are permitted to deactivate mechanisms for electrical idle (EI) exit detection and Refclk activity detection if implemented, however both ports must maintain common mode.

5.5.2.1 Exit from L1.1 §

If either the Upstream or Downstream Port needs to initiate exit from L1.1, it must assert CLKREQ# until the Link exits Recovery. The Upstream Port must assert CLKREQ# on entry to Recovery, and must continue to assert CLKREQ# until the next entry into L1, or other state allowing CLKREQ# deassertion.

- Next state is L1.0 if CLKREQ# is asserted.
 - The Refclk will eventually be turned on as defined in the PCI Express Mini CEM spec, which may be delayed according to the LTR advertised by the Upstream Port.

§ Figure 5-12 illustrates entry into L1.1 with exit driven by the Upstream Port.

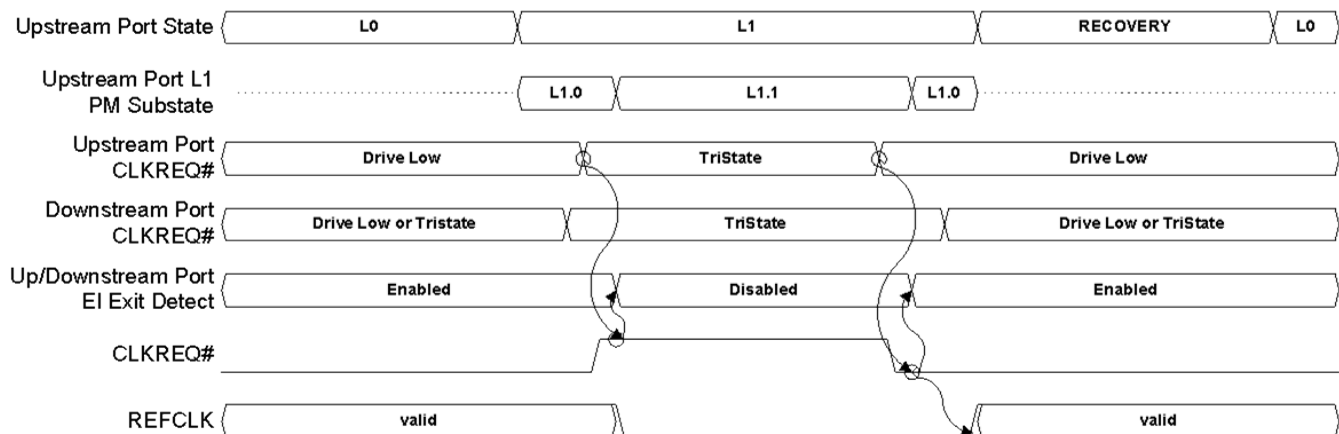

Figure 5-12 Example: L1.1 Waveforms Illustrating Upstream Port Initiated Exit §

§ Figure 5-13 illustrates entry into L1.1 with exit driven by the Downstream Port.

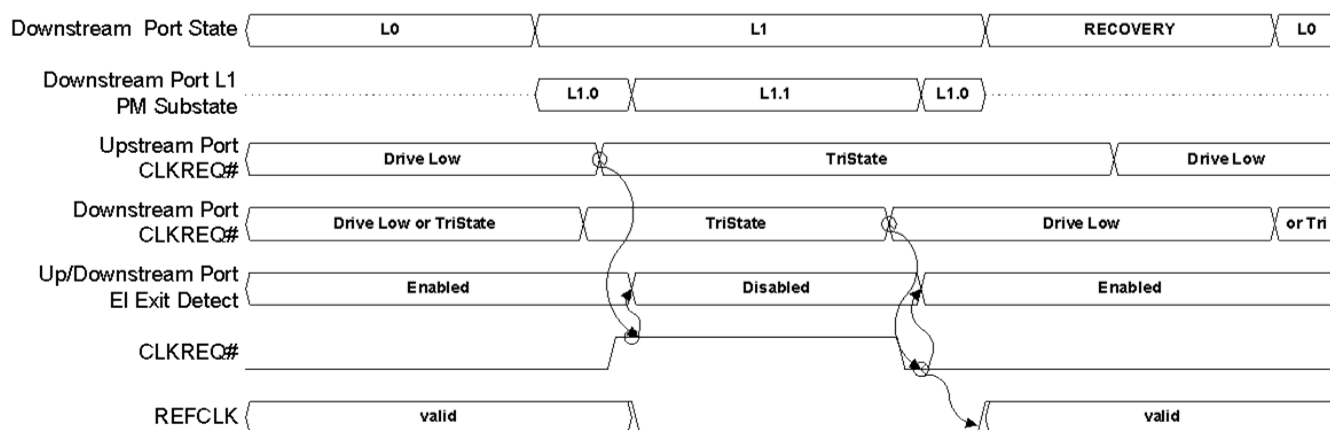

Figure 5-13 Example: L1.1 Waveforms Illustrating Downstream Port Initiated Exit §

5.5.3 L1.2 Requirements §

All Link and PHY state must be maintained during L1.2, or must be restored upon exit using implementation specific means, and the LTSSM and corresponding Port state upon exit from L1.2 must be indistinguishable from the L1.0 LTSSM and Port state.

L1.2 has additional requirements that do not apply to L1.1 These requirements are documented in this section.

L1.2 has three substates, which are defined below (see § Figure 5-14).

Figure 5-14 L1.2 Substates §

5.5.3.1 L1.2.Entry §

L1.2.Entry is a transitional state on entry into L1.2 to allow time for Refclk to turn off and to ensure both Ports have observed CLKREQ# deasserted. The following rules apply to L1.2.Entry:

- Both Upstream and Downstream Ports continue to maintain common mode.
- Both Upstream and Downstream Ports may turn off their electrical idle (EI) exit detect circuitry.
- The Upstream and Downstream Ports must not assert CLKREQ# in this state.
- Refclk must be turned off within $T_{L10_REFCLK_OFF}$.
- Next state is L1.0 if CLKREQ# is asserted, else the next state is L1.2.Idle after waiting for T_{POWER_OFF} .

Note that there is a boundary condition which can occur when one Port asserts CLKREQ# shortly after the other Port deasserts CLKREQ#, but before the first Port has observed CLKREQ# deasserted. This is an unavoidable boundary condition that implementations must handle correctly. An example of this condition is illustrated in § Figure 5-15.

Figure 5-15 Example: Illustration of Boundary Condition due to Different Sampling of CLKREQ# §

5.5.3.2 L1.2.Idle §

When requirements for the entry into L1.2.Idle state (see § Section 5.5.1) have been satisfied then the Ports enter the L1.2.Idle substate. The following rules apply in L1.2.Idle:

- Both Upstream and Downstream Ports may power-down any active logic, including circuits required to maintain common mode.
- The PHY of both Upstream and Downstream Ports may have their power removed.

The following rules apply for L1.2.Idle state when using the CLKREQ#-based mechanism:

- If either the Upstream or Downstream Port needs to exit L1.2, it must assert CLKREQ# after ensuring that $T_{L1.2}$ has been met.
- If the Downstream Port is initiating exit from L1, it must assert CLKREQ# until the Link exits Recovery. The Upstream Port must assert CLKREQ# on entry to Recovery, and must continue to assert CLKREQ# until the next entry into L1, or other state allowing CLKREQ# deassertion.
- If the Upstream Port is initiating exit from L1, it must continue to assert CLKREQ# until the next entry into L1, or other state allowing CLKREQ# deassertion.
- Both the Upstream and Downstream Ports must monitor the logical state of the CLKREQ# input signal.
- Next state is L1.2.Exit if CLKREQ# is asserted.

5.5.3.3 L1.2.Exit §

This is a transitional state on exit from L1.2 to allow time for both devices to power up. In L1.2.Exit, the following rules apply:

- The PHYs of both Upstream and Downstream Ports must be powered.
- It must not be assumed that common mode has been maintained.

5.5.3.3.1 Exit from L1.2 §

- The following rules apply for L1.2.Exit using the CLKREQ#-based mechanism:
- Both Upstream and Downstream Ports must power up any circuits required for L1.0, including circuits required to maintain common mode.
- The Upstream and Downstream Ports must not change their driving state of CLKREQ# in this state.
- Refclk must be turned on no earlier than $T_{L10_REFCLK_ON}$ minimum time, and may take up to the amount of time allowed according to the LTR advertised by the Endpoint before becoming valid.
- Next state is L1.0 after waiting for T_{POWER_ON} .
 - Common mode is permitted to be established passively during L1.0, and actively during Recovery. In order to ensure common mode has been established, the Downstream Port must maintain a timer, and the Downstream Port must continue to send TS1 training sequences until a minimum of $T_{COMMONMODE}$ has elapsed since the Downstream Port has started transmitting TS1 training sequences and has detected electrical idle exit on any Lane of the configured Link.

§ Figure 5-16 illustrates the signal relationships and timing constraints associated with L1.2 entry and Upstream Port initiated exit.

§ Figure 5-17 illustrates the signal relationships and timing constraints associated with L1.2 entry and Downstream Port initiated exit.

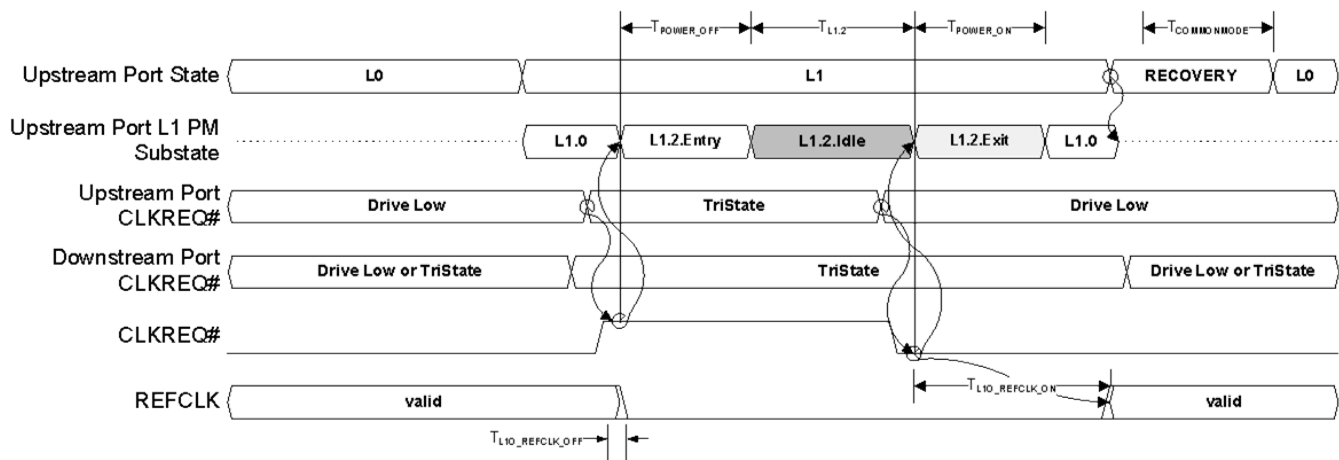

Figure 5-16 Example: L1.2 Waveforms Illustrating Upstream Port Initiated Exit §

Figure 5-17 Example: L1.2 Waveforms Illustrating Downstream Port Initiated Exit §

5.5.4 L1 PM Substates Configuration §

L1 PM Substates is considered enabled on a Port when any combination of the ASPM L1.1 Enable, ASPM L1.2 Enable, PCI-PM L1.1 Enable and PCI-PM L1.2 Enable bits associated with that Port are Set.

An L1 PM Substate enable bit must only be Set in the Upstream and Downstream Ports on a Link when the corresponding supported capability bit is Set by both the Upstream and Downstream Ports on that Link, otherwise the behavior is undefined.

The Setting of any enable bit must be performed at the Downstream Port before the corresponding bit is permitted to be Set at the Upstream Port. If any L1 PM Substates enable bit is at a later time to be cleared, the enable bit(s) must be cleared in the Upstream Port before the corresponding enable bit(s) are permitted to be cleared in the Downstream Port.

If setting either or both of the enable bits for ASPM L1 PM Substates, both ports must be configured as described in this section while ASPM L1 is disabled.

If setting either or both of the enable bits for PCI-PM L1 PM Substates, both ports must be configured as described in this section while in D0.

Prior to setting either or both of the enable bits for L1.2, the values for T_{POWER_ON}, Common_Mode_Restore_Time, and, if the ASPM L1.2 Enable bit is to be Set, the LTR_L1.2_THRESHOLD (both Value and Scale fields) must be programmed.

The T_{POWER_ON} and Common_Mode_Restore_Time fields must be programmed to the appropriate values based on the components and AC coupling capacitors used in the connection linking the two components. The determination of these values is design implementation specific.

When both the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are cleared, it is not required to program the T_{POWER_ON}, Common_Mode_Restore_Time, and LTR_L1.2_THRESHOLD Value and Scale fields, and hardware must not rely on these fields to have any particular values.

When programming LTR_L1.2_THRESHOLD Value and Scale fields, identical values must be programmed in both Ports.

5.5.5 L1 PM Substates Timing Parameters §

§ Table 5-11 defines the timing parameters associated with the L1.2 substates mechanism.

Table 5-11 L1.2 Timing Parameters §

Parameter	Description	Min	Max	Units
T_{POWER_OFF}	CLKREQ# deassertion to entry into the <u>L1.2.Idle</u> substate		2	μ s
$T_{COMMONMODE}$	Restoration of Refclk to restoration of common mode established through active transmission of TS1 training sequences (see § Section 5.5.3.3.1)	Programmable in range from 0 to 255		μ s
$T_{L10_REFCLK_OFF}$	CLKREQ# deassertion to Refclk reaching idle electrical state when entering L1.2	0	100	ns
$T_{L10_REFCLK_ON}$	CLKREQ# assertion to Refclk valid when exiting L1.2	T_{POWER_ON}	LTR value advertised by the Endpoint	μ s
T_{POWER_ON}	The minimum amount of time that each component must wait in L1.2.Exit after sampling CLKREQ# asserted before actively driving the interface to ensure no device is ever actively driving into an unpowered component.	Set in the L1 PM Substates Control 2 Register (range from 0 to 3100)		μ s
$T_{L1.2}$	Time a Port must stay in <u>L1.2</u> when CLKREQ# must remain inactive	4		μ s

5.5.6 Link Activation §

Link Activation is an optional mechanism to temporarily disable L1 Substates. Link Activation is used to bring a Link out of L1.1/L1.2, avoiding potential stalls. An example of one such stall is the stall associated with a Configuration Write to perform a D3_{Hot} to D0 transition. Link Activation can also be used to indirectly indicate to a Device that it should avoid long-latency internal power management during latency-sensitive or time critical operations.

The following rules apply to Link Activation:

- A Downstream Port is permitted to support Link Activation, as indicated by the Link Activation Supported bit in the L1 PM Substates Capabilities Register being Set.
- The Link Activation Control bit must have no effect on Port behavior unless one or more of the following bits are Set:
 - PCI-PM L1.2 Enable
 - PCI-PM L1.1 Enable
- When the Link Activation Control bit is Set, the Port that is about to enter L1 must assert, and while in L1 maintain as asserted, the CLKREQ# signal.
- If the Link Activation Control bit is Clear, the Link Activation mechanism does not impose any additional requirements on the state of the CLKREQ# signal.
- If the Port is enabled for edge-triggered interrupt signaling using MSI or MSI-X, an interrupt message must be sent every time the logical AND of the following conditions transitions from FALSE to TRUE:
 - The associated vector is unmasked (not applicable if MSI does not support PVM)
 - The Link Activation Interrupt Enable bit is Set
 - The Link Activation Control bit is Set
 - The Link Activation Status bit is Set. Note that Link Activation interrupts always use the MSI or MSI-X vector indicated by the Interrupt Message Number field in the PCI Express Capabilities Register.

- If the Port is enabled for level-triggered interrupt signaling using the INTx messages, the virtual INTx wire must be asserted whenever and as long as the following conditions are satisfied:
 - The Interrupt Disable bit in the Command Register is Clear.
 - The Link Activation Interrupt Enable bit is Set
 - The Link Activation Control bit is Set
 - The Link Activation Status bit is Set
- The Link Activation Status bit must be Set every time the logical AND of the following conditions transitions from FALSE to TRUE:
 - Either the PCI-PM L1.2 Enable bit or the PCI-PM L1.1 Enable bit (or both) are Set
 - The Link Activation Control bit is Set
 - The Link is not in an L1 Substate

5.6 Auxiliary Power Support §

The specific definition and requirements associated with auxiliary power are form factor specific, and the terms “auxiliary power” and “Vaux” should be understood in reference to the specific form factor in use. The specific mechanism(s) for supplying auxiliary power are not defined in this specification. The following text defines requirements that apply in all form factors.

Note that support for auxiliary power is optional. Some form factors do not support it. Also, some form factors have dedicated auxiliary power pins while other form factors use the main power pins in some fashion.

PCI Express PM provides a Aux Power PM Enable bit in the Device Control Register that provides the means for enabling a Function to draw the maximum allowance of auxiliary current independent of its level of support for PME generation.

A Function requests auxiliary power allocation by specifying a non-zero value in the Aux_Current field of the PMC register. Refer to § Chapter 7. for the Aux Power PM Enable register bit assignment, and access mechanism.

Allocation of auxiliary power using Aux Power PM Enable and PME_En is determined as follows:

Table 5-12 Aux Power Source and Availability §

Aux Power PM Enable	PME_En	Aux Power Detected	Aux Power Source	Aux Power Available
x	x	0b	None	None
0b	0b	1b	Form factor specific Aux Power rail / pins	Form factor specific (e.g., 10 mW in CEM)
	1b		Form factor specific Aux Power rail / pins	Aux_Current value (PMC)
1b	x		Form factor specific Aux Power rail / pins	Aux_Current value (PMC)

Aux Power PM Enable = 1b:

Auxiliary power is allocated as requested in the Aux_Current field of the PMC register, independent of the PME_En bit in the PMSCR. The PME_En bit still controls the ability to master PME.

Additional Aux power is permitted to be allocated using a firmware based mechanism (see the Request D3_{Cold} Aux Power Limit _DSM call as defined in [Firmware]).

Additional Aux power is also permitted to be allocated by selecting a PM Sub State in the Power Limit mechanism (see § Section 7.8.1.3).

Aux Power PM Enable = 0b:

Auxiliary power allocation is controlled by the PME_En bit as defined in § Section 7.5.2.2 .

Additional Aux power is permitted to be allocated using a firmware based mechanism (see the Request D3Cold Aux Power Limit_DSM call as defined in [Firmware]).

Additional Aux power is also permitted to be allocated by selecting a PM Sub State in the Power Limit mechanism (see § Section 7.8.1.3).

The Aux Power PM Enable bit is sticky (see § Section 7.4) so its state is preserved in the D3Cold state, and is not affected by the transitions from the D3Cold state to the D0uninitialized state.

5.7 Power Management System Messages and DLLPs §

§ Table 5-13 defines the location of each PM packet in the PCI Express stack.

Table 5-13 Power Management System Messages and DLLPs §

Packet	Type
<u>PM_Enter_L1</u>	DLLP
<u>PM_Enter_L23</u>	DLLP
<u>PM_Active_State_Request_L1</u>	DLLP
<u>PM_Request_Ack</u>	DLLP
<u>PM_Active_State_Nak</u>	Transaction Layer Message
<u>PM_PME</u>	Transaction Layer Message
<u>PME_Turn_Off</u>	Transaction Layer Message
<u>PME_TO_Ack</u>	Transaction Layer Message

For information on the structure of the power management DLLPs, refer to § Section 3.5 .

Power Management Messages follow the general rules for all Messages. Power Management Message fields follow the following rules:

- Length field is Reserved.
- Attribute field must be set to the default values (all 0's).
- Address field is Reserved.
- Requester ID - see § Table 2-23 in § Section 2.2.8.2 .
- Traffic Class field must use the default class (TC0).

5.8 PCI Function Power State Transitions §

All PCI-PM power management state changes are explicitly controlled by software except for Fundamental Reset which brings all Functions to the $D0_{uninitialized}$ state. § Figure 5-18 shows all supported state transitions. The unlabeled arcs represent a software initiated state transition (Set Power State operation).

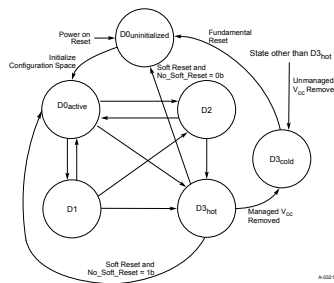

Figure 5-18 Function Power Management State Transitions §

5.9 State Transition Recovery Time Requirements §

§ Table 5-14 shows the minimum recovery times that system software must allow between the time that a Function is programmed to change state and the time that the function is next accessed (including Configuration Space), unless Readiness Notifications (see § Section 6.22) is used to indicate modified values to system software. For bridge Functions, this delay also constitutes a minimum delay between when the bridge's state is changed and when any Function on the logical bus that it originates can be accessed.

Table 5-14 PCI Function State Transition Delays §

Initial State	Next State	Minimum System Software Guaranteed Delays
$D0$	$D1$	0
$D0$ or $D1$	$D2$	200 μ s
$D0$, $D1$ or $D2$	$D3_{Hot}$	10 ms
$D1$	$D0$	0
$D2$	$D0$	200 μ s
$D3_{Hot}$	$D0$	10 ms

5.10 SR-IOV Power Management §

This section defines power management requirements that are unique to SR-IOV devices.

The PCI Power Management Capability as described elsewhere in § Chapter 5, is required for PFs.

For VFs, the PCI Power Management Capability is optional.

5.10.1 VF Device Power Management States §

If a VF does not implement the PCI Power Management Capability, then the VF behaves as if it had been programmed into the equivalent power state of its associated PF.

If a VF implements the PCI Power Management Capability, the functionality must be as defined in § Section 7.5.2.

If a VF implements the PCI Power Management Capability, the Device behavior is undefined if the PF is placed in a lower power state than the VF. Software should avoid this situation by placing all VFs in lower power state before lowering their associated PF's power state.

A VF in the D0 state is in the D0_{active} state when the VF has completed its internal initialization and either the VF's Bus Master Enable bit or the VF MSE bit in the SR-IOV Control Register (see § Section 9.3.3.3) Extended Capability is Set. The VF's internal initialization must have completed when any of the following conditions have occurred:

- The VF has responded successfully (without returning RRS) to a Configuration Request.
- After issuing an FLR to the VF, one of the following is true:
 - At least 1.0 s has passed since the FLR was issued.
 - The VF supports Function Readiness Status and, after the FLR was issued, an FRS Message from the VF with Reason Code FLR Completed has been received.
 - At least FLR time has passed since the FLR was issued. FLR Time is either (1) the FLR Time value in the Readiness Time Reporting capability associated with the VF or (2) a value determined by system software / firmware¹⁰⁰.
- After Setting VF Enable in a PF, at least one of the following is true:
 - At least 1.0 s has passed since VF Enable was Set.
 - The PF supports Function Readiness Status and, after VF Enable was Set, an FRS Message from the PF with Reason Code VF Enabled has been received.
- After transitioning a VF from D3_{Hot} to D0, at least one of the following is true:
 - At least 10 ms has passed since the request to enter D0 was issued.
 - The VF supports Function Readiness Status and, after the request to enter D0 was issued, an FRS Message from the VF with Reason Code D3_{Hot} to D0 Transition Completed has been received.
 - At least D3_{Hot} to D0 Time has passed since the request to enter D0 was issued. D3_{Hot} to D0 Time is either (1) the D3_{Hot} to D0 Time in the Readiness Time Reporting capability associated with the VF or (2) a value determined by system software / firmware¹⁰¹.

5.10.2 PF Device Power Management States §

The PF's power management state (D-state) has global impact on its associated VFs. If a VF does not implement the PCI Power Management Capability, then it behaves as if it is in an equivalent power state of its associated PF.

If a VF implements the PCI Power Management Capability, the Device behavior is undefined if the PF is placed in a lower power state than the VF. Software should avoid this situation by placing all VFs in lower power state before lowering their associated PF's power state.

When the PF is placed into the D3_{Hot} state:

100. For example, ACPI tables.

101. For example, ACPI tables.

- If the No_Soft_Reset bit is Clear then the PF performs an internal reset on the D3_{Hot} to D0 transition and all its configuration state returns to the default values.

Note: Resetting the PF resets VF Enable which means that VFs no longer exist and any VF specific context is lost after the D3_{Hot} to D0 transition is complete.

- If the No_Soft_Reset bit is Set then the internal reset does not occur. The SR-IOV extended capability retains state, and associated VFs remain enabled.

When the PF is placed into the D3_{Cold} state VFs no longer exist, any VF specific context is lost and PME events can only be initiated by the PF.

IMPLEMENTATION NOTE: NO_SOFT_RESET STRONGLY RECOMMENDED §

It is strongly recommended that the No_Soft_Reset bit be Set in all Functions of a Multi-Function Device. As indicated in the bit definition, all implementations that support Flit Mode are required to Set the No_Soft_Reset bit. This recommendation applies to PFs.

5.11 PCI Bridges and Power Management §

With power management under the direction of the operating system, each class of Functions must have a clearly defined criteria for feature availability as well as what functional context must be preserved when operating in each of the power management states. Some example Device-Class specifications have been proposed as part of the ACPI specification for various Functions ranging from audio to network add-in cards. While defining Device-Class specific behavioral policies for most Functions is outside the scope of this specification, defining the required behavior for PCI bridge functions is within the scope of this specification. The definitions here apply to all three types of PCIe Bridges:

- Host bridge, PCI Express to expansion bus bridge, or other ACPI enumerated bridge
- Switches
- PCI Express to PCI bridge
- PCI-to-CardBus bridge

The mechanisms for controlling the state of these Functions vary somewhat depending on which type of Originating Device is present. The following sections describe how these mechanisms work for the three types of bridges.

This section details the power management policies for PCI Express Bridge Functions. The PCI Express Bridge Function can be characterized as an Originating Device with a secondary bus downstream of it. This section describes the relationship of the bridge function's power management state to that of its secondary bus.

The shaded regions in § Figure 5-19 illustrate what is discussed in this section.

Figure 5-19 PCI Express Bridge Power Management Diagram §

As can be seen from § Figure 5-19, the PCI Express Bridge behavior described in this chapter is common, from the perspective of the operating system, to host bridges, Switches, and PCI Express to PCI bridges.

It is the responsibility of the system software to ensure that only valid, workable combinations of bus and downstream Function power management states are used for a given bus and all Functions residing on that bus.

5.11.1 Switches and PCI Express to PCI Bridges §

The power management policies for the secondary bus of a Switch or PCI Express to PCI bridge are identical to those defined for any Bridge Function.

The BPCCEn and B2_B3# bus power/clock control fields in the Bridge Function's PMCSR_BSE register support the same functionality as for any other Bridges.

5.12 Power Management Events §

There are two varieties of Power Management Events:

- Wakeup Events
- PME Generation

A Wakeup Event is used to request that power be turned on.

A PME Generation Event is used to identify to the system the Function requesting that power be turned on.

In conventional PCI, both events are associated with the PME# signal. The PME# signal is asserted by a Function to request a change in its power management state. When the PME_En bit is Set and the event occurs, the Function sets the PME_Status bit and asserts the PME# signal. It keeps the PME# signal asserted until either the PME_En bit or the PME_Status are Cleared (typically by software).

In PCI Express, the Wakeup Event is associated with the WAKE# signal. If supported, the WAKE# signal is defined in the associated form factor specification and is used by a Function to request a change in its PCI-PM power management state when the Function is in D3Cold and PME_En is Set.

In PCI Express, after main power has been restored and the Link is trained, the Function(s) that initiated the wakeup (e.g., that asserted WAKE#), sends a PM_PME Message to the Root Complex. The PM_PME Message provides the Root Complex with the identity of the requesting Function(s) without requiring software to poll for the PME_Status bit being Set.

6. System Architecture §

This chapter addresses various aspects of PCI Express interconnect architecture in a platform context.

6.1 Interrupt and PME Support §

The PCI Express interrupt model supports two mechanisms:

- INTx emulation
- Message Signaled Interrupt (MSI/MSI-X)

For legacy compatibility, PCI Express provides a PCI INTx emulation mechanism to signal interrupts to the system interrupt controller (typically part of the Root Complex). This mechanism is compatible with existing PCI software, and provides the same level and type of service as the corresponding PCI interrupt signaling mechanism and is independent of system interrupt controller specifics. This legacy compatibility mechanism allows boot device support without requiring complex BIOS-level interrupt configuration/control service stacks. It virtualizes PCI physical interrupt signals by using an in-band signaling mechanism.

If an implementation supports interrupts, then this specification requires support of either MSI or MSI-X or both. PCI Compatible INTx interrupt emulation is optional. Switches are required to support forwarding the INTx interrupt emulation Messages (see § Section 2.2.8.1). The PCI Express MSI and MSI-X mechanisms are compatible with those originally defined in [PCI].

For SR-IOV devices, PFs are permitted to implement INTx, and VFs must not implement INTx. Each PF and VF must implement its own unique interrupt capabilities.

6.1.1 Rationale for PCI Express Interrupt Model §

PCI Express takes an evolutionary approach from PCI with respect to interrupt support.

As required for PCI/PCI-X interrupt mechanisms, each device Function is required to differentiate between INTx and MSI/MSI-X modes of operation. The device complexity required to support both schemes is no different than that for PCI/PCI-X devices. The advantages of this approach include:

- Compatibility with existing PCI Software Models
- Direct support for boot devices
- Easier End of Life (EOL) for INTx legacy mechanisms.

The existing software model is used to differentiate INTx vs. MSI/MSI-X modes of operation; thus, no special software support is required for PCI Express.

The software model does not support changing interrupt modes while the Function is in active operation. If software does this, interrupt conditions may be dropped or replicated.

6.1.2 PCI-compatible INTx Emulation §

PCI Express emulates the PCI interrupt mechanism including the Interrupt Pin and Interrupt Line registers of the PCI Configuration Space for PCI device Functions. PCI Express non-Switch devices may optionally support these registers for backwards compatibility. Switch devices are required to support them. Actual interrupt signaling uses in-band Messages rather than being signaled using physical pins.

Two types of Messages are defined, Assert_INTx and Deassert_INTx, for emulation of PCI INTx signaling, where x is A, B, C, and D for respective PCI interrupt signals. These Messages are used to provide “virtual wires” for signaling interrupts across a Link. Switches collect these virtual wires and present a combined set at the Switch’s Upstream Port. Ultimately, the virtual wires are routed to the Root Complex which maps the virtual wires to system interrupt resources. Devices must use assert/deassert Messages in pairs to emulate PCI interrupt level-triggered signaling. Actual mapping of PCI Express INTx emulation to system interrupts is implementation specific as is mapping of physical interrupt signals in conventional PCI.

The legacy INTx emulation mechanism may be deprecated in a future version of this specification.

6.1.3 INTx Emulation Software Model §

The software model for legacy INTx emulation matches that of PCI. The system BIOS reporting of chipset/platform interrupt mapping and the association of each device Function’s interrupt with PCI interrupt lines is handled in exactly the same manner as with conventional PCI systems. Legacy software reads from each device Function’s Interrupt Pin register to determine if the Function is interrupt driven. A value between 01h and 04h indicates that the Function uses an emulated interrupt pin to generate an interrupt.

Note that similarly to physical interrupt signals, the INTx emulation mechanism may potentially cause spurious interrupts that must be handled by the system software.

6.1.4 MSI and MSI-X Operation §

Message Signaled Interrupts (MSI) is an optional feature that enables a device Function to request service by writing a system-specified data value to a system-specified address (using a DWORD Memory Write transaction). System software initializes the message address and message data (from here on referred to as the “vector”) during device configuration, allocating one or more vectors to each MSI-capable Function.

Interrupt latency (the time from interrupt signaling to interrupt servicing) is system dependent. Consistent with current interrupt architectures, Message Signaled Interrupts do not provide interrupt latency time guarantees.

MSI-X defines a separate optional extension to basic MSI functionality. Compared to MSI, MSI-X supports a larger maximum number of vectors per Function, the ability for software to control aliasing when fewer vectors are allocated than requested, plus the ability for each vector to use an independent address and data value, specified by a table that resides in Memory Space. However, most of the other characteristics of MSI-X are identical to those of MSI.

For the sake of software backward compatibility, MSI and MSI-X use separate and independent Capability structures. On Functions that support both MSI and MSI-X, system software that supports only MSI can still enable and use MSI without any modification. MSI functionality is managed exclusively through the MSI Capability structure, and MSI-X functionality is managed exclusively through the MSI-X Capability structure.

A Function is permitted to implement both MSI and MSI-X, but system software is prohibited from enabling both at the same time. If system software enables both at the same time, the behavior is undefined.

All PCI Express device Functions that are capable of generating interrupts must support MSI or MSI-X or both. The MSI and MSI-X mechanisms deliver interrupts by performing Memory Write transactions. MSI and MSI-X are edge-triggered interrupt mechanisms; neither [PCI] nor this specification support level-triggered MSI/MSI-X interrupts. Certain PCI devices and their drivers rely on INTx-type level-triggered interrupt behavior (addressed by the PCI Express legacy INTx emulation mechanism). To take advantage of the MSI or MSI-X capability and edge-triggered interrupt semantics, these devices and their drivers may have to be redesigned.

MSI and MSI-X each support Per-Vector Masking (PVM). PVM is an optional¹⁰² extension to MSI, and a standard feature with MSI-X. A Function that supports the PVM extension to MSI is backward compatible with system software that is unaware of the extension. MSI-X also supports a Function Mask bit, which when Set masks all of the vectors associated with a Function.

A Legacy Endpoint that implements MSI is required to support either the 32-bit or 64-bit Message Address version of the MSI Capability structure. A PCI Express Endpoint that implements MSI is required to support the 64-bit Message Address version of the MSI Capability structure.

The Requester of an MSI/MSI-X transaction must set the No Snoop and Relaxed Ordering attributes of the Transaction Descriptor to 0b. A Requester of an MSI/MSI-X transaction is permitted to Set the ID-Based Ordering (IDO) attribute if use of the IDO attribute is enabled.

Note that, unlike INTx emulation Messages, MSI/MSI-X transactions are not restricted to the TC0 traffic class.

IMPLEMENTATION NOTE: SYNCHRONIZATION OF DATA TRAFFIC AND MESSAGE SIGNALLED INTERRUPTS §

MSI/MSI-X transactions are permitted to use the TC that is most appropriate for the device's programming model. This is generally the same TC as is used to transfer data; for legacy I/O, TC0 should be used.

If a device uses more than one TC, it must explicitly ensure that proper synchronization is maintained between data traffic and interrupt Message(s) not using the same TC. Methods for ensuring this synchronization are implementation specific. One option is for a device to issue a zero-length Read (as described in § Section 2.2.5) using each additional TC used for data traffic prior to issuing the MSI/MSI-X transaction. Other methods are also possible. Note, however, that platform software (e.g., a device driver) is generally only capable of issuing transactions using TC0.

Within a device, different Functions are permitted to implement different sets of the MSI/MSI-X/INTx interrupt mechanisms, and system software manages each Function's interrupt mechanisms independently.

6.1.4.1 MSI Configuration §

In this section, all register and field references are in the context of the MSI Capability structure.

System software reads the Message Control register to determine the Function's MSI capabilities.

System software reads the Multiple Message Capable field (bits 3-1 of the Message Control register) to determine the number of requested vectors. MSI supports a maximum of 32 vectors per Function. System software writes to the Multiple Message Enable field (bits 6-4 of the Message Control register) to allocate either all or a subset of the requested vectors. For example, a Function can request four vectors and be allocated either four, two, or one vector. The number of

102. Exception: Within an SR-IOV Device, any PFs or VFs that implement MSI must implement MSI PVM.

vectors requested and allocated is aligned to a power of two (that is, a Function that requires three vectors must request four).

If the Per-Vector Masking Capable bit (bit 8 of the Message Control register) is Set and system software supports Per-Vector Masking, system software may mask one or more vectors by writing to the Mask Bits register.

If the 64-bit Address Capable bit (bit 7 of the Message Control register) is Set, system software initializes the MSI Capability structure's Message Address register (specifying the lower 32 bits of the message address) and the Message Upper Address register (specifying the upper 32 bits of the message address) with a system-specified message address. System software may program the Message Upper Address register to zero so that the Function uses a 32-bit address for the MSI transaction. If this bit is Clear, system software initializes the MSI Capability structure's Message Address register (specifying a 32-bit message address) with a system specified message address.

System software initializes the MSI Capability structure's Message Data register with the lower 16 bits of a system specified data value. When the Extended Message Data Capable bit is Clear, care must be taken to initialize only the Message Data register (i.e., a 2-byte value) and not modify the upper two bytes of that DWORD location.

If the Extended Message Data Capable bit is Set and system software supports 32-bit vector values, system software may initialize the MSI capability structure's Extended Message Data register with the upper 16 bits of a system specified data value, and then Set the Extended Message Data Enable bit.

6.1.4.2 MSI-X Configuration §

In this section, all register and field references are in the context of the MSI-X Capability, MSI-X Table, and MSI-X PBA structures.

System software allocates address space for the Function's standard set of Base Address registers and sets the registers accordingly. One of the Function's Base Address registers includes address space for the MSI-X Table, though the system software that allocates address space does not need to be aware of which Base Address register this is, or the fact the address space is used for the MSI-X Table. The same or another Base Address register includes address space for the MSI-X PBA, and the same point regarding system software applies.

Depending upon system software policy, system software, device driver software, or each at different times or environments may configure a Function's MSI-X Capability and table structures with suitable vectors. For example, a booting environment will likely require only a single vector, whereas a normal operating system environment for running applications may benefit from multiple vectors if the Function supports an MSI-X Table with multiple entries. For the remainder of this section, "software" refers to either system software or device driver software.

Software reads the Table Size field from the Message Control register to determine the MSI-X Table size. The field encodes the number of table entries as N-1, so software must add 1 to the value read from the field to calculate the number of table entries N. MSI-X supports a maximum table size of 2048 entries.

Software calculates the base address of the MSI-X Table by reading the 32-bit value from the Table Offset/Table BIR register, masking off the lower 3 Table BIR bits, and adding the remaining QWORD-aligned 32-bit Table offset to the address taken from the Base Address register indicated by the Table BIR. Software calculates the base address of the MSI-X PBA using the same process with the PBA Offset/PBA BIR register.

For each MSI-X Table entry that will be used, software fills in the Message Address field, Message Upper Address field, Message Data field, and Vector Control field. The Vector Control field may contain optional Steering Tag fields. Software must not modify the Address, Data, or Steering Tag fields of an entry while it is unmasked. Refer to [Section 6.1.4.5](#) for details.

IMPLEMENTATION NOTE: SPECIAL CONSIDERATIONS FOR QWORD ACCESSES §

Software is permitted to fill in MSI-X Table entry DWORD fields individually with DWORD writes, or software in certain cases is permitted to fill in appropriate pairs of DWORDs with a single QWORD write. Specifically, software is always permitted to fill in the Message Address and Message Upper Address fields with a single QWORD write. If a given entry is currently masked (via its Mask bit or the Function Mask bit), software is permitted to fill in the Message Data and Vector Control fields with a single QWORD write, taking advantage of the fact the Message Data field is guaranteed to become visible to hardware no later than the Vector Control field. However, if software wishes to mask a currently unmasked entry (without Setting the Function Mask bit), software must Set the entry's Mask bit using a DWORD write to the Vector Control field, since performing a QWORD write to the Message Data and Vector Control fields might result in the Message Data field being modified before the Mask bit in the Vector Control field becomes Set.

For potential use by future specifications, the Reserved bits in the Vector Control field must have their default values preserved by software. If software does not preserve their values, the result is undefined.

For each MSI-X Table entry that software chooses not to configure for generating messages, software can simply leave the entry in its default state of being masked.

Software is permitted to configure multiple MSI-X Table entries with the same vector, and this may indeed be necessary when fewer vectors are allocated than requested.

IMPLEMENTATION NOTE: HANDLING MSI-X VECTOR SHORTAGES §

For the case where fewer vectors are allocated to a Function than desired, software-controlled aliasing as enabled by MSI-X is one approach for handling the situation. For example, if a Function supports five queues, each with an associated MSI-X table entry, but only three vectors are allocated, the Function could be designed for software still to configure all five table entries, assigning one or more vectors to multiple table entries. Software could assign the three vectors {A,B,C} to the five entries as ABCCC, ABBCC, ABCBA, or other similar combinations.

Alternatively, the Function could be designed for software to configure it (using a device specific mechanism) to use only three queues and three MSI-X table entries. Software could assign the three vectors {A,B,C} to the five entries as ABC-, A-B-C, A-CB, or other similar combinations.

6.1.4.3 Enabling Operation §

To maintain backward compatibility, the MSI Enable bit in the Message Control Register for MSI and the MSI-X Enable bit in the Message Control Register for MSI-X are each Clear by default (MSI and MSI-X are both disabled). System configuration software Sets one of these bits to enable either MSI or MSI-X, but never both simultaneously. Behavior is undefined if both MSI and MSI-X are enabled simultaneously. Software disabling either mechanism during active operation may result in the Function dropping pending interrupt conditions or failing to recognize new interrupt conditions. While enabled for MSI or MSI-X operation, a Function is prohibited from using INTx interrupts (if implemented) to request service (MSI, MSI-X, and INTx are mutually exclusive).

6.1.4.4 Sending Messages §

Once MSI or MSI-X is enabled (the appropriate bit in one of the Message Control registers is Set), and one or more vectors is unmasked, the Function is permitted to send messages. To send a message, a Function does a DWORD Memory Write to the appropriate message address with the appropriate message data.

For MSI when the Extended Message Data Enable bit is Clear, the DWORD that is written is made up of the value in the MSI Message Data register in the lower two bytes and zeros in the upper two bytes. For MSI when the Extended Message Data Enable bit is Set, the DWORD that is written is made up of the value in the MSI Message Data register in the lower two bytes and the value in the MSI Extended Message Data register in the upper two bytes.

For MSI, if the Multiple Message Enable field (bits 6-4 of the Message Control Register for MSI) is non-zero, the Function is permitted to modify the low order bits of the message data to generate multiple vectors. For example, a Multiple Message Enable encoding of 010b indicates the Function is permitted to modify message data bits 1 and 0 to generate up to four unique vectors. If the Multiple Message Enable field is 000b, the Function is not permitted to modify the message data.

For MSI-X, the MSI-X Table contains at least one entry for every allocated vector, and the 32-bit Message Data field value from a selected table entry is used in the message without any modification to the low-order bits by the Function.

How a Function uses multiple vectors (when allocated) is device dependent. A Function must handle being allocated fewer vectors than requested.

6.1.4.5 Per-vector Masking and Function Masking §

Per-Vector Masking (PVM) is an optional¹⁰³ feature with MSI, and a standard feature in MSI-X.

Function Masking is a standard feature in MSI-X. When the MSI-X Function Mask bit is Set, all of the Function's entries must behave as being masked, regardless of the per-entry Mask bit values. Function Masking is not supported in MSI, but software can readily achieve a similar effect by Setting all MSI Mask bits using a single DWORD write.

PVM in MSI-X is controlled by a Mask bit in each MSI-X Table entry. While more accurately termed “per-entry masking”, masking an MSI-X Table entry is still referred to as “vector masking” so similar descriptions can be used for both MSI and MSI-X. However, since software is permitted to program the same vector (a unique Address/Data pair) into multiple MSI-X table entries, all such entries must be masked in order to guarantee the Function will not send a message using that Address/Data pair.

For MSI and MSI-X, while a vector is masked, the Function is prohibited from sending the associated message, and the Function must Set the associated Pending bit whenever the Function would otherwise send the message. When software unmask a vector whose associated Pending bit is Set, the Function must schedule sending the associated message, and Clear the Pending bit as soon as the message has been sent. Note that Clearing the MSI-X Function Mask bit may result in many messages needing to be sent.

If a masked vector has its Pending bit Set, and the associated underlying interrupt events are somehow satisfied (usually by software though the exact manner is Function-specific), the Function must Clear the Pending bit, to avoid sending a spurious interrupt message later when software unmask the vector. However, if a subsequent interrupt event occurs while the vector is still masked, the Function must again Set the Pending bit.

Software is permitted to mask one or more vectors indefinitely, and service their associated interrupt events strictly based on polling their Pending bits. A Function must Set and Clear its Pending bits as necessary to support this “pure polling” mode of operation.

103. Exception: Within an SR-IOV Device, any PFs or VFs that implement MSI must implement MSI PVM.

For MSI-X, a Function is permitted to cache Address and Data values from unmasked MSI-X Table entries. However, anytime software unmasks a currently masked MSI-X Table entry either by Clearing its Mask bit or by Clearing the Function Mask bit, the Function must update any Address or Data values that it cached from that entry. If software changes the Address or Data value of an entry while the entry is unmasked, the result is undefined.

IMPLEMENTATION NOTE: PER VECTOR MASKING WITH MSI/MSI-X §

Devices and drivers that use MSI or MSI-X have the challenge of coordinating exactly when new interrupt messages are generated. If hardware fails to send an interrupt message that software expects, an interrupt event might be “lost”. If hardware sends an interrupt message that software is not expecting, a “spurious” interrupt might result.

Per-Vector Masking (PVM) can be used to assist in this coordination. For example, when a software interrupt service routine begins, it can mask the vector to help avoid “spurious” interrupts. After the interrupt service routine services all the interrupt conditions that it is aware of, it can unmask the vector. If any interrupt conditions remain, hardware is required to generate a new interrupt message, guaranteeing that no interrupt events are lost.

PVM is a standard feature with MSI-X and an optional ¹⁰⁴ feature for MSI. For devices that implement MSI, implementing PVM as well is strongly recommended.

6.1.4.6 Hardware/Software Synchronization §

If a Function sends messages with the same vector multiple times before being acknowledged by software, only one message is guaranteed to be serviced. If all messages must be serviced, a device driver handshake is required. In other words, once a Function sends Vector A, it cannot send Vector A again until it is explicitly enabled to do so by its device driver (provided all messages must be serviced). If some messages can be lost, a device driver handshake is not required. For Functions that support multiple vectors, a Function can send multiple unique vectors and is guaranteed that each unique message will be serviced. For example, a Function can send Vector A followed by Vector B without any device driver handshake (both Vector A and Vector B will be serviced).

104. Exception: Within an SR-IOV Device, any PFs or VFs that implement MSI must implement MSI PVM

IMPLEMENTATION NOTE:

SERVICING MSI AND MSI-X INTERRUPTS §

When system software allocates fewer MSI or MSI-X vectors to a Function than it requests, multiple interrupt sources within the Function, each desiring a unique vector, may be required to share a single vector. Without proper handshakes between hardware and software, hardware may send fewer messages than software expects, or hardware may send what software considers to be extraneous messages.

A rather sophisticated but resource-intensive approach is to associate a dedicated event queue with each allocated vector, with producer and consumer pointers for managing each event queue. Such event queues typically reside in host memory. The Function acts as the producer and software acts as the consumer. Multiple interrupt sources within a Function may be assigned to each event queue as necessary. Each time an interrupt source needs to signal an interrupt, the Function places an entry on the appropriate event queue (assuming there's room), updates a copy of the producer pointer (typically in host memory), and sends an interrupt message with the associated vector when necessary to notify software that the event queue needs servicing. The interrupt service routine for a given event queue processes all entries it finds on its event queue, as indicated by the producer pointer. Each event queue entry identifies the interrupt source and possibly additional information about the nature of the event. The use of event queues and producer/consumer pointers can be used to guarantee that interrupt events won't get dropped when multiple interrupt sources are forced to share a vector. There's no need for additional handshaking between sending multiple messages associated with the same event queue, to guarantee that every message gets serviced. In fact, various standard techniques for "interrupt coalescing" can be used to avoid sending a separate message for every event that occurs, particularly during heavy bursts of events.

In more modest implementations, the hardware design of a Function's MSI or MSI-X logic sends a message any time a transition to assertion would have occurred on the virtual INTx wire if MSI or MSI-X had not been enabled. For example, consider a scenario in which two interrupt events (possibly from distinct interrupt sources within a Function) occur in rapid succession. The first event causes a message to be sent. Before the interrupt service routine has had an opportunity to service the first event, the second event occurs. In this case, only one message is sent, because the first event is still active at the time the second event occurs (a virtual INTx wire signal would have had only one transition to assertion).

One handshake approach for implementations like the above is to use standard Per-Vector Masking, and allow multiple interrupt sources to be associated with each vector. A given vector's interrupt service routine Sets the vector's Mask bit before it services any associated interrupting events and Clears the Mask bit after it has serviced all the events it knows about. (This could be any number of events.) Any occurrence of a new event while the Mask bit is Set results in the Pending bit being Set. If one or more associated events are still pending at the time the vector's Mask bit is Cleared, the Function immediately sends another message.

A handshake approach for MSI Functions that do not implement Per-Vector Masking is for a vector's interrupt service routine to re-inspect all of the associated interrupt events after Clearing what is presumed to be the last pending interrupt event. If another event is found to be active, it is serviced in the same interrupt service routine invocation, and the complete re-inspection is repeated until no pending events are found. This ensures that if an additional interrupting event occurs before a previous interrupt event is Cleared, whereby the Function does not send an additional interrupt message, that the new event is serviced as part of the current interrupt service routine invocation.

This alternative has the potential side effect of one vector's interrupt service routine processing an interrupting event that has already generated a new interrupt message. The interrupt service routine invocation resulting from the new message may find no pending interrupt events. Such occurrences are sometimes referred to as spurious interrupts, and software using this approach must be prepared to tolerate them.

An MSI or MSI-X message, by virtue of being a Posted Request, is prohibited by transaction ordering rules from passing Posted Requests sent earlier by the Function. The system must guarantee that an interrupt service routine invoked as a result of a given message will observe any updates performed by Posted Requests arriving prior to that message. Thus, the interrupt service routine of a device driver is not required to read from a device register in order to ensure data consistency with previous Posted Requests. However, if multiple MSI-X Table entries share the same vector, the interrupt service routine may need to read from some device specific register to determine which interrupt sources need servicing.

6.1.4.7 Message Transaction Reception and Ordering Requirements §

As with all Memory Write transactions, the device that includes the target of the interrupt message (the interrupt receiver) is required to complete all interrupt message transactions as a Completer without requiring other transactions to complete first as a Requester. In general, this means that the message receiver must complete the interrupt message transaction independent of when the CPU services the interrupt. For example, each time the interrupt receiver receives an interrupt message, it could Set a bit in an internal register indicating that this message had been received and then complete the transaction on the bus. The appropriate interrupt service routine would later be dispatched because this bit was Set. The message receiver would not be allowed to delay the completion of the interrupt message on the bus pending acknowledgement from the processor that the interrupt was being serviced. Such dependencies can lead to deadlock when multiple devices send interrupt messages simultaneously.

Although interrupt messages remain strictly ordered throughout the PCI Express Hierarchy, the order of receipt of the interrupt messages does not guarantee any order in which the interrupts will be serviced. Since the message receiver must complete all interrupt message transactions without regard to when the interrupt was actually serviced, the message receiver will generally not maintain any information about the order in which the interrupts were received. This is true both of interrupt messages received from different devices and multiple messages received from the same device. If a device requires one interrupt message to be serviced before another, the device must not send the second interrupt message until the first one has been serviced.

6.1.5 PME Support §

PCI Express supports power management events from native PCI Express devices as well as PME-capable PCI devices.

PME signaling is accomplished using an in-band Transaction Layer PME Message (PM_PME) as described in § Chapter 5.

6.1.6 Native PME Software Model §

PCI Express-aware software can enable a mode where the Root Complex signals PME via an interrupt. When configured for native PME support, a Root Port receives the PME Message and sets the PME Status bit in its Root Status Register. If software has set the PME Interrupt Enable bit in the Root Control Register to 1b, the Root Port then generates an interrupt.

If the Root Port is enabled for level-triggered interrupt signaling using the INTx messages, the virtual INTx wire must be asserted whenever and as long as all of the following conditions are satisfied:

- The Interrupt Disable bit in the Command register is set to 0b.
- The PME Interrupt Enable bit in the Root Control Register is set to 1b.
- The PME Status bit in the Root Status register is set.

Note that all other interrupt sources within the same Function will assert the same virtual INTx wire when requesting service.

If the Root Port is enabled for edge-triggered interrupt signaling using MSI or MSI-X, an interrupt message must be sent every time the logical AND of the following conditions transitions from FALSE to TRUE:

- The associated vector is unmasked (not applicable if MSI does not support PVM).
- The PME Interrupt Enable bit in the Root Control Register is set to 1b.
- The PME Status bit in the Root Status Register is set.

Note that PME and Hot-Plug Event interrupts (when both are implemented) always share the same MSI or MSI-X vector, as indicated by the Interrupt Message Number field in the PCI Express Capabilities Register.

The software handler for this interrupt can determine which device sent the PME Message by reading the PME Requester ID field in the Root Status Register in a Root Port. It dismisses the interrupt by writing a 1b to the PME Status bit in the Root Status Register. Refer to § Section 7.5.3.14 for more details.

Root Complex Event Collectors provide support for the above described functionality for Root Complex Integrated Endpoints (RCIEPs).

6.1.7 Legacy PME Software Model §

Legacy software, however, will not understand this mechanism for signaling PME. In the presence of legacy system software, the system power management logic in the Root Complex receives the PME Message and informs system software through an implementation specific mechanism. The Root Complex may utilize the Requester ID in the PM_PME to inform system software which device caused the power management event.

Since it is delivered by a Message, PME has edge-triggered semantics in PCI Express, which differs from the level-triggered PME mechanism used for conventional PCI. It is the responsibility of the Root Complex to abstract this difference from system software to maintain compatibility with conventional PCI systems.

6.1.8 Operating System Power Management Notification §

In order to maintain compatibility with non-PCI Express-aware system software, system power management logic must be configured by firmware to use the legacy mechanism of signaling PME by default. PCI Express-aware system software must notify the firmware prior to enabling native, interrupt-based PME signaling. In response to this notification, system firmware must, if needed, reconfigure the Root Complex to disable legacy mechanisms of signaling PME. The details of this firmware notification are beyond the scope of this specification, but since it will be executed at system run-time, the response to this notification must not interfere with system software. Therefore, following control handoff to the operating system, firmware must not write to available system memory or any PCI Express resources (e.g., Configuration Space structures) owned by the operating system.

6.1.9 PME Routing Between PCI Express and PCI Hierarchies §

PME-capable conventional PCI and PCI-X devices assert the PME# pin to signal a power management event. The PME# signal from PCI or PCI-X devices may either be converted to a PCI Express in-band PME Message by a PCI Express-PCI Bridge or routed directly to the Root Complex.

If the PME# signal from a PCI or PCI-X device is routed directly to the Root Complex, it signals system software using the same mechanism used in present PCI systems. A Root Complex may optionally provide support for signaling PME from PCI or PCI-X devices to system software via an interrupt. In this scenario, it is recommended for the Root Complex to detect the Bus, Device and Function Number of the PCI or PCI-X device that asserted PME#, and use this information to

fill in the PME Requester ID field in the Root Port that originated the hierarchy containing the PCI or PCI-X device. If this is not possible, the Root Complex may optionally write the Requester ID of the Root Port to this field.

Since RCiEPs are not contained in any of the hierarchy domains originated by Root Ports, RCiEPs not associated with a Root Complex Event Collector signal system software of a PME using the same mechanism used in present PCI systems. A Root Complex Event Collector, if implemented, enables the PCI Express Native PME model for associated RCiEPs.

6.2 Error Signaling and Logging §

In this document, errors which must be checked and errors which may optionally be checked are identified. Each such error is associated either with the Port or with a specific device (or Function in a Multi-Function Device), and this association is given along with the description of the error. This section will discuss how errors are classified and reported.

6.2.1 Scope §

This section explains the error signaling and logging requirements for PCI Express components. This includes errors which occur on the PCI Express interface itself, those errors which occur on behalf of transactions initiated on PCI Express, and errors which occur within a component and are related to the PCI Express interface. This section does not focus on errors which occur within the component that are unrelated to a PCI Express interface. This type of error signaling is better handled through proprietary methods employing device-specific interrupts.

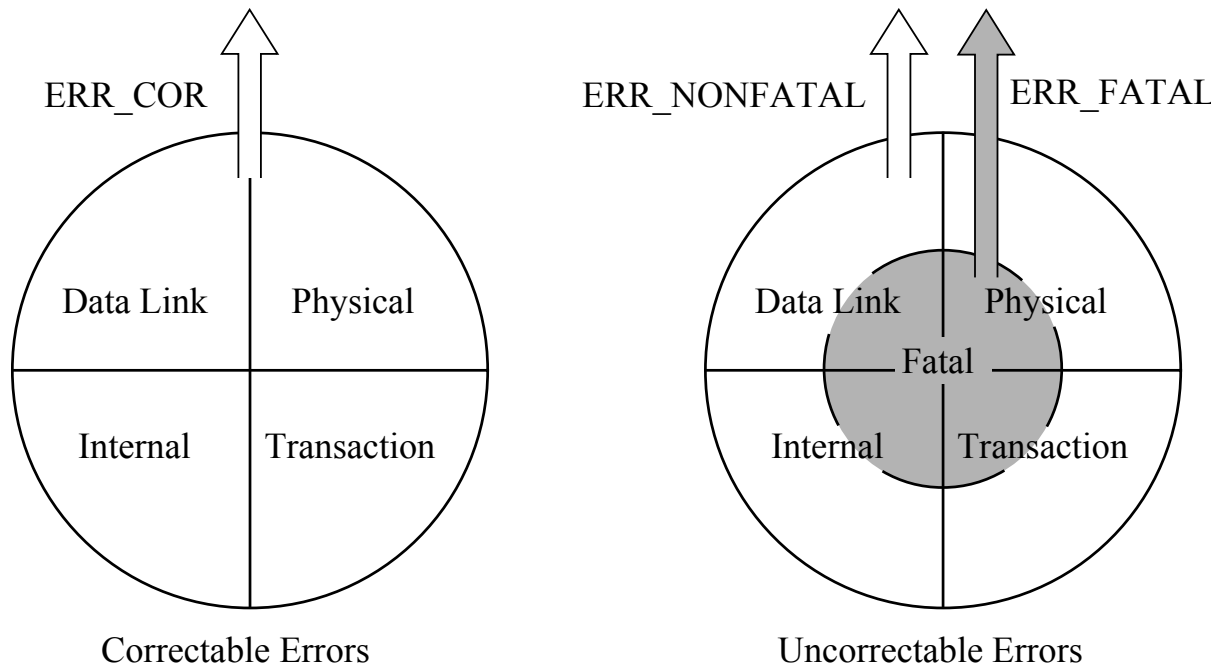

PCI Express defines two error reporting paradigms: baseline capability and Advanced Error Reporting (AER) capability. Baseline capability is required for all PCI Express devices, and it defines the minimum error reporting requirements. AER capability defines more robust error reporting and is implemented with a specific PCI Express Capability structure (refer to § Section 7.8.4 for a definition of this optional capability). This section explicitly calls out all error handling differences between baseline and AER capability.

All SR-IOV devices must support baseline Capability, with certain modifications to account for the goal of reduced cost and complexity of implementation. AER capability is optional, but if AER is not implemented in a PF, it must not be implemented in its associated VFs. If AER is implemented in the PF, it is optional in its VFs.

All PCI Express devices support existing, non-PCI Express-aware, software for error handling by mapping PCI Express errors to existing PCI reporting mechanisms, in addition to the PCI Express-specific mechanisms.

6.2.2 Error Classification §

PCI Express errors can be classified as two types: Uncorrectable errors and Correctable errors. This classification separates those errors resulting in functional failure from those errors resulting in degraded performance. Uncorrectable errors can further be classified as Fatal or Non-Fatal (see § Figure 6-1).

OM13827A

Figure 6-1 Error Classification §

Classification of error severity as Fatal, Uncorrectable, and Correctable provides the platform with mechanisms for mapping the error to a suitable handling mechanism. For example, the platform might choose to respond to correctable errors with low priority, performance monitoring software. Such software could count the frequency of correctable errors and provide Link integrity information. On the other hand, a platform designer might choose to map Fatal errors to a system-wide reset. It is the decision of the platform designer to map these PCI Express severity levels onto platform level severities.

6.2.2.1 Correctable Errors §

Correctable errors include those error conditions where hardware can recover without any loss of information. Hardware corrects these errors and software intervention is not required. For example, an LCRC error in a TLP that might be corrected by Data Link Level Retry is considered a correctable error. Measuring the frequency of Link-level correctable errors may be helpful for profiling the integrity of a Link.

Correctable errors also include transaction-level cases where one agent detects an error with a TLP, but another agent is responsible for taking any recovery action if needed, such as re-attempting the operation with a separate subsequent transaction. The detecting agent can be configured to report the error as being correctable since the recovery agent may be able to correct it. If recovery action is indeed needed, the recovery agent must report the error as uncorrectable if the recovery agent decides not to attempt recovery.

The triggering of Downstream Port Containment (DPC) is not handled as an error, but it can be signaled as if it were a correctable error, since software that takes advantage of DPC can sometimes recover from the uncorrectable error that triggered DPC. See § Section 6.2.11 . An `ERR_COR` Message that's used for DPC signaling is intended to target system firmware, and may indicate so via the `ERR_COR` Subclass field.

Similarly, `ERR_COR` may be used by the System Firmware Intermediary (SFI) capability to signal system firmware, and must indicate so via the `ERR_COR` Subclass field. See § Section 6.7.4 .

6.2.2.2 Uncorrectable Errors §

Uncorrectable errors are those error conditions that impact functionality of the interface. There is no mechanism defined in this specification to correct these errors. Reporting an uncorrectable error is analogous to asserting SERR# in PCI/PCI-X. For more robust error handling by the system, this specification further classifies uncorrectable errors as Fatal and Non-fatal.

6.2.2.2.1 Fatal Errors §

Fatal errors are uncorrectable error conditions which render the particular Link and related hardware unreliable. For Fatal errors, a reset of the components on the Link may be required to return to reliable operation. Platform handling of Fatal errors, and any efforts to limit the effects of these errors, is platform implementation specific.

6.2.2.2.2 Non-Fatal Errors §

Non-fatal errors are uncorrectable errors which cause a particular transaction to be unreliable but the Link is otherwise fully functional. Isolating Non-fatal from Fatal errors provides Requester/Receiver logic in a device or system management software the opportunity to recover from the error without resetting the components on the Link and disturbing other transactions in progress. Devices not associated with the transaction in error are not impacted by the error.

6.2.3 Error Signaling §

There are three complementary mechanisms which allow the agent detecting an error to alert the system or another device that an error has occurred. The first mechanism is through a Completion Status, the second method is with in-band error Messages, and the third is with Error Forwarding (also known as data poisoning).

Note that it is the responsibility of the agent detecting the error to signal the error appropriately.

§ Section 6.2.7 describes all the errors and how the hardware is required to respond when the error is detected.

6.2.3.1 Completion Status §

The Completion Status field (when status is not Successful Completion) in the Completion header indicates that the associated Request failed (see § Section 2.2.8.10). This is one method of error reporting which enables the Requester to associate an error with a specific Request. In other words, since Non-Posted Requests are not considered complete until after the Completion returns, the Completion Status field gives the Requester an opportunity to “fix” the problem at some higher level protocol (outside the scope of this specification). For example, if a Read is issued to prefetchable Memory Space and the Completion returns with an Unsupported Request Completion Status, the Requester would not be in violation of this specification if it chose to reissue the Read Request. Note that from a PCI Express point of view, the reissued Read Request is a distinct Request, and there is no relationship (on PCI Express) between the initial Request and the reissued Request.

6.2.3.2 Error Messages §

Error Messages are sent to the Root Complex for reporting the detection of errors according to the severity of the error.

Error messages that originate from PCI Express or Legacy Endpoints are sent to corresponding Root Ports. Errors that originate from a Root Port itself are reported through the same Root Port.

If an optional Root Complex Event Collector is implemented, errors that originate from RCiEPs are sent to the corresponding Root Complex Event Collector. Errors that originate in a Root Complex Event Collector itself are reported through the same Root Complex Event Collector. The Root Complex Event Collector must declare supported RCiEPs as part of its capabilities; each RCiEP must be associated with no more than one Root Complex Event Collector.

When multiple errors of the same severity are detected, the corresponding error Messages with the same Requester ID may be merged for different errors of the same severity. At least one error Message must be sent for detected errors of each severity level. Note, however, that the detection of a given error in some cases will preclude the reporting of certain errors. Refer to § Section 6.2.3.2.3 . Also note special rules in § Section 6.2.4 regarding non-Function-specific errors in Multi-Function Devices.

Table 6-1 Error Messages §

Error Message	Description
<u>ERR_COR</u>	This Message is issued when the Function or Device detects a correctable error on the PCI Express interface. Refer to § Section 6.2.2.1 for the definition of a correctable error.
<u>ERR_NONFATAL</u>	This Message is issued when the Function or Device detects a Non-fatal, uncorrectable error on the PCI Express interface. Refer to § Section 6.2.2.2 for the definition of a Non-fatal, uncorrectable error.
<u>ERR_FATAL</u>	This Message is issued when the Function or Device detects a Fatal, uncorrectable error on the PCI Express interface. Refer to § Section 6.2.2.2.1 for the definition of a Fatal, uncorrectable error.

For these Messages, the Root Complex identifies the initiator of the Message by the Requester ID of the Message header. The Root Complex translates these error Messages into platform level events.

IMPLEMENTATION NOTE:

USE OF ERR_COR, ERR_NONFATAL, AND ERR_FATAL §

In [PCIe-1.0a], a given error was either correctable, non-fatal, or fatal. Assuming signaling was enabled, correctable errors were always signaled with ERR_COR, non-fatal errors were always signaled with ERR_NONFATAL, and fatal errors were always signaled with ERR_FATAL.

In subsequent specifications that support Role-Based Error Reporting, non-fatal errors are sometimes signaled with ERR_NONFATAL, sometimes signaled with ERR_COR, and sometimes not signaled at all, depending upon the role of the agent that detects the error and whether the agent implements AER (see § Section 6.2.3.2.4). On some platforms, sending ERR_NONFATAL will preclude another agent from attempting recovery or determining the ultimate disposition of the error. For cases where the detecting agent is not the appropriate agent to determine the ultimate disposition of the error, a detecting agent with AER can signal the non-fatal error with ERR_COR, which serves as an advisory notification to software. For cases where the detecting agent is the appropriate one, the agent signals the non-fatal error with ERR_NONFATAL.

For a given uncorrectable error that's normally non-fatal, if software wishes to avoid continued hierarchy operation upon the detection of that error, software can configure detecting agents that implement AER to escalate the severity of that error to fatal. A detecting agent (if enabled) will always signal a fatal error with ERR_FATAL, regardless of the agent's role.

Software should recognize that a single transaction can be signaled by multiple agents using different types of error Messages. For example, a poisoned TLP might be signaled by intermediate Receivers with ERR_COR, while the ultimate destination Receiver might signal it with ERR_NONFATAL.

6.2.3.2.1 Uncorrectable Error Severity Programming (Advanced Error Reporting) §

For device Functions implementing the Advanced Error Reporting Extended Capability, the Uncorrectable Error Severity register allows each uncorrectable error to be programmed to Fatal or Non-Fatal. Uncorrectable errors are not recoverable using defined PCI Express mechanisms. However, some platforms or devices might consider a particular error fatal to a Link or device while another platform considers that error non-fatal. The default value of the Uncorrectable Error Severity register serves as a starting point for this specification but the register can be reprogrammed if the device driver or platform software requires more robust error handling.

Baseline error handling does not support severity programming.

6.2.3.2.2 Masking Individual Errors §

§ Section 6.2.7 lists all the errors governed by this specification and describes when each of the above error Messages are issued. The transmission of these error Messages by class (correctable, non-fatal, fatal) is enabled using the Reporting Enable bits of the Device Control register (see § Section 7.5.3.4) or the SERR# Enable bit in the PCI Command register (see § Section 7.5.1.1.3).

For devices implementing the Advanced Error Reporting Extended Capability the Uncorrectable Error Mask register and Correctable Error Mask register allows each error condition to be masked independently. If Messages for a particular class of error are not enabled by the combined settings in the Device Control register and the PCI Command register, then no Messages of that class will be sent regardless of the values for the corresponding mask register.

If an individual error is masked when it is detected, its error status bit is still affected, but no error reporting Message is sent to the Root Complex, and the error is not recorded in the Header Log, TLP Prefix Log, or First Error Pointer.

6.2.3.2.3 Error Pollution §

Error pollution can occur if error conditions for a given transaction are not isolated to the most significant occurrence. For example, assume the Physical Layer detects a Receiver Error. This error is detected at the Physical Layer and an error is reported to the Root Complex. To avoid having this error propagate and cause subsequent errors at upper layers (for example, a TLP error at the Data Link Layer), making it more difficult to determine the root cause of the error, subsequent errors which occur for the same packet will not be reported by the Data Link or Transaction layers. Similarly, when the Data Link Layer detects an error, subsequent errors which occur for the same packet will not be reported by the Transaction Layer. This behavior applies only to errors that are associated with a particular packet - other errors are reported for each occurrence.

Corrected Internal Errors are errors whose effect has been masked or worked around by a component; refer to § Section 6.2.10 for details. Therefore, Corrected Internal Errors do not contribute to error pollution and should be reported when detected.

For errors detected in the Transaction layer and Uncorrectable Internal Errors, it is permitted and recommended that no more than one error be reported for a single received TLP, and that the following precedence (from highest to lowest) be used:

- Uncorrectable Internal Error
- Receiver Overflow
- Malformed TLP
- IDE Check Failed

- ECRC Check Failed
- Misrouted IDE TLP
- AtomicOp, DMWr, or TLP Translation Egress Blocked
- TLP Prefix Blocked
- ACS Violation
- MC Blocked TLP
- Unsupported Request (UR), Completer Abort (CA), or Unexpected Completion
- PCRC Check Failed
- Poisoned TLP Received or Poisoned TLP Egress Blocked

The Completion Timeout error is not in the above precedence list, since it is not detected by processing a received TLP. Errors listed under the same bullet are mutually exclusive, so their relative order does not matter.

6.2.3.2.4 Advisory Non-Fatal Error Cases §

In some cases the detector of a non-fatal error is not the most appropriate agent to determine whether the error is recoverable or not, or if it even needs any recovery action at all. For example, if software attempts to perform a configuration read from a non-existent device or Function, the resulting UR Status in the Completion will signal the error to software, and software does not need for the Completer in addition to signal the error by sending an ERR_NONFATAL Message. In fact, on some platforms, signaling the error with ERR_NONFATAL results in a System Error, which breaks normal software probing.

“Advisory Non-Fatal Error” cases are predominantly determined by the role of the detecting agent (Requester, Completer, or Receiver) and the specific error. In such cases, an agent with AER signals the non-fatal error (if enabled) by sending an ERR_COR Message as an advisory to software, instead of sending ERR_NONFATAL. An agent without AER sends no error Message for these cases, since software receiving ERR_COR would be unable to distinguish Advisory Non-Fatal Error cases from the correctable error cases used to assess Link integrity.

Following are the specific cases of Advisory Non-Fatal Errors. Note that multiple errors from the same or different error classes (correctable, non-fatal, fatal) may be present with a single TLP. For example, an unexpected Completion might also be poisoned. Refer to § Section 6.2.3.2.3 for requirements and recommendations on reporting multiple errors. For the previous example, it is recommended that Unexpected Completion be reported, and that Poisoned TLP Received not be reported.

If software wishes for an agent with AER to handle what would normally be an Advisory Non-Fatal Error case as being more serious, software can escalate the severity of the uncorrectable error to fatal, in which case the agent (if enabled) will signal the error with ERR_FATAL.

This section covers Advisory Non-Fatal Error handling for errors managed by the PCI Express Extended Capability and AER. § Section 6.2.11.3 covers the RP PIO error handling mechanism for Root Ports that support RP Extensions for DPC. RP PIO advisory errors are similar in concept to AER Advisory Non-Fatal Errors, but apply to different error cases and are managed by different controls.

6.2.3.2.4.1 Completer Sending a Completion with UR/CA Status §

A Completer generally sends a Completion with an Unsupported Request or Completer Abort (UR/CA) Status to signal an uncorrectable error for a Non-Posted Request.¹⁰⁵ If the severity of the UR/CA error¹⁰⁶ is non-fatal, the Completer must handle this case as an Advisory Non-Fatal Error.¹⁰⁷ A Completer with AER signals the non-fatal error (if enabled) by sending an ERR_COR Message. A Completer without AER sends no error Message for this case.

Even though there was an uncorrectable error for this specific transaction, the Completer must handle this case as an Advisory Non-Fatal Error, since the Requester upon receiving the Completion with UR/CA Status is responsible for reporting the error (if necessary) using a Requester-specific mechanism (see § Section 6.2.3.2.5).

6.2.3.2.4.2 Intermediate Receiver §

When a Receiver that's not serving as the ultimate PCI Express destination for a TLP detects¹⁰⁸ a non-fatal error with the TLP, this "intermediate" Receiver must handle this case as an Advisory Non-Fatal Error.¹⁰⁹ A Receiver with AER signals the error (if enabled) by sending an ERR_COR Message. A Receiver without AER sends no error Message for this case. An exception to the intermediate Receiver case for Root Complexes (RCs) is noted below.

An example where the intermediate Receiver case occurs is a Switch that detects poison or bad ECRC in a TLP that it is routing. Even though this was an uncorrectable (but non-fatal) error at this point in the TLP's route, the intermediate Receiver handles it as an Advisory Non-Fatal Error, so that the ultimate Receiver of the TLP (i.e., the Completer for a Request TLP, or the Requester for a Completion TLP) is not precluded from handling the error more appropriately according to its error settings. For example, a given Completer that detects poison in a Memory Write Request¹¹⁰ might have the error masked (and thus go unsignaled), whereas a different Completer in the same hierarchy might signal that error with ERR_NONFATAL.

A Poisoned TLP Egress Blocked error is never handled as an intermediate Receiver case since it is not detected as a part of processing a received TLP.

If an RC detects a non-fatal error with a TLP it normally would forward peer-to-peer between Root Ports, but the RC does not support propagating the error related information (e.g., a TLP Digest, EP bit, or equivalent) with the forwarded transaction, the RC must signal the error (if enabled) with ERR_NONFATAL and also must not forward the transaction. An example is an RC needing to forward a poisoned TLP peer-to-peer between Root Ports, but the RC's internal fabric does not support poison indication.

6.2.3.2.4.3 Ultimate PCI Express Receiver of a Poisoned TLP or IDE TLP with PCRC Check Failed §

When a poisoned TLP is received by its ultimate PCI Express destination, if the severity is non-fatal and the Receiver legitimately chooses not to handle this case as an uncorrectable error (see below), the Receiver must handle this case as an Advisory Non-Fatal Error.¹¹¹ When a IDE TLP is determined at its ultimate destination Port to have a PCRC Check Failed error, if the severity is non-fatal and the Receiver deals with the poisoned data in a manner that permits continued operation, the Receiver must handle this case as an Advisory Non-Fatal Error. A Receiver with AER signals the error (if enabled) by sending an ERR_COR Message. A Receiver without AER sends no error Message for this case.

A Receiver must not handle this case as an Advisory Non-Fatal Error if either of the following apply:

- Handling the error as a Correctable Error and continuing operation when configured correctly could lead to silent data corruption.
- Rules in § Section 2.7.2.1 require this case to be handled as an uncorrectable error.

105. If the Completer is returning data in a Completion, and the data is bad or suspect, the Completer is permitted to signal the error using the Error Forwarding (Data Poisoning) mechanism instead of handling it as a UR or CA.

106. Certain other errors (e.g., ACS Violation) with a Non-Posted Request also result in the Completer sending a Completion with UR or CA Status. If the severity of the error (e.g., ACS Violation) is non-fatal, the Completer must also handle this case as an Advisory Non-Fatal Error. However, see § Section 2.7.2.1 regarding certain Requests with Poisoned data that must be handled as uncorrectable errors.

107. If the severity is fatal, the error is not an Advisory Non-Fatal Error, and must be signaled (if enabled) with ERR_FATAL.

108. If the Receiver does not implement ECRC Checking or ECRC Checking is not enabled, the Receiver will not detect an ECRC Error.

109. If the severity is fatal, the error is not an Advisory Non-Fatal Error, and must be signaled (if enabled) with ERR_FATAL.

110. See § Section 2.7.2.1 for special rules that apply for poisoned Memory Write Requests.

111. If the severity is fatal, the error is not an Advisory Non-Fatal Error, and must be signaled (if enabled) with ERR_FATAL.

An example is a Root Complex that receives a poisoned Memory Write TLP that targets host memory. If the Root Complex propagates the poisoned data along with its indication to host memory, it signals the error (if enabled) with an `ERR_COR`. If the Root Complex does not propagate the poison to host memory, it signals the error (if enabled) with `ERR_NONFATAL`.

Another example is a Requester that receives a poisoned Memory Read Completion TLP. If the Requester propagates the poisoned data internally or handles the error like it would for a Completion with UR/CA Status, it signals the error (if enabled) with an `ERR_COR`. If the Requester does not handle the poison in a manner that permits continued operation, it signals the error (if enabled) with `ERR_NONFATAL`.

6.2.3.2.4.4 Requester with Completion Timeout §

This section applies to Requesters other than Root Ports performing programmed I/O (PIO). See § Section 6.2.11.3 for related RP PIO functionality in Root Ports that support RP Extensions for DPC.

When the Requester of a Non-Posted Request times out while waiting for the associated Completion, the Requester is permitted to attempt to recover from the error by issuing a separate subsequent Request. The Requester is permitted to attempt recovery zero, one, or multiple (finite) times, but must signal the error (if enabled) with an uncorrectable error Message if no further recovery attempt will be made.

If the severity of the Completion Timeout is non-fatal, and the Requester elects to attempt recovery by issuing a new request, the Requester must first handle the current error case as an Advisory Non-Fatal Error.¹¹² A Requester with AER signals the error (if enabled) by sending an `ERR_COR` Message. A Requester without AER sends no error Message for this case.

Note that automatic recovery by the Requester from a Completion Timeout is generally possible only if the Non-Posted Request has no side-effects, but may also depend upon other considerations outside the scope of this specification.

6.2.3.2.4.5 Receiver of an Unexpected Completion §

When a Receiver receives an unexpected Completion and the severity of the Unexpected Completion error is non-fatal, the Receiver must handle this case as an Advisory Non-Fatal Error.¹¹³ A Receiver with AER signals the error (if enabled) by sending an `ERR_COR` Message. A Receiver without AER sends no error Message for this case.

If the unexpected Completion was a result of misrouting, the Completion Timeout mechanism at the associated Requester will trigger eventually, and the Requester may elect to attempt recovery. Interference with Requester recovery can be avoided by having the Receiver of the unexpected Completion handle the error as an Advisory Non-Fatal Error.

6.2.3.2.5 Requester Receiving a Completion with UR/CA Status §

When a Requester receives back a Completion with a UR/CA Status, generally the Completer has handled the error as an Advisory Non-Fatal Error, assuming the error severity was non-fatal at the Completer (see § Section 6.2.3.2.4.1). The Requester must determine if any error recovery action is necessary, what type of recovery action to take, and whether or not to report the error.

If the Requester needs to report the error, the Requester must do so solely through a Requester-specific mechanism. For example, many devices have an associated device driver that can report errors to software. As another important

112. If the severity is fatal, the error is not an Advisory Non-Fatal Error, and must be signaled (if enabled) with `ERR_FATAL`. The Requester is strongly discouraged from attempting recovery since sending `ERR_FATAL` will often result in the entire hierarchy going down.

113. If the severity is fatal, the error is not an Advisory Non-Fatal Error, and must be signaled (if enabled) with `ERR_FATAL`.

example, the Root Complex on some platforms returns all 1's to software if a Configuration Read Completion has a UR/CA Status.

§ Section 6.2.11.3 covers RP PIO controls for Root Ports that support RP Extensions for DPC. Outside of the RP PIO mechanisms, Requesters are not permitted to report the error using PCI Express logging and error Message signaling.

6.2.3.3 Error Forwarding (Data Poisoning) §

Error Forwarding, also known as data poisoning, is indicated by setting the EP bit in a TLP. Refer to § Section 2.7.2. This is another method of error reporting in PCI Express that enables the Receiver of a TLP to associate an error with a specific Request or Completion. Unlike the Completion Status mechanism, Error Forwarding can be used with either Requests or Completions that contain data. In addition, “intermediate” Receivers along the TLP’s route, not just the Receiver at the ultimate destination, are required to detect and report (if enabled) receiving the poisoned TLP. This can help software determine if a particular Switch along the path poisoned the TLP.

6.2.3.4 Optional Error Checking §

This specification contains a number of optional error checks. Unless otherwise specified, behavior is undefined if an optional error check is not performed and the error occurs.

When an optional error check involves multiple rules, unless otherwise specified, each rule is independently optional. An implementation may check against all of the rules, none of them or any combination.

Unless otherwise specified, implementation specific criteria are used in determining whether an optional error check is performed.

6.2.4 Error Logging §

§ Section 6.2.7 lists all the errors governed by this specification and for each error, the logging requirements are specified. Device Functions that do not support the Advanced Error Reporting Extended Capability log only the Device Status register bits indicating that an error has been detected. Note that some errors are also reported using the reporting mechanisms in the PCI-compatible (Type 00h and 01h) configuration registers. § Section 7.5.1 describes how these register bits are affected by the different types of error conditions described in this section.

For device Functions supporting the Advanced Error Reporting Extended Capability, each of the errors in § Table 6-3, § Table 6-4, and § Table 6-5 corresponds to a particular bit in the Uncorrectable Error Status register or Correctable Error Status register. These registers are used by software to determine more precisely which error and what severity occurred. For specific Transaction Layer errors and Uncorrectable Internal Errors, the associated TLP header is recorded.

In a Multi-Function Device other than an SR-IOV device, PCI Express errors not specific to any single Function within the device must be logged in the corresponding status and logging registers of all Functions in that device.

In an SR-IOV device, errors identified as non-Function-specific must be logged in all PFs, and not in their associated VFs. Such errors must also be logged in any non-IOV Functions.

The following PCI Express errors are not Function-specific:

- All Physical Layer errors
- All Data Link Layer errors
- These Transaction Layer errors:
 - ECRC Check Failed

- Unsupported Request, when caused by no Function claiming a TLP
- Receiver Overflow
- Flow Control Protocol Error
- Malformed TLP
- Unexpected Completion, when caused by no Function claiming a Completion
- Unexpected Completion, when caused by a Completion that cannot be forwarded by a Switch, and the Ingress Port is a Switch Upstream Port associated with a Multi-Function Device
- Some Transaction Layer errors (e.g., Poisoned TLP Received) may be Function-specific or not, depending upon whether the associated TLP targets a single Function or all Functions in that device.
- Some Internal Errors
 - The determination of whether an Internal Error is Function-specific or not is implementation specific.

On the detection of one of these errors, a Multi-Function Device should generate at most one error reporting Message of a given severity, where the Message must report the Requester ID of a Function of the device that is enabled to report that specific type of error. If no Function is enabled to send a reporting Message, the device does not send a reporting Message. If all reporting-enabled Functions have the same severity level set for the error, only one error Message is sent. If all reporting-enabled Functions do not have the same severity level set for the error, one error Message for each severity level is sent. Software is responsible for scanning all Functions in a Multi-Function Device when it detects one of those errors.

6.2.4.1 Root Complex Considerations (Advanced Error Reporting) §

6.2.4.1.1 Error Source Identification §

In addition to the above logging, a Root Port or Root Complex Event Collector that supports the Advanced Error Reporting Extended Capability is required to implement the Error Source Identification register, which records the Requester ID of the first ERR_NONFATAL/ERR_FATAL (uncorrectable errors) and ERR_COR (correctable errors) Messages received by the Root Port or Root Complex Event Collector. System software written to support Advanced Error Reporting can use the Root Error Status register to determine which fields hold valid information.

If an RCiEP is associated with a Root Complex Event Collector, the RCiEP must report its errors through that Root Complex Event Collector.

For both Root Ports and Root Complex Event Collectors, in order for a received error Message or an internally generated error Message to be recorded in the Root Error Status register and the Error Source Identification register, the error Message must be “transmitted”. Refer to § Section 6.2.8.1 for information on how received Messages are forwarded and transmitted. Internally generated error Messages are enabled for transmission with the SERR# Enable bit in the Command register (ERR_NONFATAL and ERR_FATAL) or the Reporting Enable bits in the Device Control register (ERR_COR, ERR_NONFATAL, and ERR_FATAL).

6.2.4.1.2 Interrupt Generation §

The Root Error Command register allows further control of Root Complex response to Correctable, Non-Fatal, and Fatal error Messages than the basic Root Complex capability to generate system errors in response to error Messages. Bit fields enable or disable generation of interrupts for the three types of error Messages. System error generation in response to error Messages may be disabled via the PCI Express Capability structure.

If a Root Port or Root Complex Event Collector is enabled for level-triggered interrupt signaling using the INTx messages, the virtual INTx wire must be asserted whenever and as long as all of the following conditions are satisfied:

- The Interrupt Disable bit in the Command register is set to 0b.
- At least one Error Reporting Enable bit in the Root Error Command register and its associated error Messages Received bit in the Root Error Status register are both set to 1b.

Note that all other interrupt sources within the same Function will assert the same virtual INTx wire when requesting service.

If a Root Port or Root Complex Event Collector is enabled for edge-triggered interrupt signaling using MSI or MSI-X, an interrupt message must be sent every time the logical AND of the following conditions transitions from FALSE to TRUE:

- The associated vector is unmasked (not applicable if MSI does not support PVM).
- At least one Error Reporting Enable bit in the Root Error Command register and its associated error Messages Received bit in the Root Error Status register are both set to 1b.

Note that Advanced Error Reporting MSI/MSI-X interrupts always use the vector indicated by the Advanced Error Interrupt Message Number field in the Root Error Status register.

6.2.4.2 Multiple Error Handling (Advanced Error Reporting Extended Capability) §

For the Advanced Error Reporting Extended Capability, the Uncorrectable Error Status register and Correctable Error Status register accumulate the collection of errors which correspond to that particular PCI Express interface. The bits remain set until explicitly cleared by software or reset. Since multiple bits might be set in the Uncorrectable Error Status register, the First Error Pointer (when valid) points to the oldest uncorrectable error that is recorded. The First Error Pointer is valid when the corresponding bit of the Uncorrectable Error Status register is set. The First Error Pointer is invalid when the corresponding bit of the Uncorrectable Error Status register is not set, or is an undefined bit.

The Advanced Error Reporting Extended Capability provides the ability to record headers¹¹⁴ for errors that require header logging. An implementation may support the recording of multiple headers, but at a minimum must support the ability of recording at least one. The ability to record multiple headers is indicated by the state of the Multiple Header Recording Capable bit and enabled by the Multiple Header Recording Enable bit of the Advanced Error Capabilities and Control register. When multiple header recording is supported and enabled, errors are recorded in the order in which they are detected.

If no header recording resources are available when an unmasked uncorrectable error is detected, its error status bit is Set, but the error is not recorded. If an uncorrectable error is masked when it is detected, its error status bit is Set, but the error is not recorded.

When software is ready to dismiss a recorded error indicated by the First Error Pointer, software writes a 1b to the indicated error status bit to clear it, which causes hardware to free up the associated recording resources. If another instance of that error is still recorded, hardware is permitted but not required to leave that error status bit set. If any error instance is still recorded, hardware must immediately update the Header Log, TLP Prefix Log, TLP Prefix Log Present bit, First Error Pointer, and Uncorrectable Error Status register to reflect the next recorded error. If no other error is recorded, it is recommended that hardware update the First Error Pointer to indicate a status bit that it will never set, e.g., a Reserved status bit. See the Implementation Note below.

If multiple header recording is supported and enabled, and the First Error Pointer is valid, it is recommended that software not write a 1b to any status bit other than the one indicated by the First Error Pointer¹¹⁵. If software writes a 1b to such non-indicated bits, hardware is permitted to clear any associated recorded errors, but is not required to do so.

114. If a Function supports TLP Prefixes, then its AER Capability also records any accompanying TLP Prefix along with each recorded header. References to header recording also imply TLP Prefix recording.

If software observes that the First Error Pointer is invalid, and software wishes to clear any unmasked status bits that were set because of earlier header recording resource overflow, software should be aware of the following race condition. If any new instances of those errors happen to be recorded before software clears those status bits, one or more of the newly recorded errors might be lost.

If multiple header recording is supported and enabled, software must use special care when clearing the Multiple Header Recording Enable bit. Hardware behavior is undefined if software clears that bit while the First Error Pointer is valid. Before clearing the Multiple Header Recording Enable bit, it is recommended that software temporarily mask all uncorrectable errors, and then repetitively dismiss each error indicated by the First Error Pointer.

Since an implementation only has the ability to record a finite number of headers, it is important that software services the First Error Pointer, Header Log, and TLP Prefix Log registers in a timely manner, to limit the risk of missing this information for subsequent errors. A Header Log Overflow occurs when an error that requires header logging is detected and either the number of recorded headers supported by an implementation has been reached, or the Multiple Header Recording Enable bit is not Set and the First Error Pointer is valid.

Implementations may optionally check for this condition and report a Header Log Overflow error. This is a reported error associated with the detecting Function.

The setting of Multiple Header Recording Capable and the checking for Header Log Overflow are independently optional.

115. Status bits for masked errors are an exception. Software can safely clear them if software is certain that they have no recorded headers, as would be the case if they have remained masked since the First Error Pointer was last invalid.

IMPLEMENTATION NOTE:

FIRST ERROR POINTER REGISTER BEING VALID §

The First Error Pointer (FEP) field is defined to be valid when the corresponding bit of the Uncorrectable Error Status register is set. To avoid ambiguity with certain cases, the following is recommended:

- After an uncorrectable error has been recorded, when the associated bit in the Uncorrectable Error Status register is cleared by software writing a 1b to it, hardware should update the FEP to point to a status bit that it will never set, e.g., a Reserved status bit. (This assumes that the Function does not already have another recorded error to report, as could be the case if it supports multiple header recording.)
- The default value for the FEP should point to a status bit that hardware will never set, e.g., a Reserved status bit.

Here is an example case of ambiguity with Unsupported Request (UR) if the above recommendations are not followed:

- UR and Advisory Non-Fatal Error are unmasked while system firmware does its Configuration Space probing.
- The Function encounters a UR due to normal probing, logs it, and sets the FEP to point to UR.
- System firmware clears the UR Status bit, and hardware leaves the FEP pointing to UR.
- After the operating system has booted, it masks UR.
- Normal probing sets the UR Status bit, but the error is not recorded since UR is masked.

At this point, there's the ambiguity of the FEP pointing to a status bit that is set (thus being valid), when in fact, there is no recorded error that needs to be processed by software.

If hardware relies on this definition of the FEP being valid to determine when it's possible to record a new error, the Function can fail to record new unmasked errors, falsely determining that it has no available recording resources. Hardware implementations that rely on other internal state to determine when it's possible to record a new error might not have this problem; however, hardware implementations should still follow the above recommendations to avoid presenting this ambiguity to software.

6.2.4.2.1 Multiple Error Handling in VFs §

Header Log space for a PF is independent of that for its associated VFs, and must be implemented with dedicated storage space.

VFs that implement AER may share Header Log space among all the VFs associated with a single PF. Especially when sharing Header Log space, VFs may not have room to log a header associated with an error. In this case, the Function must update the Uncorrectable Error Status Register and Advanced Error Capabilities and Control register as required by § Section 6.2.4.2 ; however, when the Header Log Register is read, it must return all 1s to indicate an overflow condition and that no header was logged. If Flit Mode Supported in the PCI Express Capabilities Register is Set, in addition to returning all 1s, the associated Logged TLP Size field must contain 0.

The VF's header log entry shall be locked and remain valid while that VF's First Error Pointer is valid. As defined in § Section 6.2.4.2 , the First Error Pointer register is valid when the corresponding bit of the Uncorrectable Error Status

register is Set. While the header log entry is locked, additional errors shall not overwrite the locked entry for this or any other VF. When a header entry is unlocked, it shall be available to record a new error for any VF sharing the header logs.

6.2.4.3 Advisory Non-Fatal Error Logging §

§ Section 6.2.3.2.4 describes Advisory Non-Fatal Error cases, under which an agent with AER detecting an uncorrectable error of non-fatal severity signals the error (if enabled) using ERR_COR instead of ERR_NONFATAL. For the same cases, an agent without AER sends no error Message. The remaining discussion in this section is in the context of agents that do implement AER.

For Advisory Non-Fatal Error cases, since an uncorrectable error is signaled using the correctable error Message, control/status/mask bits involving both uncorrectable and correctable errors apply. § Figure 6-2 shows a flowchart of the sequence. Following are some of the unique aspects for logging Advisory Non-Fatal Errors.

First, the uncorrectable error needs to be of severity non-fatal, as determined by the associated bit in the Uncorrectable Error Severity register. If the severity is fatal, the error does not qualify as an Advisory Non-Fatal Error, and will be signaled (if enabled) with ERR_FATAL.

Next, the specific error case needs to be one of the Advisory Non-Fatal Error cases documented in § Section 6.2.3.2.4. If not, the error does not qualify as an Advisory Non-Fatal Error, and will be signaled (if enabled) with an uncorrectable error Message.

Next, the Advisory Non-Fatal Error Status bit is Set in the Correctable Error Status register to indicate the occurrence of the advisory error, and the Advisory Non-Fatal Error Mask bit in the Correctable Error Mask register is checked, and, if set, no further processing is done.

If the Advisory Non-Fatal Error Mask bit is clear, logging proceeds by setting the “corresponding” bit in the Uncorrectable Error Status register, based upon the specific uncorrectable error that’s being reported as an advisory error. If the “corresponding” uncorrectable error bit in the Uncorrectable Error Mask register is clear and the error is one that requires header logging, then the prefix and header are recorded, subject to the availability of resources. See § Section 6.2.4.2.

Finally, an ERR_COR Message is sent if the Correctable Error Reporting Enable bit is Set in the Device Control Register.

6.2.4.4 End-End TLP Prefix Logging - Non-Flit Mode §

For any device Function that supports both TLP Prefixes and Advanced Error Reporting the TLP Prefixes associated with the TLP in error are recorded in the TLP Prefix Log register according to the same rules as the Header Log register (such that both the TLP Prefix Log and Header Log registers always correspond to the error indicated in the First Error Pointer, when the First Error Pointer is valid).

The TLP Prefix Log Present bit (see § Section 7.8.4.7) indicates that the TLP Prefix Log register (see § Section 7.8.4.12) contains information.

Only End-End TLP Prefixes are logged by AER. Logging of Local TLP Prefixes may occur elsewhere using prefix-specific mechanisms.

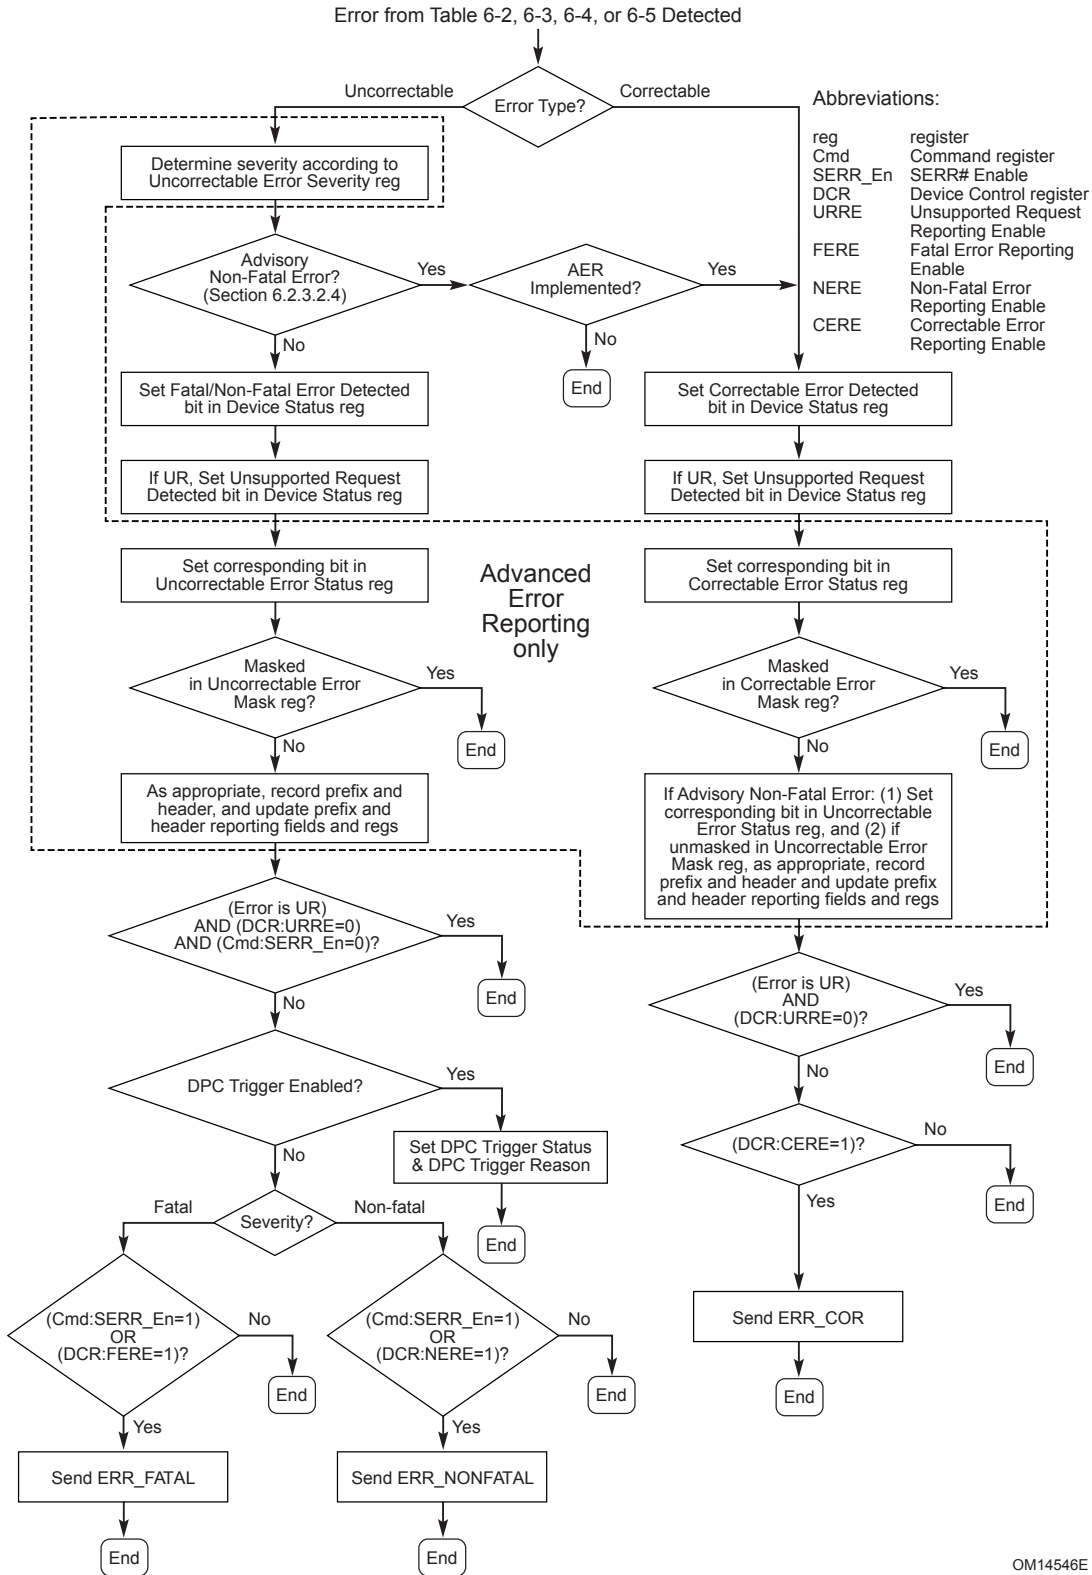

End-End TLP Prefixes are logged in the TLP Prefix Log register. The underlying TLP Header is logged in the Header Log register subject to two exceptions:

- If the Extended Fmt Field Supported bit is Set (see § Section 7.5.3.15), a Function that does not support End-End TLP Prefixes and receives a TLP containing an End-End TLP Prefix must signal Malformed TLP, and the Header Log register must contain the first four DWs of the TLP (End-End TLP Prefixes followed by as much of the TLP Header as will fit).

- A Function that receives a TLP containing more End-End TLP Prefixes than are indicated by the Function's Max End-End TLP Prefixes field must handle the TLP as an error (see § Section 2.2.10.4 for specifics) and store the first overflow End-End TLP Prefix in the 1st DW of the Header Log register with the remainder of the Header Log register being undefined.

6.2.5 Sequence of Device Error Signaling and Logging Operations §

§ Figure 6-2 shows the sequence of operations related to signaling and logging of errors detected by a device.

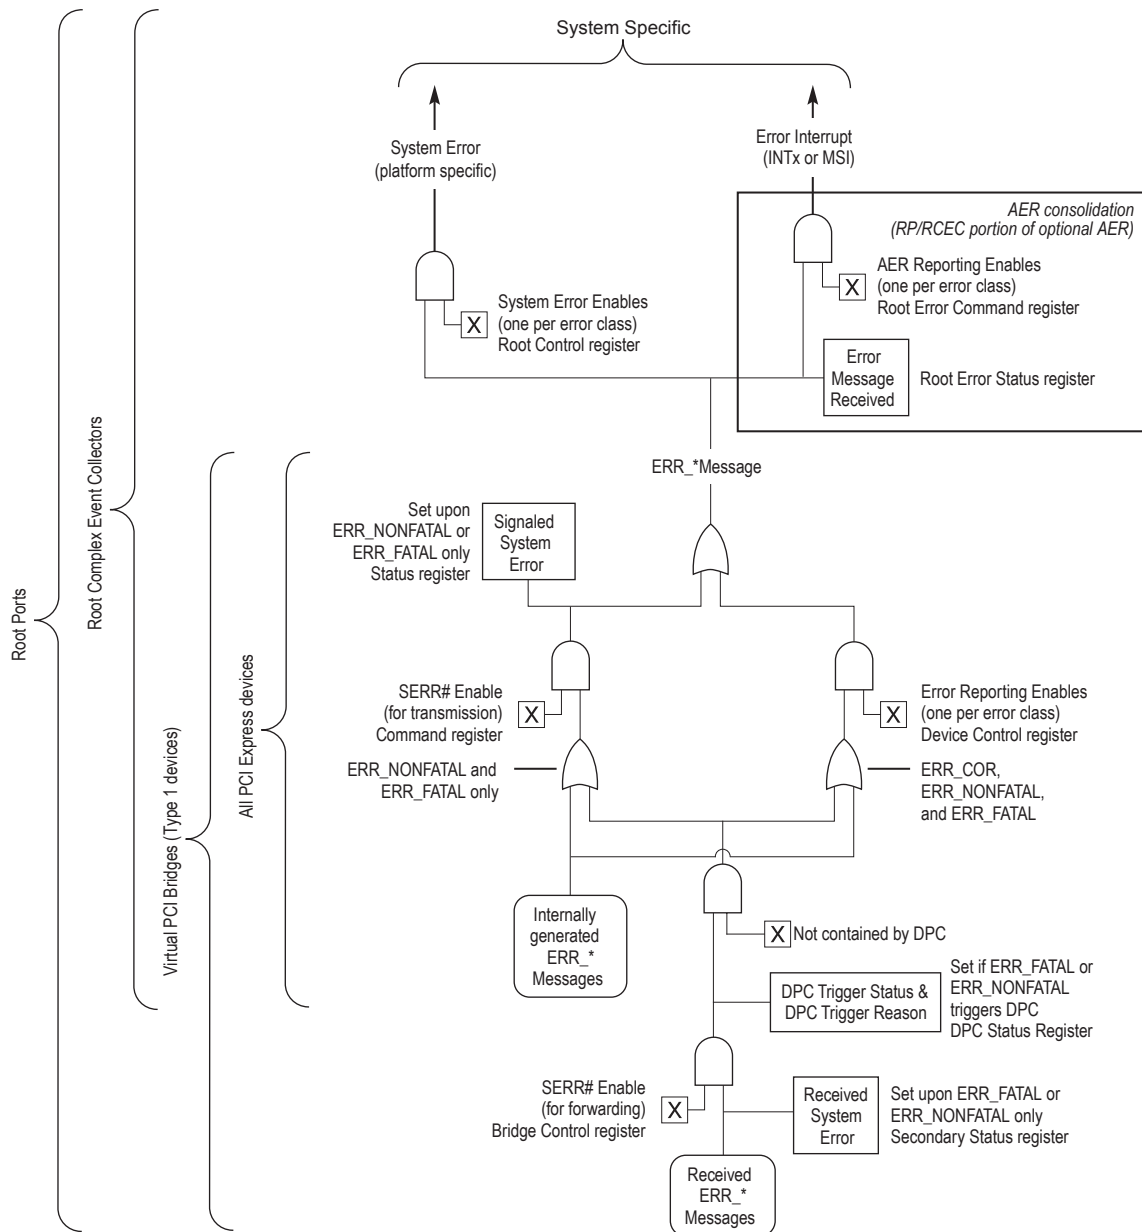

OM14546E

Figure 6-2 Flowchart Showing Sequence of Device Error Signaling and Logging Operations §

6.2.6 Error Message Controls §

Error Messages have a complex set of associated control and status bits. § Figure 6-3 provides a high-level summary in the form of a pseudo logic diagram for how error Messages are generated, logged, forwarded, and ultimately notified to the system. Not all control and status bits are shown. The logic gates shown in this diagram are intended for conveying general concepts, and not for direct implementation.

A-0479B

Figure 6-3 Pseudo Logic Diagram for Selected Error Message Control and Status Bits §

6.2.7 Error Listing and Rules §

§ Table 6-2 through § Table 6-4 list all of the PCI Express errors that are defined by this specification. Each error is listed with a short-hand name, how the error is detected in hardware, the default severity of the error, and the expected action taken by the agent which detects the error. These actions form the rules for PCI Express error reporting and logging.

The Default Severity column specifies the default severity for the error without any software reprogramming. For device Functions supporting the Advanced Error Reporting Extended Capability, the uncorrectable errors are programmable to Fatal or Non-fatal with the Error Severity register. Device Functions without Advanced Error Reporting Extended Capability use the default associations and are not reprogrammable.

The detecting agent action for Downstream Ports that implement Downstream Port Containment (DPC) and have it enabled will be different if the error triggers DPC. DPC behavior is not described in the following tables. See § Section 6.2.11 for the description of DPC behavior.

Table 6-2 General PCI Express Error List §

Error Name	Error Type (Default Severity)	Detecting Agent Action ¹¹⁶	References
Corrected Internal Error	Correctable (masked by default)	<i>Component:</i> Send <u>ERR_COR</u> to Root Complex.	§ Section 6.2.10
Uncorrectable Internal Error	Uncorrectable (Fatal and masked by default)	<i>Component:</i> Send <u>ERR_FATAL</u> to Root Complex. Optionally, log the prefix/header of the first TLP associated with the error.	§ Section 6.2.10
Header Log Overflow	Correctable (masked by default)	<i>Component:</i> Send <u>ERR_COR</u> to Root Complex.	§ Section 6.2.4.2

Table 6-3 Physical Layer Error List §

IDE Check Failed		<i>Receiving IDE Terminus:</i> Enter Insecure All subsequent IDE TLPs over this stream treated as having MAC check failure Send ERR_FATAL to root complex. Transmit IDE Fail Message to the Partner Port Log the prefix/header of the TLP that encountered the error	<u>§ Section 6.33</u>
Misrouted IDE TLP	Uncorrectable (Non-Fatal)	<i>Ingress/Egress Port:</i> Send ERR_NONFATAL to Root Complex. Log the prefix/header of the TLP that encountered the error	<u>§ Section 6.33</u>
PCRC Check Failed		<i>Receiving IDE Terminus:</i> Send ERR_NONFATAL to Root Complex or ERR_COR for the Advisory Non-Fatal Error cases described in <u>§ Section 6.2.3.2.4.3</u> . Log the prefix/header of the TLP that encountered the error	<u>§ Section 6.33</u>

For all errors listed above, the appropriate status bit(s) must be set upon detection of the error. For Unsupported Request (UR), additional detection and reporting enable bits apply (see § Section 6.2.5).

IMPLEMENTATION NOTE: DEVICE UR REPORTING COMPATIBILITY WITH LEGACY AND 1.0A SOFTWARE §

With [PCIe-1.0a] device Functions that do not implement Role-Based Error Reporting,¹²¹ the Unsupported Request Reporting Enable bit in the Device Control Register, when clear, prevents the Function from sending any error Message to signal a UR error. With Role-Based Error Reporting Functions, if the SERR# Enable bit in the Command Register is set, the Function is implicitly enabled¹²² to send ERR_NONFATAL or ERR_FATAL messages to signal UR errors, even if the Unsupported Request Reporting Enable bit is clear. This raises a backward compatibility concern with software (or firmware) written for [PCIe-1.0a] devices.

With software/firmware that sets the SERR# Enable bit but leaves the Unsupported Request Reporting Enable and Correctable Error Reporting Enable bits clear, a Role-Based Error Reporting Function that encounters a UR error will send no error Message if the Request was non-posted, and will signal the error with ERR_NONFATAL if the Request was posted. The behavior with non-posted Requests supports PC-compatible Configuration Space probing, while the behavior with posted Requests restores error reporting compatibility with PCI and PCI-X, avoiding the potential in this area for silent data corruption. Thus, Role-Based Error Reporting devices are backward compatible with envisioned legacy and [PCIe-1.0a] software and firmware.

6.2.7.1 Conventional PCI Mapping §

In order to support conventional PCI driver and software compatibility, PCI Express error conditions, where appropriate, must be mapped onto the PCI Status register bits for error reporting.

In other words, when certain PCI Express errors are detected, the appropriate PCI Status register bit is Set alerting the error to legacy PCI software. While the PCI Express error results in setting the PCI Status register, clearing the PCI Status register will not result in clearing bits in the Uncorrectable Error Status register and Correctable Error Status register. Similarly, clearing bits in the Uncorrectable Error Status register and Correctable Error Status register will not result in clearing the PCI Status register.

The PCI command register has bits which control PCI error reporting. However, the PCI Command register does not affect the setting of the PCI Express error register bits.

6.2.8 Virtual PCI Bridge Error Handling §

Virtual PCI Bridge configuration headers are associated with each PCI Express Port in a Root Complex or a Switch. For these cases, PCI Express error concepts require appropriate mapping to the PCI error reporting structures.

6.2.8.1 Error Message Forwarding and PCI Mapping for Bridge - Rules §

In general, a TLP is either passed from one side of the Virtual PCI Bridge to the other, or is handled at the ingress side of the Bridge according to the same rules which apply to the ultimate recipient of a TLP. The following rules cover PCI Express specific error related cases. Refer to § Section 6.2.6 for a conceptual summary of Error Message Controls.

121. As indicated by the Role-Based Error Reporting bit in the Device Capabilities register. See § Section 7.8.3.

122. Assuming the Unsupported Request Error Mask bit is not set in the Uncorrectable Error Mask Register if the device implements AER.

- If a Request does not address a space mapped to either the Bridge’s internal space, or to the egress side of the Bridge, the Request is terminated at the ingress side as an Unsupported Request
- Poisoned TLPs are forwarded according to the same rules as non-Poisoned TLPs
 - When forwarding a Poisoned Request Downstream:
 - Set the Detected Parity Error bit in the Status register
 - Set the Master Data Parity Error bit in the Secondary Status register if the Parity Error Response Enable bit in the Bridge Control Register is set
 - When forwarding a Poisoned Completion Downstream:
 - Set the Detected Parity Error bit in the Status register
 - Set the Master Data Parity Error bit in the Status register if the Parity Error Response bit in the Command register is set
 - When forwarding a Poisoned Request Upstream:
 - Set the Detected Parity Error bit in the Secondary Status register
 - Set the Master Data Parity Error bit in the Status register if the Parity Error Response bit in the Command register is set
 - When forwarding a Poisoned Completion Upstream:
 - Set the Detected Parity Error bit in the Secondary Status register
 - Set the Master Data Parity Error bit in the Secondary Status register if the Parity Error Response Enable bit in the Bridge Control Register is set
- ERR_COR, ERR_NONFATAL, and ERR_FATAL are forwarded from the secondary interface to the primary interface, if the SERR# Enable bit in the Bridge Control Register is set. A Bridge forwarding an error Message must not set the corresponding Error Detected bit in the Device Status register. Transmission of forwarded error Messages by the primary interface is controlled by multiple bits, as shown in § Figure 6-3.
- For a Root Port, error Messages forwarded from the secondary interface to the primary interface must be enabled for “transmission” by the primary interface in order to cause a System Error via the Root Control Register or (when the Advanced Error Reporting Extended Capability is present) reporting via the Root Error Command register and logging in the Root Error Status register and Error Source Identification register.
- For a Root Complex Event Collector (technically not a Bridge), error Messages “received” from associated RCiEPs must be enabled for “transmission” in order to cause a System Error via the Root Control Register or (when the Advanced Error Reporting Extended Capability is present) reporting via the Root Error Command register and logging in the Root Error Status register and Error Source Identification register.

6.2.9 SR-IOV Baseline Error Handling §

All SR-IOV devices must support baseline capability, with certain modifications to account for the goal of reduced cost and complexity of implementation.

The following error handling control bits are only implemented in the PF. They are RsvdP in VFs, and VFs must use the control bits in their associated PF for managing their error handling behavior.

- Command register (see § Section 7.5.1.1.3)
 - SERR# Enable
 - Parity Error Response
- Device Control register (see § Section 7.5.3.4)
 - Correctable Reporting Enable

- Non-Fatal Reporting Enable
- Fatal Reporting Enable
- Unsupported Request (UR) Reporting Enable

Each VF must report its error status independently of any other Function. This is necessary to provide SI isolation for errors that are Function-specific. The following baseline error handling status bits must be implemented in each VF:

- Status register (see § Section 7.5.1.1.4)
 - Master Data Parity Error
 - Signaled Target Abort
 - Received Target Abort
 - Received Master Abort
 - Signaled System Error
 - Detected Parity Error
- Device Status register (see § Section 7.5.3.5)
 - Correctable Error Detected
 - Non-Fatal Error Detected
 - Fatal Error Detected
 - Unsupported Request Detected

Each VF must use its own Routing ID when signaling errors.

6.2.10 Internal Errors §

An Internal Error is an error associated with a PCI Express interface that occurs within a component and which may not be attributable to a packet or event on the PCI Express interface itself or on behalf of transactions initiated on PCI Express. The determination of what is considered an Internal Error is implementation specific and is outside the scope of this specification.

Internal Errors may be classified as Corrected Internal Errors or Uncorrectable Internal Errors. A Corrected Internal Error is an error that occurs within a component that has been masked or worked around by hardware without any loss of information or improper operation. An example of a possible Corrected Internal Error is an internal packet buffer memory error corrected by an Error Correcting Code (ECC). An Uncorrectable Internal Error is an error that occurs within a component that results in improper operation of the component. An example of a possible Uncorrectable Internal Error is a memory error that cannot be corrected by an ECC. The only method of recovering from an Uncorrectable Internal Error is reset or hardware replacement.

Reporting of Corrected Internal Errors and Uncorrectable Internal Errors is independently optional. If either is reported, then AER must be implemented.

Header logging is optional for Uncorrectable Internal Errors. When a header is logged, the header is that of the first TLP that was lost or corrupted by the Uncorrectable Internal Error. When header logging is not implemented or a header is not available, a header of all ones is recorded.

Internal Errors that can be associated with a specific PCI Express interface are reported by the Function(s) associated with that Port. Internal Errors detected within Switches that cannot be associated with a specific PCI Express interface are reported by the Upstream Port. Reporting of Internal Errors that cannot be associated with a specific PCI Express interface in all other multi-Port components (e.g., Root Complexes) is outside the scope of this specification.

6.2.11 Downstream Port Containment (DPC) §

Downstream Port Containment (DPC) is an optional normative feature of a Downstream Port. DPC halts PCI Express traffic below a Downstream Port after an unmasked uncorrectable error is detected at or below the Port, avoiding the potential spread of any data corruption, and supporting Containment Error Recovery (CER) if implemented by software. A Downstream Port indicates support for DPC by implementing a DPC Extended Capability structure, which contains all DPC control and status bits. See § Section 7.9.14 .

DPC is disabled by default, and cannot be triggered unless enabled by software using the DPC Trigger Enable field. When the DPC Trigger Enable field is set to 01b, DPC is enabled and is triggered when the Downstream Port detects an unmasked uncorrectable error or when the Downstream Port receives an ERR_FATAL Message. When the DPC Trigger Enable field is set to 10b, DPC is enabled and is triggered when the Downstream Port detects an unmasked uncorrectable error or when the Downstream Port receives an ERR_NONFATAL or ERR_FATAL Message. In addition to uncorrectable errors of the type managed by the PCI Express Extended Capability and Advanced Error Reporting (AER), RP PIO errors can be handled as uncorrectable errors. See § Section 6.2.11.3 . There is also a mechanism described in § Section 6.2.11.4 for software or firmware to trigger DPC.

When DPC is triggered due to receipt of an uncorrectable error Message, the Requester ID from the Message is recorded in the DPC Error Source ID Register and that Message is discarded and not forwarded Upstream. When DPC is triggered by an unmasked uncorrectable error, that error will not be signaled with an uncorrectable error Message, even if otherwise enabled. However, when DPC is triggered, DPC can signal an interrupt or send an ERR_COR Message if enabled. See § Section 6.2.11.1 and § Section 6.2.11.2 .

When DPC is triggered, the Downstream Port immediately Sets the DPC Trigger Status bit and DPC Trigger Reason field to indicate the triggering condition (unmasked uncorrectable error, ERR_NONFATAL, ERR_FATAL, RP_PIO error, or software triggered), and disables its Link by directing the LTSSM to the Disabled state. Once the LTSSM reaches the Disabled state, it remains in that state until the DPC Trigger Status bit is Cleared. To ensure that the LTSSM has time to reach the Disabled state or at least to bring the Link down under a variety of error conditions, software must leave the Downstream Port in DPC until the Data Link Layer Link Active bit in the Link Status Register reads 0b; otherwise, the result is undefined. See § Section 7.5.3.8 . See § Section 2.9.3 for other important details on Transaction Layer behavior during DPC.

After DPC has been triggered in a Root Port that supports RP Extensions for DPC, the Root Port may require some time to quiesce and clean up its internal activities, such as those associated with DMA read Requests. When the DPC Trigger Status bit is Set and the DPC RP Busy bit is Set, software must leave the Root Port in DPC until the DPC RP Busy bit reads 0b.

After software releases the Downstream Port from DPC, the Port's LTSSM must transition to the Detect state, where the Link will attempt to retrain. Software can use Data Link Layer State Changed interrupts, DL_ACTIVE ERR_COR signaling, or both, to signal when the Link reaches the DL_Active state again. See § Section 6.7.3.3 and § Section 6.2.11.5 .

IMPLEMENTATION NOTE: DATA VALUE OF ALL 1'S §

Many platforms, including those supporting RP Extensions for DPC, can return a data value of all 1's to software when an error is associated with a PCI Express Configuration, I/O, or Memory Read Request. During DPC, the Downstream Port discards Requests destined for the Link and completes them with an error (i.e., either with an Unsupported Request (UR) or Completer Abort (CA) Completion Status). By ending a series of MMIO or configuration space operations with a read to an address with a known data value not equal to all 1's, software may determine if a Completer has been removed or DPC has been triggered.

Also see the Implementation Note "Use of RP PIO Advisory Error Handling"

IMPLEMENTATION NOTE: SELECTING NON-POSTED REQUEST RESPONSE DURING DPC §

The DPC Completion Control bit determines how a Downstream Port responds to a Non-Posted Request (NPR) received during DPC. The selection needs to take into account how the rest of the platform handles Containment Error Recovery (CER).

While specific CER policy details in a platform are outside the scope of this specification, here are some guidelines based on general considerations.

If the platform or drivers do not support CER policies, it's recommended to select UR Completions, which is the standard behavior when a device is not present.

If the CER strategy relies on software detecting containment by looking for all 1's returned by PIO reads, then a UR Completion may be the more appropriate selection, assuming the RP synthesizes an all 1's return value for PIO reads that return UR Completions. The all 1's synthesis would need to occur for PIO reads that target Configuration Space, Memory Space, and perhaps I/O Space.

If the CER strategy utilizes a mechanism that handles UR and CA Completions differently for PIO reads, then a CA Completion might be the more appropriate selection. CA Completions coming back from a PCIe device normally indicate a device programming model violation, which may need to trigger Port containment and error recovery.

IMPLEMENTATION NOTE: SELECTING THE DPC TRIGGER CONDITION §

Non-Fatal Errors are uncorrectable errors that indicate that a particular TLP was unreliable, and in general the associated Function should not continue its normal operation. Fatal errors are uncorrectable errors that indicate that a particular Link and its related hardware are unreliable, and in general the entire hierarchy below that Link should not continue normal operation. This distinction between Non-Fatal and Fatal errors together with the Root Port error containment capabilities can sometimes be used to select the appropriate DPC trigger condition. The following assumes that there is no peer-to-peer traffic between devices.

Some RCs implement a proprietary feature that will be referred to generically as "Function Level Containment" (FLC). This is not an architected feature of PCI Express. A Root Port that implements FLC is capable of containing the traffic associated with a specific Function when a Non-Fatal Error is detected in that traffic. Switch Downstream Ports below a Root Port with FLC should be configured to trigger DPC when the Downstream Port detects an unmasked uncorrectable error itself or when the Downstream Port receives an ERR_FATAL Message. Under this mode, the Switch Downstream Port passes ERR_NONFATAL Messages it receives Upstream without triggering DPC. This enables Root Port FLC to handle Non-Fatal Errors that render a specific Function unreliable and Switch Downstream Port DPC to handle errors that render a subtree of the hierarchy domain unreliable. The Downstream Port still needs to trigger DPC for all unmasked uncorrectable errors it detects, since an ERR_NONFATAL it generates will have its own Requester ID, and the FLC hardware in the Root Port would not be able to determine which specific Function below the Switch Downstream Port was responsible for the Non-Fatal Error.

Switch Downstream Ports below a Root Port without FLC should be configured to trigger DPC when the Switch Downstream Port detects an unmasked uncorrectable error or when the Switch Downstream Port receives an ERR_NONFATAL or ERR_FATAL Message. This enables DPC to contain the error to the affected hierarchy below the Link and allow continued normal operation of the unaffected portion of the hierarchy domain.

IMPLEMENTATION NOTE: SOFTWARE POLLING THE DPC RP BUSY BIT §

The DPC RP Busy bit is a means for hardware to indicate to software that the RP needs to remain in DPC containment while the RP does some internal cleanup and quiescing activities. While the details of these activities are implementation specific, the activities will typically complete within a few microseconds or less. However, under worst-case conditions such as those that might occur with certain internal errors in large systems, the busy period might extend substantially, possibly into multiple seconds. If software is unable to tolerate such lengthy delays within the current software context, software may need to rely on using timer interrupts to schedule polling under interrupt.

IMPLEMENTATION NOTE: DETERMINATION OF DPC CONTROL §

DPC may be controlled in some configurations by platform firmware and in other configurations by the operating system. DPC functionality is strongly linked with the functionality in Advanced Error Reporting. To avoid conflicts over whether platform firmware or the operating system have control of DPC, it is recommended that platform firmware and operating systems always link the control of DPC to the control of Advanced Error Reporting.

6.2.11.1 DPC Interrupts §

A DPC-capable Downstream Port must support the generation of DPC interrupts. DPC interrupts are enabled by the DPC Interrupt Enable bit in the DPC Control Register. DPC interrupts are indicated by the DPC Interrupt Status bit in the DPC Status Register.

If the Port is enabled for level-triggered interrupt signaling using INTx messages, the virtual INTx wire must be asserted whenever and as long as the following conditions are satisfied:

- The value of the Interrupt Disable bit in the Command register is 0b.
- The value of the DPC Interrupt Enable bit is 1b.
- The value of the DPC Interrupt Status bit is 1b.

Note that all other interrupt sources within the same Function will assert the same virtual INTx wire when requesting service.

If the Port is enabled for edge-triggered interrupt signaling using MSI or MSI-X, an interrupt message must be sent every time the logical AND of the following conditions transitions from FALSE to TRUE:

- The associated vector is unmasked (not applicable if MSI does not support PVM).
- The value of the DPC Interrupt Enable bit is 1b.
- The value of the DPC Interrupt Status bit is 1b.

The Port may optionally send an interrupt message if interrupt generation has been disabled, and the logical AND of the above conditions is TRUE when interrupt generation is subsequently enabled.

The interrupt message will use the vector indicated by the DPC Interrupt Message Number field in the DPC Capability register. This vector may be the same or may be different from the vectors used by other interrupt sources within this Function.

6.2.11.2 DPC ERR_COR Signaling §

A DPC-capable Downstream Port must support ERR_COR signaling, independent of whether it supports Advanced Error Reporting (AER) or not. DPC ERR_COR signaling is enabled by the DPC ERR_COR Enable bit in the DPC Control Register. DPC triggering is indicated by the DPC Trigger Status bit in the DPC Status Register. DPC ERR_COR signaling is managed independently of DPC interrupts, and it is permitted to use both mechanisms concurrently.

If the DPC ERR_COR Enable bit is Set, and the Correctable Error Reporting Enable bit in the Device Control Register or the DPC SIG_SFW Enable bit in the DPC Control Register is Set, the Port must send an ERR_COR Message each time the DPC Trigger Status bit transitions from Clear to Set. DPC ERR_COR signaling must not Set the Correctable Error Detected bit in the Device Status Register, since this event is not handled as an error. If the Downstream Port supports ERR_COR Subclass capability, this DPC ERR_COR signaling event must set the DPC SIG_SFW Status bit in the DPC Status Register and also set the ERR_COR Subclass field in the ERR_COR Message to indicate ECS SIG_SFW.

For a given DPC trigger event, if a Port is going to send both an ERR_COR Message and an MSI/MSI-X transaction, then the Port must send the ERR_COR Message prior to sending the MSI/MSI-X transaction. There is no corresponding requirement if the INTx mechanism is being used to signal DPC interrupts, since INTx Messages won't necessarily remain ordered with respect to ERR_COR Messages when passing through routing elements.

IMPLEMENTATION NOTE: USE OF DPC ERR_COR SIGNALING §

It is recommended that operating systems use DPC interrupts for signaling when DPC has been triggered. While DPC ERR_COR signaling indicates the same event, DPC ERR_COR signaling is primarily intended for use by system firmware, when it needs to be notified in order to do its own logging of the event or provide firmware first services.

6.2.11.3 Root Port Programmed I/O (RP PIO) Error Controls §

The RP PIO error control registers enable fine-grained control over what happens when Non-Posted Requests that are tracked by the Root Port encounter certain uncorrectable or advisory errors. See § Section 2.9.3 for a description of which Non-Posted Requests are tracked. A set of control and status bits exists for receiving Completion with Unsupported Request status (UR Cpl), receiving Completion with Completer Abort status (CA Cpl), and Completion Timeout (CTO) errors. Independent sets of these error bits exist for Configuration Requests, I/O Requests, and Memory Requests. This finer granularity enables more precise error handling for this subset of uncorrectable errors (UR Cpl, CA Cpl, and CTO). As a key example, UR Cpl errors with Memory Read Requests can be configured to trigger DPC for proper containment and error handling, while UR Cpl errors with Configuration Requests can be configured to return all 1's (without triggering DPC) for normal probing and enumeration.

A UR or CA error logged in AER is the result of the Root Port operating in the role of a Completer, and for a received Non-Posted Request, returning a Completion. In contrast, a UR Cpl or CA Cpl error logged as an RP PIO error is the result of the Root Port operating in the role of a Requester, and for an outstanding Non-Posted Request, receiving a Completion. CTO errors logged in both AER and RP PIO are the result of the Root Port operating in the role of a Requester, though the RP PIO error controls support per-space granularity. Depending upon the control register settings,

CTO errors can be logged in AER registers, in RP PIO registers, or both. If software unmask CTO errors in RP PIO, it is recommended that software mask CTO errors in AER in order to avoid unintended interactions.

The RP PIO Header Log Register, RP PIO ImpSpec Log Register, and RP PIO TLP Prefix Log Registers are referred to collectively as the RP PIO log registers. The RP PIO Header Log Register must be implemented; the RP PIO ImpSpec Log Register and RP PIO TLP Prefix Log Register are optional. The RP PIO Log Size field indicates how many DWORDs are allocated for the RP PIO log registers, and from this the allocated size for the RP PIO TLP Prefix Log Register can be calculated. See § Section 7.9.14.2 . The RP PIO log registers always record information from a PIO Request, not any associated Completions.

When Flit Mode Supported is Set and the link is operating in Flit Mode, the RP PIO Header Log Register extends into additional DWs as indicated by the RP PIO Log Size field. Software must parse the Type and OHC fields to determine the size and layout of a TLP recorded in the RP PIO Header Log Register. Hardware is not required to support logging of TLP Headers larger than the largest size supported by the Port. Hardware is not required to support logging of OHC types not supported by the Port. TLP Trailers are not logged in the RP PIO Header Log Register. The required minimum size of the RP PIO Header Log Register is determined by the largest Header Base Size implemented by the Port (up to the maximum defined of 7 DW - See § Table 2-5), plus the largest number of OHC implemented by the Port (up to the maximum defined of 7 DW). Hardware must hardwire to zero the DW of the RP PIO Header Log Register beyond those required to log the largest supported TLP Header and the overall length of the Advanced Error Reporting Extended Capability is reduced accordingly. As in Non-Flit Mode, Local TLP Prefixes are not logged.

The RP PIO Status, Mask, and Severity registers behave similarly to the Uncorrectable Error Status, Mask, and Severity registers in AER. See § Section 7.8.4.2 , § Section 7.8.4.3 , and § Section 7.8.4.4 >. When an RP PIO error is detected while it is unmasked, the associated bit in the RP PIO Status Register is Set, and the error is recorded in the RP PIO log registers (assuming that RP PIO error logging resources are available). When an RP PIO error is detected while it is masked, the associated bit is still Set in the RP PIO Status Register, but the error does not trigger DPC and the error is not recorded in the RP PIO log registers.

Each unmasked RP PIO error is handled either as uncorrectable or advisory, as determined by the value of the corresponding bit in the RP PIO Severity Register. If the associated Severity bit is Set, the error is handled as uncorrectable, triggering DPC (assuming that DPC is enabled) and signaling this event with a DPC interrupt and/or ERR_COR (if enabled). If the associated Severity bit is Clear, the error is handled as advisory (without triggering DPC) and signaled with ERR_COR (if enabled).

IMPLEMENTATION NOTE:

USE OF RP PIO ADVISORY ERROR HANDLING §

Each RP PIO error can be handled either as uncorrectable or advisory. Uncorrectable error handling usually logs the error, triggers DPC, and signals the event either with a DPC interrupt, an ERR_COR, or both. Advisory error handling usually logs the error and signals the event with ERR_COR.

RP PIO advisory error handling can be used by software in certain cases to handle RP PIO errors robustly without incurring the disruption caused if DPC is triggered in the RP. If an RP PIO Exception is not enabled for a given error, an all 1's value is returned whenever the error occurs. If the error does not trigger DPC, software may be uncertain if the all 1's value returned by a given PIO read is the actual data value returned by the Completion versus indicating that an error occurred with that PIO read. If software enables advisory error handling for that error, instances of that error will be logged, enabling software to distinguish the two cases.

The use of RP PIO advisory error handling is notably beneficial if DPC is triggered in a Switch Downstream Port, and that causes one or more Completion Timeouts in the RP as a side-effect, as described in § Section 2.9.3 . If the RP handles Completion Timeout errors as advisory, this avoids DPC being triggered in the RP, permitting continued operation with the other Switch Downstream Ports.

The RP PIO First Error Pointer, RP PIO Header Log, and RP PIO TLP Prefix Log behave similarly to the First Error Pointer, Header Log, and TLP Prefix Log in AER. The RP PIO First Error Pointer is defined to be valid when its value indicates a bit in the RP PIO Status Register that is Set. When the RP PIO First Error Pointer is valid, the RP PIO log registers contain the information associated with the indicated error. The RP PIO ImpSpec Log, if implemented, contains implementation specific information, e.g., the source of the Request TLP.

In contrast to AER, where the recording of CTO error information in the AER log registers is optional, RP PIO implementations must support recording RP PIO CTO error information in the RP PIO log registers.

If an error is detected with a received Completion TLP associated with an outstanding PIO Request, the set of RP PIO error control bits used to govern the error handling is determined in a similar manner. The DPC Completion Control bit determines whether UR or CA applies, and the Space (Configuration, I/O, or Memory) is that of the associated PIO Request. For example, if the DPC Completion Control bit is configured for CA, and a Root Port receives a poisoned Completion for a PIO Memory Read Request, the Mem CA Cpl bit (bit 17) is used in the RP PIO control and status registers for handling the error.

The RP PIO SysError Register provides a means to generate a System Error when an RP PIO error occurs. If an unmasked RP PIO error is detected while its associated bit in the RP PIO SysError Register is Set, a System Error is generated.

The RP PIO Exception Register provides a means to generate a synchronous processor exception¹²³ when an error occurs with certain tracked Non-Posted Requests that are generated by a processor instruction. See § Section 2.9.3. This exception must support all such tracked read Requests, and may optionally support Configuration write, I/O write, and AtomicOp Requests. If an error with an exception-supported Non-Posted Request is detected¹²⁴ or a Completion for it is synthesized, and its associated bit in the RP PIO Exception Register is Set, the processor instruction that generated the Non-Posted Request must take a synchronous exception. This still applies even if the RP PIO or AER controls specify that the error be handled as masked or advisory.

The details of a processor instruction taking a synchronous exception are processor-specific, but at a minimum, the mechanism must be able to interrupt the normal processor instruction flow either before completion of the instruction that generated the Non-Posted Request, or immediately following that instruction. The intent is that exception handling routines in system firmware, the operating system, or both, can examine the cause of the exception and take corrective action if necessary.

If an RP PIO error occurs with a processor-generated read or AtomicOp Request, and the RP PIO Exception Register value does not cause an exception, a value of all 1's must be returned for the instruction that generated the Request.

IMPLEMENTATION NOTE: SYNCHRONOUS EXCEPTION IMPLEMENTATION §

The exact mechanism for implementing synchronous exceptions is processor and platform specific. One possible implementation is poisoning the data returned to the processor for a read or AtomicOp Request that encounters an error. While this approach is likely to work with those Requests, it might not work with Configuration and I/O write Requests since they return no data.

Another possible implementation is marking the response transaction for processor-generated Non-Posted Requests with some other type of indication of the Request having failed, e.g., a “hard fail” response. This approach is more likely to work with all processor-generated Non-Posted Requests.

123. “Exception” is used as a generic term for a variety of mechanisms used by processors, including interrupts, traps, machine checks, instruction aborts, etc.

124. This includes any errors with the Completion TLP itself (e.g., Malformed TLP) or where the Completion Status is other than Successful Completion.

IMPLEMENTATION NOTE:

RP PIO MASK BIT BEHAVIOR AND RATIONALE §

For a given RP PIO error, the associated mask bit in the RP PIO Mask Register affects its associated status bit setting, error logging, and error signaling in a manner that closely parallels the behavior of mask bits in AER.

SysError generation for a given RP PIO error is primarily controlled by the associated bit in the RP PIO SysError Register, but is also contingent upon the associated RP PIO mask bit being Clear. This behavior was chosen for consistency with AER, and also since it is poor practice to generate a SysError without logging the reason.

Exception generation for a given RP PIO error is independent of the associated RP PIO mask bit value. Usage Models are envisioned where an RP PIO error needs to generate an Exception without logging an RP PIO error or triggering DPC.

Root Port error handling for tracked Non-Posted Requests with errors other than receiving UR and CA Completions is governed by a combination of AER and RP PIO error controls. Examples are CTO¹²⁵, Poisoned TLP Received, and Malformed TLP. For a given error managed by AER, the associated AER Mask and Severity bits determine if the error must be handled as an uncorrectable error, handled as an Advisory Non-Fatal Error, or handled as a masked error.

- If the AER-managed error is to be handled as an uncorrectable error (see § Section 6.2.2.2), DPC is triggered. The RP PIO SysError and RP PIO Exception bits associated with the Request type and Completion Status apply.
- If the AER-managed error is to be handled as an Advisory Non-Fatal Error (see § Section 6.2.3.2.4), DPC is not triggered. The RP PIO SysError and RP PIO Exception bits do apply.
- If the AER-managed error is to be handled as a masked error (see § Section 6.2.3.2.2), DPC is not triggered. RP PIO SysError bit does not apply, but the RP PIO Exception bit does apply.

6.2.11.4 Software Triggering of DPC §

If the DPC Software Triggering Supported bit in the DPC Capability register is Set, then software can trigger DPC by writing a 1b to the DPC Software Trigger bit in the DPC Control Register, assuming that DPC is enabled and the Port isn't currently in DPC. This mechanism is envisioned to be useful for software and/or firmware development and testing. It also supports usage models where software or firmware examines RP PIO Exceptions or RP PIO advisory errors, and decides to trigger DPC based upon the situation.

When this mechanism triggers DPC, the DPC Trigger Reason and DPC Trigger Reason Extension fields in the DPC Status Register will indicate this as the reason.

If a Port is already in DPC when a 1b is written to the DPC Software Trigger bit, the Port remains in DPC, and the DPC Trigger Reason and DPC Trigger Reason Extension fields are not modified.

125. CTO errors have status and mask bits in both AER and RP PIO, though RP PIO has independent sets of bits for each of the 3 spaces. Other errors in AER have no equivalent errors in RP PIO.

IMPLEMENTATION NOTE: AVOID DISABLE LINK AND HOT-PLUG SURPRISE USE WITH DPC §

It is recommended that software not Set the Link Disable bit in the Link Control register while DPC is enabled but not triggered. Setting the Link Disable bit will cause the Link to be directed to DL_Down, invoking some semantics similar to those in DPC, but lacking others. If DPC is enabled, the subsequent arrival of any Posted Requests will likely trigger DPC anyway. If DPC is enabled, the recommended method for software to disable the Link is to write a 1b to the optional DPC Software Trigger bit in the DPC Control Register. If the DPC Software Trigger bit is not implemented, software should disable DPC and use Link Disable instead. If the operating system is performing this action, but DPC is owned by system firmware, the operating system should coordinate disabling DPC with system firmware.

DPC is not recommended for use concurrently with the Hot-Plug Surprise mechanism, indicated by the Hot-Plug Surprise bit in the Slot Capabilities register being Set. Having this bit Set blocks the reporting of Surprise Down errors, preventing DPC from being triggered by this important error, greatly reducing the benefit of DPC. See § Section 6.7.4.5 for guidance on slots supporting both mechanisms.

6.2.11.5 DL_Active ERR_COR Signaling §

Support for this feature is indicated by the DL_Active ERR_COR Signaling Supported bit in the DPC Capability register. The feature is enabled by the DL_ACTIVE ERR_COR Enable bit in the DPC Control Register. The DL_ACTIVE state is indicated by the Data Link Layer Link Active bit in the Link Status Register. DL_ACTIVE ERR_COR signaling is managed independently of Data Link Layer State Changed interrupts, and it is permitted to use both mechanisms concurrently.

If the DL_ACTIVE ERR_COR Enable bit is Set, and the Correctable Error Reporting Enable bit in the Device Control register or the DPC SIG_SFW Enable bit in the DPC Control Register is Set, the Port must send an ERR_COR Message each time the Link transitions into the DL_Active state. DL_ACTIVE ERR_COR signaling must not Set the Correctable Error Detected bit in the Device Status register, since this event is not handled as an error. If the Downstream Port supports ERR_COR Subclass capability, this DPC ERR_COR signaling event must set the DPC SIG_SFW Status bit in the DPC Status register and also set the ERR_COR Subclass field in the ERR_COR Message to indicate ECS SIG_SFW. In contrast to Data Link Layer State Changed interrupts, DL_ACTIVE ERR_COR signaling only indicates the Link enters the DL_Active state, not when the Link exits the DL_Active state.

For a given DL_ACTIVE event, if a Port is going to send both an ERR_COR Message and an MSI/MSI-X transaction, then the Port must send the ERR_COR Message prior to sending the MSI/MSI-X transaction. There is no corresponding requirement if the INTx mechanism is being used to signal DL_ACTIVE interrupts, since INTx Messages won't necessarily remain ordered with respect to ERR_COR Messages when passing through routing elements.

IMPLEMENTATION NOTE: USE OF DL_ACTIVE ERR_COR SIGNALING §

It is recommended that operating systems use Data Link Layer State Changed interrupts for signaling when DL_ACTIVE changes state. While DL_ACTIVE ERR_COR signaling indicates a subset of the same events, DL_ACTIVE ERR_COR signaling is primarily intended for use by system firmware, when it needs to be notified in order to do Downstream Port configuration or provide firmware first services.

6.3 Virtual Channel Support §

6.3.1 Introduction and Scope §

The Virtual Channel mechanism provides a foundation for supporting differentiated services within the PCI Express fabric. It enables deployment of independent physical resources that together with traffic labeling are required for optimized handling of differentiated traffic. Traffic labeling is supported using Traffic Class TLP-level labels. The policy for traffic differentiation is determined by the TC/VC mapping and by the VC-based, Port-based, and Function-based arbitration mechanisms supported by certain VC capabilities. The TC/VC mapping depends on the platform application requirements. These requirements drive the choice of the arbitration algorithms and configurability/programmability of arbiters allows detailed tuning of the traffic servicing policy.

The definition of the Virtual Channel and associated Traffic Class mechanisms is covered in § Chapter 2. . The VC configuration/programming models are defined in § Section 7.9.1 , § Section 7.9.2 , and § Section 7.9.29 .

This section covers VC mechanisms from the system perspective. It addresses the next level of details on:

- Supported TC/VC configurations
- VC-based arbitration - algorithms and rules
- Traffic ordering considerations
- Isochronous support as a specific usage model
- SVC and VC/MFVC capability coexistence

6.3.2 TC/VC Mapping and Example Usage §

A Virtual Channel is established when one or more TCs are associated with a physical resource designated by a VC ID. Every Traffic Class that is supported on a given path within the fabric must be mapped to one of the enabled Virtual Channels. Every Port must support the default TC0/VC0 pair - this is “hardwired”. Any additional TC mapping or additional VC resource enablement is optional and is controlled by system software using the programming model described in Sections 7.9.1 and 7.9.2.

The number of VC resources provisioned within a component or enabled within a given fabric may vary due to implementation and usage model requirements, due to Hot-Plug of disparate components with varying resource capabilities, or due to system software restricting what resources may be enabled on a given path within the fabric.

Some examples to illustrate:

- A set of components (Root Complex, Endpoints, Switches) may only support the mandatory VC0 resource that must have TC0 mapped to VC0. System software may, based on application usage requirements, map one or all non-zero TCs to VC0 as well on any or all paths within the fabric.
- A set of components may support two VC resources, e.g., VC0 and VC1. System software must map TC0/VC0 and in addition, may map one or all non-zero TC labels to either VC0 or VC1. As above, these mappings may be enabled on any or all paths within the fabric. Refer to the examples below for additional information.
- A Switch may be implemented with eight Ports - seven x1 Links with two VC resources and one x16 Link with one VC resource. System software may enable both VC resources on the x1 Links and assign one or more additional TCs to either VC thus allowing the Switch to differentiate traffic flowing between any Ports. The x16 Link must also be configured to map any non-TC0 traffic to VC0 if such traffic is to flow on this Link. Note:

multi-Port components (Switches and Root Complex) are required to support independent TC/VC mapping per Port.

In any of the above examples, system software has the ability to map one, all, or a subset of the TCs to a given VC. Should system software wish to restrict the number of traffic classes that may flow through a given Link, it may configure only a subset of the TCs to the enabled VC resources. Any TLP indicating a TC that has not been mapped to an enabled VC resource must be treated as a Malformed TLP. This is referred to as TC Filtering. Flow Control credits for this TLP will be lost, and an uncorrectable error will be generated, so software intervention will usually be required to restore proper operation after a TC Filtering event occurs.

A graphical example of TC filtering is illustrated in § Figure 6-4, where TCs (2:6) are not mapped to the Link that connects Endpoint A and the Switch. This means that the TLPs with TCs (2:6) are not allowed between the Switch and Endpoint A.

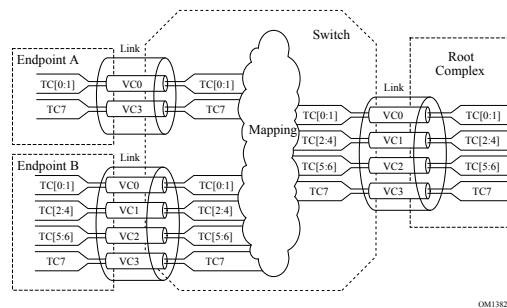

Figure 6-4 TC Filtering Example §

§ Figure 6-5 shows an example of TC to VC mapping. A simple Switch with one Downstream Port and one Upstream Port connects an Endpoint to a Root Complex. At the Upstream Port, two VCs (VC0 and VC1) are enabled with the following mapping: TC(0-6)/VC0, TC7/VC1. At the Downstream Port, only VC0 is enabled and all TCs are mapped to VC0. In this example while TC7 is mapped to VC0 at the Downstream Port, it is re-mapped to VC1 at the Upstream Port. Although the Endpoint only supports VC0, when it labels transactions with different TCs, transactions associated with TC7 from/to the Endpoint can take advantage of the second Virtual Channel enabled between the Switch and the Root Complex.

Figure 6-5 TC to VC Mapping Example §

IMPLEMENTATION NOTE: MULTIPLE TCS OVER A SINGLE VC §

A single VC implementation may benefit from using multiple TCS. TCS provide ordering domains that may be used to differentiate traffic within the Endpoint or the Root Complex independent of the number of VCs supported.

In a simple configuration, where only VC0 is supported, traffic differentiation may not be accomplished in an optimum manner since the different TCs cannot be physically segregated. However, the benefits of carrying multiple TCs can still be exploited particularly in the small and “shallow” topologies where Endpoints are connected directly to Root Complex rather than through cascaded Switches. In these topologies traffic that is targeting Root Complex only needs to traverse a single Link, and an optimized scheduling of packets on both sides (Endpoint and Root Complex) based on TCs may accomplish significant improvement over the case when a single TC is used. Still, the inability to route differentiated traffic through separate resources with fully independent flow control and independent ordering exposes all of the traffic to the potential head-of-line blocking conditions. Optimizing Endpoint internal architecture to minimize the exposure to the blocking conditions can reduce those risks.

6.3.3 VC Arbitration §

Arbitration is one of the key aspects of the Virtual Channel mechanism and is defined in a manner that fully enables configurability to the specific application. In general, the definition of the VC-based arbitration mechanism is driven by the following objectives:

- To prevent false transaction timeouts and to guarantee data flow forward progress
- To provide differentiated services between data flows within the fabric
- To provide guaranteed bandwidth with deterministic (and reasonably small) end-to-end latency between components

Links are bidirectional, i.e., each Port can be an Ingress or an Egress Port depending on the direction of traffic flow. This is illustrated by the example of a 3-Port Switch in § Figure 6-6, where the paths for traffic flowing between Switch Ports are highlighted with different types of lines. In the following sections, VC Arbitration is defined using a Switch arbitration model since the Switch represents a functional superset from the arbitration perspective.

In addition, one-directional data flow is used in the description.

Figure 6-6 An Example of Traffic Flow Illustrating Ingress and Egress §

6.3.3.1 Traffic Flow and Switch Arbitration Model §

The following set of figures (§ Figure 6-7 and § Figure 6-8) illustrates traffic flow through the Switch and summarizes the key aspects of the arbitration.

Figure 6-7 An Example of Differentiated Traffic Flow Through a Switch §

At each Ingress Port an incoming traffic stream is represented in § Figure 6-7 by small boxes. These boxes represent packets that are carried within different VCs that are distinguished using different levels of gray. Each of the boxes that represents a packet belonging to different VC includes designation of Ingress and Egress Ports to indicate where the packet is coming from and where it is going to. For example, designation “3.0” means that this packet is arriving at Port #0 (Ingress) and is destined to Port #3 (Egress). Within the Switch, packets are routed and serviced based on Switch internal arbitration mechanisms.

Switch arbitration model defines a required arbitration infrastructure and functionality within a Switch. This functionality is needed to support a set of arbitration policies that control traffic contention for an Egress Port from multiple Ingress Ports.

§ Figure 6-8 shows a conceptual model of a Switch highlighting resources and associated functionality in ingress to egress direction. Note that each Port in the Switch can have the role of an Ingress or Egress Port. Therefore, this figure only shows one particular scenario where the 4-Port Switch in this example has ingress traffic on Port #0 and Port #1, that targets Port #2 as an Egress Port. A different example may show different flow of traffic implying different roles for Ports on the Switch. The PCI Express architecture enables peer-to-peer communication through the Switch and, therefore, possible scenarios using the same example may include multiple separate and simultaneous ingress to egress flows (e.g., Port 0 to Port 2 and Port 1 to Port 3).

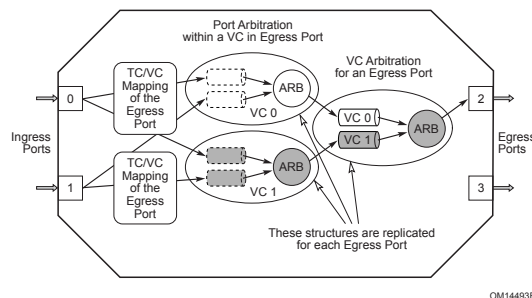

Figure 6-8 Switch Arbitration Structure §

The following two steps conceptually describe routing of traffic received by the Switch on Port 0 and Port 1 and destined to Port 2. First, the target Egress Port is determined based on address/routing information in the TLP header. Secondly,

the target VC of the Egress Port is determined based on the TC/VC map of the Egress Port. Transactions that target the same VC in the Egress Port but are from different Ingress Ports must be arbitrated before they can be forwarded to the corresponding resource in the Egress Port. This arbitration is referred to as the Port Arbitration.

Once the traffic reaches the destination VC resource in the Egress Port, it is subject to arbitration for the shared Link. From the Egress Port point of view this arbitration can be conceptually defined as a simple form of multiplexing where the multiplexing control is based on arbitration policies that are either fixed or configurable/programmable. This stage of arbitration between different VCs at an Egress Port is called the VC Arbitration of the Egress Port.

Independent of VC arbitration policy, a management/control logic associated with each VC must observe transaction ordering and flow control rules before it can make pending traffic visible to the arbitration mechanism.

IMPLEMENTATION NOTE: VC CONTROL LOGIC AT THE EGRESS PORT §

VC control logic at every Egress Port includes:

- VC Flow Control logic
- VC Ordering Control logic

Flow control credits are exchanged between two Ports connected to the same Link. Availability of flow control credits is one of the qualifiers that VC control logic must use to decide when a VC is allowed to compete for the shared Link resource (i.e., Data Link Layer transmit/retry buffer). If a candidate packet cannot be submitted due to the lack of an adequate number of flow control credits, VC control logic must mask the presence of pending packet to prevent blockage of traffic from other VCs. Note that since each VC includes buffering resources for Posted Requests, Non-Posted Requests, and Completion packets, the VC control logic must also take into account availability of flow control credits for the particular candidate packet. In addition, VC control logic must observe ordering rules (see § Section 2.4 for more details) for Posted/Non-Posted/Completion transactions to prevent deadlocks and violation of producer/consumer ordering model.

6.3.3.2 VC Arbitration - Arbitration Between VCs §

This specification defines a default VC prioritization via the VC Identification (VC ID) assignment, i.e., the VC IDs are arranged in ascending order of relative priority in the Virtual Channel Capability structure or Multi-Function Virtual Channel Capability structure. The example in § Figure 6-9 illustrates a Port that supports eight VCs with VC0 treated as the lowest priority and VC7 as the highest priority.

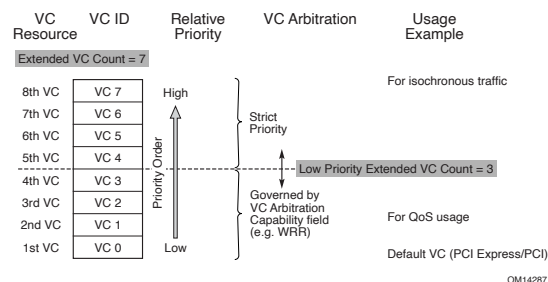

Figure 6-9 VC ID and Priority Order - An Example §

The availability of default prioritization does not restrict the type of algorithms that may be implemented to support VC arbitration - either implementation specific or one of the architecture-defined methods:

- Strict Priority - Based on inherent prioritization, i.e., VC0 = lowest, VC7 = highest
- Round Robin (RR) - Simplest form of arbitration where all VCs have equal priority
- Weighted RR - Programmable weight factor determines the level of service

If strict priority arbitration is supported by the hardware for a subset of the VC resources, software can configure the VCs into two priority groups - a lower and an upper group. The upper group is treated as a strict priority arbitration group while the lower group is arbitrated to only when there are no packets to process in the upper group. § Figure 6-9 illustrates an example configuration that supports eight VCs separated into two groups - the lower group consisting of VC0-VC3 and the upper group consisting of VC4-VC7. The arbitration within the lower group can be configured to one of the supported arbitration methods. The Low Priority Extended VC Count field in the Port VC Capability Register 1 indicates the size of this group. The arbitration methods are listed in the VC Arbitration Capability field in the Port VC Capability Register 2. Refer to § Section 7.9.1 and § Section 7.9.2 for details. When the Low Priority Extended VC Count field is set to zero, all VCs are governed by the strict-priority VC arbitration; when the field is equal to the Extended VC Count, all VCs are governed by the VC arbitration indicated by the VC Arbitration Capability field.

6.3.3.2.1 Strict Priority Arbitration Model §

Strict priority arbitration enables minimal latency for high-priority transactions. However, there is potential danger of bandwidth starvation should it not be applied correctly. Using strict priority requires all high-priority traffic to be regulated in terms of maximum peak bandwidth and Link usage duration. Regulation must be applied either at the transaction injection Port/Function or within subsequent Egress Ports where data flows contend for a common Link. System software must configure traffic such that lower priority transactions will be serviced at a sufficient rate to avoid transaction timeouts.

6.3.3.2.2 Round Robin Arbitration Model §

Round Robin arbitration is used to provide, at the transaction level, equal¹²⁶ opportunities to all traffic. Note that this scheme is used where different unordered streams need to be serviced with the same priority.

In the case where differentiation is required, a Weighted Round Robin scheme can be used. The WRR scheme is commonly used in the case where bandwidth regulation is not enforced by the sources of traffic and therefore it is not possible to use the priority scheme without risking starvation of lower priority traffic. The key is that this scheme provides fairness during traffic contention by allowing at least one arbitration win per arbitration loop. Assigned weights regulate both minimum allowed bandwidth and maximum burstiness for each VC during the contention. This means that it bounds the arbitration latency for traffic from different VCs. Note that latencies are also dependent on the maximum packet sizes allowed for traffic that is mapped onto those VCs.

One of the key usage models of the WRR scheme is support for QoS policy where different QoS levels can be provided using different weights.

Although weights can be fixed (by hardware implementation) for certain applications, to provide more generic support for different applications, components that support the WRR scheme are recommended to implement programmable WRR. Programming of WRR is controlled using the software interface defined in Sections 7.9.1 and 7.9.2.

126. Note that this does not imply equivalence and fairness in the terms of bandwidth usage.

6.3.3.3 Port Arbitration - Arbitration Within VC §

For Switches, Port Arbitration refers to the arbitration at an Egress Port between traffic coming from other Ingress Ports that is mapped to the same VC. For Root Ports, Port Arbitration refers to the arbitration at a Root Egress Port between peer-to-peer traffic coming from other Root Ingress Ports that is mapped to the same VC. For RCRBs, Port Arbitration refers to the arbitration at the RCRB (e.g., for host memory) between traffic coming from Root Ports that is mapped to the same VC. An inherent prioritization scheme for arbitration among VCs in this context is not applicable since it would imply strict arbitration priority for different Ports. Traffic from different Ports can be arbitrated using the following supported schemes:

- Hardware-fixed arbitration scheme, e.g., Round Robin
- Programmable WRR arbitration scheme
- Programmable Time-based WRR arbitration scheme

Hardware-fixed RR or RR-like scheme is the simplest to implement since it does not require any programmability. It makes all Ports equal priority, which is acceptable for applications where no software-managed differentiation or per-Port-based bandwidth budgeting is required.

Programmable WRR allows flexibility since it can operate as flat RR or if differentiation is required, different weights can be applied to traffic coming from different Ports in the similar manner as described in § Section 6.3.3.2 . This scheme is used where different allocation of bandwidth needs to be provided for different Ports.

A Time-based WRR is used for applications where not only different allocation of bandwidth is required but also a tight control of usage of that bandwidth. This scheme allows control of the amount of traffic that can be injected from different Ports within a certain fixed period of time. This is required for certain applications such as isochronous services, where traffic needs to meet a strict deadline requirement. § Section 6.3.4 provides basic rules to support isochronous applications. For more details on time-based arbitration and on the isochronous service as a usage model for this arbitration scheme refer to Appendix A.

6.3.3.4 Multi-Function Devices and Function Arbitration §

The multi-Function arbitration model defines an optional arbitration infrastructure and functionality within a Multi-Function Device. This functionality is needed to support a set of arbitration policies that control traffic contention for the device's Upstream Egress Port from its multiple Functions.

§ Figure 6-10 shows a conceptual model of a Multi-Function Device highlighting resources and associated functionality. Note that each Function optionally contains a VC Extended Capability structure, which if present manages TC/VC mapping, optional Port Arbitration, and optional VC Arbitration, all within the Function. The MFVC Extended Capability structure manages TC/VC mapping, optional Function Arbitration, and optional VC Arbitration for the device's Upstream Egress Port. Together these resources enable enhanced QoS management for Upstream requests. However, unlike a complete Switch with devices on its Downstream Ports, the Multi-Function Device model does not support full QoS management for peer-to-peer requests between Functions or for Downstream requests.

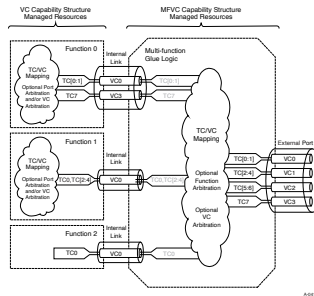

Figure 6-10 Multi-Function Arbitration Model §

QoS for an Upstream request originating at a Function is managed as follows. First, a Function-specific mechanism applies a TC to the request. For example, a device driver might configure a Function to tag all its requests with TC7.

Next, if the Function contains a VC Extended Capability structure, it specifies the TC/VC mapping to one of the Function's VC resources (perhaps the Function's single VC resource). In addition, the VC Extended Capability structure supports the enablement and configuration of the Function's VC resources.

If the Function is a Switch and the target VC resource supports Port Arbitration, this mechanism governs how the Switch's multiple Downstream Ingress Ports arbitrate for that VC resource. If the Port Arbitration mechanism supports time-based WRR, this also governs the injection rate of requests from each Downstream Ingress Port.

If the Function supports VC arbitration, this mechanism manages how the Function's multiple VC resources arbitrate for the conceptual internal link to the MFVC resources.

Once a request packet conceptually arrives at MFVC resources, address/routing information in the TLP header determines whether the request goes Upstream or peer-to-peer to another Function. For the case of peer-to-peer, QoS management is left to unarchitected device-specific mechanisms. For the case of Upstream, TC/VC mapping in the MFVC Extended Capability structure determines which VC resource the request will target. The MFVC Extended Capability structure also supports enablement and configuration of the VC resources in the multi-Function glue logic. If the target VC resource supports Function Arbitration, this mechanism governs how the multiple Functions arbitrate for this VC resource. If the Function Arbitration mechanism supports time-based WRR, this governs the injection rate of requests for each Function into this VC resource.

Finally, if the MFVC Extended Capability structure supports VC Arbitration, this mechanism governs how the MFVC's multiple VCs compete for the device's Upstream Egress Port. Independent of VC arbitration policy, management/control logic associated with each VC must observe transaction ordering and flow control rules before it can make pending traffic visible to the arbitration mechanism.

IMPLEMENTATION NOTE: MULTI-FUNCTION ARBITRATION ERROR BEHAVIOR §

§ Table 6-6 shows the expected error behavior associated with the example topology shown in § Figure 6-10.

Table 6-6 Multi-Function Arbitration Error Model Example §

Source	TC	Destination			
		Function 0	Function 1	Function 2	External Port
Function 0	0	n/a	OK	OK	OK
	1		MF @ F1	MF @ F2	OK
	2 - 6		MF @ F0	MF @ F0	MF @ F0
	7		MF @ F1	MF @ F2	OK
Function 1	0	OK	n/a	OK	OK
	1	MF @ F1		MF @ F1	MF @ F1
	2 - 4	MF @ F0		MF @ F2	OK
	5 - 7	MF @ F1		MF @ F1	MF @ F1
Function 2	0	OK	OK	n/a	OK
	1 - 7	MF @ F2	MF @ F2		MF @ F2
External Port	0	OK	OK	OK	n/a
	1	OK	MF @ F1	MF @ F2	
	2 - 4	MF @ F0	OK		
	5 - 6	MF @ F0	MF @ F1		
	7			OK	

Legend:

OK	Success
MF @ F0	Malformed TLP, reported at Function 0
MF @ F1	Malformed TLP, reported at Function 1
MF @ F2	Malformed TLP, reported at Function 2
n/a	Not Applicable (Function/Port sending to itself)

IMPLEMENTATION NOTE: MULTI-FUNCTION DEVICES WITHOUT THE MFVC EXTENDED CAPABILITY STRUCTURE §

If a Multi-Function Device lacks an MFVC Extended Capability structure, the arbitration of data flows from different Functions of a Multi-Function Device is beyond the scope of this specification.

However, as stated in this specification, if a Multi-Function Device supports TCs other than TC0 and does not implement an MFVC Extended Capability structure, it is required to implement a single VC Extended Capability structure in Function 0 to provide architected TC/VC mappings for the Link.

6.3.4 Isochronous Support §

Servicing isochronous data transfer requires a system to provide not only guaranteed data bandwidth but also deterministic service latency. The isochronous support mechanisms are defined to ensure that isochronous traffic receives its allocated bandwidth over a relevant period of time while also preventing starvation of the other traffic in the system. Isochronous support mechanisms apply to communication between Endpoint and Root Complex as well as to peer-to-peer communication.

Isochronous service is realized through proper use of mechanisms such as TC transaction labeling, VC data-transfer protocol, and TC-to-VC mapping. End-to-end isochronous service requires software to set up proper configuration along the path between the Requester and the Completer. This section describes the rules for software configuration and the rules hardware components must follow to provide end-to-end isochronous services. More information and background material regarding isochronous applications and isochronous service design guidelines can be found in Appendix A.

6.3.4.1 Rules for Software Configuration §

System software must obey the following rules to configure PCI Express fabric for isochronous traffic:

- Software must designate one or more TCs for isochronous transactions.
- Software must ensure that the Attribute fields of all isochronous requests targeting the same Completer are fixed and identical.
- Software must configure all VC resources used to support isochronous traffic to be serviced (arbitrated) at the requisite bandwidth and latency to meet the application objectives. This may be accomplished using strict priority, WRR, or hardware-fixed arbitration.
- Software should not intermix isochronous traffic with non-isochronous traffic on a given VC.
- Software must observe the Maximum Time Slots capability reported by the Port or RCRB.
- Software must not assign all Link capacity to isochronous traffic. This is required to ensure the requisite forward progress of other non-isochronous transactions to avoid false transaction timeouts.
- Software must limit the Max_Payload_Size for each path that supports isochronous to meet the isochronous latency. For example, all traffic flowing on a path from an isochronous capable device to the Root Complex should be limited to packets that do not exceed the Max_Payload_Size required to meet the isochronous latency requirements.

- Software must set Max_Read_Request_Size of an isochronous-configured device with a value that does not exceed the Max_Payload_Size set for the device.

6.3.4.2 Rules for Requesters §

A Requester requiring isochronous services must obey the following rules:

- The value in the Length field of read requests must never exceed Max_Payload_Size.
- If isochronous traffic targets the Root Complex and the RCRB indicates it cannot meet the isochronous bandwidth and latency requirements without requiring all transactions to set the No Snoop attribute bit, indicated by setting the Reject Snoop Transactions bit, then this bit must be set within the TLP header else the transaction will be rejected.

6.3.4.3 Rules for Completers §

A Completer providing isochronous services must obey the following rules:

- A Completer should not apply flow control induced backpressure to uniformly injected isochronous requests under normal operating conditions.
- A Completer must report its isochronous bandwidth capability in the Maximum Time Slots field in the VC Resource Capability register. Note that a Completer must account for partial writes.
- A Completer must observe the maximum isochronous transaction latency.
- A Root Complex as a Completer must implement at least one RCRB and support time-based Port Arbitration for the associated VCs. Note that time-based Port Arbitration only applies to request transactions.

6.3.4.4 Rules for Switches and Root Complexes §

A Switch providing isochronous services must obey the following rules. The same rules apply to Root Complexes that support isochronous data flows peer-to-peer between Root Ports, abbreviated in this section as “P2P-RC”.

- An isochronous-configured Switch or P2P-RC Port should not apply flow control induced backpressure to uniformly injected isochronous requests under normal operating conditions.
- An isochronous-configured Switch or P2P-RC Port must observe the maximum isochronous transaction latency.
- A Switch or P2P-RC component must support time-based Port Arbitration for each Port that supports one or more VCs capable of supporting isochronous traffic. Note that time-based Port Arbitration applies to request transactions but not to completion transactions.

6.3.4.5 Rules for Multi-Function Devices §

A Multi-Function Device that includes an MFVC Extended Capability structure providing isochronous services must obey the following rules:

- MFVC glue logic configured for isochronous operation should not apply backpressure to uniformly injected isochronous requests from its Functions under normal operating conditions.

- The MFVC Extended Capability structure must support time-based Function Arbitration for each VC capable of supporting isochronous traffic. Note that time-based Function Arbitration applies only to Upstream request transactions; it does not apply to any Downstream or peer-to-peer request transactions, nor to any completion transactions.

A Multi-Function Device that lacks an MFVC Extended Capability structure has no architected mechanism to provide isochronous services for its multiple Functions concurrently.

6.3.5 SVC and VC/MFVC Capability Coexistence §

The Virtual Channel Extended Capability (VC capability) and Multi-Function Virtual Channel Extended Capability (MFVC capability) are referred to as VC/MFVC capabilities. A Port is permitted to implement a Streamlined Virtual Channel Extended Capability (SVC capability) as well as one or more VC/MFVC capabilities. During Link training, VC0 in each VC/MFVC capability will automatically initialize, and VC0 in the SVC capability will remain disabled. This ensures backward compatibility with software that is unaware of SVC.

SVC capability is incompatible with VC/MFVC capabilities, and hardware mechanisms ensure that for a given Port, SVC capability is never enabled at the same time as VC/MFVC capabilities.

SVC-aware software chooses when to use SVC capability instead of VC/MFVC capabilities on a Port that implements both. Before configuring VC/MFVC capabilities, software Clears the Use VC/MFVC bit in the SVC Port Status register. Doing so immediately clears the VC Enable bit for each VC resource in every VC/MFVC capability (VC Resource Control Register or MFVC VC Resource Control Register). This also Sets the SVC VC Enable bit for VC0 in its SVC Resource Control Register. The Use VC/MFVC bit will remain Clear until the next Conventional Reset. This presents a simplified and consistent operational state, reducing hardware and software complexity.

If a Port implements an SVC capability and no VC/MFVC capabilities, the Use VC/MFVC bit in the SVC Port Status register must be hardwired to 0b. During Link training, VC0 in the SVC capability automatically initializes. See the Use VC/MFVC bit description for further required semantics.

6.4 Device Synchronization §

System software requires a “stop” mechanism for ensuring that there are no outstanding transactions for a particular device in a system. For example, without such a mechanism renumbering Bus Numbers during system operation may cause the Requester ID (which includes the Bus Number) for a given device to change while Requests or Completions for that device are still in flight, and may thus be rendered invalid due to the change in the Requester ID. It is also desirable to be able to ensure that there are no outstanding transactions during a Hot-Plug orderly removal.

The details of stop mechanism implementation depend on the device hardware, device driver software, and system software. However, the fundamental requirements which must be supported to allow system software management of the fabric include the abilities to:

- Block the device from generating new Requests
- Block the generation of Requests issued to the device
- Determine that all Requests being serviced by the device have been completed
- Determine that all non-posted Requests initiated by the device have completed
- Determine that all posted Requests initiated by the device have reached their destination

The ability of the driver and/or system software to block new Requests from the device is supported by the Bus Master Enable, SERR# Enable, and Interrupt Disable bits in the Command register (Section 7.5.1.1.3) of each device Function, and other such control bits.

Requests issued to the device are generally under the direct control of the driver, so system software can block these Requests by directing the driver to stop generating them (the details of this communication are system software specific). Similarly, Requests serviced by the device are normally under the device driver's control, so determining the completion of such requests is usually trivial.

The Transactions Pending bit provides a consistent way on a per-Function basis for software to determine that all non-posted Requests issued by the device have been completed (see § Section 7.5.3.5).

Determining that posted Requests have reached their destination is handled by generating a transaction to “flush” any outstanding Requests. Writes to system memory using TC0 will be flushed by host reads of the device, and so require no explicit flush protocol. Writes using TCs other than TC0 require some type of flush synchronization mechanism. The mechanism itself is implementation specific to the device and its driver software. However, in all cases the device hardware and software implementers should thoroughly understand the ordering rules described in § Section 2.4. This is especially true if the Relaxed Ordering or ID-Based Ordering attributes are set for any Requests initiated by the device.

IMPLEMENTATION NOTE: FLUSH MECHANISMS §

In a simple case such as that of an Endpoint communicating only with host memory through TC0, “flush” can be implemented simply by reading from the Endpoint. If the Endpoint issues writes to main memory using TCs other than TC0, “flush” can be implemented with a memory read on the corresponding TCs directed to main memory. The memory read needs to be performed on all TCs that the Endpoint is using.

If a memory read is used to “flush” outstanding transactions, but no actual read is required, it may be desirable to use the zero-length read semantic described in § Section 2.2.5.

Peer-to-peer interaction between devices requires an explicit synchronization protocol between the involved devices, even if all communication is through TC0. For a given system, the model for managing peer-to-peer interaction must be established. System software, and device hardware and software must then conform to this model. The requirements for blocking Request generation and determining completion of Requests match the requirements for non-peer interaction, however the determination that Posted Requests have reached peer destination device(s) requires an explicit synchronization mechanism. The mechanism itself is implementation specific to the device, its driver software, and the model used for the establishment and disestablishment of peer communications.

6.5 Locked Transactions §

6.5.1 Introduction §

Locked Transaction support is required to prevent deadlock in systems that use legacy software which causes the accesses to I/O devices. Note that some CPUs may generate locked accesses as a result of executing instructions that implicitly trigger lock. Some legacy software misuses these transactions and generates locked sequences even when exclusive access is not required. Since locked accesses to I/O devices introduce potential deadlocks apart from those mentioned above, as well as serious performance degradation, PCI Express Endpoints are prohibited from supporting locked accesses, and new software must not use instructions which will cause locked accesses to I/O devices. Legacy Endpoints support locked accesses only for compatibility with existing software.

Only the Root Complex is allowed to initiate Locked Requests on PCI Express. Locked Requests initiated by Endpoints and Bridges are not supported. This is consistent with limitations for locked transaction use outlined in [PCI] (§ Appendix F. - Exclusive Accesses).

This section specifies the rules associated with supporting locked accesses from the Host CPU to Legacy Endpoints, including the propagation of those transactions through Switches and PCI Express/PCI Bridges.

6.5.2 Initiation and Propagation of Locked Transactions - Rules §

Locked transaction sequences are generated by the Host CPU(s) as one or more reads followed by a number of writes to the same location(s). When a lock is established, all other traffic is blocked from using the path between the Root Complex and the locked Legacy Endpoint or Bridge.

- A locked transaction sequence or attempted locked transaction sequence is initiated on PCI Express using the “lock”-type Read Request/Completion (MRdLk/CplDLk) and terminated with the Unlock Message
 - Locked Requests which are completed with a status other than Successful Completion do not establish lock (explained in detail in the following sections)
 - Regardless of the status of any of the Completions associated with a locked sequence, all locked sequences and attempted locked sequences must be terminated by the transmission of an Unlock Message.
 - MRdLk, CplDLk, and Unlock semantics are allowed only for the default Traffic Class (TC0)
 - Only one locked transaction sequence attempt may be in progress at a given time within a single hierarchy domain
- The Unlock Message is sent from the Root Complex down the locked transaction path to the Completer, and may be broadcast from the Root Complex to all Endpoints and Bridges
 - Any device which is not involved in the locked sequence must ignore this Message
- Any violation of the rules for initiation and propagation of locked transactions can result in undefined device and/or system behavior
 - The initiation and propagation of a locked transaction sequence through PCI Express is performed as follows:
- A locked transaction sequence is started with a MRdLk Request
 - Any successive reads for the locked transaction sequence must also use MRdLk Requests
 - The Completions for any MRdLk Request use the CplDLk Completion type for successful Requests, and the CplLk Completion type for unsuccessful Requests
- If any read associated with a locked sequence is completed unsuccessfully, the Requester must assume that the atomicity of the lock is no longer assured, and that the path between the Requester and Completer is no longer locked
- All writes for the locked sequence use MWr Requests
- The Unlock Message is used to indicate the end of a locked sequence
 - A Switch propagates Unlock Messages to the locked Egress Port
- Upon receiving an Unlock Message, a Legacy Endpoint or Bridge must unlock itself if it is in a locked state
 - If not locked, or if the Receiver is a PCI Express Endpoint or Bridge which does not support lock, the Unlock Message is ignored and discarded

6.5.3 Switches and Lock - Rules §

Switches must distinguish transactions associated with locked sequences from other transactions to prevent other transactions from interfering with the lock and potentially causing deadlock. The following rules cover how this is done. Note that locked accesses are limited to TC0, which is always mapped to VC0.

- When a Switch propagates a MRdLk Request from the Ingress Port (closest to the Root Complex) to the Egress Port, it must block all Requests which map to the default Virtual Channel (VC0) from being propagated to the Egress Port
 - If a subsequent MRdLk Request is Received at this Ingress Port addressing a different Egress Port, the behavior of the Switch is undefined

Note: This sort of split-lock access is not supported by PCI Express and software must not cause such a locked access. System deadlock may result from such accesses.
- When the CplDLk for the first MRdLk Request is returned, if the Completion indicates a Successful Completion status, the Switch must block all Requests from all other Ports from being propagated to either of the Ports involved in the locked access, except for Requests which map to non-VC0 on the Egress Port
- The two Ports involved in the locked sequence must remain blocked as described above until the Switch receives the Unlock Message (at the Ingress Port for the initial MRdLk Request)
 - The Unlock Message must be forwarded to the locked Egress Port
 - The Unlock Message may be broadcast to all other Ports
 - The Ingress Port is unblocked once the Unlock Message arrives, and the Egress Port(s) which were blocked are unblocked following the Transmission of the Unlock Message out of the Egress Ports
 - Ports which were not involved in the locked access are unaffected by the Unlock Message

6.5.4 PCI Express/PCI Bridges and Lock - Rules §

The requirements for PCI Express/PCI Bridges are similar to those for Switches, except that, because PCI Express/PCI Bridges use only the default Virtual Channel and Traffic Class, all other traffic is blocked during the locked access. The requirements on the PCI bus side of the PCI Express/PCI Bridge match the requirements for a PCI/PCI Bridge (see [\[PCI-to-PCI-Bridge\]](#) and [\[PCIe-to-PCI-PCI-X-Bridge\]](#)).

6.5.5 Root Complex and Lock - Rules §

A Root Complex is permitted to support locked transactions as a Requester. If locked transactions are supported, a Root Complex must follow the sequence described in [§ Section 6.5.2](#) to perform a locked access. The mechanisms used by the Root Complex to interface PCI Express to the Host CPU(s) are outside the scope of this document.

6.5.6 Legacy Endpoints §

Legacy Endpoints are permitted to support locked accesses, although their use is discouraged. If locked accesses are supported, Legacy Endpoints must handle them as follows:

- The Legacy Endpoint becomes locked when it Transmits the first Completion for the first Read Request of the locked access with a Successful Completion status
 - If the completion status is not Successful Completion, the Legacy Endpoint does not become locked

- Once locked, the Legacy Endpoint must remain locked until it receives the Unlock Message
- While locked, a Legacy Endpoint must not issue any Requests using TCs which map to the default Virtual Channel (VC0)
Note that this requirement applies to all possible sources of Requests within the Endpoint, in the case where there is more than one possible source of Requests.
 - Requests may be issued using TCs which map to VCs other than the default Virtual Channel

6.5.7 PCI Express Endpoints §

PCI Express Endpoints do not support lock. A PCI Express Endpoint must treat a MRdLk Request as an Unsupported Request (see § Chapter 2.).

6.6 PCI Express Reset - Rules §

This section specifies the PCI Express Reset mechanisms. This section covers the relationship between the architectural mechanisms defined in this document and the reset mechanisms defined in this document. Any relationship between the PCI Express Conventional Reset and component or platform reset is component or platform specific (except as explicitly noted).

6.6.1 Conventional Reset §

Conventional Reset includes all reset mechanisms other than Function Level Reset. There are two categories of Conventional Resets: Fundamental Reset and resets that are not Fundamental Reset. This section applies to all types of Conventional Reset.

In all form factors and system hardware configurations, there must, at some level, be a hardware mechanism for setting or returning all Port states to the initial conditions specified in this document - this mechanism is called “Fundamental Reset”. This mechanism can take the form of an auxiliary signal provided by the system to a component or adapter card, in which case the signal must be called PERST#, and must conform to the rules specified in § Section 4.2.5.9.1 . When PERST# is provided to a component or adapter, this signal must be used by the component or adapter as Fundamental Reset. When PERST# is not provided to a component or adapter, Fundamental Reset is generated autonomously by the component or adapter, and the details of how this is done are outside the scope of this document. If a Fundamental Reset is generated autonomously by the component or adapter, and if power is supplied by the platform to the component/adapter, the component/adapter must generate a Fundamental Reset to itself if the supplied power goes outside of the limits specified for the form factor or system.

- There are three distinct types of Conventional Reset: Cold, Warm, and Hot:
 - A Fundamental Reset must occur following the application of power to the component. This is called a Cold Reset.
 - In some cases, it may be possible for the Fundamental Reset mechanism to be triggered by hardware without the removal and re-application of power to the component. This is called a Warm Reset.
 - This document does not specify a means for generating a Warm or Cold Reset.
 - There is an in-band mechanism for propagating Conventional Reset across a Link. This is called a Hot Reset and is described in § Section 4.2.5.9.2 .

There is an in-band mechanism for software to force a Link into Electrical Idle, “disabling” the Link. The Disabled LTSSM state is described in § Section 4.2.6.10 , the Link Disable control bit is described

in § Section 7.5.3.7, and the Downstream Port Containment mechanism is described in § Section 6.2.11. Disabling a Link causes Downstream components to undergo a hot reset.

See § Section 2.9 for additional requirements regarding the effects of the Data Link Layer reporting DL_Down status, and how those effects relate to hot reset.

- On exit from any type of Conventional Reset (cold, warm, or hot), all Port registers and state machines must be set to their initialization values as specified in this document, except for sticky registers (see § Section 7.4).
 - Note that, from a device point of view, any type of Conventional Reset (cold, warm, hot, or DL_Down) has the same effect at the Transaction Layer and above as would RST# assertion and deassertion in conventional PCI.
- On exit from a Fundamental Reset, the Physical Layer will attempt to bring up the Link (see § Section 4.2.6). Once both components on a Link have entered the initial Link Training state, they will proceed through Link initialization for the Physical Layer and then through Flow Control initialization for VC0, making the Data Link and Transaction Layers ready to use the Link.
 - Following Flow Control initialization for VC0, it is possible for TLPs and DLLPs to be transferred across the Link.

Following exit from a Conventional Reset, some devices may require additional time before they are able to respond to Requests they receive. Particularly for Configuration Requests it is necessary that components and devices behave in a deterministic way, which the following rules address.

The first set of rules addresses requirements for components and devices:

- A component that supports Link speeds greater than 5.0 GT/s must enter the LTSSM Detect state within 100 ms of the end of Fundamental Reset (Link Training is described in § Section 4.2.5). A component that supports only Link speeds 5.0 GT/s or less must do this within 20 ms. All components are strongly encouraged to minimize this time period. This also applies to Retimers, see § Section 4.3.4.
 - Note: In some systems, it is possible that the components on a Link may exit Fundamental Reset at different times. Each component must observe the requirement to enter the initial active Link Training state within the applicable time period based on the end of Fundamental Reset from its own point of view.
- On the completion of Link Training (entering the DL_Active state, see § Section 3.2), a component must be able to receive and process TLPs and DLLPs.
- Following exit from a Conventional Reset of a device, within 1.0 s the device must be able to receive a Configuration Request and return a Successful Completion if the Request is valid. This period is independent of how quickly Link training completes. If Readiness Notifications mechanisms are used (see § Section 6.22.), this period may be shorter, or, with appropriate system support, longer.

The second set of rules addresses requirements placed on the system:

- To allow components to perform internal initialization, system software must wait a specified minimum period following exit from a Conventional Reset of one or more devices before it is permitted to issue Configuration Requests to those devices, unless Readiness Notifications mechanisms are used (see § Section 6.22). System software is also exempted from these minimum waiting period requirements if it knows of the specific device's requirements via means outside the scope of this specification.
- System software is permitted to immediately issue Configuration Requests to a device/Function if Immediate Readiness is indicated by the device/Function (see § Section 3.3 and § Section 7.9.16 for two ways Immediate Readiness support is permitted to be indicated)
- System software is permitted to immediately issue Configuration Requests to a device/Function below a Downstream Port if the DRS Message Received bit is Set.

- Devices that support Flit Mode are required to implement DRS
- Because DRS *MUST@FLIT* be supported, system software can use the Downstream Component Presence and Flit Mode Status fields in a Downstream Port to determine that DRS is supported by the attached Device. For cases where system software cannot determine that DRS is supported by the attached device, or by the Downstream Port above the attached device:
 - With a Downstream Port that does not support Link speeds greater than 5.0 GT/s, software must wait a minimum of 100 ms following exit from a Conventional Reset before sending a Configuration Request to the device immediately below that Port.
 - With a Downstream Port that supports Link speeds greater than 5.0 GT/s, software must wait a minimum of 100 ms after Link training completes before sending a Configuration Request to the device immediately below that Port. Software can determine when Link training completes by polling the Data Link Layer Link Active bit or by setting up an associated interrupt (see § Section 6.7.3.3). It is strongly recommended for software to use this mechanism whenever the Downstream Port supports it.
 - For a Device that implements the Readiness Time Reporting Extended Capability, and has reported a Reset Time shorter than 100ms, software is permitted to send a Configuration Request to the Device after waiting the reported Reset Time from Conventional Reset.
 - A system must guarantee that all components intended to be software visible at boot time are ready to receive Configuration Requests within the applicable minimum period based on the end of Conventional Reset at the Root Complex - how this is done is beyond the scope of this specification.
 - It is strongly recommended that software use 100 ms wait periods only if software enables Configuration RRS Software Visibility. Otherwise, Completion timeouts, platform timeouts, or lengthy processor instruction stalls may result. See the Request Retry Status for Configuration Requests Implementation Note in § Section 2.3.1.
 - Unless Readiness Notifications mechanisms are used, the Root Complex and/or system software must allow at least 1.0 s following exit from a Conventional Reset of a device, before determining that the device is broken if it fails to return a Successful Completion status for a valid Configuration Request. This period is independent of how quickly Link training completes.
Note: This delay is analogous to the T_{rhfa} parameter specified for PCI/PCI-X, and is intended to allow an adequate amount of time for devices which require self initialization.
- When attempting a Configuration access to devices on a PCI or PCI-X bus segment behind a PCI Express/PCI(-X) Bridge, the timing parameter T_{rhfa} must be respected.

For this second set of rules, if system software does not have direct visibility into the state of Fundamental Reset (e.g., Hot-Plug; see § Section 6.7), software must base these timing parameters on an event known to occur after the end of Fundamental Reset.

When a Link is in normal operation, the following rules apply:

- If, for whatever reason, a normally operating Link goes down, the Transaction and Data Link Layers will enter the DL_Inactive state (see § Section 2.9 and § Section 3.2.1).
- For any Root or Switch Downstream Port, setting the Secondary Bus Reset bit of the Bridge Control Register associated with the Port must cause a hot reset to be sent (see § Section 4.2.5.9.2).
- For a Switch, the following must cause a hot reset to be sent on all Downstream Ports:
 - Setting the Secondary Bus Reset bit of the Bridge Control Register associated with the Upstream Port
 - The Data Link Layer of the Upstream Port reporting DL_Down status. In Switches that support Link speeds greater than 5.0 GT/s, the Upstream Port must direct the LTSSM of each Downstream Port to the Hot Reset state, but not hold the LTSSMs in that state. This permits each Downstream Port to

begin Link training immediately after its hot reset completes. This behavior is recommended for all Switches.

- Receiving a hot reset on the Upstream Port

Certain aspects of Fundamental Reset are specified in this document and others are specific to a platform, form factor and/or implementation. Specific platforms, form factors or application spaces may require the additional specification of the timing and/or sequencing relationships between the components of the system for Fundamental Reset. For example, it might be required that all PCI Express components within a chassis observe the assertion and deassertion of Fundamental Reset at the same time (to within some tolerance). In a multi-chassis environment, it might be necessary to specify that the chassis containing the Root Complex be the last to exit Fundamental Reset.

In all cases where power and PERST# are supplied, the following parameters must be defined:

- T_{pvperl} - PERST# must remain asserted at least this long after power becomes valid
- T_{perst} - When asserted, PERST# must remain asserted at least this long
- T_{fail} - When power becomes invalid, PERST# must be asserted within this time
- $T_{perstslw}$ - The slew rate of PERST# transition to deasserted through its logic input switching range. $T_{perstslw}$ is specified as a minimum of 50 mV/ns unless the form factor specification states otherwise.

Additional parameters may be specified.

In all cases where a reference clock is supplied, the following parameter must be defined:

- $T_{perst-clk}$ - PERST# must remain asserted at least this long after any supplied reference clock is stable

Additional parameters may be specified.

6.6.2 Function Level Reset (FLR) §

The FLR mechanism enables software to quiesce and reset Endpoint hardware with Function-level granularity. Three example usage models illustrate the benefits of this feature:

- In some systems, it is possible that the software entity that controls a Function will cease to operate normally. To prevent data corruption, it is necessary to stop all PCI Express and external I/O (not PCI Express) operations being performed by the Function. Other defined reset operations do not guarantee that external I/O operations will be stopped.
- In a partitioned environment where hardware is migrated from one partition to another, it is necessary to ensure that no residual “knowledge” of the prior partition be retained by hardware, for example, a user’s secret information entrusted to the first partition but not to the second. Further, due to the wide range of Functions, it is necessary that this be done in a Function-independent way.
- When system software is taking down the software stack for a Function and then rebuilding that stack, it is sometimes necessary to return the state to an uninitialized state before rebuilding the Function’s software stack.

Implementation of FLR is optional (not required), but is strongly recommended.

FLR applies on a per Function basis. Only the targeted Function is affected by the FLR operation. The Link state must not be affected by an FLR.

FLR modifies the Function state described by this specification as follows:

- Function registers and Function-specific state machines must be set to their initialization values as specified in this document, except that in the following cases, the values are not affected by FLR:
 - sticky-type registers (ROS, RWS, RW1CS)
 - registers defined as type HwInit
 - these other fields or registers:
 - Captured Slot Power Limit Value in the Device Capabilities Register
 - Captured Slot Power Limit Scale in the Device Capabilities Register
 - Max_Payload_Size in the Device Control Register
 - Active State Power Management (ASPM) Control in the Link Control Register
 - Read Completion Boundary (RCB) in the Link Control Register
 - Common Clock Configuration in the Link Control Register
 - Extended Synch in the Link Control Register
 - Enable Clock Power Management in the Link Control Register
 - Hardware Autonomous Width Disable in Link Control Register
 - Hardware Autonomous Speed Disable in the Link Control 2 Register
 - Link Equalization Request 8.0 GT/s in the Link Status 2 Register
 - Link Equalization Request 16.0 GT/s in the 16.0 GT/s Status Register
 - Enable Lower SKP OS Generation Vector in the Link Control 3 register
 - Lane Equalization Control Register in the Secondary PCI Express Extended Capability structure
 - 16.0 GT/s Lane Equalization Control Register in the Physical Layer 16.0 GT/s Extended Capability structure
 - All registers in the Virtual Channel Extended Capability structure
 - All registers in the Multi-Function Virtual Channel Extended Capability structure
 - All registers in the Streamlined Virtual Channel Extended Capability structure
 - All registers in the Data Link Feature Extended Capability structure
 - All registers in the Physical Layer 16.0 GT/s Extended Capability structure
 - All registers in the Physical Layer 32.0 GT/s Extended Capability structure
 - All registers in the Physical Layer 64.0 GT/s Extended Capability structure
 - All registers in the Lane Margining at the Receiver Extended Capability structure
 - All registers in the Flit Logging Extended Capability structure
 - All registers in the Flit Error Injection Extended Capability structure
 - All registers in the Flit Performance Measurement Extended Capability structure
 - CMA-SPDM session state
- The following registers *MUST@FLIT* also not reset to their initialization values:
 - ARI Control Register in the ARI Extended Capability Structure
 - All registers in the L1 PM Substates Extended Capability structure
 - All registers in the Latency Tolerance Reporting Extended Capability structure
 - All registers in the Precision Time Measurement Extended Capability structure

Note that the controls that enable the Function to initiate requests on PCI Express are cleared, including Bus Master Enable, MSI Enable, and the like, effectively causing the Function to become quiescent on the Link.

Note that Port state machines associated with Link functionality including those in the Physical and Data Link Layers are not reset by FLR, and VC0 remains initialized following an FLR.

- Any outstanding INTx interrupt asserted by the Function must be deasserted by sending the corresponding Deassert_INTx Message prior to starting the FLR.

Note that when the FLR is initiated to a Function of a Multi-Function Device, if another Function continues to assert a matching INTx, no Deassert_INTx Message will be transmitted.

After an FLR has been initiated by writing a 1b to the Initiate Function Level Reset bit, the Function must complete the FLR within 100 ms. If software initiates an FLR when the Transactions Pending bit is 1b, then software must not initialize the Function until allowing adequate time for any associated Completions to arrive, or to achieve reasonable certainty that any remaining Completions will never arrive. For this purpose, it is recommended that software allow as much time as provided by the pre-FLR value for Completion Timeout on the device. If Completion Timeouts were disabled on the Function when FLR was issued, then the delay is system dependent but must be no less than 100 ms. If Function Readiness Status (FRS - see § Section 6.22.2) is implemented, then system software is permitted to issue Configuration Requests to the Function immediately following receipt of an FRS Message indicating Configuration-Ready, however, this does not necessarily indicate that outstanding Requests initiated by the Function have completed.

Note that upon receipt of an FLR, a device Function may either clear all transaction status including Transactions Pending or set the Completion Timeout to its default value so that all pending transactions will time out during FLR execution. Regardless, the Transactions Pending bit must be clear upon completion of the FLR.

Since FLR modifies Function state not described by this specification (in addition to state that is described by this specification), it is necessary to specify the behavior of FLR using a set of criteria that, when applied to the Function, show that the Function has satisfied the requirements of FLR. The following criteria must be applied using Function-specific knowledge to evaluate the Function's behavior in response to an FLR:

- The Function must not give the appearance of an initialized adapter with an active host on any external interfaces controlled by that Function. The steps needed to terminate activity on external interfaces are outside of the scope of this specification.
 - For example, a network adapter must not respond to queries that would require adapter initialization by the host system or interaction with an active host system, but is permitted to perform actions that it is designed to perform without requiring host initialization or interaction. If the network adapter includes multiple Functions that operate on the same external network interface, this rule affects only those aspects associated with the particular Function reset by FLR.
- The Function must not retain within itself software readable state that potentially includes secret information associated with any preceding use of the Function. Main host memory assigned to the Function must not be modified by the Function.
 - For example, a Function with internal memory readable directly or indirectly by host software must clear or randomize that memory.
- The Function must return to a state such that normal configuration of the Function's PCI Express interface will cause it to be useable by drivers normally associated with the Function

When an FLR is initiated, the targeted Function must behave as follows:

- The Function must return the Completion for the configuration write that initiated the FLR operation and then initiate the FLR.
- While an FLR is in progress:

- If a Request arrives, the Request is permitted to be silently discarded (following update of flow control credits) without logging or signaling it as an error.
- If a Completion arrives, the Completion is permitted to be handled as an Unexpected Completion or to be silently discarded (following update of flow control credits) without logging or signaling it as an error.
- While a Function is required to complete the FLR operation within the time limit described above, the subsequent Function-specific initialization sequence may require additional time. If additional time is required, the Function must return a Request Retry Status (RRS) Completion Status when a Configuration Request is received after the time limit above. After the Function responds to a Configuration Request with a Completion status other than RRS, it is not permitted to return RRS in response to a Configuration Request until it is reset again.

IMPLEMENTATION NOTE:

AVOIDING DATA CORRUPTION FROM STALE COMPLETIONS §

An FLR causes a Function to lose track of any outstanding non-posted Requests. Any corresponding Completions that later arrive are referred to as being "stale". If software issues an FLR while there are outstanding Requests, and then re-enables the Function for operation without waiting for potential stale Completions, any stale Completions that arrive afterwards may cause data corruption by being mistaken by the Function as belonging to Requests issued since the FLR.

Software can avoid data corruption from stale Completions in a variety of ways. Here's a possible algorithm:

1. Software that's performing the FLR synchronizes with other software that might potentially access the Function directly, and ensures such accesses do not occur during this algorithm.
2. Software clears the entire Command register, disabling the Function from issuing any new Requests.
3. Software polls the Transactions Pending bit in the Device Status register either until it is clear or until it has been long enough that software is reasonably certain that Completions associated with any remaining outstanding Transactions will never arrive. On many platforms, the Transactions Pending bit will usually clear within a few milliseconds, so software might choose to poll during this initial period using a tight software loop. On rare cases when the Transactions Pending bit does not clear by this time, software will need to poll for a much longer platform-specific period (potentially seconds), so software might choose to conduct this polling using a timer-based interrupt polling mechanism.
4. Software initiates the FLR.
5. Software waits 100 ms.
6. Software reconfigures the Function and enables it for normal operation.

6.7 PCI Express Native Hot-Plug §

The PCI Express architecture is designed to natively support both hot-add and hot-removal ("hot-plug") of cables, add-in cards, and modules. PCI Express native hot-plug provides a "toolbox" of mechanisms that allow different user/operator models to be supported using a self-consistent infrastructure. These mechanisms may be used to implement orderly addition/removal that relies on coordination with the operating system (e.g., traditional PCI hot-plug), as well as async removal, which proceeds without lock-step synchronization with the operating system. This section defines the set of hot-plug mechanisms and specifies how the elements of hot-plug, such as indicators and push buttons, must behave if implemented in a system.

6.7.1 Elements of Hot-Plug §

§ Table 6-7 lists the physical elements comprehended in this specification for support of hot-plug models. A form factor specification must define how these elements are used in that form factor. For a given form factor specification, it is possible that only some of the available hot-plug elements are required, or even that none of these elements are required. In all cases, the form factor specification must define all assumptions and limitations placed on the system or the user by the choice of elements included. Silicon component implementations that are intended to be used only with selected form factors are permitted to support only those elements that are required by the associated form factor(s).

Table 6-7 Elements of Hot-Plug §

Element	Purpose
Indicators	Show the power and attention state of the slot
Manually-operated Retention Latch (MRL)	Holds adapter in place
MRL Sensor	Allows the Port and system software to detect the MRL being opened
Electromechanical Interlock	Prevents removal of adapter from slot
Attention Button	Allows user to request hot-plug operations
Software User Interface	Allows user to request hot-plug operations
Slot Numbering	Provides visual identification of slots
Power Controller	Software-controlled electronic component or components that control power to a slot or adapter and monitor that power for fault conditions
Out-of-band Presence Detect	Method of determining physical presence of an adapter in a slot that does not rely on the Physical Layer

6.7.1.1 Indicators §

Two indicators are defined: the Power Indicator and the Attention Indicator. Each indicator is in one of three states: on, off, or blinking. Hot-plug system software has exclusive control of the indicator states by writing the command registers associated with the indicator (with one exception noted below). The indicator requirements must be included in all form factor specifications. For a given form factor, the indicators may be required or optional or not applicable at all.

The hot-plug capable Port controls blink frequency, duty cycle, and phase of the indicators. Blinking indicators must operate at a frequency of between 1 and 2 Hz, with a 50% (+/- 5%) duty cycle. Blinking indicators are not required to be synchronous or in-phase between Ports.

Indicators may be physically located on the chassis or on the adapter (see the associated form factor specification for Indicator location requirements). Regardless of the physical location, logical control of the indicators is by the Downstream Port of the Upstream component on the Link.

The Downstream Port must not change the state of an indicator unless commanded to do so by software, except for platforms capable of detecting stuck-on power faults (relevant only when a power controller is implemented). In the case of a stuck-on power fault, the platform is permitted to override the Downstream Port and force the Power Indicator to be on (as an indication that the adapter should not be removed). The handling by system software of stuck-on faults is optional and not described in this specification. Therefore, the platform vendor must ensure that this feature, if implemented, is addressed via other software, platform documentation, or by other means.

6.7.1.1.1 Attention Indicator §

The Attention Indicator, which must be yellow or amber in color, indicates that an operational problem exists or that the hot-plug slot is being identified so that a human operator can locate it easily.

Table 6-8 Attention Indicator States §

Indicator Appearance	Meaning
Off	Normal - Normal operation
On	Attention - Operational problem at this slot
Blinking	Locate - Slot is being identified at the user's request

Attention Indicator Off

The Attention Indicator in the Off state indicates that neither the adapter (if one is present) nor the hot-plug slot requires attention.

Attention Indicator On

The Attention Indicator in the On state indicates that an operational problem exists at the adapter or slot.

An operational problem is a condition that prevents continued operation of an adapter. The operating system or other system software determines whether a specific condition prevents continued operation of an adapter and whether lighting the Attention Indicator is appropriate. Examples of operational problems include problems related to external cabling, adapter, software drivers, and power faults. In general, the Attention Indicator in the On state indicates that an operation was attempted and failed or that an unexpected event occurred.

The Attention Indicator is not used to report problems detected while validating the request for a hot-plug operation. Validation is a term applied to any check that system software performs to assure that the requested operation is viable, permitted, and will not cause problems. Examples of validation failures include denial of permission to perform a hot-plug operation, insufficient power budget, and other conditions that may be detected before a hot-plug request is accepted.

Attention Indicator Blinking

A blinking Attention Indicator indicates that system software is identifying this slot for a human operator to find. This behavior is controlled by a user (for example, from a software user interface or management tool).

6.7.1.1.2 Power Indicator §

The Power Indicator, which must be green in color, indicates the power state of the slot. § Table 6-9 lists the Power Indicator states.

Table 6-9 Power Indicator States §

Indicator Appearance	Meaning
Off	Power Off - Insertion or removal of the adapter is permitted.
On	Power On - Insertion or removal of the adapter is not permitted.
Blinking	Power Transition - Hot-plug operation is in progress and insertion or removal of the adapter is not permitted.

Power Indicator Off

The Power Indicator in the Off state indicates that insertion or removal of the adapter is permitted. Main power to the slot is off if required by the form factor. Note that, depending on the form factor, other power/signals may remain on, even when main power is off and the Power Indicator is off. In an example using the [CEM] form factor, if the platform provides Vaux to hot-plug slots and the MRL is closed, any signals switched by the MRL are connected to the slot even when the Power Indicator is off. Signals switched by the MRL are disconnected when the MRL is opened. System software must cause a slot's Power Indicator to be turned off when the slot is not powered and/or it is permissible to insert or remove an adapter. Refer to the appropriate form factor specification for details.

Power Indicator On

The Power Indicator in the On state indicates that the hot-plug operation is complete and that main power to the slot is On and that insertion or removal of the adapter is not permitted.

Power Indicator Blinking

A blinking Power Indicator indicates that the slot is powering up or powering down and that insertion or removal of the adapter is not permitted.

The blinking Power Indicator also provides visual feedback to the operator when the Attention Button is pressed or when hot-plug operation is initiated through the hot-plug software interface.

6.7.1.2 Manually-operated Retention Latch (MRL) §

An MRL is a manually-operated retention mechanism that holds an adapter in the slot and prevents the user from removing the device. The MRL rigidly holds the adapter in the slot so that cables may be attached without the risk of creating intermittent contact. MRLs that hold down two or more adapters simultaneously are permitted in platforms that do not provide MRL Sensors.

6.7.1.3 MRL Sensor §

The MRL Sensor is a switch, optical device, or other type of sensor that reports the position of a slot's MRL to the Downstream Port. The MRL Sensor reports closed when the MRL is fully closed and open at all other times (that is, if the MRL fully open or in an intermediate position).

If a power controller is implemented for the slot, the slot main power must be automatically removed from the slot when the MRL Sensor indicates that the MRL is open. If signals such as Vaux and SMBus are switched by the MRL, then these signals must be automatically removed from the slot when the MRL Sensor indicates that the MRL is open and must be restored to the slot when the MRL Sensor indicates that MRL has closed again. Refer to the appropriate form factor specification to identify the signals, if any, switched by the MRL.

Note that the Hot-Plug Controller does not autonomously change the state of either the Power Indicator or the Attention Indicator based on MRL sensor changes.

IMPLEMENTATION NOTE: MRL SENSOR HANDLING §

In the absence of an MRL sensor, for some form factors, out-of-band presence detect may be used to handle the switched signals. In this case, when out-of-band presence detect indicates the absence of an adapter in a slot, the switched signals will be automatically removed from the slot.

If an MRL Sensor is implemented without a corresponding MRL Sensor input on the Hot-Plug Controller, it is recommended that the MRL Sensor be routed to power fault input of the Hot-Plug Controller. This allows an active adapter to be powered off when the MRL is opened.

6.7.1.4 Electromechanical Interlock §

An electromechanical interlock is a mechanism for physically locking the adapter or MRL in place until system software releases it. The state of the electromechanical interlock is set by software and must not change except in response to a subsequent software command. In particular, the state of the electromechanical interlock must be maintained even when power to the hot-plug slot is removed.

The current state of the electromechanical interlock must be reflected at all times in the Electromechanical Interlock Status bit in the Slot Status register, which must be updated within 200 ms of any commanded change. Software must wait at least 1 second after issuing a command to toggle the state of the Electromechanical Interlock before another command to toggle the state can be issued. Systems may optionally expand control of interlocks to provide physical security of the adapter.

6.7.1.5 Attention Button §

The Attention Button is a momentary-contact push button switch, located adjacent to each hot-plug slot or on the adapter that is pressed by the user to initiate a hot-plug operation at that slot. Regardless of the physical location of the button, the signal is processed and indicated to software by hot-plug hardware associated with the Downstream Port corresponding to the slot.

The Attention Button must allow the user to initiate both hot add and hot remove operations regardless of the physical location of the button.

If present, the Power Indicator provides visual feedback to the human operator (if the system software accepts the request initiated by the Attention Button) by blinking. Once the Power Indicator begins blinking, a 5-second abort interval exists during which a second depression of the Attention Button cancels the operation.

If an operation initiated by an Attention Button fails for any reason, it is recommended that system software present an error message explaining the failure via a software user interface or add the error message to a system log.

6.7.1.6 Software User Interface §

System software provides a user interface that allows hot insertions and hot removals to be initiated and that allows occupied slots to be monitored. A detailed discussion of hot-plug user interfaces is operating system specific and is therefore beyond the scope of this document.

On systems with multiple hot-plug slots, the system software must allow the user to initiate operations at each slot independent of the states of all other slots. Therefore, the user is permitted to initiate a hot-plug operation on one slot

using either the software user interface or the Attention Button while a hot-plug operation on another slot is in process, regardless of which interface was used to start the first operation.

6.7.1.7 Slot Numbering §

A Physical Slot Identifier (as defined in [PCI-Hot-Plug-1.1], § Section 1.5) consists of an optional chassis number and the physical slot number of the slot. The physical slot number is a chassis unique identifier for a slot. System software determines the physical slot number from registers in the Port. Chassis number 0 is reserved for the main chassis. The chassis number for other chassis must be a non-zero value obtained from a PCI-to-PCI Bridge's Chassis Number register (see [PCI-to-PCI-Bridge], Section 13.4).

Regardless of the form factor associated with each slot, each physical slot number must be unique within a chassis.

IMPLEMENTATION NOTE:

DETERMINATION OF SLOT NUMBER INFORMATION §

The Slot Numbering Capability, as defined in the PCI-to-PCI Bridge Specification, is being considered for deprecation in future versions of this specification. System software should use other means to identify physical slot number or chassis ID. Examples include ACPI _DSM for PCI Express Slot Number method (see [Firmware]), ACPI _SUN method (see [UEFI]), and the SMBIOS Type 9 structure (see [SMBIOS]).

6.7.1.8 Power Controller §

The power controller is an element composed of one or more discrete components that acts under control of software to set the power state of the hot-plug slot as appropriate for the specific form factor. The power controller must also monitor the slot for power fault conditions (as defined in the associated form factor specification) that occur on the slot's main power rails and, if supported, auxiliary power rail.

If a power controller is not present, the power state of the hot-plug slot must be set automatically by the hot-plug controller in response to changes in the presence of an adapter in the slot.

The power controller monitors main and auxiliary power faults independently. If a power controller detects a main power fault on the hot-plug slot, it must automatically set its internal main power fault latch and remove main power from the hot-plug slot (without affecting auxiliary power). Similarly, if a power controller detects an auxiliary power fault on the hot-plug slot, it must automatically set its internal auxiliary power fault latch and remove auxiliary power from the hot-plug slot (without affecting main power). Power must remain off to the slot as long as the power fault condition remains latched, regardless of any writes by software to turn on power to the hot-plug slot. The main power fault latch is cleared when software turns off power to the hot-plug slot. The mechanism by which the auxiliary power fault latch is cleared is form factor specific but generally requires auxiliary power to be removed from the hot-plug slot. For example, one form factor may remove auxiliary power when the MRL for the slot is opened while another may require the adapter to be physically removed from the slot. Refer to the associated form factor specifications for specific requirements.

Since the Power Controller Control bit in the Slot Control register reflects the last value written and not the actual state of the power controller, this means there may be an inconsistency between the value of the Power Controller Control bit and the state of the power to the slot in a power fault condition. To determine whether slot is off due to a power fault, software must use the power fault software notification to detect power faults. To determine that a requested power-up operation has otherwise failed, software must use the hot-plug slot power-up time out mechanism described in § Section 6.7.3.3 .

Software must not assume that writing to the Slot Control register to change the power state of a hot-plug slot causes an immediate power state transition. After turning power on, software must wait for a Data Link Layer State Changed event,

as described in § Section 6.7.3.3 . After turning power off, software must wait for at least 1 second before taking any action that relies on power having been removed from the hot-plug slot. For example, software is not permitted to turn off the power indicator (if present) or attempt to turn on the power controller before completing the 1 second wait period.

6.7.2 Registers Grouped by Hot-Plug Element Association §

The registers described in this section are grouped by hot-plug element to convey all registers associated with implementing each element. Register fields associated with each Downstream Port implementing a hot-plug capable slot are located in the Device Capabilities, Slot Capabilities, Slot Control, Slot Status, and Slot Capabilities 2 registers in the PCI Express Capability structure (see § Section 7.5.3). Registers reporting the presence of hot-plug elements associated with the device Function on an adapter are located in the Device Capabilities register (also in the PCI Express Capability structure).

6.7.2.1 Attention Button Registers §

Attention Button Present (Slot Capabilities Register and Device Capabilities Register) - This bit indicates if an Attention Button is electrically controlled by the chassis (Slot Capabilities Register) or by the adapter (Device Capabilities Register).

Attention Button Pressed (Slot Status Register) - This bit is Set when an Attention Button electrically controlled by the chassis is pressed.

Attention Button Pressed Enable (Slot Control Register) - When Set, this bit enables software notification on an Attention Button Pressed event (see § Section 6.7.3.4).

6.7.2.2 Attention Indicator Registers §

Attention Indicator Present (Slot Capabilities Register and Device Capabilities Register) - This bit indicates if an Attention Indicator is electrically controlled by the chassis (Slot Capabilities Register) or by the adapter (Device Capabilities Register).

Attention Indicator Control (Slot Control Register) - When written, sets an Attention Indicator electrically controlled by the chassis to the written state.

6.7.2.3 Power Indicator Registers §

Power Indicator Present (Slot Capabilities Register and Device Capabilities Register) - This bit indicates if a Power Indicator is electrically controlled by the chassis (Slot Capabilities Register) or by the adapter (Device Capabilities Register).

Power Indicator Control (Slot Control Register) - When written, sets a Power Indicator electrically controlled by the chassis to the written state.

6.7.2.4 Power Controller Registers §

Power Controller Present (Slot Capabilities Register) - This bit indicates if a Power Controller is implemented.

Power Controller Control (Slot Control Register) - Turns the Power Controller on or off according to the value written.

Power Fault Detected (Slot Status Register) - This bit is Set when a power fault is detected at the slot or the adapter.

Power Fault Detected Enable (Slot Control Register) - When Set, this bit enables software notification on a power fault event (see § Section 6.7.3.4).

6.7.2.5 Presence Detect Registers §

In-Band PD Disable Supported (Slot Capabilities 2 Register) - This bit indicates if the slot supports the disabling of in-band presence detect, which allows the out-of-band presence detect state to be reported independently of the in-band presence detect state.

In-Band PD Disable (Slot Control Register) - When Set, this bit disables the in-band presence detect mechanism from affecting the Presence Detect State bit, allowing that bit to be dedicated to reporting out-of-band presence detect.

Presence Detect State (Slot Status Register) - This bit indicates the presence of an adapter in the slot.

Presence Detect Changed (Slot Status Register) - This bit is Set when a presence detect state change is detected.

Presence Detect Changed Enable (Slot Control Register) - When Set, this bit enables software notification on a presence detect changed event (see § Section 6.7.3.4).

6.7.2.6 MRL Sensor Registers §

MRL Sensor Present (Slot Capabilities Register) - This bit indicates if an MRL Sensor is implemented.

MRL Sensor Changed (Slot Status Register) - This bit is Set when the value of the MRL Sensor state changes.

MRL Sensor Changed Enable (Slot Control Register) - When Set, this bit enables software notification on a MRL Sensor changed event (see § Section 6.7.3.4).

MRL Sensor State (Slot Status Register) - This register reports the status of the MRL Sensor if one is implemented.

6.7.2.7 Electromechanical Interlock Registers §

Electromechanical Interlock Present (Slot Capabilities Register) - This bit indicates if an Electromechanical Interlock is implemented.

Electromechanical Interlock Status (Slot Status Register) - This bit reflects the current state of the Electromechanical Interlock.

Electromechanical Interlock Control (Slot Control Register) - This bit when set to 1b toggles the state of the Electromechanical Interlock.

6.7.2.8 Command Completed Registers §

No Command Completed Support (Slot Capabilities Register) - This bit when set to 1b indicates that this slot does not generate software notification when an issued command is completed by the Hot-Plug Controller.

Command Completed (Slot Status Register) - This bit is Set when the Hot-Plug Controller completes an issued command and is ready to accept the next command.

Command Completed Interrupt Enable (Slot Control Register) - When Set, this bit enables software notification (see § Section 6.7.3.4) when a command is completed by the hot-plug control logic.

6.7.2.9 Port Capabilities and Slot Information Registers §

Slot Implemented (PCI Express Capabilities Register) - When Set, this bit indicates that the Link associated with this Downstream Port is connected to a slot.

Physical Slot Number (Slot Capabilities Register) - This hardware initialized field indicates the physical slot number attached to the Port.

Hot-Plug Capable (Slot Capabilities Register) - When Set, this bit indicates this slot is capable of supporting hot-plug.

Hot-Plug Surprise (Slot Capabilities Register) - When Set, this bit indicates that the Hot-Plug Surprise mechanism for handling async removal is enabled for this slot. See § Section 6.7.6 .

6.7.2.10 Hot-Plug Interrupt Control Register §

Hot-Plug Interrupt Enable (Slot Control Register) - When Set, this bit enables generation of the hot-plug interrupt on enabled hot-plug events.

6.7.3 PCI Express Hot-Plug Events §

A Downstream Port with hot-plug capabilities supports the following hot-plug events:

- Slot Events:
 - Attention Button Pressed
 - Power Fault Detected
 - MRL Sensor Changed
 - Presence Detect Changed
- Command Completed Events
- Data Link Layer State Changed Events

Each of these events has a status field, which indicates that an event has occurred but has not yet been processed by software, and an enable field, which indicates whether the event is enabled for software notification. Some events also have a capability field, which indicates whether the event type is supported on the Port. The grouping of these fields by event type is listed in § Section 6.7.2 , and each individual field is described in § Section 7.5.3 .

6.7.3.1 Slot Events §

A Downstream Port with hot-plug capabilities monitors the slot it controls for the slot events listed above. When one of these slot events is detected, the Port indicates that the event has occurred by setting the status field associated with the event. At that point, the event is pending until software clears the status field.

Once a slot event is pending on a particular slot, all subsequent events of that type are ignored on that slot until the event is cleared. The Port must continue to monitor the slot for all other slot event types and report them as they occur.

If enabled through the associated enable field, slot events must generate a software notification. If the event is not supported on the Port as indicated by the associated capability field, software must not enable software notification for the event. The mechanism by which this notification is reported to software is described in § Section 6.7.3.4 .

6.7.3.2 Command Completed Events §

Since changing the state of some hot-plug elements may not happen instantaneously, PCI Express supports hot-plug commands and command completed events. All hot-plug capable Ports are required to support hot-plug commands and, if the capability is reported, command completed events.

Software issues a command to a hot-plug capable Downstream Port by issuing a write transaction that targets any portion of the Port's Slot Control register. A single write to the Slot Control register is considered to be a single command, even if the write affects more than one field in the Slot Control register. In response to this transaction, the Port must carry out the requested actions and then set the associated status field for the command completed event. The Port must process the command normally even if the status field is already set when the command is issued. If a single command results in more than one action being initiated, the order in which the actions are executed is unspecified. All actions associated with a single command execution must not take longer than 1 second.

If command completed events are not supported as indicated by a value of 1b in the No Command Completed Support field of the Slot Capabilities register, a hot-plug capable Port must process a write transaction that targets any portion of the Port's Slot Control register without any dependency on previous Slot Control writes. Software is permitted to issue multiple Slot Control writes in sequence without any delay between the writes.

If command completed events are supported, then software must wait for a command to complete before issuing the next command. However, if the status field is not set after the 1 second limit on command execution, software is permitted to repeat the command or to issue the next command. If software issues a write before the Port has completed processing of the previous command and before the 1 second time limit has expired, the Port is permitted to either accept or discard the write. Such a write is considered a programming error, and could result in a discrepancy between the Slot Control register and the hot plug element state. To recover from such a programming error and return the controller to a consistent state, software must issue a write to the Slot Control register which conforms to the command completion rules.

If enabled through the associated enable field, the completion of a command must generate a software notification. The exception to this rule is a command that occurs as a result of a write to the Slot Control register that disables software notification of command completed events. Such a command must be processed as described above, but must not generate a software notification.

6.7.3.3 Data Link Layer State Changed Events §

The Data Link Layer State Changed event provides an indication that the state of the Data Link Layer Link Active bit in the Link Status Register has changed. Support for Data Link Layer State Changed events and software notification of these events are required for hot-plug capable Downstream Ports. If this event is supported, the Port sets the status field associated with the event when the value in the Data Link Layer Link Active bit changes.

This event allows software to indirectly determine when power has been applied to a newly hot-plugged adapter. Software must wait for 100 ms after the Data Link Layer Link Active bit reads 1b before initiating a configuration access to the hot added device (see § Section 6.6). Software must allow 1 second after the Data Link Layer Link Active bit reads 1b before it is permitted to determine that a hot plugged device which fails to return a Successful Completion for a Valid Configuration Request is a broken device (see § Section 6.6).

The Data Link Layer State Changed event must occur within 1 second of the event that initiates the hot-insertion. If a power controller is supported, the time out interval is measured from when software initiated a write to the Slot Control register to turn on the power. If the Power Disable mechanism is supported, the time out interval is measured from when that mechanism is deasserted (power is restored). If neither mechanism is supported, the time out interval is measured from presence detect slot event. Software is allowed to time out on a hot add operation if the Data Link Layer State Changed event does not occur within 1 second. The action taken by software after such a timeout is implementation specific.

6.7.3.4 Software Notification of Hot-Plug Events §

A hot-plug capable Downstream Port must support generation of an interrupt on a hot-plug event. As described in Sections 6.7.3.1 and 6.7.3.2, each hot-plug event has both an enable bit for interrupt generation and a status bit that indicates when an event has occurred but has not yet been processed by software. There is also a Hot-Plug Interrupt Enable bit in the Slot Control register that serves as a master enable/disable bit for all hot-plug events.

If the Port is enabled for level-triggered interrupt signaling using the INTx messages, the virtual INTx wire must be asserted whenever and as long as the following conditions are satisfied:

- The Interrupt Disable bit in the Command register is set to 0b.
- The Hot-Plug Interrupt Enable bit in the Slot Control register is set to 1b.
- At least one hot-plug event status bit in the Slot Status register and its associated enable bit in the Slot Control register are both set to 1b.

Note that all other interrupt sources within the same Function will assert the same virtual INTx wire when requesting service.

If the Port is enabled for edge-triggered interrupt signaling using MSI or MSI-X, an interrupt message must be sent every time the logical AND of the following conditions transitions from FALSE to TRUE:

- The associated vector is unmasked (not applicable if MSI does not support PVM).
- The Hot-Plug Interrupt Enable bit in the Slot Control register is set to 1b.
- At least one hot-plug event status bit in the Slot Status register and its associated enable bit in the Slot Control register are both set to 1b.

Note that PME and Hot-Plug Event interrupts (when both are implemented) always share the same MSI or MSI-X vector, as indicated by the Interrupt Message Number field in the PCI Express Capabilities register.

The Port may optionally send an MSI when there are hot-plug events that occur while interrupt generation is disabled, and interrupt generation is subsequently enabled.

If wake generation is required by the associated form factor specification, a hot-plug capable Downstream Port must support generation of a wakeup event (using the PME mechanism) on hot-plug events that occur when the system is in a sleep state or the Port is in device state D1, D2, or D3_{Hot}.

Software enables a hot-plug event to generate a wakeup event by enabling software notification of the event as described in § Section 6.7.3.1 . Note that in order for software to disable interrupt generation while keeping wakeup generation enabled, the Hot-Plug Interrupt Enable bit must be cleared. For form factors that support wake generation, a wakeup event must be generated if all three of the following conditions occur:

- The status register for an enabled event transitions from Clear to Set
- The Port is in device state D1, D2, or D3_{Hot}, and
- The PME_En bit in the Port's Power Management Control/Status register is Set

Note that the Hot-Plug Controller generates the wakeup on behalf of the hot-plugged device, and it is not necessary for that device to have auxiliary (or main) power.

6.7.4 System Firmware Intermediary (SFI) Support §

The System Firmware Intermediary (SFI) Capability is an optional normative feature of a Downstream Port. Some SFI functionality is focused on hot-pluggable slots, as indicated by the Hot-Plug Capable bit in the Slot Capabilities register being Set, while some SFI functionality is useful outside that context. If a Downstream Port supports an SFI Capability structure, the following bits must be Set:

- Data Link Layer Link Active Reporting Capable bit in the Link Capabilities register
- DRS Supported bit in the Link Capabilities 2 register
- ERR_COR Subclass Capable bit in the Device Capabilities register

6.7.4.1 SFI ERR_COR Event Signaling §

The SFI Capability has no support for generating INTx or MSI/MSI-X interrupts, since the capability is intended for use by system firmware.

A Downstream Port with SFI must support ERR_COR signaling, regardless of whether it supports Advanced Error Reporting (AER) or not. SFI ERR_COR event signaling is enabled independently by the SFI OOB PD Changed Enable, SFI DLL State Changed Enable, and SFI DRS Signaling Enable bits in the SFI Control Register. These events are indicated by the SFI OOB PD Changed, SFI DLL State Changed, and SFI DRS Received bits in the SFI Status Register.

If the Correctable Error Reporting Enable bit in the Device Control Register is Set, the Port must send an ERR_COR Message each time one of the enabled conditions becomes satisfied. SFI ERR_COR event signaling must not Set the Correctable Error Detected bit in the Device Status Register, since this event is not handled as an error.

IMPLEMENTATION NOTE:

ERR_COR SIGNALING FOR DPC DL_ACTIVE VS. SFI DLL STATE CHANGED §

DPC implements ERR_COR signaling for DL_Active, whereas SFI implements ERR_COR signaling for SFI DLL State Changed, which are related but non-identical conditions. The DL_Active condition occurs when the Data Link Layer Link Active bit in the Link Status register changes from 0b to 1b, and this bit can be masked by the SFI DLL State Mask bit in the SFI Control register. The SFI DLL State Changed condition occurs when the SFI DLL State bit in the SFI Status Register changes its value either by becoming Set or becoming Clear, and this condition is always based on the actual Data Link Layer state.

6.7.4.2 SFI Downstream Port Filtering (DPF) §

Downstream Port Filtering (DPF) is a mechanism where a Downstream Port can handle specified Request TLPs that target Components below it as if the Link is in DL_Down. See § Section 2.9.1 .

DPF has two modes of filtering Request TLPs that target Components below the Downstream Port. The first mode filters all such Request TLPs; the second mode filters only Configuration Request TLPs. Other TLPs must not be filtered or blocked by DPF.

One key use case for DPF is guaranteeing that asynchronous system software activities like bus scans do not unintentionally send Configuration Requests to devices that are not yet ready following a Conventional Reset, since such accesses result in undefined hardware behavior. See § Section 6.6.1 .

Another key use case for DPF is supporting firmware first functionality, enabling system firmware, when notified of an async hot add, to configure the newly added device before making the device visible to the operating system. For this use case, the SFI CAM mechanism enables the Downstream Port itself to generate Configuration Request TLPs targeting Downstream Components, and those TLPs are not filtered or blocked by the DPF mechanism. See § Section 6.7.4.3 , § Section 7.9.20.5 , and § Section 7.9.20.6 .

6.7.4.3 SFI CAM §

The SFI Configuration Access Method (CAM) provides a means for SFI-aware system firmware to have the Downstream Port proxy (pass through) Configuration Requests targeting Components below the Downstream Port when DPF is enabled. The SFI CAM is always enabled.

To use the SFI CAM, software first writes to the SFI CAM Address Register, specifying the target Configuration address. Software then reads or writes the SFI CAM Data Register to cause a proxied Configuration Request to be generated and transmitted to the Downstream Component.

The following rules apply:

- All TLP fields used for the proxied Configuration Request are identical to those in the Configuration Request that targeted the SFI CAM Data Register, with the following exceptions:
 - The target Bus Number, Device Number, and Function Number come from the SFI CAM Address Register.
 - The Extended Register Number and Register Number come from the SFI CAM Address Register.
 - The LCRC is regenerated.
 - If present, the ECRC is regenerated.
- The SFI CAM must not apply the Completion Timeout mechanism to the Request.
- System firmware must ensure that between the time it writes to the SFI CAM Address Register and its subsequent read or write of the SFI CAM Data Register completes, no other threads modify the SFI CAM Address Register; otherwise, the result is undefined.
- If there is a detected error associated with the proxied Configuration Request, this is a reported error associated with the Downstream Port implementing the SFI CAM (see § Section 6.2).
- Completions flowing Upstream must be passed through the Downstream Port unmodified.

IMPLEMENTATION NOTE: SERIALIZED USE OF THE SFI CAM ADDRESS AND DATA REGISTERS §

As described above, system firmware must ensure that between the time it writes to the SFI CAM Address Register and its subsequent read or write of the SFI CAM Data Register completes, no other threads modify the SFI CAM Address Register. For example, a semaphore or other synchronization mechanism can be used to ensure this serialization.

For platforms where a processor store instruction to Configuration Space is effectively posted, software must still ensure that the resulting Configuration Write completes before another software thread modifies the SFI CAM Data Register. On such platforms, the mechanism for determining when a Configuration Write completes is platform specific.

Given appropriate serialization, the SFI CAM works correctly with Configuration Requests that result in RRS Completions, even when the Root Complex automatically re-issues the Configuration Request as a new Request. The re-issued Configuration Request will again be sent to the SFI CAM Data Register, and the associated Downstream Port will again generate a Configuration Request targeting the Downstream Component. As long as the SFI CAM Address Register isn't modified by other software until the Configuration Request completes, the sequence can repeat indefinitely until a non-RRS Completion is returned or a Completion Timeout occurs.

When Configuration RRS Software Visibility is enabled, the SFI CAM still works correctly with Configuration Requests that result in RRS Completions. Any Completions with a RRS Completion Status flow back to the original Requester, which handles them as required by Configuration RRS Software Visibility semantics. See § Section 2.3.2.

IMPLEMENTATION NOTE: USE OF ASSIGNED BUS NUMBERS WITH THE SFI CAM §

When a Downstream Port has DPF enabled, the SFI CAM can be used by SFI-aware system firmware to configure and access the sub-hierarchy below the Port without other software being able to do so. While the Bus Number configuration below the Port is generally not visible to other software, Bus Numbers configured for use below the Port should be limited to those already assigned to the Port since TLPs coming Upstream through the Port may contain IDs with the configured Bus Numbers. If any errors are detected and logged with those TLPs, the Bus Numbers can become visible to other software, creating confusion if they overlap with Bus Numbers used elsewhere in the system.

6.7.4.4 SFI Interactions with Readiness Notifications §

The SFI Capability is able to mask the reporting of received Device Readiness Status (DRS) Messages as well as emulate them being received. This functionality is useful when SFI's Downstream Port Filtering (DPF) mechanism is being used to block operating system visibility of a device or sub-hierarchy below the Downstream Port.

Rules:

- When the SFI DRS Mask bit is Set, the DRS Message Received bit in the Link Status 2 Register value must be 0b.

- The SFI DRS Received bit must always indicate the actual state of the DRS Message Received condition.
- When the SFI DRS Mask bit is Clear and a 1b is written to the SFI DRS Trigger bit, the Downstream Port must behave as if a DRS Message was received.

IMPLEMENTATION NOTE: SFI TRANSPARENT OPTIMIZATIONS FOR DEVICE READINESS §

Certain devices may need more time to become Configuration-Ready following a hot-add operation than permitted. See § Section 6.6.1 .

If system firmware is aware of such devices, it can use the SFI DPF mechanism to block operating system visibility of a newly added device, wait the necessary amount of time for the device to become Configuration-Ready, and then expose the device to the operating system.

To avoid the operating system from unnecessarily waiting additional time for the newly exposed device to become Configuration-Ready, system firmware can use the SFI DRS Trigger bit to have the Downstream Port emulate the reception of a DRS Message. An operating system that supports DRS can then immediately discover and configure the newly exposed device.

The newly exposed device doesn't necessarily need to be DRS capable itself. Since an Upstream Port is expressly permitted to send DRS Messages even when its DRS Supported bit is Clear, the Downstream Port above it can legitimately emulate receiving a DRS Message from it even if it is incapable of sending DRS Messages.

It should also be noted that in cases where system firmware is aware of a device becoming Configuration-Ready early, system firmware can expose this to the operating system using the SFI DRS Trigger mechanism.

Although SFI is not intended to be used by operating system software, it is recommended that operating systems used in platforms supporting SFI implement support for DRS, so that the system as a whole can have the benefits of this optimized Device Readiness timing.

IMPLEMENTATION NOTE: SFI DPF AND FUNCTION READINESS STATUS (FRS) MESSAGES §

Downstream Port Filtering (DPF) does not affect the generation or propagation of FRS Messages. No FRS Messages are generated by a device when it becomes ready as part of an async hot-add operation. However, if system firmware performs operations on a device that result in FRS events, the resulting FRS Messages may be visible to the operating system. See § Section 2.2.8.6.3 and § Section 6.22.2 .

6.7.4.5 SFI Suppression of Hot-Plug Surprise Functionality §

If a slot supports Hot-Plug Surprise (HPS) functionality as indicated by the Hot-Plug Surprise bit in the Slot Capabilities Register being Set, the SFI HPS Suppress bit in the SFI Control Register can be used to force the Hot-Plug Surprise bit to be Clear, and disable the associated Hot-Plug Surprise functionality.

HPS suppression is useful when a Downstream Port / slot combination supports both HPS and Downstream Port Containment (DPC). DPC is not recommended for concurrent use with HPS, so if a slot has HPS capability enabled, DPC

should not be enabled. If software wishes to use DPC, software should first Set the SFI HPS Suppress bit in order to disable HPS functionality, allowing DPC to function properly.

IMPLEMENTATION NOTE: SOFTWARE NEGOTIATION OF HOT-PLUG SURPRISE FUNCTIONALITY §

Assuming that system firmware owns the SFI Capability structure, it is recommended that for backward compatibility with older operating systems, Hot-Plug Surprise functionality be enabled by default on slots supporting async removal. Then, if the slot also supports DPC and the operating system wishes to use it instead, the operating system will request that HPS be suppressed by system firmware, and system firmware will determine whether to Set or Clear the SFI HPS Suppress bit.

6.7.5 Firmware Support for Hot-Plug §

Some systems that include hot-plug capable Root Ports and Switches that are released before ACPI-compliant operating systems with native hot-plug support are available, can use ACPI firmware for propagating hot-plug events. Firmware control of the hot-plug registers must be disabled if an operating system with native support is used. Platforms that provide ACPI firmware to propagate hot-plug events must also provide a mechanism to transfer control to the operating system. The details of this method are described in the *PCI Firmware Specification*.

6.7.6 Async Removal §

Async removal refers to the removal of an adapter or disabling of a Downstream Port Link due to error containment without prior warning to the operating system. This is in contrast to orderly removal, where removal operations are performed in a lock-step manner with the operating system through a well defined sequence of user actions and system management facilities. For example, the user presses the Attention Button to request permission from the operating system to remove the adapter, but the user doesn't actually remove the adapter from the slot until the operating system has quiesced activity to the adapter and granted permission for removal.

Since async removal proceeds before the rest of the PCI Express hierarchy or operating system necessarily becomes aware of the event, special consideration is required beyond that needed for standard PCI hot-plug. This section outlines PCI Express events that may occur as a side effect of async removal and mechanisms for handling async removal.

Since async removal may be unexpected to both the Physical and Data Link Layers of the Downstream Port associated with the slot, Correctable Errors may be reported as a side effect of the event (i.e., Receiver Error, Bad TLP, and Bad DLLP). If these errors are reported, software should handle them as an expected part of this event.

Requesters may experience Completion Timeouts associated with Requests that were accepted, but will never be completed by removed Completers. Any resulting Completion Timeout errors in this context should be handled as an expected part of this event.

Async removal may result in a transition from DL_Active to DL_Down in the Downstream port. This transition may result in a Surprise Down error. In addition, Requesters in the PCI Express hierarchy domain may not become immediately aware of this transition and continue to issue Requests to removed Completers that must be handled by the Downstream Port associated with the slot.

Either Downstream Port Containment (DPC) or the Hot-Plug Surprise (HPS) mechanism may be used to support async removal as part of an overall async hot-plug architecture. See § Appendix I. for the associated reference model.

IMPLEMENTATION NOTE: HOT-PLUG SURPRISE MECHANISM DEPRECATED FOR ASYNC HOT-PLUG §

The Hot-Plug Surprise (HPS) mechanism, as indicated by the Hot-Plug Surprise bit in the Slot Capabilities Register being Set, is deprecated for use with async hot-plug. DPC is the recommended mechanism for supporting async hot-plug. See § Section 6.7.4.4 for guidance on slots supporting both mechanisms.

With async removal, using HPS has serious downsides. Uncorrectable errors other than those that inherently bring down the Link need to be configured either to crash the system, be handled asynchronously by software, or be ignored. These include uncorrectable errors associated with Posted Memory Writes, TLPs with poisoned data, and Completion Timeouts. Uncorrectable errors ignored or handled asynchronously by software may make it impossible for the driver to determine which high-level operations complete successfully versus those that do not.

DPC provides a robust mechanism for supporting async removal. The TLP stream cleanly stops upon an uncorrectable error that triggers DPC. Operating System / driver stacks that support Containment Error Recovery (CER) can fully and transparently recover from many transient PCIe uncorrectable errors. DPC can support async removal and CER concurrently

6.8 Power Budgeting Mechanism §

With the addition of a hot-plug capability for adapters, the need arises for the system to be capable of properly allocating power to any new devices added to the system. This capability is a separate and distinct function from power management and a basic level of support is required to ensure proper operation of the system. The power budgeting concept puts in place the building blocks that allow devices to interact with systems to achieve these goals. There are many ways in which the system can implement the actual power budgeting capabilities, and as such, they are beyond the scope of this specification.

Implementation of the Power Budgeting Extended Capability is optional for devices that are implemented either in a form factor that does not require hot-plug support, or that are integrated on the system board. Form factor specifications may require support for power budgeting. The devices and/or adapters are required to remain under the configuration power limit specified in the corresponding electromechanical specification until they have been configured and enabled by the system. The system should guarantee that power has been properly budgeted prior to enabling an adapter.

When enabled, Extended Power Budgeting provides power consumption information on a per-connector basis. This allows a system to manage power consumption more accurately.

§ Table 6-10 shows the deployment mechanisms for Power Budgeting.

Table 6-10 Power Budgeting Deployments §

Device Type	Power Budgeting Extended Capability	Description	Notes
Single Function, Multi-Function Device, or Multi-Device add-in card	Not Present	No Power Budgeting information is available	Some form factors may not permit this combination

Device Type	Power Budgeting Extended Capability	Description	Notes
Single Function Device	Present	Power Budgeting represents Device power	
Multi-Function Device	Present in exactly one Function		
Multi-Function Device	Present in more than one Function	Power Budgeting represents per-Function power	<p>Sum of all Functions represents power consumed by the Device.</p> <p>Functions that do not implement Power Budgeting have negligible power consumption.</p> <p>Power that is not associated with a specific Function is included in an implementation specific manner.</p>
Multi-Device add-in card	Present in one or more Functions of exactly one Device	Power Budgeting represents add-in card power	<p>Sum of all Functions represents power consumed by the add-in card.</p> <p>Functions and Devices that do not implement Power Budgeting have negligible power consumption.</p> <p>Power that is not associated with a specific Function is included in an implementation specific manner.</p>
Multi-Device add-in card	Present in more than one Device	Power Budgeting represents per-Device power	<p>Sum of all Devices represents power consumed by the add-in card.</p> <p>Devices that do not implement Power Budgeting have negligible power consumption.</p> <p>Power that is not associated with a specific Device is included in an implementation specific manner.</p>

6.8.1 System Power Budgeting Process Recommendations §

It is recommended that system firmware provide the power budget management agent the following information:

- Total system power budget (power supply information).
- Total power allocated by system firmware (system board devices).
- Total number of slots and the types of slots.

System firmware is responsible for allocating power for all devices on the system board that do not have power budgeting capabilities. The firmware may or may not include devices that are connected to the standard power rails. When the firmware allocates the power for a device that implements the Power Budgeting Extended Capability it must set the System Allocated bit to 1b in the Power Budget Capability register to indicate that it has been properly allocated. The power budget manager is responsible for allocating all PCI Express devices including system board devices that have the Power Budgeting Extended Capability and have the System Allocated bit Clear. The power budget manager is responsible for determining if hot-plugged devices can be budgeted and enabled in the system.

There are alternate methods which may provide the same functionality, and it is not required that the power budgeting process be implemented in this manner.

6.8.2 Device Power Considerations §

When the Power Budgeting Extended Capability is present in more than one Function of a Device (or the only Function of a Single Function Device), power is reported on a per-Function basis (see § Section 7.8.1). When Power Budgeting is present in exactly one Function of a Multi-Function Device, power is reported on a per-Device basis. When Power Budgeting is present in more than one Function, but not in all Functions, power is reported on a per-Function basis and the missing Functions are treated as consuming negligible power.

When Power Budgeting is present in exactly one Function, this represents per-Device Power. When Power Budgeting is present in exactly one Device of a Multi-Device add-in card, power is reported on a per-add-in card basis. The following rules apply:

- When all Functions in the Device are in the same PM State, power budgeting for that PM State applies.
 - If no power budgeting is reported for a given PM State, the next higher PM State that is reported applies.
- When Functions are in different PM States, power budgeting is at an implementation specific value between the power budgeting reported for highest and lowest power PM State (e.g., if no Functions are in D0, one Function is in D1 and another Function is in D3, power budgeting is somewhere between the values reported for D1 and D3, inclusive).
 - If no power budgeting is reported for the highest PM State, power budgeting for the next higher PM State that is reported applies.
 - If no power budgeting is reported for the lowest PM State, power budgeting for the next lower PM State that is reported applies.

6.8.3 Power Limit Mechanisms §

An add-in card must not consume more power than it is granted by the system. There are six mechanisms defined to grant power to an add-in card:

1. **Initial Power** – this is power granted to all similarly situated add-in cards by the form factor. This value is form factor specific and typically is based on factors like add-in card size and external power configuration.
2. **Set_Slot_Power_Limit power** – this is power granted to an add-in card when it receives a Set_Slot_Power_Limit message with a power value greater than the Initial Power grant for the add-in card.
3. **Power Limit PM Sub State power** – this is power granted to an add-in card through the Power Limit mechanism (see below). This mechanism overrides power grants from either the Initial Power or Set_Slot_Power_Limit mechanisms. Unlike Set_Slot_Power_Limit, this mechanism is permitted to grant a power level that is lower than the Initial Power grant.
4. **Out of Band Power Limit PM Sub State power** – this is power granted to an add-in card through the Out of Band Power Limit mechanism (see below). This mechanism overrides power grants from either the Initial Power or Set_Slot_Power_Limit mechanisms. Unlike Set_Slot_Power_Limit, this mechanism is permitted to grant a power level that is lower than the Initial Power grant.
5. **Firmware based additional Aux Power** – this is Aux power granted when the driver uses the Request D3_{Cold} Aux Power Limit_DSM call as defined in [Firmware]. This mechanism overrides Aux power grants using any of the above mechanisms.

6. **Form factor specific or Device Class (specific e.g., NVMe) mechanisms** – this is power granted to an add-in card using mechanisms defined by other specifications and are outside the scope of this specification. Interactions between these mechanisms and the mechanisms listed above are form factor or Device Class specific.

The Power Limit mechanism is optional. Support is indicated by the Power Limit Supported bit in the lowest-numbered Function that contains a Power Budgeting Extended Capability. The Power Limit fields in that Function control power for the entire add-in card.

The Power Budgeting Data Register (see § Section 7.8.1.3) contains a PM Sub State field. This permits a Device to report power consumption for up to 8 PM Sub States. This PM Sub State is implementation specific and is unrelated to other similarly named concepts in PCIe (e.g., PM State, L1 PM Substates).

Each PM Sub State represents additional optional power consumption levels. Each PM Sub State is mutually exclusive. At any specific point in time, a Device operates in exactly one PM Sub State. Each defined power consumption level includes a full complement of Data entries (e.g., Aux Power, Thermal, Max, Min for all appropriate connectors and power rails).

Device behavior is undefined if software attempts to transition the Device to a PM Sub State for which there are no Data entries.

When both the Power Limit Enable and the Out of Band Power Limit Enable bits are Clear, for each power rail and connector combination, the Device must operate in the PM Sub State determined by an implementation specific mechanism.

When both the Power Limit Enable and Out of Band Power Limit Enable bits are Set, individually for each power rail and connector combination, the Device must operate in the PM Sub State indicated by the smaller power consumption indicated by Power Limit PM Sub State or Out of Band Power Limit PM Sub State fields.

The Power Limit Enable and Power Limit PM Sub State fields are configured using Configuration Write transactions while all Functions of the Device are in DO_{uninitialized}. Behavior is undefined if these fields change after any Function exits DO_{uninitialized}.

The Out of Band Power Limit Enable and Out of Band Power Limit PM Sub State values are configured using implementation specific mechanisms. The mechanism used for out of band configuration is outside the scope of this specification.

6.9 Slot Power Limit Control §

PCI Express provides a mechanism for software controlled limiting of the Maximum Power per slot that an adapter (associated with that slot) can consume. If supported, the Emergency Power Reduction State, over-rides the mechanisms listed here (see § Section 6.24). The key elements of this mechanism are:

- Slot Power Limit Value and Scale fields of the Slot Capabilities register implemented in the Downstream Ports of a Root Complex or a Switch
- Captured Slot Power Limit Value and Scale fields of the Device Capabilities register implemented in Endpoint, Switch, or PCI Express-PCI Bridge Functions present in an Upstream Port
- Set_Slot_Power_Limit Message that conveys the content of the Slot Power Limit Value and Scale fields of the Slot Capabilities register of the Downstream Port (of a Root Complex or a Switch) to the corresponding Captured Slot Power Limit Value and Scale fields of the Device Capabilities register in the Upstream Port of the component connected to the same Link

Power limits on the platform are typically controlled by the software (for example, platform firmware) that comprehends the specifics of the platform such as:

- Partitioning of the platform, including slots for I/O expansion using adapters
- Power delivery capabilities
- Thermal capabilities

This software is responsible for correctly programming the Slot Power Limit Value and Scale fields of the Slot Capabilities registers of the Downstream Ports connected to slots. After the value has been written into the register within the Downstream Port, it is conveyed to the adapter using the Set_Slot_Power_Limit Message (see § Section 2.2.8.5). The recipient of the Message must use the value in the Message data payload to limit usage of the power for the entire adapter, unless the adapter will never exceed the lowest value specified in the corresponding form factor specification. It is required that device driver software associated with the adapter be able (by reading the values of the Captured Slot Power Limit Value and Scale fields of the Device Capabilities register) to configure hardware of the adapter to guarantee that the adapter will not exceed the imposed limit. In the case where the platform imposes a limit that is below the minimum needed for adequate operation, the device driver will be able to communicate this discrepancy to higher level configuration software. Configuration software is required to set the Slot Power Limit to one of the maximum values specified for the corresponding form factor based on the capability of the platform.

The following rules cover the Slot Power Limit control mechanism:

For Adapters:

- Until and unless a Set_Slot_Power_Limit Message is received indicating a Slot Power Limit value greater than the lowest value specified in the form factor specification for the adapter's form factor, the adapter must not consume more than the lowest value specified.
- An adapter must never consume more power than what was specified in the most recently received Set_Slot_Power_Limit Message or the minimum value specified in the corresponding form factor specification, whichever is higher.
- Components with Endpoint, Switch, or PCI Express-PCI Bridge Functions that are targeted for integration on an adapter where total consumed power is below the lowest limit defined for the targeted form factor are permitted to ignore Set_Slot_Power_Limit Messages, and to return a value of 0 in the Captured Slot Power Limit Value and Scale fields of the Device Capabilities register
 - Such components still must be able to receive the Set_Slot_Power_Limit Message without error but simply discard the Message value

For Root Complex and Switches which source slots:

- Configuration software must not program a Set_Slot_Power_Limit value that indicates a limit that is lower than the lowest value specified in the form factor specification for the slot's form factor.

IMPLEMENTATION NOTE: EXAMPLE ADAPTER BEHAVIOR BASED ON THE SLOT POWER LIMIT CONTROL CAPABILITY §

The following power limit scenarios are examples of how an adapter must behave based on the Slot Power Limit control capability. The form factor limits are representations, and should not be taken as actual requirements.

Note: Form factor #1 has a Maximum Power requirement of 40 W and 25 W; form factor #2 has a Maximum Power requirement of 15 W.

Scenario 1: An Adapter Consuming 12 W

- If the adapter is plugged into a form factor #1 40 W slot, the Slot Power Limit control mechanism is followed, and the adapter operates normally.
- If the adapter is plugged into a form factor #1 25 W slot, the Slot Power Limit control mechanism is followed, and the adapter operates normally.
- If the adapter is plugged into a form factor #2 15 W slot, the Slot Power Limit control mechanism is followed, and the adapter operates normally.

In all cases, since the adapter operates normally within all the form factors, it can ignore any of the slot power limit Messages.

Scenario 2: An Adapter Consuming 18 W

- If the adapter is plugged into a form factor #1 40 W slot, the Slot Power Limit control mechanism is followed, and the adapter operates normally.
- If the adapter is plugged into a form factor #1 25 W slot, the Slot Power Limit control mechanism is followed, and the adapter operates normally.
- If the adapter is plugged into a form factor #2 15 W slot, the Slot Power Limit control mechanism is followed, and the adapter must scale down to 15 W or disable operation. An adapter that does not scale within any of the power limits for a given form factor will always be disabled in that form factor and should not be used.

In this case, if the adapter is only to be used in form factor #1, it can ignore any of the slot power limit Messages. To be useful in form factor #2, the adapter should be capable of scaling to the power limit of form factor #2.

Scenario 3: An Adapter Consuming 30 W

- If the adapter is plugged into a form factor #1 40 W slot, the Slot Power Limit control mechanism is followed, and the device operates normally.
- If the adapter is plugged into a form factor #1 25 W slot, the Slot Power Limit control mechanism is followed, and the device must scale down to 25 W or disable operation.
- If the adapter is plugged into a form factor #2 15 W slot, the Slot Power Limit control mechanism is followed, and the adapter must scale down to 15 W or disable operation. An adapter that does not scale within any of the power limits for a given form factor will always be disabled in that form factor and should not be used.

In this case, since the adapter consumes power above the lowest power limit for a slot, the adapter must be capable of scaling or disabling to prevent system failures. Operation of adapters at power levels that exceed the capabilities of the slots in which they are plugged must be avoided.

IMPLEMENTATION NOTE: SLOT POWER LIMIT CONTROL REGISTERS §

Typically Slot Power Limit register fields within Downstream Ports of a Root Complex or a Switch will be programmed by platform-specific software. Some implementations may use a hardware method for initializing the values of these registers and, therefore, do not require software support.

Components with Endpoint, Switch, or PCI Express-PCI Bridge Functions that are targeted for integration on the adapter where total consumed power is below the lowest limit defined for that form factor are allowed to ignore Set_Slot_Power_Limit Messages. Note that components that take this implementation approach may not be compatible with potential future defined form factors. Such form factors may impose lower power limits that are below the minimum required by a new adapter based on the existing component.

IMPLEMENTATION NOTE: AUTO SLOT POWER LIMIT DISABLE §

In some environments host software may wish to directly manage the transmission of a Set_Slot_Power_Limit message by performing a Configuration Write to the Slot Capabilities register rather than have the transmission automatically occur when the Link transitions from a non-DL_Up to a DL_Up status. This allows host software to limit power supply surge current by staggering the transition of Endpoints to a higher power state following a Link Down or when multiple Endpoints are simultaneously hot-added due to cable or adapter insertion.

6.10 Root Complex Topology Discovery §

A Root Complex may present one of the following topologies to configuration software:

- A single opaque Root Complex such that software has no visibility with respect to internal operation of the Root Complex. All Root Ports are independent of each other from a software perspective; no mechanism exists to manage any arbitration among the various Root Ports for any differentiated services.
- A single Root Complex Component such that software has visibility and control with respect to internal operation of the Root Complex Component. As shown in § Figure 6-11, software views the Root Ports as Ingress Ports for the component. The Root Complex internal Port for traffic aggregation to a system Egress Port or an internal sink unit (such as memory) is represented by an RCRB structure. Controls for differentiated services are provided through a Virtual Channel Capability structure located in the RCRB.

Figure 6-11 Root Complex Represented as a Single Component §

- Multiple Root Complex Components such that software not only has visibility and control with respect to internal operation of a given Root Complex Component but also has the ability to discover and control arbitration between different Root Complex Components. As shown in § Figure 6-12, software views the Root Ports as Ingress Ports for a given component. An RCRB structure controls egress from the component to other Root Complex Components (RCRB C) or to an internal sink unit such as memory (RCRB A). In addition, an RCRB structure (RCRB B) may also be present in a given component to control traffic from other Root Complex Components. Controls for differentiated services are provided through Virtual Channel Capability structures located appropriately in the RCRBs respectively.

More complex topologies are possible as well.

A Root Complex topology can be represented as a collection of logical Root Complex Components such that each logical component has:

- One or more Ingress Ports.
- An Egress Port.
- Optional associated Virtual Channel capabilities located either in the Configuration Space (for Root Ports) or in an RCRB (for internal Ingress/Egress Ports) if the Root Complex supports Virtual Channels.
- Optional devices/Functions integrated in the Root Complex.

In order for software to correctly program arbitration and other control parameters for PCI Express differentiated services, software must be able to discover a Root Complex's internal topology. Root Complex topology discovery is accomplished by means of the Root Complex Link Declaration Capability as described in § Section 7.9.8 .

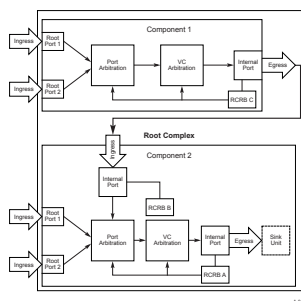

Figure 6-12 Root Complex Represented as Multiple Components §

6.11 Link Speed Management §

This section describes how Link speed management is coordinated between the LTSSM (§ Section 4.2.7) and the software Link observation and control mechanisms (see § Section 7.5.3.6, § Section 7.5.3.7, § Section 7.5.3.8, § Section 7.5.3.18, § Section 7.5.3.19, and § Section 7.5.3.20).

The Target Link Speed field in the Link Control 2 register in the Downstream Port sets the upper bound for the Link speed. Except as described below, the Upstream component must attempt to maintain the Link at the Target Link Speed, or at the highest speed supported by both components on the Link (as reported by the values in the training sets - see § Section 4.2.5.1), whichever is lower.

Any Upstream Port or Downstream Port with the Hardware Autonomous Speed Disable bit in the Link Control 2 register clear is permitted to autonomously change the Link speed using implementation specific criteria.

If the reliability of the Link is unacceptably low, then either component is permitted to lower the Link speed by removing the unreliable Link speed from the list of supported speeds advertised in the training sets the component transmits. The criteria for determination of acceptable Link reliability are implementation specific, and are not dependent on the setting of the Hardware Autonomous Speed Disable bit.

During any given speed negotiation it is possible that one or both components will advertise a subset of all speeds supported, as a means to cap the post-negotiation Link speed. It is permitted for a component to change its set of advertised supported speeds without requesting a Link speed change by driving the Link through Recovery without setting the speed change bit.

When a component's attempt to negotiate to a particular Link speed fails, that component is not permitted to attempt negotiation to that Link speed, or to any higher Link speed, until 200 ms has passed from the return to L0 following the failed attempt, or until the other component on the Link advertises support for the higher Link speed through its transmitted training sets (with or without a request to change the Link speed), whichever comes first.

Software is permitted to restrict the maximum speed of Link operation and set the preferred Link speed by setting the value in the Target Link Speed field in the Upstream component. After modifying the value in the Target Link Speed field, software must trigger Link retraining by writing 1b to the Retrain Link bit. Software is notified of any Link speed changes (as well as any Link width changes) through the Link Bandwidth Notification Mechanism.

Software is permitted to cause a Link to transition to the Polling.Compliance LTSSM state at a particular speed by writing the Link Control 2 register in both components with the same value in the Target Link Speed field and Setting the Enter Compliance bit, and then initiating a Hot Reset on the Link (through the Downstream Port).

Note that this will take the Link to a DL_Down state and therefore cannot be done transparently to other software that is using the Link. The Downstream Port will return to Polling.Active when the Enter Compliance bit is cleared.

6.12 Access Control Services (ACS) §

ACS defines a set of control points within a PCI Express topology to determine whether a TLP is to be routed normally, blocked, or redirected. ACS is applicable to RCs, Switches, and Multi-Function Devices.¹²⁷ For ACS requirements, single-Function devices that are SR-IOV capable must be handled as if they were Multi-Function Devices, since they essentially behave as Multi-Function Devices after their Virtual Functions (VFs) are enabled.

Implementation of ACS in RCiEPs is permitted but not required. It is explicitly permitted that, within a single Root Complex, some RCiEPs implement ACS and some do not. It is strongly recommended that Root Complex implementations ensure that all accesses originating from RCiEPs (PFs and VFs) without ACS capability are first

127. Applicable Functions within Multi-Function Devices specifically include PCI Express Endpoints, Switch Upstream Ports, Legacy PCI Express Endpoints, and Root Complex Integrated Endpoints.

subjected to processing by the Translation Agent (TA) in the Root Complex before further decoding and processing. The details of such Root Complex handling are outside the scope of this specification.

ACS provides the following types of access control:

- [ACS Source Validation](#)
- [ACS Translation Blocking](#)
- [ACS P2P Request Redirect](#)
- [ACS P2P Completion Redirect](#)
- [ACS Upstream Forwarding](#)
- [ACS P2P Egress Control](#)
- [ACS Direct Translated P2P](#)
- [ACS I/O Request Blocking](#)
- [ACS DSP Memory Target Access](#)
- [ACS USP Memory Target Access](#)
- [ACS Unclaimed Request Redirect](#)

The specific requirements for each of these are discussed in the following section.

ACS hardware functionality is disabled by default, and is enabled only by ACS-aware software. With the exception of ACS Source Validation, ACS access controls are not applicable to Multicast TLPs (see § [Section 6.14](#)), and have no effect on them.

6.12.1 ACS Component Capability Requirements §

ACS functionality is reported and managed via ACS Extended Capability structures. PCI Express components are permitted to implement ACS Extended Capability structures in some, none, or all of their applicable Functions. The extent of what is implemented is communicated through capability bits in each ACS Extended Capability structure. A given Function with an ACS Extended Capability structure may be required or forbidden to implement certain capabilities, depending upon the specific type of the Function and whether it is part of a [Multi-Function Device](#).

ACS is never applicable to a PCI Express to PCI Bridge Function or a Root Complex Event Collector Function, and such Functions must never implement an ACS Extended Capability structure.

6.12.1.1 ACS Downstream Ports §

This section applies to Root Ports and Switch Downstream Ports that implement an ACS Extended Capability structure. This section applies to Downstream Port Functions both for single-Function devices and [Multi-Function Devices](#).

- [ACS Source Validation](#): must be implemented.

When enabled, the Downstream Port tests the Bus Number from the Requester ID of each Upstream Request received by the Port to determine if it is associated with the Secondary side of the virtual bridge associated with the Downstream Port, by either or both of:

- Determining that the Requester ID falls within the Bus Number “aperture” of the Port - the inclusive range specified by the Secondary Bus Number register and the Subordinate Bus Number register.

- If FPB is implemented and enabled, determining that the Requester ID is associated with the bridge's Secondary Side by the application of the FPB Routing ID mechanism.
If the Bus Number from the Requester ID of the Request is not within this aperture, this is a reported error (ACS Violation) associated with the Receiving Port (see § Section 6.12.5 .)

Completions are never affected by ACS Source Validation.

IMPLEMENTATION NOTE: UPSTREAM MESSAGES AND ACS SOURCE VALIDATION §

Functions are permitted to transmit Upstream Messages before they have been assigned a Bus Number. Such messages will have a Requester ID with a Bus Number of 00h. If the Downstream Port has ACS Source Validation enabled, these Messages (see § Table F-1, § Section 2.2.8.2 , and § Section 6.22.1) will likely be detected as an ACS Violation error.

- ACS Translation Blocking: must be implemented.
When enabled, the Downstream Port checks the Address Type (AT) field of each Upstream Memory Request and, in Flit mode only, of each Upstream Address Routed Message received by the Port. If the AT field is not the default value, this is a reported error (ACS Violation) associated with the Receiving Port (see § Section 6.12.5). This error must take precedence over ACS Upstream Forwarding and any applicable ACS P2P control mechanisms.

Completions are never affected by ACS Translation Blocking.

- ACS P2P Request Redirect: must be implemented by Root Ports that support peer-to-peer traffic with other Root Ports;¹²⁸ must be implemented by Switch Downstream Ports.

ACS P2P Request Redirect is subject to interaction with the ACS P2P Egress Control and ACS Direct Translated P2P mechanisms (if implemented). Refer to § Section 6.12.3 for more information.

When ACS P2P Request Redirect is enabled in a Switch Downstream Port, peer-to-peer Requests must be redirected Upstream towards the RC.

When ACS P2P Request Redirect is enabled in a Root Port, peer-to-peer Requests must be sent to Redirected Request Validation logic within the RC that determines whether the Request is “reflected” back Downstream towards its original target, or blocked as an ACS Violation error. The algorithms and specific controls for making this determination are not architected by this specification.

Downstream Ports never redirect Requests that are traveling Downstream.

Completions are never affected by ACS P2P Request Redirect.

- ACS P2P Completion Redirect: must be implemented by Root Ports that implement ACS P2P Request Redirect; must be implemented by Switch Downstream Ports.

The intent of ACS P2P Completion Redirect is to avoid ordering rule violations between Completions and Requests when Requests are redirected. Refer to § Section 6.12.6 for more information.

ACS P2P Completion Redirect does not interact with ACS controls that govern Requests.

128. Root Port indication of ACS P2P Request Redirect or ACS P2P Completion Redirect support does not imply any particular level of peer-to-peer support by the Root Complex, or that peer-to-peer traffic is supported at all

When ACS P2P Completion Redirect is enabled in a Switch Downstream Port, peer-to-peer Completions¹²⁹ that do not have the Relaxed Ordering Attribute bit set (1b) must be redirected Upstream towards the RC. Otherwise, peer-to-peer Completions must be routed normally.

When ACS P2P Completion Redirect is enabled in a Root Port, peer-to-peer Completions that do not have the Relaxed Ordering bit set must be handled such that they do not pass Requests that are sent to Redirected Request Validation logic within the RC. Such Completions must eventually be sent Downstream towards their original peer-to-peer targets, without incurring additional ACS access control checks.

Downstream Ports never redirect Completions that are traveling Downstream.

Requests are never affected by ACS P2P Completion Redirect.

- ACS Upstream Forwarding: must be implemented by Root Ports if the RC supports Redirected Request Validation; must be implemented by Switch Downstream Ports. When ACS Upstream Forwarding is enabled in a Switch Downstream Port, and its Ingress Port receives an Upstream Request or Completion TLP targeting the Port's own Egress Port, the Port must instead forward the TLP Upstream towards the RC.

When ACS Upstream Forwarding is enabled in a Root Port, and its Ingress Port receives an Upstream Request or Completion TLP that targets the Port's own Egress Port, the Port must handle the TLP as follows. For a Request, the Root Port must handle it the same as a Request that the Port "redirects" with the ACS P2P Request Redirect mechanism. For a Completion, the Root Port must handle it the same as a Completion that the Port "redirects" with the ACS P2P Completion Redirect mechanism.

When ACS Upstream Forwarding is not enabled on a Downstream Port, and its Ingress Port receives an Upstream Request or Completion TLP that targets the Port's own Egress Port, the handling of the TLP is undefined.

- ACS P2P Egress Control: implementation is optional. ACS P2P Egress Control is subject to interaction with the ACS P2P Request Redirect and ACS Direct Translated P2P mechanisms (if implemented). Refer to § Section 6.12.3 for more information.

A Switch that supports ACS P2P Egress Control can be selectively configured to block peer-to-peer Requests between its Downstream Ports. Software can configure the Switch to allow none or only a subset of its Downstream Ports to send peer-to-peer Requests to other Downstream Ports. This is configured on a per Downstream Port basis.

An RC that supports ACS P2P Egress Control can be selectively configured to block peer-to-peer Requests between its Root Ports. Software can configure the RC to allow none or only a subset of the Hierarchy Domains to send peer-to-peer Requests to other Hierarchy Domains. This is configured on a per Root Port basis.

With ACS P2P Egress Control in Downstream Ports, controls in the Ingress Port ("sending" Port) determine if the peer-to-peer Request is blocked, and if so, the Ingress Port handles the ACS Violation error per § Section 6.12.5.

Completions are never affected by ACS P2P Egress Control.

- ACS Direct Translated P2P: must be implemented by Root Ports that support Address Translation Services (ATS) and also support peer-to-peer traffic with other Root Ports;¹³⁰ must be implemented by Switch Downstream Ports.

When ACS Direct Translated P2P is enabled in a Downstream Port, peer-to-peer Memory Requests and, in Flit mode only, peer-to-peer Address Routed Messages whose Address Type (AT) field indicates a Translated

129. This includes Read Completions, AtomicOp Completions, and other Completions with or without Data.

130. Root Port indication of ACS Direct Translated P2P support does not imply any particular level of peer-to-peer support by the Root Complex, or that peer-to-peer traffic is supported at all.

address must be routed normally (“directly”) to the peer Egress Port, regardless of ACS P2P Request Redirect and ACS P2P Egress Control settings. All other peer-to-peer Requests must still be subject to ACS P2P Request Redirect and ACS P2P Egress Control settings.

Completions are never affected by ACS Direct Translated P2P.

- ACS I/O Request Blocking: must be implemented by Root Ports and Switch Downstream Ports that support ACS Enhanced Capability.

When enabled, the Port must handle an Upstream I/O Request received by the Port’s Ingress as an ACS Violation.

- ACS DSP Memory Target Access: must be implemented by Root Ports and Switch Downstream Ports that support ACS Enhanced Capability and that have applicable Memory BAR Space to protect.

ACS DSP Memory Target Access determines how an Upstream Request received by the Downstream Port’s Ingress and targeting any Memory BAR Space¹³¹ associated with an applicable Downstream Port is handled. The Request can be blocked, redirected, or allowed to proceed directly to its target. In a Switch, all Downstream Ports are applicable, including the one on which the Request was received. In a Root Complex, the set of applicable Root Ports is implementation specific, but always includes the one on which the Request was received.

- ACS USP Memory Target Access: must be implemented by Switch Downstream Ports that support ACS Enhanced Capability and that have applicable Memory BAR Space in the Switch Upstream Port to protect; is not applicable to Root Ports.

ACS USP Memory Target Access determines how an Upstream Request received by the Switch Downstream Port’s Ingress and targeting any Memory BAR Space¹³² associated with the Switch’s Upstream Port is handled. The Request can be blocked, redirected, or allowed to proceed directly to its target.

If any Functions other than the Switch Upstream Port are associated with the Upstream Port, this field has no effect on accesses to their Memory BAR Space¹³³. Such access is controlled by the ACS Extended Capability (if present) in the Switch Upstream Port.

- ACS Unclaimed Request Redirect: must be implemented by Switch Downstream Ports that support ACS Enhanced Capability; is not applicable to Root Ports.

When enabled, incoming Requests received by the Switch Downstream Port’s Ingress and targeting Memory Space within the memory window of a Switch Upstream Port that is not within a memory window or Memory BAR Target of any Downstream Port within the Switch are redirected Upstream out of the Switch.

When not enabled, such Requests are handled by the Switch Downstream Port as an Unsupported Request (UR).

6.12.1.2 ACS Functions in SR-IOV Capable and Multi-Function Devices §

This section applies to Multi-Function Device ACS Functions, with the exception of Downstream Port Functions, which are covered in the preceding section. For ACS requirements, single-Function devices that are SR-IOV capable must be handled as if they were Multi-Function Devices.

131. This also includes any Memory Space allocated by an Expansion ROM Base Address register (BAR). This also includes any Memory Space allocated by EA entries with a BEI value of 0, 1, 7, or 8. See § Section 7.8.5.3 .

132. This also includes any Memory Space allocated by an Expansion ROM Base Address register (BAR). This also includes any Memory Space allocated by EA entries with a BEI value of 0, 1, 7, or 8. See § Section 7.8.5.3 .

133. This also includes any Memory Space allocated by an Expansion ROM Base Address register (BAR). This also includes any Memory Space allocated by EA entries with a BEI value of 0, 1, 7, or 8. See § Section 7.8.5.3 .

- ACS Source Validation: must not be implemented.
- ACS Translation Blocking: must not be implemented.
- ACS P2P Request Redirect: must be implemented by Functions that support peer-to-peer traffic with other Functions. This includes SR-IOV Virtual Functions (VFs).

ACS P2P Request Redirect is subject to interaction with the ACS P2P Egress Control and ACS Direct Translated P2P mechanisms (if implemented). Refer to § Section 6.12.3 for more information.

When ACS P2P Request Redirect is enabled in a Multi-Function Device that is not an RCiEP, peer-to-peer Requests (between Functions of the device) must be redirected Upstream towards the RC.

It is permitted but not required to implement ACS P2P Request Redirect in an RCiEP. When ACS P2P Request Redirect is enabled in an RCiEP, peer-to-peer Requests, defined as all Requests that do not target system memory, must be sent to implementation specific logic within the Root Complex that determines whether the Request is directed towards its original target, or blocked as an ACS Violation error. The algorithms and specific controls for making this determination are not architected by this specification.

Completions are never affected by ACS P2P Request Redirect.

- ACS P2P Completion Redirect: must be implemented by Functions that implement ACS P2P Request Redirect. The intent of ACS P2P Completion Redirect is to avoid ordering rule violations between Completions and Requests when Requests are redirected. Refer to § Section 6.12.6 for more information.

ACS P2P Completion Redirect does not interact with ACS controls that govern Requests.

When ACS P2P Completion Redirect is enabled in a Multi-Function Device that is not an RCiEP, peer-to-peer Completions that do not have the Relaxed Ordering bit set must be redirected Upstream towards the RC. Otherwise, peer-to-peer Completions must be routed normally.

Requests are never affected by ACS P2P Completion Redirect.

- ACS Upstream Forwarding: must not be implemented.
- ACS P2P Egress Control: implementation is optional; is based on Function Numbers or Function Group Numbers; controls peer-to-peer Requests between the different Functions within the multi-Function or SR-IOV capable device.

ACS P2P Egress Control is subject to interaction with the ACS P2P Request Redirect and ACS Direct Translated P2P mechanisms (if implemented). Refer to § Section 6.12.3 for more information.

Each Function within a Multi-Function Device that supports ACS P2P Egress Control can be selectively enabled to block peer-to-peer communication with other Functions or Function Groups¹³⁴ within the device. This is configured on a per Function basis.

With ACS P2P Egress Control in multi-Function or SR-IOV capable devices, controls in the "sending" Function determine if the Request is blocked, and if so, the "sending" Function handles the ACS Violation error per § Section 6.12.5.

When ACS Function Groups are enabled in an ARI Device (ACS Function Groups Enable is Set), ACS P2P Egress Controls are enforced on a per Function Group basis instead of a per Function basis. See § Section 6.13.

Completions are never affected by ACS P2P Egress Control.

- ACS Direct Translated P2P: must be implemented if the Multi-Function Device Function supports Address Translation Services (ATS) and also peer-to-peer traffic with other Functions.

134. ACS Function Groups capability is optional for ARI Devices that implement ACS P2P Egress Controls.

When ACS Direct Translated P2P is enabled in a Multi-Function Device, peer-to-peer Memory Requests whose Address Type (AT) field indicates a Translated address must be routed normally (“directly”) to the peer Function, regardless of ACS P2P Request Redirect and ACS P2P Egress Control settings. All other peer-to-peer Requests must still be subject to ACS P2P Request Redirect and ACS P2P Egress Control settings.

Completions are never affected by ACS Direct Translated P2P.

6.12.1.3 Functions in Single-Function Devices §

This section applies to single-Function device Functions, with the exception of Downstream Port Functions and SR-IOV capable Functions, which are covered in a preceding section. For ACS requirements, single-Function devices that are SR-IOV capable must be handled as if they were Multi-Function Devices.

No ACS capabilities are applicable, and the Function must not implement an ACS Extended Capability structure.

6.12.2 Interoperability §

The following rules govern interoperability between ACS and non-ACS components:

- When ACS P2P Request Redirect and ACS P2P Completion Redirect are not being used, ACS and non-ACS components may be intermixed within a topology and will interoperate fully. ACS can be enabled in a subset of the ACS components without impacting interoperability.
- When ACS P2P Request Redirect, ACS P2P Completion Redirect, or both are being used, certain components in the PCI Express hierarchy must support ACS Upstream Forwarding (of Upstream redirected Requests). Specifically:
The associated Root Port ¹³⁵ must support ACS Upstream Forwarding. Otherwise, how the Root Port handles Upstream redirected Request or Completion TLPs is undefined. The RC must also implement Redirected Request Validation.

Between each ACS component where P2P TLP redirection is enabled and its associated Root Port, any intermediate Switches must support ACS Upstream Forwarding. Otherwise, how such Switches handle Upstream redirected TLPs is undefined.

6.12.3 ACS Peer-to-Peer Control Interactions §

With each peer-to-peer Request, multiple ACS control mechanisms may interact to determine whether the Request is routed directly towards its peer-to-peer target, blocked immediately as an ACS Violation, or redirected Upstream towards the RC for access validation. Peer-to-peer Completion redirection is determined exclusively by the ACS P2P Completion Redirect mechanism.

If ACS Direct Translated P2P is enabled in a Port/Function, peer-to-peer Memory Requests whose Address Type (AT) field indicates a Translated address must be routed normally (“directly”) to the peer Port/Function, regardless of ACS P2P Request Redirect and ACS P2P Egress Control settings. Otherwise such Requests, and unconditionally all other peer-to-peer Requests, must be subject to ACS P2P Request Redirect and ACS P2P Egress Control settings. Specifically, the applicable Egress Control Vector bit, along with the ACS P2P Egress Control Enable bit (E) and the ACS P2P Request Redirect Enable bit (R), determine how the Request is handled. It must be noted that atomicity of accesses cannot be guaranteed if ACS peer-to-peer Request Redirect targets a legacy device location that can be the target of a locked access. Refer to § Section 7.7.11 for descriptions of these control bits. § Table 6-11 specifies the interactions.

135. Not applicable for ACS Redirect between Functions of a multi-Function Root Complex Integrated Endpoint.

Table 6-11 ACS P2P Request Redirect and ACS P2P Egress Control Interactions §

Control Bit E (b)	Control Bit R (b)	Egress Control Vector Bit for the Associated Egress Switch Port, Root Port, Function, or <u>Function Group</u>	Required Handling for Peer-to-Peer Requests
0	0	X - Don't care	Route directly to peer-to-peer target
0	1	X - Don't Care	Redirect Upstream
1	0	1	Handle as an ACS Violation
1	0	0	Route directly to peer-to-peer target
1	1	1	Redirect Upstream
1	1	0	Route directly to peer-to-peer target

IMPLEMENTATION NOTE:

ACCESS CONTROL SERVICES IN SYSTEMS THAT SUPPORT DIRECT ASSIGNMENT OF FUNCTIONS §

General-purpose VIs typically have separate address spaces for each SI and for the VI itself. If such a VI also supports direct assignment of a Function to an SI, Untranslated Memory Request transactions issued by directly assigned Functions are under the complete control of software operating within the associated SI and typically reference the address space associated with that SI. In contrast, Memory Request transactions issued by the Host (MMIO requests) and by Functions that are not directly assigned are under the control of the VI and typically reference one or more system address spaces (e.g., the PCIe physical address space, the address space associated with the VI, or the address space associated with some designated SI). General-purpose VIs are not expected to establish a dependency between these various address spaces. Consequently, these address spaces may freely overlap which could lead to unintended routing of TLPs by Switches. For example, Upstream Memory Request TLPs originated by a directly assigned Function and intended for main memory could instead be routed to a Downstream Port if the address in the Request falls within the MMIO address region associated with that Downstream Port. Such unintended routing poses a threat to SI and/or VI stability and integrity.

To guard against this concern, vendors are strongly recommended to implement ACS in platforms that support general purpose VIs with direct assignment of Functions. Such support should include:

- In Switches or Root Complexes located below the TA, the level of ACS support should follow the guidelines established in this document for Downstream Switch Ports that implement an ACS Extended Capability structure.

Note: Components located above the TA only see Translated Memory Requests, consequently this concern does not apply to those components.

- In SR-IOV devices that are capable of peer-to-peer transactions, ACS support is required.
- In Multi-Function Devices that are capable of peer-to-peer transactions, vendors are strongly recommended to implement ACS with ACS P2P Egress Control.

Additionally, platform vendors should test for the presence of ACS and enable it in Root Complexes and Switches on the path from the TA to a Function prior to directly assigning that Function. If the Function is peer-to-peer capable, ACS should be enabled in the Function as well.

6.12.4 ACS Enhanced Capability §

ACS Enhanced Capability is an additional set of ACS control mechanisms to improve the level of isolation and protection provided by ACS. ACS Enhanced Capability defines the following additional access control mechanisms:

- ACS I/O Request Blocking
- ACS DSP Memory Target Access
- ACS USP Memory Target Access
- ACS Unclaimed Request Redirect

Through these mechanisms, ACS Enhanced Capability provides protection and consistent handling of Requests directed toward regions not covered by the original ACS mechanisms.

IMPLEMENTATION NOTE:

ACS REDIRECT AND GUEST PHYSICAL ADDRESSES (GPAS) §

ACS redirect mechanisms were originally architected to enable fine-grained access control for P2P Memory Requests, by redirecting selected Requests Upstream to the RC, where validation logic determines whether to allow or deny access. However, ACS redirect mechanisms can also ensure that Functions under the direct control of VMs have their DMA Requests routed correctly to the Translation Agent in the host, which then translates their guest physical addresses (GPAs) into host physical addresses (HPAs).

GPA ranges used for Memory Space vs. DMA are not guaranteed to coincide with HPA ranges, which the PCIe fabric uses for Memory Request routing and access control. If any GPAs used for DMA fall within the HPA ranges used for Memory Space, legitimate or malicious packet misrouting can result.

ACS redirect mechanisms can ensure that Upstream Memory Requests with GPAs intended for DMA never get routed to HPA Memory ranges. ACS P2P Request Redirect handles this for (1) peer accesses between Functions within a Multi-Function Device and (2) peer accesses between Downstream Ports within a Switch or RC. ACS P2P Egress Control with redirect handles this in a more fine-grained manner for the same two cases.

Redirect mechanisms introduced with ACS Enhanced Capability handle this for additional cases. ACS DSP Memory Target Access with redirect handles this for Downstream Port Memory Resource ranges. ACS USP Memory Target Access with redirect handles this for Switch Upstream Port Memory Resource ranges. In Switches, ACS Unclaimed Request Redirect handles this for any areas within Upstream Port Memory apertures that are not handled by the other ACS redirect mechanisms.

Together these ACS redirect mechanisms can ensure that Upstream Memory Requests with GPAs intended for DMA are always routed or redirected to the Translation Agent in the host, and those with GPAs intended for P2P are still routed as originally architected.

6.12.5 ACS Violation Error Handling §

ACS Violations may occur due to either hardware or software defects/failures. To assist in fault isolation and root cause analysis, it is recommended that AER be implemented in ACS components. AER prefix/header logging and the Prefix Log/Header Log registers may be used to determine the prefix/header of the offending Request. The ACS Violation Status, Mask, and Severity bits provide positive identification of the error and increased control over error logging and signaling.

When an ACS Violation is detected, the ACS component that operates as the Completer¹³⁶ must do the following:

- For Non-Posted Requests, the Completer must generate a Completion with a Completer Abort (CA) Completion Status.
- The Completer must log and signal the ACS Violation as indicated in § Figure 6-2. Note the following:
 - Even though the Completer uses a CA Completion Status when it sends a Completion, the Completer must log an ACS Violation error instead of a Completer Abort error.
 - If the severity of the ACS Violation is non-fatal and the Completer sends a Completion with CA Completion Status, this case must be handled as an Advisory Non-Fatal Error as described in § Section 6.2.3.2.4.1 .

136. In all cases but one, the ACS component that detects the ACS Violation also operates as the Completer. The exception case is when Root Complex Redirected Request Validation logic disallows a redirected Request. If the redirected Request came through a Root Port, that Root Port must operate as the Completer. If the redirected Request came from a Root Complex Integrated Endpoint, the associated Root Complex Event Collector must operate as the Completer.

- The Completer¹³⁷ must set the Signaled Target Abort bit in either its Status register or Secondary Status register as appropriate.

6.12.6 ACS Redirection Impacts on Ordering Rules §

When ACS P2P Request Redirect is enabled, some or all peer-to-peer Requests are redirected, which can cause ordering rule violations in some cases. This section explores those cases, plus a similar case that occurs with RCs that implement “Request Retargeting” as an alternative mechanism for enforcing peer-to-peer access control.

6.12.6.1 Completions Passing Posted Requests §

When a peer-to-peer Posted Request is redirected, a subsequent peer-to-peer non-RO¹³⁸ Completion that is routed directly can effectively pass the redirected Posted Request, violating the ordering rule that non-RO Completions must not pass Posted Requests. Refer to § Section 2.4.1 for more information.

ACS P2P Completion Redirect can be used to avoid violating this ordering rule. When ACS P2P Completion Redirect is enabled, all peer-to-peer non-RO Completions will be redirected, thus taking the same path as redirected peer-to-peer Posted Requests. Enabling ACS P2P Completion Redirect when some or all peer-to-peer Requests are routed directly will not cause any ordering rule violations, since it is permitted for a given Completion to be passed by any TLP other than another Completion with the same Transaction ID.

As an alternative mechanism to ACS P2P Request Redirect for enforcing peer-to-peer access control, some RCs implement “Request Retargeting”, where the RC supports special address ranges for “peer-to-peer” traffic, and the RC will retarget validated Upstream Requests to peer devices. Upon receiving an Upstream Request targeting a special address range, the RC validates the Request, translates the address to target the appropriate peer device, and sends the Request back Downstream. With retargeted Requests that are Non-posted, if the RC does not modify the Requester ID, the resulting Completions will travel “directly” peer-to-peer back to the original Requester, creating the possibility of non-RO Completions effectively passing retargeted Posted Requests, violating the same ordering rule as when ACS P2P Request Redirect is being used. ACS P2P Completion Redirect can be used to avoid violating this ordering rule here as well.

If ACS P2P Request Redirect and RC P2P Request Retargeting are not being used, there is no envisioned benefit to enabling ACS P2P Completion Redirect, and it is recommended not to do so because of potential performance impacts.

137. Similarly, if the Request was Non-Posted, when the Requester receives the resulting Completion with CA Completion Status, the Requester must set the Received Target Abort bit in either its Status register or Secondary Status register as appropriate. Note that for the case of a Multi-Function Device incurring an ACS Violation error with a peer-to-peer Request between its Functions, the same Function might serve both as Requester and Completer.

138. In this section, “non-RO” is an abbreviation characterizing TLPs whose Relaxed Ordering Attribute field is not set.

IMPLEMENTATION NOTE: PERFORMANCE IMPACTS WITH ACS P2P COMPLETION REDIRECT §

While the use of ACS P2P Completion Redirect can avoid ordering violations with Completions passing Posted Requests, it also may impact performance. Specifically, all redirected Completions will have to travel up to the RC from the point of redirection and back, introducing extra latency and possibly increasing Link and RC congestion.

Since peer-to-peer Completions with the Relaxed Ordering bit set are never redirected (thus avoiding performance impacts), it is strongly recommended that Requesters be implemented to maximize the proper use of Relaxed Ordering, and that software enable Requesters to utilize Relaxed Ordering by setting the Enable Relaxed Ordering bit in the Device Control Register.

If software enables ACS P2P Request Redirect, RC P2P Request Retargeting, or both, and software is certain that proper operation is not compromised by peer-to-peer non-RO Completions passing peer-to-peer¹³⁹ Posted Requests, it is recommended that software leave ACS P2P Completion Redirect disabled as a way to avoid its performance impacts.

6.12.6.2 *Requests Passing Posted Requests* §

When some peer-to-peer Requests are redirected but other peer-to-peer Requests are routed directly, the possibility exists of violating the ordering rules where Non-posted Requests or non-RO Posted Requests must not pass Posted Requests. Refer to § Section 2.4.1 for more information.

These ordering rule violation possibilities exist only when ACS P2P Request Redirect and ACS Direct Translated P2P are both enabled. Software should not enable both these mechanisms unless it is certain either that such ordering rule violations cannot occur, or that proper operation will not be compromised if such ordering rule violations do occur.

139. These include true peer-to-peer Requests that are redirected by the ACS P2P Request Redirect mechanism, as well as “logically peer-to-peer” Requests routed to the Root Complex that the Root Complex then retargets to the peer device.

IMPLEMENTATION NOTE: ENSURING PROPER OPERATION WITH ACS DIRECT TRANSLATED P2P §

The intent of ACS Direct Translated P2P is to optimize performance in environments where Address Translation Services (ATS) are being used with peer-to-peer communication whose access control is enforced by the RC. Permitting peer-to-peer Requests with Translated addresses to be routed directly avoids possible performance impacts associated with redirection, which introduces extra latency and may increase Link and RC congestion.

For the usage model where peer-to-peer Requests with Translated addresses are permitted, but those with Untranslated addresses are to be blocked as ACS Violations, it is recommended that software enable ACS Direct Translated P2P and ACS P2P Request Redirect, and configure the Redirected Request Validation logic in the RC to block the redirected Requests with Untranslated addresses. This configuration has no ordering rule violations associated with Requests passing Posted Requests.

For the usage model where some Requesters use Translated addresses exclusively with peer-to-peer Requests and some Requesters use Untranslated addresses exclusively with peer-to-peer Requests, and the two classes of Requesters do not communicate peer-to-peer with each other, proper operation is unlikely to be compromised by redirected peer-to-peer Requests (with Untranslated addresses) being passed by direct peer-to-peer Requests (with Translated addresses). It is recommended that software not enable ACS Direct Translated P2P unless software is certain that proper operation is not compromised by the resulting ordering rule violations.

For the usage model where a single Requester uses both Translated and Untranslated addresses with peer-to-peer Requests, again it is recommended that software not enable ACS Direct Translated P2P unless software is certain that proper operation is not compromised by the resulting ordering rule violations. This requires a detailed analysis of the peer-to-peer communications models being used, and is beyond the scope of this specification.

6.13 Alternative Routing-ID Interpretation (ARI) §

Routing IDs, Requester IDs, and Completer IDs are 16-bit identifiers traditionally composed of three fields: an 8-bit Bus Number, a 5-bit Device Number, and a 3-bit Function Number. With ARI, the 16-bit field is interpreted as two fields instead of three: an 8-bit Bus Number and an 8-bit Function Number - the Device Number field is eliminated. This new interpretation enables an ARI Device to support up to 256 Functions [0..255] instead of 8 Functions [0..7].

ARI is controlled by a new set of optional capability and control register bits. These provide:

- Software the ability to detect whether a component supports ARI.
- Software the ability to configure an ARI Downstream Port so the logic that determines when to turn a Type 1 Configuration Request into a Type 0 Configuration Request no longer enforces a restriction on the traditional Device Number field being 0.
- Software the ability to configure an ARI Device to assign each Function to a Function Group. Controls based on Function Groups may be preferable when finer granularity controls based on individual Functions are not required.
 - If Multi-Function VC arbitration is supported and enabled, arbitration can optionally be based on Function Groups instead of individual Functions.

- If ACS P2P Egress Controls are supported and enabled, access control can optionally be based on Function Groups instead of individual Functions.

The following illustrates an example flow for enabling these capabilities and provides additional details on their usage:

1. Software enumerates the PCI Express hierarchy and determines whether the ARI Extended Capability is supported.
 - a. For an ARI Downstream Port, the capability is communicated through the Device Capabilities 2 register.
 - b. For an ARI Device, the capability is communicated through the ARI Extended Capability structure.
 - c. ARI has no impact on the base enumeration algorithms used in platforms today.
2. Software enables ARI functionality in each component.
 - a. In an ARI Downstream Port immediately above an ARI Device, software sets the ARI Forwarding Enable bit in the Device Control 2 register. Setting this bit ensures the logic that determines when to turn a Type 1 Configuration Request into a Type 0 Configuration Request no longer enforces a restriction on the traditional Device Number field being 0.
 - b. In an ARI Device, Extended Functions must respond if addressed with a Type 0 Configuration Request. It is necessary for ARI-aware software to enable ARI Forwarding in the Downstream Port immediately above the ARI Device, in order for ARI-aware software to discover and configure the Extended Functions.
 - c. If an ARI Device implements a Multi-Function VC Extended Capability structure with Function arbitration, and also implements MFVC Function Groups, ARI-aware software categorizes Functions into Function Groups.
 - i. Each Function is assigned to a Function Group represented by a **Function Group Number**.
 - ii. A maximum of 8 Function Groups can be configured.
 - iii. Within the Multi-Function VC Arbitration Table, a Function Group Number is used in place of a Function Number in each arbitration slot.
 1. Arbitration occurs on a Function Group basis instead of an individual Function basis.
 2. All other aspects of Multi-Function VC arbitration remain unchanged. See § Section 7.9.2.10 for additional details.
 - iv. Function arbitration within each Function Group is implementation specific.
 - d. If an ARI Device supports ACS P2P Egress Control, access control can be optionally implemented on a Function Group basis.
 - e. To improve the enumeration performance and create a more deterministic solution, software can enumerate Functions through a linked list of Function Numbers. The next linked list element is communicated through each Function's ARI Capability Register.
 - i. Function 0 acts as the head of a linked list of Function Numbers. Software detects a non-Zero Next Function Number field within the ARI Capability Register as the next Function within the linked list. Software issues a configuration probe using the Bus Number captured by the Device and the Function Number derived from the ARI Capability Register to locate the next associated Function's configuration space.
 - ii. Function Numbers may be sparse and non-sequential in their consumption by an ARI Device.

With an ARI Device, the Phantom Functions Supported field within each Function's Device Capabilities register (see § Section 7.5.3.3 , § Table 7-20) must be set to 00b to indicate that Phantom Functions are not supported. The Extended

Tag Field Enable bit, the 10-Bit Tag Requester Enable bit, and the 14-Bit Tag Requester Enable bit can still be used to enable each Function to support higher numbers of outstanding Requests. See § Section 2.2.6.2 .

§ Figure 6-13 shows an example system topology with two ARI Devices, one below a Root Port and one below a Switch. For access to Extended Functions in ARI Device X, Root Port A must support ARI Forwarding and have it enabled by software. For access to Extended Functions in ARI Device Y, Switch Downstream Port D must support ARI Forwarding and have it enabled by software. With this configuration, it is recommended that software not enable ARI Forwarding in Root Port B or Switch Downstream Port C.

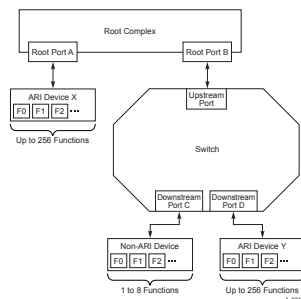

Figure 6-13 Example System Topology with ARI Devices §

IMPLEMENTATION NOTE:

ARI FORWARDING ENABLE BEING SET INAPPROPRIATELY §

It is strongly recommended that software in general Set the ARI Forwarding Enable bit in a Downstream Port only if software is certain that the device immediately below the Downstream Port is an ARI Device. If the bit is Set when a non-ARI Device is present, the non-ARI Device can respond to Configuration Space accesses under what it interprets as being different Device Numbers, and its Functions can be aliased under multiple Device Numbers, generally leading to undesired behavior.

Following a hot-plug event below a Downstream Port, it is strongly recommended that software Clear the ARI Forwarding Enable bit in the Downstream Port until software determines that a newly added component is in fact an ARI Device.

IMPLEMENTATION NOTE:

ARI FORWARDING ENABLE SETTING AT FIRMWARE/ OPERATING SYSTEM CONTROL HANDOFF §

It is strongly recommended that firmware not have the ARI Forwarding Enable bit Set in a Downstream Port upon control handoff to an operating system unless firmware knows that the operating system is ARI-aware. With this bit Set, a non-ARI-aware operating system might be able to discover and enumerate Extended Functions in an ARI Device below the Downstream Port, but such an operating system would generally not be able to manage Extended Functions successfully, since it would interpret there being multiple Devices below the Downstream Port instead of a single ARI Device. As one example of many envisioned problems, the interrupt binding for INTx virtual wires would not be consistent with what the non-ARI-aware operating system would expect.

6.14 Multicast Operations §

The Multicast Capability structure defines a Multicast address range, the segmentation of that range into a number, N, of equal sized Multicast Windows, and the association of each Multicast Window with a Multicast Group, MCG. Each Function that supports Multicast within a component implements a Multicast Capability structure that provides routing directions and permission checking for each MCG for TLPs passing through or to the Function. The Multicast Group is a field of up to 6 bits in width embedded in the address beginning at the MC_Index_Position, as defined in § Section 7.9.11.4 .

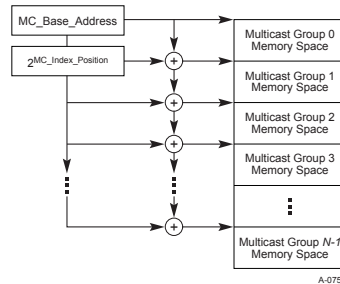

Figure 6-14 Segmentation of the Multicast Address Range §

6.14.1 Multicast TLP Processing §

A Multicast Hit occurs if all of the following are true:

- MC_Enable is Set
- TLP is a non-UIO Memory Write Request or an Address Routed Message, both of which are non-UIO Posted Requests
- $\text{Address}_{\text{TLP}} \geq \text{MC_Base_Address}$
- $\text{Address}_{\text{TLP}} < (\text{MC_Base_Address} + (2^{\text{MC_Index_Position}} * (\text{MC_Num_Group} + 1)))$

In this step, each Switch Ingress Port and other components use values of MC_Enable, MC_Base_Address, MC_Index_Position, and MC_Num_Group from any one of their Functions. Software is required to configure all Functions of a Switch and all Functions of a Multi-Function Upstream Port to have the same values in each of these fields and results are indeterminate if this is not the case.

If the address in a Non-Posted Memory Request hits in a Multicast Window, no Multicast Hit occurs and the TLP is processed normally per the base specification - i.e., as a unicast.

If a Multicast Hit occurs, the only ACS access control that can still apply is ACS Source Validation. In particular, neither ACS P2P Request Redirect nor ACS P2P Egress Control affects operations during a Multicast Hit. See § Section 6.12 .

If a Multicast Hit occurs, normal address routing rules do not apply. Instead, the TLP is processed as follows:

The Multicast Group is extracted from the address in the TLP using any Function's values for MC_Base_Address and MC_Index_Position. Specifically:

$$\text{MCG} = ((\text{Address}_{\text{TLP}} - \text{MC_Base_Address}) \gg \text{MC_Index_Position}) \& 3\text{Fh}$$

In this process, the component may use any Function's values for MC_Base_Address and MC_Index_Position. Which Function's values are used is device-specific.

Components next check the MC_Block_All and the MC_Block_Untranslated bits corresponding to the extracted MCG. Switches and Root Ports check Multicast TLPs in their Ingress Ports using the MC_Block_All and MC_Block_Untranslated registers associated with the Ingress Port. Endpoint Functions check Multicast TLPs they are preparing to send, using their MC_Block_All and MC_Block_Untranslated registers. If the MC_Block_All bit corresponding to the extracted MCG is set, the TLP is handled as an MC Blocked TLP. If the MC_Block_Untranslated bit corresponding to the extracted MCG is set and the TLP contains an Untranslated Address, the TLP, is also handled as an MC Blocked TLP.

IMPLEMENTATION NOTE:

MC_BLOCK_UNTRANSLATED AND PIO WRITES §

Programmed I/O (PIO) Writes to Memory Space generally have Untranslated addresses since there is no architected mechanism for software to control the Address Type (AT) field for PIO Requests. Thus, if it's necessary for a given Switch to Multicast any PIO Writes, software should ensure that the appropriate MC_Block_Untranslated bits in the Upstream Port of that Switch are Clear. Otherwise, the Switch Upstream Port may block PIO Writes that legitimately target Multicast Windows. Since it may be necessary for software to clear MC_Block_Untranslated bits in a Switch Upstream Port for the sake of PIO Writes, the following are strongly recommended for a Root Complex capable of Address translation:

- All Integrated Endpoints each implement a Multicast Capability structure to provide access control for sending Untranslated Multicast TLPs.
- All peer-to-peer capable Root Ports each implement a Multicast Capability structure to provide access control for Untranslated Multicast TLPs that are forwarded peer-to-peer.

For similar reasons, with Multicast-capable Switch components where the Upstream Port is a Function in a Multi-Function Device, it is strongly recommended that any Endpoints in that Multi-Function Device each implement a Multicast Capability structure.

IMPLEMENTATION NOTE:

MULTICAST WINDOW SIZE §

Each ultimate Receiver of a Multicast TLP may have a different Multicast Window size requirement. At one extreme, a Multicast Window may be required to cover a range of memory implemented within the device. At the other, it may only need to cover a particular offset at which a FIFO register is located. The MC_Window_Size_Requested field within the Multicast Capability register is used by an Endpoint to advertise the size of Multicast Window that it requires.

Unless available address space is limited, resource allocation software may be able to treat each request as a minimum and set the Multicast Window size via MC_Index_Position to accommodate the largest request. In some cases, a request for a larger window size can be satisfied by configuring a smaller window size and assigning the same membership to multiple contiguous MCGs.

IMPLEMENTATION NOTE: MULTICAST, ATS, AND REDIRECTION §

The ACS P2P Request Redirect and ACS Direct Translated P2P mechanisms provide a means where P2P Requests with Untranslated Addresses can be redirected to the Root Complex (RC) for access control checking, whereas P2P Requests with Translated Addresses can be routed “directly” to their P2P targets for improved performance. See § Section 6.12 . No corresponding redirection mechanism exists for Multicast TLPs.

To achieve similar functionality, an RC might be configured to provide one or more target Memory Space ranges that are not in the Multicast address range, but the RC maps to “protected” Multicast Windows. Multicast TLP senders either with or without ATS capability then target these RC Memory Space ranges in order to access the protected Multicast Windows indirectly. When either type of sender targets these ranges with Memory Writes, each TLP that satisfies the access control checks will be reflected back down by the RC with a Translated Address targeting a protected Multicast Window.¹⁴⁰ ATS-capable senders can request and cache Translated Addresses using the RC Memory Space range, and then later use those Translated Addresses for Memory Writes that target protected Multicast Windows directly and can be Multicast without a taking a trip through the RC.

For hardware enforcement that only Translated Addresses can be used to target the protected Multicast Windows directly, software Sets appropriate MCG bits in the `MC_Block_Untranslated` register in all applicable Functions throughout the platform. Each MCG whose bit is Set will cause its associated Multicast Window to be protected from direct access using Untranslated Addresses.

If the TLP is not blocked in a Switch or Root Complex it is forwarded out all of the Ports, except its Ingress Port, whose `MC_Receive` bit corresponding to the extracted MCG is set. In an Endpoint, it is consumed by all Functions whose `MC_Receive` bit corresponding to the extracted MCG is set. If no Ports forward the TLP or no Functions consume it, the TLP is silently dropped.

To prevent loops, it is prohibited for a Root Port or a Switch Port to forward a TLP back out its Ingress Port, even if so specified by the `MC_Receive` register associated with the Port. An exception is the case described in the preceding Implementation Note, where an RC reflects a unicast TLP that came in on an Ingress Root Port to a Multicast Window. In that case, when specified by the `MC_Receive` register associated with that Ingress Root Port, the RC is required to send the reflected TLP out the same Root Port that it originally came in.

A Multicast Hit suspends normal address routing, including default Upstream routing in Switches. When a Multicast Hit occurs, the TLP will be forwarded out only those Egress Ports whose `MC_Receive` bit associated with the MCG extracted from the address in the TLP is set. If the address in the TLP does not decode to any Downstream Port using normal address decode, the TLP will be copied to the Upstream Port only if so specified by the Upstream Port’s `MC_Receive` register.

6.14.2 Multicast Ordering §

No new ordering rules are defined for processing Multicast TLPs. All Multicast TLPs are Posted Requests and follow Posted Request ordering rules. Multicast TLPs are ordered per normal ordering rules relative to other TLPs in a component’s ingress stream through the point of replication. Once copied into an egress stream, a Multicast TLP follows the same ordering as other Posted Requests in the stream.

140. If the original sender belongs to the MCG associated with this Window, the original sender will also receive a copy of the reflected TLP.

6.14.3 Multicast Capability Structure Field Updates §

Some fields of the Multicast Capability structure may be changed at any time. Others cannot be changed with predictable results unless the MC_Enable bit is Clear in every Function of the component. The latter group includes MC_Base_Address and MC_Index_Position.

Fields which software may change at any time include MC_Enable, MC_Num_Group, MC_Receive, MC_Block_All, and MC_Block_Untranslated. Updates to these fields must themselves be ordered. Consider, for example, TLPs A and B arriving in that order at the same Ingress Port and in the same TC. If A uses value X for one of these fields, then B must use the same value or a newer value.

For Multi-Function Upstream Switch Ports Multicast TLPs received by one Switch or transmitted by one Endpoint Function are presented to the other parallel Endpoint Functions and the Downstream Switch Ports of the other parallel Switches (Functions are considered to be parallel if they are in the same Device. A single Multicast TLP is forwarded Upstream when any of the Upstream Switch Functions has the appropriate MC_Receive bit Set.

6.14.4 MC Blocked TLP Processing §

When a TLP is blocked by the MC_Block_All or the MC_Block_Untranslated mechanisms, the TLP is dropped. The Function blocking the TLP serves as the Completer. The Completer must log and signal this MC Blocked TLP error as indicated in § Figure 6-2. In addition, the Completer must set the Signaled Target Abort bit in either its Status register or Secondary Status register as appropriate. To assist in fault isolation and root cause analysis, it is strongly recommended that AER be implemented in Functions with Multicast capability.

In Root Complexes and Switches, if the error occurs with a TLP received by an Ingress Port, the error is reported by that Ingress Port. If the error occurs in an Endpoint Function preparing to send the TLP, the error is reported by that Endpoint Function.

6.14.5 MC_Overlay Mechanism §

The MC_Overlay mechanism is provided to allow a single BAR in an Endpoint that doesn't contain a Multicast Capability structure to be used for both Multicast and unicast TLP reception. Software can configure the MC_Overlay mechanism to affect this by setting the MC_Overlay_BAR in a Downstream Port so that the Multicast address range, or a portion of it, is remapped (overlaid) onto the Memory Space range accepted by the Endpoint's BAR. At the Upstream Port of a Switch, the mechanism can be used to overlay a portion of the Multicast address range onto a Memory Space range associated with host memory.

A Downstream Port's MC_Overlay mechanism applies to TLPs exiting that Port. An Upstream Port's MC_Overlay mechanism applies to TLPs exiting the Switch heading Upstream. A Port's MC_Overlay mechanism does not apply to TLPs received by the Port, to TLPs targeting memory space within the Port, or to TLPs routed Peer-to-Peer between Functions in a Multi-Function Upstream Port.

When enabled, the overlay operation specifies that bits in the address in the Multicast TLP, whose bit numbers are equal to or higher than the MC_Overlay_Size field, be replaced by the corresponding bits in the MC_Overlay_BAR. In other words:

```

If (MC_Overlay_Size < 6)
  Then Egress_TLP_Addr = Ingress_TLP_Addr;
  Else Egress_TLP_Addr = { MC_Overlay_BAR[63:MC_Overlay_Size],
                          Ingress_TLP_Addr[MC_Overlay_Size-1:0] };

```

Equation 6-1 MC_Overlay Transform rules §

If the TLP with modified address contains the optional ECRC, the unmodified ECRC will almost certainly indicate an error. The action to be taken if a TLP containing an ECRC is Multicast copied to an Egress Port that has `MC_Overlay` enabled depends upon whether or not optional support for ECRC regeneration is implemented. All of the contingent actions are outlined in § Table 6-12. If `MC_Overlay` is not enabled, the TLP is forwarded unmodified. If `MC_Overlay` is enabled and the TLP has no ECRC, the modified TLP, with its address replaced as specified in the previous paragraph is forwarded. If the TLP has an ECRC but ECRC regeneration is not supported, then the modified TLP is forwarded with its ECRC dropped and the TD bit in the header cleared to indicate no ECRC attached. If the TLP has an ECRC and ECRC regeneration is supported, then an ECRC check is performed before the TLP is forwarded. If the ECRC check passes, the TLP is forwarded with regenerated ECRC. If the ECRC check fails, the TLP is forwarded with inverted regenerated ECRC.

Table 6-12 ECRC Rules for MC_Overlay §

MC_Overlay Enabled	TLP has ECRC	ECRC Regeneration Supported	Action if ECRC Check Passes	Action if ECRC Check Fails
No	x	x	Forward TLP unmodified	
Yes	No	x	Forward modified TLP	
Yes	Yes	No	Forward modified TLP with ECRC dropped and TD bit clear	
Yes	Yes	Yes	Forward modified TLP with regenerated ECRC	Forward modified TLP with inverted regenerated ECRC

IMPLEMENTATION NOTE: MC_OVERLAY AND ECRC REGENERATION §

Switch and Root Complex Ports have the option to support ECRC regeneration. If ECRC regeneration is supported, then it is strongly recommended to do so robustly by minimizing the time between checking the ECRC of the original TLP and replacing it with an ECRC computed on the modified TLP. The TLP is unprotected during this time, leaving a data integrity hole if the pre-check and regeneration aren't accomplished in the same pipeline stage.

Stripping the ECRC from Multicast TLPs passing through a Port that has `MC_Overlay` enabled but doesn't support ECRC regeneration allows the receiving Endpoint to enable ECRC checking. In such a case, the Endpoint will enjoy the benefits of ECRC on non-Multicast TLPs without detecting ECRC on Multicast TLPs modified by the `MC_Overlay` mechanism.

When Multicast ECRC regeneration is supported, and an ECRC error is detected prior to TLP modification, then inverting the regenerated ECRC ensures that the ECRC error isn't masked by the regeneration process.

IMPLEMENTATION NOTE: MULTICAST TO ENDPOINTS THAT DON'T HAVE MULTICAST CAPABILITY §

An Endpoint Function that doesn't contain a Multicast Capability structure cannot distinguish Multicast TLPs from unicast TLPs. It is possible for a system designer to take advantage of this fact to employ such Endpoints as Multicast targets. The primary requirement for doing so is that the base and limit registers of the virtual PCI to PCI Bridge in the Switch Port above the device be configured to overlap at least part of the Multicast address range or that the MC_Overlay mechanism be employed. Extending this reasoning, it is even possible that a single Multicast target Function could be located on the PCI/PCI-X side of a PCI Express to PCI/PCI-X Bridge.

If an Endpoint without a Multicast Capability structure is being used as a Multicast target and the MC_Overlay mechanism isn't used, then it may be necessary to read from the Endpoint's Memory Space using the same addresses used for Multicast TLPs. Therefore, Memory Reads that hit in a Multicast Window aren't necessarily errors. Memory Reads that hit in a Multicast Window and that don't also hit in the aperture of an RCiEP or the Downstream Port of a Switch will be routed Upstream, per standard address routing rules, and be handled as a UR there.

IMPLEMENTATION NOTE: MULTICAST IN A ROOT COMPLEX §

A Root Complex with multiple Root Ports that supports Multicast may implement as many Multicast Capability structures as its implementation requires. If it implements more than one, software should ensure that certain fields, as specified in § Section 6.14.3, are configured identically. To support Multicast to RCiEPs, the implementation needs to expose all TLPs identified as Multicast via the MC_Base_Address register to all potential Multicast target Endpoints integrated within it. Each such Integrated Endpoint then uses the MC_Receive register in its Multicast Capability structure to determine if it should receive the TLP.

IMPLEMENTATION NOTE: MULTICAST AND MULTI-FUNCTION DEVICES §

All Port Functions and Endpoint Functions that are potential Multicast targets need to implement a Multicast Capability structure so that each has its own MC_Receive vector. Within a single component, software should configure the MC_Enable, MC_Base_Address, MC_Index_Position, and MC_Num_Group fields of these Capability structures identically. That being the case, it is sufficient to implement address decoding logic on only one instance of the Multicast BAR in the component.

IMPLEMENTATION NOTE: CONGESTION AVOIDANCE §

The use of Multicast increases the output link utilization of Switches to a degree proportional to both the size of the Multicast groups used and the fraction of Multicast traffic to total traffic. This results in an increased risk of congestion and congestion spreading when Multicast is used.

To mitigate this risk, components that are intended to serve as Multicast targets should be designed to consume Multicast TLPs at wire speed. Components that are intended to serve as Multicast sources should consider adding a rate limiting mechanism.

In many applications, the application's Multicast data flow will have an inherent rate limit and can be accommodated without causing congestion. Others will require an explicit mechanism to limit the injection rate, selection of a Switch with buffers adequate to hold the requisite bursts of Multicast traffic without asserting flow control, or selection of Multicast target components capable of sinking the Multicast traffic at the required rate. It is the responsibility of the system designer to choose the appropriate mechanisms and components to serve the application.

IMPLEMENTATION NOTE: THE HOST AS A MULTICAST RECIPIENT §

For general-purpose systems, it is anticipated that the Multicast address range will usually not be configured to overlap with Memory Space that's directly mapped to host memory. If host memory is to be included as a Multicast recipient, the Root Complex may need to have some sort of I/O Memory Management Unit (IOMMU) that is capable of remapping portions of Multicast Windows to host memory, perhaps with page-level granularity. Alternatively, the MC_Overlay mechanism in the Upstream Port of a Switch can be used to overlay a portion of the Multicast address range onto host memory.

For embedded systems that lack an IOMMU, it may be feasible to configure Multicast Windows overlapping with Memory Space that's directly mapped to host memory, thus avoiding the need for an IOMMU. Specific details of this approach are beyond the scope of this specification.

6.15 Atomic Operations (AtomicOps) §

An Atomic Operation (AtomicOp) is a single PCI Express transaction that targets a location in Memory Space, reads the location's value, potentially writes a new value back to the location, and returns the original value. This “read-modify-write” sequence to the location is performed atomically. AtomicOps include the following:

- FetchAdd (Fetch and Add): Request contains a single operand, the “add” value
